MATLAB® 7
Function Reference: Volume 1 (A-E)

MATLAB®

The MathWorks™
Accelerating the pace of engineering and science

How to Contact The MathWorks

`www.mathworks.com`	Web
`comp.soft-sys.matlab`	Newsgroup
`www.mathworks.com/contact_TS.html`	Technical Support

`suggest@mathworks.com`	Product enhancement suggestions
`bugs@mathworks.com`	Bug reports
`doc@mathworks.com`	Documentation error reports
`service@mathworks.com`	Order status, license renewals, passcodes
`info@mathworks.com`	Sales, pricing, and general information

508-647-7000 (Phone)

508-647-7001 (Fax)

The MathWorks, Inc.
3 Apple Hill Drive
Natick, MA 01760-2098

For contact information about worldwide offices, see the MathWorks Web site.

MATLAB Function Reference

Revision History

December 1996	First printing	For MATLAB 5.0 (Release 8)
June 1997	Online only	Revised for MATLAB 5.1 (Release 9)
October 1997	Online only	Revised for MATLAB 5.2 (Release 10)
January 1999	Online only	Revised for MATLAB 5.3 (Release 11)
June 1999	Second printing	For MATLAB 5.3 (Release 11)
June 2001	Online only	Revised for MATLAB 6.1 (Release 12.1)
July 2002	Online only	Revised for 6.5 (Release 13)
June 2004	Online only	Revised for 7.0 (Release 14)
September 2006	Online only	Revised for 7.3 (Release 2006b)
September 2007	Online only	Revised for 7.5 (Release 2007b)

Contents

1 Functions — By Category

Functions — By Category

Creating Graphical User Interfaces (p. 1-104)	GUIDE, programming graphical user interfaces
External Interfaces (p. 1-109)	Interfaces to DLLs, Java, COM and ActiveX, Web services, and serial port devices, and C and Fortran routines

Desktop Tools and Development Environment

Startup and Shutdown

exit	Terminate MATLAB (same as `quit`)
finish	MATLAB termination M-file
matlab (UNIX)	Start MATLAB (UNIX systems)
matlab (Windows)	Start MATLAB (Windows systems)
matlabrc	MATLAB startup M-file for single-user systems or system administrators
prefdir	Directory containing preferences, history, and layout files
preferences	Open Preferences dialog box for MATLAB and related products

quit	Terminate MATLAB
startup	MATLAB startup M-file for user-defined options

Command Window and History

clc	Clear Command Window
commandhistory	Open Command History window, or select it if already open
commandwindow	Open Command Window, or select it if already open
diary	Save session to file
dos	Execute DOS command and return result
format	Set display format for output
home	Move cursor to upper-left corner of Command Window
matlabcolon (matlab:)	Run specified function via hyperlink
more	Control paged output for Command Window
perl	Call Perl script using appropriate operating system executable
system	Execute operating system command and return result
unix	Execute UNIX command and return result

Help for Using MATLAB

builddocsearchdb	Build searchable documentation database
demo	Access product demos via Help browser
doc	Reference page in Help browser
docopt	Web browser for UNIX platforms
docsearch	Open Help browser **Search** pane and search for specified term
echodemo	Run M-file demo step-by-step in Command Window
help	Help for MATLAB functions in Command Window
helpbrowser	Open Help browser to access all online documentation and demos
helpwin	Provide access to M-file help for all functions
info	Information about contacting The MathWorks
lookfor	Search for keyword in all help entries
playshow	Run M-file demo (deprecated; use `echodemo` instead)
support	Open MathWorks Technical Support Web page
web	Open Web site or file in Web browser or Help browser
whatsnew	Release Notes for MathWorks products

Workspace, Search Path, and File Operations

Workspace

assignin	Assign value to variable in specified workspace
clear	Remove items from workspace, freeing up system memory
evalin	Execute MATLAB expression in specified workspace
exist	Check existence of variable, function, directory, or Java class
openvar	Open workspace variable in Array Editor or other tool for graphical editing
pack	Consolidate workspace memory
uiimport	Open Import Wizard to import data
which	Locate functions and files
workspace	Open Workspace browser to manage workspace

Search Path

addpath	Add directories to MATLAB search path
genpath	Generate path string
partialpath	Partial pathname description

path	View or change MATLAB directory search path
path2rc	Save current MATLAB search path to `pathdef.m` file
pathdef	Directories in MATLAB search path
pathsep	Path separator for current platform
pathtool	Open Set Path dialog box to view and change MATLAB path
restoredefaultpath	Restore default MATLAB search path
rmpath	Remove directories from MATLAB search path
savepath	Save current MATLAB search path to `pathdef.m` file

File Operations

See also "File I/O" on page 1-76 functions.

cd	Change working directory
copyfile	Copy file or directory
delete	Remove files or graphics objects
dir	Directory listing
exist	Check existence of variable, function, directory, or Java class
fileattrib	Set or get attributes of file or directory
filebrowser	Current Directory browser
isdir	Determine whether input is a directory
lookfor	Search for keyword in all help entries

ls	Directory contents on UNIX system
matlabroot	Root directory of MATLAB installation
mkdir	Make new directory
movefile	Move file or directory
pwd	Identify current directory
recycle	Set option to move deleted files to recycle folder
rehash	Refresh function and file system path caches
rmdir	Remove directory
toolboxdir	Root directory for specified toolbox
type	Display contents of file
web	Open Web site or file in Web browser or Help browser
what	List MATLAB files in current directory
which	Locate functions and files

Programming Tools

Edit and Debug M-Files (p. 1-9)	Edit and debug M-files
Improve Performance and Tune M-Files (p. 1-9)	Improve performance and find potential problems in M-files
Source Control (p. 1-10)	Interface MATLAB with source control system
Publishing (p. 1-10)	Publish M-file code and results

Edit and Debug M-Files

clipboard	Copy and paste strings to and from system clipboard
datatipinfo	Produce short description of input variable
dbclear	Clear breakpoints
dbcont	Resume execution
dbdown	Change local workspace context when in debug mode
dbquit	Quit debug mode
dbstack	Function call stack
dbstatus	List all breakpoints
dbstep	Execute one or more lines from current breakpoint
dbstop	Set breakpoints
dbtype	List M-file with line numbers
dbup	Change local workspace context
debug	List M-file debugging functions
edit	Edit or create M-file
keyboard	Input from keyboard

Improve Performance and Tune M-Files

memory	Help for memory limitations
mlint	Check M-files for possible problems
mlintrpt	Run `mlint` for file or directory, reporting results in browser
pack	Consolidate workspace memory
profile	Profile execution time for function

profsave	Save profile report in HTML format
rehash	Refresh function and file system path caches
sparse	Create sparse matrix
zeros	Create array of all zeros

Source Control

checkin	Check files into source control system (UNIX)
checkout	Check files out of source control system (UNIX)
cmopts	Name of source control system
customverctrl	Allow custom source control system (UNIX)
undocheckout	Undo previous checkout from source control system (UNIX)
verctrl	Source control actions (Windows)

Publishing

grabcode	MATLAB code from M-files published to HTML
notebook	Open M-book in Microsoft Word (Windows)
publish	Publish M-file containing cells, saving output to file of specified type

System

Operating System Interface (p. 1-11)	Exchange operating system information and commands with MATLAB
MATLAB Version and License (p. 1-12)	Information about MATLAB version and license

Operating System Interface

clipboard	Copy and paste strings to and from system clipboard
computer	Information about computer on which MATLAB is running
dos	Execute DOS command and return result
getenv	Environment variable
hostid	MATLAB server host identification number
maxNumCompThreads	Controls maximum number of computational threads
perl	Call Perl script using appropriate operating system executable
setenv	Set environment variable
system	Execute operating system command and return result
unix	Execute UNIX command and return result
winqueryreg	Item from Microsoft Windows registry

MATLAB Version and License

ismac	Determine whether running Macintosh OS X versions of MATLAB
ispc	Determine whether PC (Windows) version of MATLAB
isstudent	Determine whether Student Version of MATLAB
isunix	Determine whether UNIX version of MATLAB
javachk	Generate error message based on Java feature support
license	Return license number or perform licensing task
prefdir	Directory containing preferences, history, and layout files
usejava	Determine whether Java feature is supported in MATLAB
ver	Version information for MathWorks products
verLessThan	Compare toolbox version to specified version string
version	Version number for MATLAB

Mathematics

Arrays and Matrices (p. 1-14)	Basic array operators and operations, creation of elementary and specialized arrays and matrices
Linear Algebra (p. 1-19)	Matrix analysis, linear equations, eigenvalues, singular values, logarithms, exponentials, factorization
Elementary Math (p. 1-23)	Trigonometry, exponentials and logarithms, complex values, rounding, remainders, discrete math
Polynomials (p. 1-28)	Multiplication, division, evaluation, roots, derivatives, integration, eigenvalue problem, curve fitting, partial fraction expansion
Interpolation and Computational Geometry (p. 1-28)	Interpolation, Delaunay triangulation and tessellation, convex hulls, Voronoi diagrams, domain generation
Cartesian Coordinate System Conversion (p. 1-31)	Conversions between Cartesian and polar or spherical coordinates
Nonlinear Numerical Methods (p. 1-31)	Differential equations, optimization, integration
Specialized Math (p. 1-35)	Airy, Bessel, Jacobi, Legendre, beta, elliptic, error, exponential integral, gamma functions
Sparse Matrices (p. 1-36)	Elementary sparse matrices, operations, reordering algorithms, linear algebra, iterative methods, tree operations
Math Constants (p. 1-39)	Pi, imaginary unit, infinity, Not-a-Number, largest and smallest positive floating point numbers, floating point relative accuracy

Arrays and Matrices

Basic Information (p. 1-14)	Display array contents, get array information, determine array type
Operators (p. 1-15)	Arithmetic operators
Elementary Matrices and Arrays (p. 1-16)	Create elementary arrays of different types, generate arrays for plotting, array indexing, etc.
Array Operations (p. 1-17)	Operate on array content, apply function to each array element, find cumulative product or sum, etc.
Array Manipulation (p. 1-17)	Create, sort, rotate, permute, reshape, and shift array contents
Specialized Matrices (p. 1-18)	Create Hadamard, Companion, Hankel, Vandermonde, Pascal matrices, etc.

Basic Information

disp	Display text or array
display	Display text or array (overloaded method)
isempty	Determine whether array is empty
isequal	Test arrays for equality
isequalwithequalnans	Test arrays for equality, treating NaNs as equal
isfinite	Array elements that are finite
isfloat	Determine whether input is floating-point array
isinf	Array elements that are infinite
isinteger	Determine whether input is integer array

islogical	Determine whether input is logical array
isnan	Array elements that are NaN
isnumeric	Determine whether input is numeric array
isscalar	Determine whether input is scalar
issparse	Determine whether input is sparse
isvector	Determine whether input is vector
length	Length of vector
max	Largest elements in array
min	Smallest elements in array
ndims	Number of array dimensions
numel	Number of elements in array or subscripted array expression
size	Array dimensions

Operators

+	Addition
+	Unary plus
-	Subtraction
-	Unary minus
*	Matrix multiplication
^	Matrix power
\	Backslash or left matrix divide
/	Slash or right matrix divide
’	Transpose
.’	Nonconjugated transpose
.*	Array multiplication (element-wise)

.^	Array power (element-wise)
.\	Left array divide (element-wise)
./	Right array divide (element-wise)

Elementary Matrices and Arrays

blkdiag	Construct block diagonal matrix from input arguments
diag	Diagonal matrices and diagonals of matrix
eye	Identity matrix
freqspace	Frequency spacing for frequency response
ind2sub	Subscripts from linear index
linspace	Generate linearly spaced vectors
logspace	Generate logarithmically spaced vectors
meshgrid	Generate `X` and `Y` arrays for 3-D plots
ndgrid	Generate arrays for N-D functions and interpolation
ones	Create array of all ones
rand	Uniformly distributed pseudorandom numbers
randn	Normally distributed random numbers
sub2ind	Single index from subscripts
zeros	Create array of all zeros

Array Operations

See “Linear Algebra” on page 1-19 and “Elementary Math” on page 1-23 for other array operations.

accumarray	Construct array with accumulation
arrayfun	Apply function to each element of array
bsxfun	Apply element-by-element binary operation to two arrays with singleton expansion enabled
cast	Cast variable to different data type
cross	Vector cross product
cumprod	Cumulative product
cumsum	Cumulative sum
dot	Vector dot product
idivide	Integer division with rounding option
kron	Kronecker tensor product
prod	Product of array elements
sum	Sum of array elements
tril	Lower triangular part of matrix
triu	Upper triangular part of matrix

Array Manipulation

blkdiag	Construct block diagonal matrix from input arguments
cat	Concatenate arrays along specified dimension
circshift	Shift array circularly

diag	Diagonal matrices and diagonals of matrix
end	Terminate block of code, or indicate last array index
flipdim	Flip array along specified dimension
fliplr	Flip matrix left to right
flipud	Flip matrix up to down
horzcat	Concatenate arrays horizontally
inline	Construct inline object
ipermute	Inverse permute dimensions of N-D array
permute	Rearrange dimensions of N-D array
repmat	Replicate and tile array
reshape	Reshape array
rot90	Rotate matrix 90 degrees
shiftdim	Shift dimensions
sort	Sort array elements in ascending or descending order
sortrows	Sort rows in ascending order
squeeze	Remove singleton dimensions
vectorize	Vectorize expression
vertcat	Concatenate arrays vertically

Specialized Matrices

compan	Companion matrix
gallery	Test matrices
hadamard	Hadamard matrix
hankel	Hankel matrix

hilb	Hilbert matrix
invhilb	Inverse of Hilbert matrix
magic	Magic square
pascal	Pascal matrix
rosser	Classic symmetric eigenvalue test problem
toeplitz	Toeplitz matrix
vander	Vandermonde matrix
wilkinson	Wilkinson's eigenvalue test matrix

Linear Algebra

Matrix Analysis (p. 1-19)	Compute norm, rank, determinant, condition number, etc.
Linear Equations (p. 1-20)	Solve linear systems, least squares, LU factorization, Cholesky factorization, etc.
Eigenvalues and Singular Values (p. 1-21)	Eigenvalues, eigenvectors, Schur decomposition, Hessenburg matrices, etc.
Matrix Logarithms and Exponentials (p. 1-22)	Matrix logarithms, exponentials, square root
Factorization (p. 1-22)	Cholesky, LU, and QR factorizations, diagonal forms, singular value decomposition

Matrix Analysis

cond	Condition number with respect to inversion
condeig	Condition number with respect to eigenvalues

det	Matrix determinant
norm	Vector and matrix norms
normest	2-norm estimate
null	Null space
orth	Range space of matrix
rank	Rank of matrix
rcond	Matrix reciprocal condition number estimate
rref	Reduced row echelon form
subspace	Angle between two subspaces
trace	Sum of diagonal elements

Linear Equations

chol	Cholesky factorization
cholinc	Sparse incomplete Cholesky and Cholesky-Infinity factorizations
cond	Condition number with respect to inversion
condest	1-norm condition number estimate
funm	Evaluate general matrix function
ilu	Sparse incomplete LU factorization
inv	Matrix inverse
linsolve	Solve linear system of equations
lscov	Least-squares solution in presence of known covariance
lsqnonneg	Solve nonnegative least-squares constraints problem
lu	LU matrix factorization

luinc	Sparse incomplete LU factorization
pinv	Moore-Penrose pseudoinverse of matrix
qr	Orthogonal-triangular decomposition
rcond	Matrix reciprocal condition number estimate

Eigenvalues and Singular Values

balance	Diagonal scaling to improve eigenvalue accuracy
cdf2rdf	Convert complex diagonal form to real block diagonal form
condeig	Condition number with respect to eigenvalues
eig	Find eigenvalues and eigenvectors
eigs	Find largest eigenvalues and eigenvectors of sparse matrix
gsvd	Generalized singular value decomposition
hess	Hessenberg form of matrix
ordeig	Eigenvalues of quasitriangular matrices
ordqz	Reorder eigenvalues in QZ factorization
ordschur	Reorder eigenvalues in Schur factorization
poly	Polynomial with specified roots
polyeig	Polynomial eigenvalue problem

rsf2csf	Convert real Schur form to complex Schur form
schur	Schur decomposition
sqrtm	Matrix square root
ss2tf	Convert state-space filter parameters to transfer function form
svd	Singular value decomposition
svds	Find singular values and vectors

Matrix Logarithms and Exponentials

expm	Matrix exponential
logm	Matrix logarithm
sqrtm	Matrix square root

Factorization

balance	Diagonal scaling to improve eigenvalue accuracy
cdf2rdf	Convert complex diagonal form to real block diagonal form
chol	Cholesky factorization
cholinc	Sparse incomplete Cholesky and Cholesky-Infinity factorizations
cholupdate	Rank 1 update to Cholesky factorization
gsvd	Generalized singular value decomposition
ilu	Sparse incomplete LU factorization
lu	LU matrix factorization

luinc	Sparse incomplete LU factorization
planerot	Givens plane rotation
qr	Orthogonal-triangular decomposition
qrdelete	Remove column or row from QR factorization
qrinsert	Insert column or row into QR factorization
qrupdate	
qz	QZ factorization for generalized eigenvalues
rsf2csf	Convert real Schur form to complex Schur form
svd	Singular value decomposition

Elementary Math

Trigonometric (p. 1-24)	Trigonometric functions with results in radians or degrees
Exponential (p. 1-25)	Exponential, logarithm, power, and root functions
Complex (p. 1-26)	Numbers with real and imaginary components, phase angles
Rounding and Remainder (p. 1-27)	Rounding, modulus, and remainder
Discrete Math (e.g., Prime Factors) (p. 1-27)	Prime factors, factorials, permutations, rational fractions, least common multiple, greatest common divisor

Trigonometric

acos	Inverse cosine; result in radians
acosd	Inverse cosine; result in degrees
acosh	Inverse hyperbolic cosine
acot	Inverse cotangent; result in radians
acotd	Inverse cotangent; result in degrees
acoth	Inverse hyperbolic cotangent
acsc	Inverse cosecant; result in radians
acscd	Inverse cosecant; result in degrees
acsch	Inverse hyperbolic cosecant
asec	Inverse secant; result in radians
asecd	Inverse secant; result in degrees
asech	Inverse hyperbolic secant
asin	Inverse sine; result in radians
asind	Inverse sine; result in degrees
asinh	Inverse hyperbolic sine
atan	Inverse tangent; result in radians
atan2	Four-quadrant inverse tangent
atand	Inverse tangent; result in degrees
atanh	Inverse hyperbolic tangent
cos	Cosine of argument in radians
cosd	Cosine ofo argument in degrees
cosh	Hyperbolic cosine
cot	Cotangent of argument in radians
cotd	Cotangent of argument in degrees
coth	Hyperbolic cotangent
csc	Cosecant of argument in radians

cscd	Cosecant of argument in degrees
csch	Hyperbolic cosecant
hypot	Square root of sum of squares
sec	Secant of argument in radians
secd	Secant of argument in degrees
sech	Hyperbolic secant
sin	Sine of argument in radians
sind	Sine of argument in degrees
sinh	Hyperbolic sine of argument in radians
tan	Tangent of argument in radians
tand	Tangent of argument in degrees
tanh	Hyperbolic tangent

Exponential

exp	Exponential
expm1	Compute `exp(x)-1` accurately for small values of `x`
log	Natural logarithm
log10	Common (base 10) logarithm
log1p	Compute `log(1+x)` accurately for small values of `x`
log2	Base 2 logarithm and dissect floating-point numbers into exponent and mantissa
nextpow2	Next higher power of 2
nthroot	Real `n`th root of real numbers
pow2	Base 2 power and scale floating-point numbers

reallog	Natural logarithm for nonnegative real arrays
realpow	Array power for real-only output
realsqrt	Square root for nonnegative real arrays
sqrt	Square root

Complex

abs	Absolute value and complex magnitude
angle	Phase angle
complex	Construct complex data from real and imaginary components
conj	Complex conjugate
cplxpair	Sort complex numbers into complex conjugate pairs
i	Imaginary unit
imag	Imaginary part of complex number
isreal	Determine whether input is real array
j	Imaginary unit
real	Real part of complex number
sign	Signum function
unwrap	Correct phase angles to produce smoother phase plots

Rounding and Remainder

ceil	Round toward infinity
fix	Round toward zero
floor	Round toward minus infinity
idivide	Integer division with rounding option
mod	Modulus after division
rem	Remainder after division
round	Round to nearest integer

Discrete Math (e.g., Prime Factors)

factor	Prime factors
factorial	Factorial function
gcd	Greatest common divisor
isprime	Array elements that are prime numbers
lcm	Least common multiple
nchoosek	Binomial coefficient or all combinations
perms	All possible permutations
primes	Generate list of prime numbers
rat, rats	Rational fraction approximation

Polynomials

conv	Convolution and polynomial multiplication
deconv	Deconvolution and polynomial division
poly	Polynomial with specified roots
polyder	Polynomial derivative
polyeig	Polynomial eigenvalue problem
polyfit	Polynomial curve fitting
polyint	Integrate polynomial analytically
polyval	Polynomial evaluation
polyvalm	Matrix polynomial evaluation
residue	Convert between partial fraction expansion and polynomial coefficients
roots	Polynomial roots

Interpolation and Computational Geometry

Interpolation (p. 1-29)	Data interpolation, data gridding, polynomial evaluation, nearest point search
Delaunay Triangulation and Tessellation (p. 1-30)	Delaunay triangulation and tessellation, triangular surface and mesh plots
Convex Hull (p. 1-30)	Plot convex hull, plotting functions
Voronoi Diagrams (p. 1-30)	Plot Voronoi diagram, patch graphics object, plotting functions
Domain Generation (p. 1-31)	Generate arrays for 3-D plots, or for N-D functions and interpolation

Interpolation

dsearch	Search Delaunay triangulation for nearest point
dsearchn	N-D nearest point search
griddata	Data gridding
griddata3	Data gridding and hypersurface fitting for 3-D data
griddatan	Data gridding and hypersurface fitting (dimension >= 2)
interp1	1-D data interpolation (table lookup)
interp1q	Quick 1-D linear interpolation
interp2	2-D data interpolation (table lookup)
interp3	3-D data interpolation (table lookup)
interpft	1-D interpolation using FFT method
interpn	N-D data interpolation (table lookup)
meshgrid	Generate `X` and `Y` arrays for 3-D plots
mkpp	Make piecewise polynomial
ndgrid	Generate arrays for N-D functions and interpolation
padecoef	Padé approximation of time delays
pchip	Piecewise Cubic Hermite Interpolating Polynomial (PCHIP)
ppval	Evaluate piecewise polynomial
spline	Cubic spline data interpolation
tsearchn	N-D closest simplex search
unmkpp	Piecewise polynomial details

Delaunay Triangulation and Tessellation

delaunay	Delaunay triangulation
delaunay3	3-D Delaunay tessellation
delaunayn	N-D Delaunay tessellation
dsearch	Search Delaunay triangulation for nearest point
dsearchn	N-D nearest point search
tetramesh	Tetrahedron mesh plot
trimesh	Triangular mesh plot
triplot	2-D triangular plot
trisurf	Triangular surface plot
tsearch	Search for enclosing Delaunay triangle
tsearchn	N-D closest simplex search

Convex Hull

convhull	Convex hull
convhulln	N-D convex hull
patch	Create patch graphics object
plot	2-D line plot
trisurf	Triangular surface plot

Voronoi Diagrams

dsearch	Search Delaunay triangulation for nearest point
patch	Create patch graphics object
plot	2-D line plot

voronoi	Voronoi diagram
voronoin	N-D Voronoi diagram

Domain Generation

meshgrid	Generate `X` and `Y` arrays for 3-D plots
ndgrid	Generate arrays for N-D functions and interpolation

Cartesian Coordinate System Conversion

cart2pol	Transform Cartesian coordinates to polar or cylindrical
cart2sph	Transform Cartesian coordinates to spherical
pol2cart	Transform polar or cylindrical coordinates to Cartesian
sph2cart	Transform spherical coordinates to Cartesian

Nonlinear Numerical Methods

Ordinary Differential Equations (IVP) (p. 1-32)	Solve stiff and nonstiff differential equations, define the problem, set solver options, evaluate solution
Delay Differential Equations (p. 1-33)	Solve delay differential equations with constant and general delays, set solver options, evaluate solution
Boundary Value Problems (p. 1-33)	Solve boundary value problems for ordinary differential equations, set solver options, evaluate solution

Partial Differential Equations (p. 1-34)	Solve initial-boundary value problems for parabolic-elliptic PDEs, evaluate solution
Optimization (p. 1-34)	Find minimum of single and multivariable functions, solve nonnegative least-squares constraint problem
Numerical Integration (Quadrature) (p. 1-34)	Evaluate Simpson, Lobatto, and vectorized quadratures, evaluate double and triple integrals

Ordinary Differential Equations (IVP)

decic	Compute consistent initial conditions for `ode15i`
deval	Evaluate solution of differential equation problem
ode15i	Solve fully implicit differential equations, variable order method
ode23, ode45, ode113, ode15s, ode23s, ode23t, ode23tb	Solve initial value problems for ordinary differential equations
odefile	Define differential equation problem for ordinary differential equation solvers
odeget	Ordinary differential equation options parameters
odeset	Create or alter options structure for ordinary differential equation solvers
odextend	Extend solution of initial value problem for ordinary differential equation

Delay Differential Equations

dde23	Solve delay differential equations (DDEs) with constant delays
ddeget	Extract properties from delay differential equations options structure
ddesd	Solve delay differential equations (DDEs) with general delays
ddeset	Create or alter delay differential equations options structure
deval	Evaluate solution of differential equation problem

Boundary Value Problems

bvp4c	Solve boundary value problems for ordinary differential equations
bvp5c	Solve boundary value problems for ordinary differential equations
bvpget	Extract properties from options structure created with `bvpset`
bvpinit	Form initial guess for `bvp4c`
bvpset	Create or alter options structure of boundary value problem
bvpxtend	Form guess structure for extending boundary value solutions
deval	Evaluate solution of differential equation problem

Partial Differential Equations

pdepe	Solve initial-boundary value problems for parabolic-elliptic PDEs in 1-D
pdeval	Evaluate numerical solution of PDE using output of pdepe

Optimization

fminbnd	Find minimum of single-variable function on fixed interval
fminsearch	Find minimum of unconstrained multivariable function using derivative-free method
fzero	Find root of continuous function of one variable
lsqnonneg	Solve nonnegative least-squares constraints problem
optimget	Optimization options values
optimset	Create or edit optimization options structure

Numerical Integration (Quadrature)

dblquad	Numerically evaluate double integral
quad	Numerically evaluate integral, adaptive Simpson quadrature
quadgk	Numerically evaluate integral, adaptive Gauss-Kronrod quadrature
quadl	Numerically evaluate integral, adaptive Lobatto quadrature

quadv	Vectorized quadrature
triplequad	Numerically evaluate triple integral

Specialized Math

airy	Airy functions
besselh	Bessel function of third kind (Hankel function)
besseli	Modified Bessel function of first kind
besselj	Bessel function of first kind
besselk	Modified Bessel function of second kind
bessely	Bessel function of second kind
beta	Beta function
betainc	Incomplete beta function
betaln	Logarithm of beta function
ellipj	Jacobi elliptic functions
ellipke	Complete elliptic integrals of first and second kind
erf, erfc, erfcx, erfinv, erfcinv	Error functions
expint	Exponential integral
gamma, gammainc, gammaln	Gamma functions
legendre	Associated Legendre functions
psi	Psi (polygamma) function

Sparse Matrices

Elementary Sparse Matrices (p. 1-36)	Create random and nonrandom sparse matrices
Full to Sparse Conversion (p. 1-37)	Convert full matrix to sparse, sparse matrix to full
Working with Sparse Matrices (p. 1-37)	Test matrix for sparseness, get information on sparse matrix, allocate sparse matrix, apply function to nonzero elements, visualize sparsity pattern.
Reordering Algorithms (p. 1-37)	Random, column, minimum degree, Dulmage-Mendelsohn, and reverse Cuthill-McKee permutations
Linear Algebra (p. 1-38)	Compute norms, eigenvalues, factorizations, least squares, structural rank
Linear Equations (Iterative Methods) (p. 1-38)	Methods for conjugate and biconjugate gradients, residuals, lower quartile
Tree Operations (p. 1-39)	Elimination trees, tree plotting, factorization analysis

Elementary Sparse Matrices

spdiags	Extract and create sparse band and diagonal matrices
speye	Sparse identity matrix
sprand	Sparse uniformly distributed random matrix
sprandn	Sparse normally distributed random matrix
sprandsym	Sparse symmetric random matrix

Full to Sparse Conversion

find	Find indices and values of nonzero elements
full	Convert sparse matrix to full matrix
sparse	Create sparse matrix
spconvert	Import matrix from sparse matrix external format

Working with Sparse Matrices

issparse	Determine whether input is sparse
nnz	Number of nonzero matrix elements
nonzeros	Nonzero matrix elements
nzmax	Amount of storage allocated for nonzero matrix elements
spalloc	Allocate space for sparse matrix
spfun	Apply function to nonzero sparse matrix elements
spones	Replace nonzero sparse matrix elements with ones
spparms	Set parameters for sparse matrix routines
spy	Visualize sparsity pattern

Reordering Algorithms

amd	Approximate minimum degree permutation
colamd	Column approximate minimum degree permutation

colperm	Sparse column permutation based on nonzero count
dmperm	Dulmage-Mendelsohn decomposition
ldl	Block ldl' factorization for Hermitian indefinite matrices
randperm	Random permutation
symamd	Symmetric approximate minimum degree permutation
symrcm	Sparse reverse Cuthill-McKee ordering

Linear Algebra

cholinc	Sparse incomplete Cholesky and Cholesky-Infinity factorizations
condest	1-norm condition number estimate
eigs	Find largest eigenvalues and eigenvectors of sparse matrix
ilu	Sparse incomplete LU factorization
luinc	Sparse incomplete LU factorization
normest	2-norm estimate
spaugment	Form least squares augmented system
sprank	Structural rank
svds	Find singular values and vectors

Linear Equations (Iterative Methods)

bicg	Biconjugate gradients method
bicgstab	Biconjugate gradients stabilized method

cgs	Conjugate gradients squared method
gmres	Generalized minimum residual method (with restarts)
lsqr	LSQR method
minres	Minimum residual method
pcg	Preconditioned conjugate gradients method
qmr	Quasi-minimal residual method
symmlq	Symmetric LQ method

Tree Operations

etree	Elimination tree
etreeplot	Plot elimination tree
gplot	Plot nodes and links representing adjacency matrix
symbfact	Symbolic factorization analysis
treelayout	Lay out tree or forest
treeplot	Plot picture of tree

Math Constants

eps	Floating-point relative accuracy
i	Imaginary unit
Inf	Infinity
intmax	Largest value of specified integer type
intmin	Smallest value of specified integer type
j	Imaginary unit

NaN	Not-a-Number
pi	Ratio of circle's circumference to its diameter, π
realmax	Largest positive floating-point number
realmin	Smallest positive normalized floating-point number

Data Analysis

Basic Operations

cumprod	Cumulative product
cumsum	Cumulative sum
prod	Product of array elements
sort	Sort array elements in ascending or descending order
sortrows	Sort rows in ascending order
sum	Sum of array elements

Descriptive Statistics

corrcoef	Correlation coefficients
cov	Covariance matrix
max	Largest elements in array
mean	Average or mean value of array
median	Median value of array

min	Smallest elements in array
mode	Most frequent values in array
std	Standard deviation
var	Variance

Filtering and Convolution

conv	Convolution and polynomial multiplication
conv2	2-D convolution
convn	N-D convolution
deconv	Deconvolution and polynomial division
detrend	Remove linear trends
filter	1-D digital filter
filter2	2-D digital filter

Interpolation and Regression

interp1	1-D data interpolation (table lookup)
interp2	2-D data interpolation (table lookup)
interp3	3-D data interpolation (table lookup)
interpn	N-D data interpolation (table lookup)
mldivide \, mrdivide /	Left or right matrix division
polyfit	Polynomial curve fitting
polyval	Polynomial evaluation

Fourier Transforms

abs	Absolute value and complex magnitude
angle	Phase angle
cplxpair	Sort complex numbers into complex conjugate pairs
fft	Discrete Fourier transform
fft2	2-D discrete Fourier transform
fftn	N-D discrete Fourier transform
fftshift	Shift zero-frequency component to center of spectrum
fftw	Interface to FFTW library run-time algorithm tuning control
ifft	Inverse discrete Fourier transform
ifft2	2-D inverse discrete Fourier transform
ifftn	N-D inverse discrete Fourier transform
ifftshift	Inverse FFT shift
nextpow2	Next higher power of 2
unwrap	Correct phase angles to produce smoother phase plots

Derivatives and Integrals

cumtrapz	Cumulative trapezoidal numerical integration
del2	Discrete Laplacian
diff	Differences and approximate derivatives

gradient	Numerical gradient
polyder	Polynomial derivative
polyint	Integrate polynomial analytically
trapz	Trapezoidal numerical integration

Time Series Objects

General Purpose (p. 1-44)	Combine `timeseries` objects, query and set `timeseries` object properties, plot `timeseries` objects
Data Manipulation (p. 1-45)	Add or delete data, manipulate `timeseries` objects
Event Data (p. 1-46)	Add or delete events, create new `timeseries` objects based on event data
Descriptive Statistics (p. 1-46)	Descriptive statistics for `timeseries` objects

General Purpose

get (timeseries)	Query `timeseries` object property values
getdatasamplesize	Size of data sample in `timeseries` object
getqualitydesc	Data quality descriptions
isempty (timeseries)	Determine whether `timeseries` object is empty
length (timeseries)	Length of time vector
plot (timeseries)	Plot time series
set (timeseries)	Set properties of `timeseries` object
size (timeseries)	Size of `timeseries` object

timeseries	Create `timeseries` object
tsdata.event	Construct event object for `timeseries` object
tsprops	Help on `timeseries` object properties
tstool	Open Time Series Tools GUI

Data Manipulation

addsample	Add data sample to `timeseries` object
ctranspose (timeseries)	Transpose `timeseries` object
delsample	Remove sample from `timeseries` object
detrend (timeseries)	Subtract mean or best-fit line and all `NaN`s from time series
filter (timeseries)	Shape frequency content of time series
getabstime (timeseries)	Extract date-string time vector into cell array
getinterpmethod	Interpolation method for `timeseries` object
getsampleusingtime (timeseries)	Extract data samples into new `timeseries` object
idealfilter (timeseries)	Apply ideal (noncausal) filter to `timeseries` object
resample (timeseries)	Select or interpolate `timeseries` data using new time vector
setabstime (timeseries)	Set times of `timeseries` object as date strings
setinterpmethod	Set default interpolation method for `timeseries` object

synchronize	Synchronize and resample two `timeseries` objects using common time vector
transpose (timeseries)	Transpose `timeseries` object
vertcat (timeseries)	Vertical concatenation of `timeseries` objects

Event Data

addevent	Add event to `timeseries` object
delevent	Remove `tsdata.event` objects from `timeseries` object
gettsafteratevent	New `timeseries` object with samples occurring at or after event
gettsafterevent	New `timeseries` object with samples occurring after event
gettsatevent	New `timeseries` object with samples occurring at event
gettsbeforeatevent	New `timeseries` object with samples occurring before or at event
gettsbeforeevent	New `timeseries` object with samples occurring before event
gettsbetweenevents	New `timeseries` object with samples occurring between events

Descriptive Statistics

iqr (timeseries)	Interquartile range of `timeseries` data
max (timeseries)	Maximum value of `timeseries` data
mean (timeseries)	Mean value of `timeseries` data
median (timeseries)	Median value of `timeseries` data

min (timeseries)	Minimum value of `timeseries` data
std (timeseries)	Standard deviation of `timeseries` data
sum (timeseries)	Sum of `timeseries` data
var (timeseries)	Variance of `timeseries` data

Time Series Collections

General Purpose (p. 1-47)	Query and set `tscollection` object properties, plot `tscollection` objects
Data Manipulation (p. 1-48)	Add or delete data, manipulate `tscollection` objects

General Purpose

get (tscollection)	Query `tscollection` object property values
isempty (tscollection)	Determine whether `tscollection` object is empty
length (tscollection)	Length of time vector
plot (timeseries)	Plot time series
set (tscollection)	Set properties of `tscollection` object
size (tscollection)	Size of `tscollection` object
tscollection	Create `tscollection` object
tstool	Open Time Series Tools GUI

Data Manipulation

addsampletocollection	Add sample to `tscollection` object
addts	Add `timeseries` object to `tscollection` object
delsamplefromcollection	Remove sample from `tscollection` object
getabstime (tscollection)	Extract date-string time vector into cell array
getsampleusingtime (tscollection)	Extract data samples into new `tscollection` object
gettimeseriesnames	Cell array of names of `timeseries` objects in `tscollection` object
horzcat (tscollection)	Horizontal concatenation for `tscollection` objects
removets	Remove `timeseries` objects from `tscollection` object
resample (tscollection)	Select or interpolate data in `tscollection` using new time vector
setabstime (tscollection)	Set times of `tscollection` object as date strings
settimeseriesnames	Change name of `timeseries` object in `tscollection`
vertcat (tscollection)	Vertical concatenation for `tscollection` objects

Programming and Data Types

Data Types

Cell Arrays (p. 1-53)	Data of varying types and sizes stored in cells of array
Function Handles (p. 1-54)	Invoke a function indirectly via handle
MATLAB Classes and Objects (p. 1-55)	MATLAB object-oriented class system
Java Classes and Objects (p. 1-55)	Access Java classes through MATLAB interface
Data Type Identification (p. 1-57)	Determine data type of a variable

Numeric Types

arrayfun	Apply function to each element of array
cast	Cast variable to different data type
cat	Concatenate arrays along specified dimension
class	Create object or return class of object
find	Find indices and values of nonzero elements
intmax	Largest value of specified integer type
intmin	Smallest value of specified integer type
intwarning	Control state of integer warnings
ipermute	Inverse permute dimensions of N-D array
isa	Determine whether input is object of given class
isequal	Test arrays for equality

isequalwithequalnans	Test arrays for equality, treating NaNs as equal
isfinite	Array elements that are finite
isinf	Array elements that are infinite
isnan	Array elements that are NaN
isnumeric	Determine whether input is numeric array
isreal	Determine whether input is real array
isscalar	Determine whether input is scalar
isvector	Determine whether input is vector
permute	Rearrange dimensions of N-D array
realmax	Largest positive floating-point number
realmin	Smallest positive normalized floating-point number
reshape	Reshape array
squeeze	Remove singleton dimensions
zeros	Create array of all zeros

Characters and Strings

See “String Functions” on page 1-63 for all string-related functions.

cellstr	Create cell array of strings from character array
char	Convert to character array (string)
eval	Execute string containing MATLAB expression
findstr	Find string within another, longer string

isstr	Determine whether input is character array
regexp, regexpi	Match regular expression
sprintf	Write formatted data to string
sscanf	Read formatted data from string
strcat	Concatenate strings horizontally
strcmp, strcmpi	Compare strings
strings	MATLAB string handling
strjust	Justify character array
strmatch	Find possible matches for string
strread	Read formatted data from string
strrep	Find and replace substring
strtrim	Remove leading and trailing white space from string
strvcat	Concatenate strings vertically

Structures

arrayfun	Apply function to each element of array
cell2struct	Convert cell array to structure array
class	Create object or return class of object
deal	Distribute inputs to outputs
fieldnames	Field names of structure, or public fields of object
getfield	Field of structure array
isa	Determine whether input is object of given class
isequal	Test arrays for equality

isfield	Determine whether input is structure array field
isscalar	Determine whether input is scalar
isstruct	Determine whether input is structure array
isvector	Determine whether input is vector
orderfields	Order fields of structure array
rmfield	Remove fields from structure
setfield	Set value of structure array field
struct	Create structure array
struct2cell	Convert structure to cell array
structfun	Apply function to each field of scalar structure

Cell Arrays

cell	Construct cell array
cell2mat	Convert cell array of matrices to single matrix
cell2struct	Convert cell array to structure array
celldisp	Cell array contents
cellfun	Apply function to each cell in cell array
cellplot	Graphically display structure of cell array
cellstr	Create cell array of strings from character array
class	Create object or return class of object
deal	Distribute inputs to outputs

isa	Determine whether input is object of given class
iscell	Determine whether input is cell array
iscellstr	Determine whether input is cell array of strings
isequal	Test arrays for equality
isscalar	Determine whether input is scalar
isvector	Determine whether input is vector
mat2cell	Divide matrix into cell array of matrices
num2cell	Convert numeric array to cell array
struct2cell	Convert structure to cell array

Function Handles

class	Create object or return class of object
feval	Evaluate function
func2str	Construct function name string from function handle
functions	Information about function handle
function_handle (@)	Handle used in calling functions indirectly
isa	Determine whether input is object of given class
isequal	Test arrays for equality
str2func	Construct function handle from function name string

MATLAB Classes and Objects

class	Create object or return class of object
fieldnames	Field names of structure, or public fields of object
inferiorto	Establish inferior class relationship
isa	Determine whether input is object of given class
isobject	Determine whether input is MATLAB OOPs object
loadobj	User-defined extension of `load` function for user objects
methods	Information on class methods
methodsview	Information on class methods in separate window
saveobj	User-defined extension of `save` function for user objects
subsasgn	Subscripted assignment for objects
subsindex	Subscripted indexing for objects
subsref	Subscripted reference for objects
substruct	Create structure argument for `subsasgn` or `subsref`
superiorto	Establish superior class relationship

Java Classes and Objects

cell	Construct cell array
class	Create object or return class of object
clear	Remove items from workspace, freeing up system memory
depfun	List dependencies of M-file or P-file

exist	Check existence of variable, function, directory, or Java class
fieldnames	Field names of structure, or public fields of object
im2java	Convert image to Java image
import	Add package or class to current Java import list
inmem	Names of M-files, MEX-files, Java classes in memory
isa	Determine whether input is object of given class
isjava	Determine whether input is Java object
javaaddpath	Add entries to dynamic Java class path
javaArray	Construct Java array
javachk	Generate error message based on Java feature support
javaclasspath	Set and get dynamic Java class path
javaMethod	Invoke Java method
javaObject	Construct Java object
javarmpath	Remove entries from dynamic Java class path
methods	Information on class methods
methodsview	Information on class methods in separate window
usejava	Determine whether Java feature is supported in MATLAB
which	Locate functions and files

Data Type Identification

is*	Detect state
isa	Determine whether input is object of given class
iscell	Determine whether input is cell array
iscellstr	Determine whether input is cell array of strings
ischar	Determine whether item is character array
isfield	Determine whether input is structure array field
isfloat	Determine whether input is floating-point array
isinteger	Determine whether input is integer array
isjava	Determine whether input is Java object
islogical	Determine whether input is logical array
isnumeric	Determine whether input is numeric array
isobject	Determine whether input is MATLAB OOPs object
isreal	Determine whether input is real array
isstr	Determine whether input is character array
isstruct	Determine whether input is structure array

validateattributes	Check validity of array
who, whos	List variables in workspace

Data Type Conversion

Numeric (p. 1-58)	Convert data of one numeric type to another numeric type
String to Numeric (p. 1-58)	Convert characters to numeric equivalent
Numeric to String (p. 1-59)	Convert numeric to character equivalent
Other Conversions (p. 1-59)	Convert to structure, cell array, function handle, etc.

Numeric

cast	Cast variable to different data type
double	Convert to double precision
int8, int16, int32, int64	Convert to signed integer
single	Convert to single precision
typecast	Convert data types without changing underlying data
uint8, uint16, uint32, uint64	Convert to unsigned integer

String to Numeric

base2dec	Convert base N number string to decimal number
bin2dec	Convert binary number string to decimal number
cast	Cast variable to different data type

hex2dec	Convert hexadecimal number string to decimal number
hex2num	Convert hexadecimal number string to double-precision number
str2double	Convert string to double-precision value
str2num	Convert string to number
unicode2native	Convert Unicode characters to numeric bytes

Numeric to String

cast	Cast variable to different data type
char	Convert to character array (string)
dec2base	Convert decimal to base N number in string
dec2bin	Convert decimal to binary number in string
dec2hex	Convert decimal to hexadecimal number in string
int2str	Convert integer to string
mat2str	Convert matrix to string
native2unicode	Convert numeric bytes to Unicode characters
num2str	Convert number to string

Other Conversions

cell2mat	Convert cell array of matrices to single matrix
cell2struct	Convert cell array to structure array

datestr	Convert date and time to string format
func2str	Construct function name string from function handle
logical	Convert numeric values to logical
mat2cell	Divide matrix into cell array of matrices
num2cell	Convert numeric array to cell array
num2hex	Convert singles and doubles to IEEE hexadecimal strings
str2func	Construct function handle from function name string
str2mat	Form blank-padded character matrix from strings
struct2cell	Convert structure to cell array

Operators and Special Characters

Arithmetic Operators (p. 1-60)	Plus, minus, power, left and right divide, transpose, etc.
Relational Operators (p. 1-61)	Equal to, greater than, less than or equal to, etc.
Logical Operators (p. 1-61)	Element-wise and short circuit and, or, not
Special Characters (p. 1-62)	Array constructors, line continuation, comments, etc.

Arithmetic Operators

+	Plus
-	Minus

.	Decimal point
=	Assignment
*	Matrix multiplication
/	Matrix right division
\	Matrix left division
^	Matrix power
'	Matrix transpose
.*	Array multiplication (element-wise)
./	Array right division (element-wise)
.\	Array left division (element-wise)
.^	Array power (element-wise)
.'	Array transpose

Relational Operators

<	Less than
<=	Less than or equal to
>	Greater than
>=	Greater than or equal to
==	Equal to
~=	Not equal to

Logical Operators

See also "Logical Functions" on page 1-66 for functions like `xor`, `all`, `any`, etc.

&&	Logical AND
||	Logical OR
&	Logical AND for arrays

|	Logical OR for arrays
~	Logical NOT

Special Characters

:	Create vectors, subscript arrays, specify for-loop iterations
( )	Pass function arguments, prioritize operators
[ ]	Construct array, concatenate elements, specify multiple outputs from function
{ }	Construct cell array, index into cell array
.	Insert decimal point, define structure field, reference methods of object
.( )	Reference dynamic field of structure
..	Reference parent directory
...	Continue statement to next line
,	Separate rows of array, separate function input/output arguments, separate commands
;	Separate columns of array, suppress output from current command
%	Insert comment line into code
%{ %}	Insert block of comments into code
!	Issue command to operating system
' '	Construct character array
@	Construct function handle, reference class directory

String Functions

Description of Strings in MATLAB

strings	MATLAB string handling

String Creation

blanks	Create string of blank characters
cellstr	Create cell array of strings from character array
char	Convert to character array (string)
sprintf	Write formatted data to string
strcat	Concatenate strings horizontally
strvcat	Concatenate strings vertically

String Identification

class	Create object or return class of object
isa	Determine whether input is object of given class
iscellstr	Determine whether input is cell array of strings
ischar	Determine whether item is character array
isletter	Array elements that are alphabetic letters
isscalar	Determine whether input is scalar
isspace	Array elements that are space characters
isstrprop	Determine whether string is of specified category
isvector	Determine whether input is vector
validatestring	Check validity of text string

String Manipulation

deblank	Strip trailing blanks from end of string
lower	Convert string to lowercase
strjust	Justify character array
strrep	Find and replace substring
strtrim	Remove leading and trailing white space from string
upper	Convert string to uppercase

String Parsing

findstr	Find string within another, longer string
regexp, regexpi	Match regular expression
regexprep	Replace string using regular expression
regexptranslate	Translate string into regular expression
sscanf	Read formatted data from string
strfind	Find one string within another
strread	Read formatted data from string
strtok	Selected parts of string

String Evaluation

eval	Execute string containing MATLAB expression
evalc	Evaluate MATLAB expression with capture
evalin	Execute MATLAB expression in specified workspace

String Comparison

strcmp, strcmpi	Compare strings
strmatch	Find possible matches for string
strncmp, strncmpi	Compare first n characters of strings

Bit-wise Functions

bitand	Bitwise AND
bitcmp	Bitwise complement
bitget	Bit at specified position
bitmax	Maximum double-precision floating-point integer
bitor	Bitwise OR
bitset	Set bit at specified position
bitshift	Shift bits specified number of places
bitxor	Bitwise XOR
swapbytes	Swap byte ordering

Logical Functions

all	Determine whether all array elements are nonzero
and	Find logical AND of array or scalar inputs
any	Determine whether any array elements are nonzero
false	Logical 0 (false)
find	Find indices and values of nonzero elements
isa	Determine whether input is object of given class
iskeyword	Determine whether input is MATLAB keyword
isvarname	Determine whether input is valid variable name
logical	Convert numeric values to logical

not	Find logical NOT of array or scalar input
or	Find logical OR of array or scalar inputs
true	Logical 1 (true)
xor	Logical exclusive-OR

See “Operators and Special Characters” on page 1-60 for logical operators.

Relational Functions

eq	Test for equality
ge	Test for greater than or equal to
gt	Test for greater than
le	Test for less than or equal to
lt	Test for less than
ne	Test for inequality

See “Operators and Special Characters” on page 1-60 for relational operators.

Set Functions

intersect	Find set intersection of two vectors
ismember	Array elements that are members of set
issorted	Determine whether set elements are in sorted order
setdiff	Find set difference of two vectors
setxor	Find set exclusive OR of two vectors
union	Find set union of two vectors
unique	Find unique elements of vector

Date and Time Functions

addtodate	Modify date number by field
calendar	Calendar for specified month
clock	Current time as date vector
cputime	Elapsed CPU time
date	Current date string
datenum	Convert date and time to serial date number
datestr	Convert date and time to string format
datevec	Convert date and time to vector of components
eomday	Last day of month
etime	Time elapsed between date vectors
now	Current date and time
weekday	Day of week

Programming in MATLAB

M-File Functions and Scripts (p. 1-69)	Declare functions, handle arguments, identify dependencies, etc.
Evaluation of Expressions and Functions (p. 1-70)	Evaluate expression in string, apply function to array, run script file, etc.
Timer Functions (p. 1-71)	Schedule execution of MATLAB commands
Variables and Functions in Memory (p. 1-72)	List files in memory, clear M-files in memory, assign to variable in nondefault workspace, refresh caches

Control Flow (p. 1-73)	if-then-else, for loops, switch-case, try-catch
Error Handling (p. 1-74)	Generate warnings and errors, test for and catch errors, retrieve most recent error message
MEX Programming (p. 1-75)	Compile MEX function from C or Fortran code, list MEX-files in memory, debug MEX-files

M-File Functions and Scripts

addOptional (inputParser)	Add optional argument to `inputParser` schema
addParamValue (inputParser)	Add parameter-value argument to `inputParser` schema
addRequired (inputParser)	Add required argument to `inputParser` schema
createCopy (inputParser)	Create copy of `inputParser` object
depdir	List dependent directories of M-file or P-file
depfun	List dependencies of M-file or P-file
echo	Echo M-files during execution
end	Terminate block of code, or indicate last array index
function	Declare M-file function
input	Request user input
inputname	Variable name of function input
inputParser	Construct input parser object
mfilename	Name of currently running M-file
namelengthmax	Maximum identifier length
nargchk	Validate number of input arguments

nargin, nargout	Number of function arguments
nargoutchk	Validate number of output arguments
parse (inputParser)	Parse and validate named inputs
pcode	Create preparsed pseudocode file (P-file)
script	Script M-file description
syntax	Two ways to call MATLAB functions
varargin	Variable length input argument list
varargout	Variable length output argument list

Evaluation of Expressions and Functions

ans	Most recent answer
arrayfun	Apply function to each element of array
assert	Generate error when condition is violated
builtin	Execute built-in function from overloaded method
cellfun	Apply function to each cell in cell array
echo	Echo M-files during execution
eval	Execute string containing MATLAB expression
evalc	Evaluate MATLAB expression with capture
evalin	Execute MATLAB expression in specified workspace
feval	Evaluate function

iskeyword	Determine whether input is MATLAB keyword
isvarname	Determine whether input is valid variable name
pause	Halt execution temporarily
run	Run script that is not on current path
script	Script M-file description
structfun	Apply function to each field of scalar structure
symvar	Determine symbolic variables in expression
tic, toc	Measure performance using stopwatch timer

Timer Functions

delete (timer)	Remove timer object from memory
disp (timer)	Information about timer object
get (timer)	Timer object properties
isvalid (timer)	Determine whether timer object is valid
set (timer)	Configure or display timer object properties
start	Start timer(s) running
startat	Start timer(s) running at specified time
stop	Stop timer(s)
timer	Construct timer object
timerfind	Find timer objects

timerfindall	Find timer objects, including invisible objects
wait	Wait until timer stops running

Variables and Functions in Memory

ans	Most recent answer
assignin	Assign value to variable in specified workspace
datatipinfo	Produce short description of input variable
genvarname	Construct valid variable name from string
global	Declare global variables
inmem	Names of M-files, MEX-files, Java classes in memory
isglobal	Determine whether input is global variable
mislocked	Determine whether M-file or MEX-file cannot be cleared from memory
mlock	Prevent clearing M-file or MEX-file from memory
munlock	Allow clearing M-file or MEX-file from memory
namelengthmax	Maximum identifier length
pack	Consolidate workspace memory
persistent	Define persistent variable
rehash	Refresh function and file system path caches

Control Flow

break	Terminate execution of `for` or `while` loop
case	Execute block of code if condition is `true`
catch	Specify how to respond to error in `try` statement
continue	Pass control to next iteration of `for` or `while` loop
else	Execute statements if condition is false
elseif	Execute statements if additional condition is true
end	Terminate block of code, or indicate last array index
error	Display message and abort function
for	Execute block of code specified number of times
if	Execute statements if condition is true
otherwise	Default part of switch statement
return	Return to invoking function
switch	Switch among several cases, based on expression
try	Attempt to execute block of code, and catch errors
while	Repeatedly execute statements while condition is true

Error Handling

addCause (MException)	Append `MException` objects
assert	Generate error when condition is violated
catch	Specify how to respond to error in `try` statement
disp (MException)	Display `MException` object
eq (MException)	Compare `MException` objects for equality
error	Display message and abort function
ferror	Query MATLAB about errors in file input or output
getReport (MException)	Get error message for exception
intwarning	Control state of integer warnings
isequal (MException)	Compare `MException` objects for equality
last (MException)	Last uncaught exception
lasterr	Last error message
lasterror	Last error message and related information
lastwarn	Last warning message
MException	Construct `MException` object
ne (MException)	Compare `MException` objects for inequality
rethrow	Reissue error
rethrow (MException)	Reissue existing exception
throw (MException)	Terminate function and issue exception

try	Attempt to execute block of code, and catch errors
warning	Warning message

MEX Programming

dbmex	Enable MEX-file debugging
inmem	Names of M-files, MEX-files, Java classes in memory
mex	Compile MEX-function from C, C++, or Fortran source code
mexext	MEX-filename extension

File I/O

File Name Construction (p. 1-76)	Get path, directory, filename information; construct filenames
Opening, Loading, Saving Files (p. 1-77)	Open files; transfer data between files and MATLAB workspace
Memory Mapping (p. 1-77)	Access file data via memory map using MATLAB array indexing
Low-Level File I/O (p. 1-77)	Low-level operations that use a file identifier
Text Files (p. 1-78)	Delimited or formatted I/O to text files
XML Documents (p. 1-79)	Documents written in Extensible Markup Language
Spreadsheets (p. 1-79)	Excel and Lotus 1-2-3 files
Scientific Data (p. 1-80)	CDF, FITS, HDF formats
Audio and Audio/Video (p. 1-81)	General audio functions; SparcStation, WAVE, AVI files
Images (p. 1-83)	Graphics files
Internet Exchange (p. 1-84)	URL, FTP, zip, tar, and e-mail

To see a listing of file formats that are readable from MATLAB, go to file formats.

File Name Construction

filemarker	Character to separate file name and internal function name
fileparts	Parts of file name and path
filesep	Directory separator for current platform
fullfile	Build full filename from parts

tempdir	Name of system's temporary directory
tempname	Unique name for temporary file

Opening, Loading, Saving Files

daqread	Read Data Acquisition Toolbox (.daq) file
filehandle	Construct file handle object
importdata	Load data from disk file
load	Load workspace variables from disk
open	Open files based on extension
save	Save workspace variables to disk
uiimport	Open Import Wizard to import data
winopen	Open file in appropriate application (Windows)

Memory Mapping

disp (memmapfile)	Information about memmapfile object
get (memmapfile)	Memmapfile object properties
memmapfile	Construct memmapfile object

Low-Level File I/O

fclose	Close one or more open files
feof	Test for end-of-file
ferror	Query MATLAB about errors in file input or output

fgetl	Read line from file, discarding newline character
fgets	Read line from file, keeping newline character
fopen	Open file, or obtain information about open files
fprintf	Write formatted data to file
fread	Read binary data from file
frewind	Move file position indicator to beginning of open file
fscanf	Read formatted data from file
fseek	Set file position indicator
ftell	File position indicator
fwrite	Write binary data to file

Text Files

csvread	Read comma-separated value file
csvwrite	Write comma-separated value file
dlmread	Read ASCII-delimited file of numeric data into matrix
dlmwrite	Write matrix to ASCII-delimited file
textread	Read data from text file; write to multiple outputs
textscan	Read formatted data from text file or string

XML Documents

xmlread	Parse XML document and return Document Object Model node
xmlwrite	Serialize XML Document Object Model node
xslt	Transform XML document using XSLT engine

Spreadsheets

Microsoft Excel Functions (p. 1-79)	Read and write Microsoft Excel spreadsheet
Lotus 1-2-3 Functions (p. 1-79)	Read and write Lotus WK1 spreadsheet

Microsoft Excel Functions

xlsfinfo	Determine whether file contains Microsoft Excel (`.xls`) spreadsheet
xlsread	Read Microsoft Excel spreadsheet file (`.xls`)
xlswrite	Write Microsoft Excel spreadsheet file (`.xls`)

Lotus 1-2-3 Functions

wk1finfo	Determine whether file contains 1-2-3 WK1 worksheet
wk1read	Read Lotus 1-2-3 WK1 spreadsheet file into matrix
wk1write	Write matrix to Lotus 1-2-3 WK1 spreadsheet file

Scientific Data

Common Data Format (CDF) (p. 1-80)	Work with CDF files
Flexible Image Transport System (p. 1-80)	Work with FITS files
Hierarchical Data Format (HDF) (p. 1-81)	Work with HDF files
Band-Interleaved Data (p. 1-81)	Work with band-interleaved files

Common Data Format (CDF)

cdfepoch	Construct `cdfepoch` object for Common Data Format (CDF) export
cdfinfo	Information about Common Data Format (CDF) file
cdfread	Read data from Common Data Format (CDF) file
cdfwrite	Write data to Common Data Format (CDF) file
todatenum	Convert CDF epoch object to MATLAB datenum

Flexible Image Transport System

fitsinfo	Information about FITS file
fitsread	Read data from FITS file

Hierarchical Data Format (HDF)

hdf	Summary of MATLAB HDF4 capabilities
hdf5	Summary of MATLAB HDF5 capabilities
hdf5info	Information about HDF5 file
hdf5read	Read HDF5 file
hdf5write	Write data to file in HDF5 format
hdfinfo	Information about HDF4 or HDF-EOS file
hdfread	Read data from HDF4 or HDF-EOS file
hdftool	Browse and import data from HDF4 or HDF-EOS files

Band-Interleaved Data

multibandread	Read band-interleaved data from binary file
multibandwrite	Write band-interleaved data to file

Audio and Audio/Video

General (p. 1-82)	Create audio player object, obtain information about multimedia files, convert to/from audio signal
SPARCstation-Specific Sound Functions (p. 1-82)	Access NeXT/SUN (`.au`) sound files

Microsoft WAVE Sound Functions (p. 1-83)	Access Microsoft WAVE (`.wav`) sound files
Audio/Video Interleaved (AVI) Functions (p. 1-83)	Access Audio/Video interleaved (`.avi`) sound files

General

audioplayer	Create audio player object
audiorecorder	Create audio recorder object
beep	Produce beep sound
lin2mu	Convert linear audio signal to mu-law
mmfileinfo	Information about multimedia file
mmreader	Create multimedia reader object for reading video files
mu2lin	Convert mu-law audio signal to linear
read	Read video frame data from multimedia reader object
sound	Convert vector into sound
soundsc	Scale data and play as sound

SPARCstation-Specific Sound Functions

aufinfo	Information about NeXT/SUN (`.au`) sound file
auread	Read NeXT/SUN (`.au`) sound file
auwrite	Write NeXT/SUN (`.au`) sound file

Microsoft WAVE Sound Functions

wavfinfo	Information about Microsoft WAVE (`.wav`) sound file
wavplay	Play recorded sound on PC-based audio output device
wavread	Read Microsoft WAVE (`.wav`) sound file
wavrecord	Record sound using PC-based audio input device
wavwrite	Write Microsoft WAVE (`.wav`) sound file

Audio/Video Interleaved (AVI) Functions

addframe	Add frame to Audio/Video Interleaved (AVI) file
avifile	Create new Audio/Video Interleaved (AVI) file
aviinfo	Information about Audio/Video Interleaved (AVI) file
aviread	Read Audio/Video Interleaved (AVI) file
close (avifile)	Close Audio/Video Interleaved (AVI) file
movie2avi	Create Audio/Video Interleaved (AVI) movie from MATLAB movie

Images

exifread	Read EXIF information from JPEG and TIFF image files
im2java	Convert image to Java image

imfinfo	Information about graphics file
imread	Read image from graphics file
imwrite	Write image to graphics file

Internet Exchange

URL, Zip, Tar, E-Mail (p. 1-84)	Send e-mail, read from given URL, extract from tar or zip file, compress and decompress files
FTP Functions (p. 1-84)	Connect to FTP server, download from server, manage FTP files, close server connection

URL, Zip, Tar, E-Mail

gunzip	Uncompress GNU zip files
gzip	Compress files into GNU zip files
sendmail	Send e-mail message to address list
tar	Compress files into tar file
untar	Extract contents of tar file
unzip	Extract contents of zip file
urlread	Read content at URL
urlwrite	Save contents of URL to file
zip	Compress files into zip file

FTP Functions

ascii	Set FTP transfer type to ASCII
binary	Set FTP transfer type to binary

cd (ftp)	Change current directory on FTP server
close (ftp)	Close connection to FTP server
delete (ftp)	Remove file on FTP server
dir (ftp)	Directory contents on FTP server
ftp	Connect to FTP server, creating FTP object
mget	Download file from FTP server
mkdir (ftp)	Create new directory on FTP server
mput	Upload file or directory to FTP server
rename	Rename file on FTP server
rmdir (ftp)	Remove directory on FTP server

Graphics

Basic Plots and Graphs (p. 1-86)	Linear line plots, log and semilog plots
Plotting Tools (p. 1-87)	GUIs for interacting with plots
Annotating Plots (p. 1-87)	Functions for and properties of titles, axes labels, legends, mathematical symbols
Specialized Plotting (p. 1-88)	Bar graphs, histograms, pie charts, contour plots, function plotters
Bit-Mapped Images (p. 1-92)	Display image object, read and write graphics file, convert to movie frames
Printing (p. 1-92)	Printing and exporting figures to standard formats
Handle Graphics (p. 1-93)	Creating graphics objects, setting properties, finding handles

Basic Plots and Graphs

box	Axes border
errorbar	Plot error bars along curve
hold	Retain current graph in figure
LineSpec	Line specification string syntax
loglog	Log-log scale plot
plot	2-D line plot
plot3	3-D line plot
plotyy	2-D line plots with y-axes on both left and right side
polar	Polar coordinate plot

semilogx, semilogy	Semilogarithmic plots
subplot	Create axes in tiled positions

Plotting Tools

figurepalette	Show or hide figure palette
pan	Pan view of graph interactively
plotbrowser	Show or hide figure plot browser
plotedit	Interactively edit and annotate plots
plottools	Show or hide plot tools
propertyeditor	Show or hide property editor
rotate3d	Rotate 3-D view using mouse
showplottool	Show or hide figure plot tool
zoom	Turn zooming on or off or magnify by factor

Annotating Plots

annotation	Create annotation objects
clabel	Contour plot elevation labels
datacursormode	Enable or disable interactive data cursor mode
datetick	Date formatted tick labels
gtext	Mouse placement of text in 2-D view
legend	Graph legend for lines and patches
line	Create line object
rectangle	Create 2-D rectangle object
texlabel	Produce TeX format from character string

title	Add title to current axes
xlabel, ylabel, zlabel	Label *x*-, *y*-, and *z*-axis

Specialized Plotting

Area, Bar, and Pie Plots (p. 1-88)	1-D, 2-D, and 3-D graphs and charts
Contour Plots (p. 1-89)	Unfilled and filled contours in 2-D and 3-D
Direction and Velocity Plots (p. 1-89)	Comet, compass, feather and quiver plots
Discrete Data Plots (p. 1-89)	Stair, step, and stem plots
Function Plots (p. 1-89)	Easy-to-use plotting utilities for graphing functions
Histograms (p. 1-90)	Plots for showing distributions of data
Polygons and Surfaces (p. 1-90)	Functions to generate and plot surface patches in two or more dimensions
Scatter/Bubble Plots (p. 1-91)	Plots of point distributions
Animation (p. 1-91)	Functions to create and play movies of plots

Area, Bar, and Pie Plots

area	Filled area 2-D plot
bar, barh	Plot bar graph (vertical and horizontal)
bar3, bar3h	Plot 3-D bar chart
pareto	Pareto chart
pie	Pie chart
pie3	3-D pie chart

Contour Plots

contour	Contour plot of matrix
contour3	3-D contour plot
contourc	Low-level contour plot computation
contourf	Filled 2-D contour plot
ezcontour	Easy-to-use contour plotter
ezcontourf	Easy-to-use filled contour plotter

Direction and Velocity Plots

comet	2-D comet plot
comet3	3-D comet plot
compass	Plot arrows emanating from origin
feather	Plot velocity vectors
quiver	Quiver or velocity plot
quiver3	3-D quiver or velocity plot

Discrete Data Plots

stairs	Stairstep graph
stem	Plot discrete sequence data
stem3	Plot 3-D discrete sequence data

Function Plots

ezcontour	Easy-to-use contour plotter
ezcontourf	Easy-to-use filled contour plotter
ezmesh	Easy-to-use 3-D mesh plotter

ezmeshc	Easy-to-use combination mesh/contour plotter
ezplot	Easy-to-use function plotter
ezplot3	Easy-to-use 3-D parametric curve plotter
ezpolar	Easy-to-use polar coordinate plotter
ezsurf	Easy-to-use 3-D colored surface plotter
ezsurfc	Easy-to-use combination surface/contour plotter
fplot	Plot function between specified limits

Histograms

hist	Histogram plot
histc	Histogram count
rose	Angle histogram plot

Polygons and Surfaces

convhull	Convex hull
cylinder	Generate cylinder
delaunay	Delaunay triangulation
delaunay3	3-D Delaunay tessellation
delaunayn	N-D Delaunay tessellation
dsearch	Search Delaunay triangulation for nearest point
dsearchn	N-D nearest point search
ellipsoid	Generate ellipsoid

fill	Filled 2-D polygons
fill3	Filled 3-D polygons
inpolygon	Points inside polygonal region
pcolor	Pseudocolor (checkerboard) plot
polyarea	Area of polygon
rectint	Rectangle intersection area
ribbon	Ribbon plot
slice	Volumetric slice plot
sphere	Generate sphere
tsearch	Search for enclosing Delaunay triangle
tsearchn	N-D closest simplex search
voronoi	Voronoi diagram
waterfall	Waterfall plot

Scatter/Bubble Plots

plotmatrix	Scatter plot matrix
scatter	Scatter plot
scatter3	3-D scatter plot

Animation

frame2im	Convert movie frame to indexed image
getframe	Capture movie frame
im2frame	Convert image to movie frame

movie	Play recorded movie frames
noanimate	Change `EraseMode` of all objects to `normal`

Bit-Mapped Images

frame2im	Convert movie frame to indexed image
im2frame	Convert image to movie frame
im2java	Convert image to Java image
image	Display image object
imagesc	Scale data and display image object
imfinfo	Information about graphics file
imformats	Manage image file format registry
imread	Read image from graphics file
imwrite	Write image to graphics file
ind2rgb	Convert indexed image to RGB image

Printing

frameedit	Edit print frames for Simulink and Stateflow block diagrams
hgexport	Export figure
orient	Hardcopy paper orientation
print, printopt	Print figure or save to file and configure printer defaults
printdlg	Print dialog box

printpreview	Preview figure to print
saveas	Save figure or Simulink block diagram using specified format

Handle Graphics

Finding and Identifying Graphics Objects (p. 1-93)	Find and manipulate graphics objects via their handles
Object Creation Functions (p. 1-94)	Constructors for core graphics objects
Plot Objects (p. 1-94)	Property descriptions for plot objects
Figure Windows (p. 1-95)	Control and save figures
Axes Operations (p. 1-96)	Operate on axes objects
Operating on Object Properties (p. 1-96)	Query, set, and link object properties

Finding and Identifying Graphics Objects

allchild	Find all children of specified objects
ancestor	Ancestor of graphics object
copyobj	Copy graphics objects and their descendants
delete	Remove files or graphics objects
findall	Find all graphics objects
findfigs	Find visible offscreen figures
findobj	Locate graphics objects with specific properties
gca	Current axes handle
gcbf	Handle of figure containing object whose callback is executing

gcbo	Handle of object whose callback is executing
gco	Handle of current object
get	Query object properties
ishandle	Is object handle valid
propedit	Open Property Editor
set	Set object properties

Object Creation Functions

axes	Create axes graphics object
figure	Create figure graphics object
hggroup	Create hggroup object
hgtransform	Create hgtransform graphics object
image	Display image object
light	Create light object
line	Create line object
patch	Create patch graphics object
rectangle	Create 2-D rectangle object
root object	Root object properties
surface	Create surface object
text	Create text object in current axes
uicontextmenu	Create context menu

Plot Objects

Annotation Arrow Properties	Define annotation arrow properties
Annotation Doublearrow Properties	Define annotation doublearrow properties

Annotation Ellipse Properties	Define annotation ellipse properties
Annotation Line Properties	Define annotation line properties
Annotation Rectangle Properties	Define annotation rectangle properties
Annotation Textarrow Properties	Define annotation textarrow properties
Annotation Textbox Properties	Define annotation textbox properties
Areaseries Properties	Define areaseries properties
Barseries Properties	Define barseries properties
Contourgroup Properties	Define contourgroup properties
Errorbarseries Properties	Define errorbarseries properties
Image Properties	Define image properties
Lineseries Properties	Define lineseries properties
Quivergroup Properties	Define quivergroup properties
Scattergroup Properties	Define scattergroup properties
Stairseries Properties	Define stairseries properties
Stemseries Properties	Define stemseries properties
Surfaceplot Properties	Define surfaceplot properties

Figure Windows

clf	Clear current figure window
close	Remove specified figure
closereq	Default figure close request function
drawnow	Flushes event queue and updates figure window
gcf	Current figure handle
hgload	Load Handle Graphics object hierarchy from file

hgsave	Save Handle Graphics object hierarchy to file
newplot	Determine where to draw graphics objects
opengl	Control OpenGL rendering
refresh	Redraw current figure
saveas	Save figure or Simulink block diagram using specified format

Axes Operations

axis	Axis scaling and appearance
box	Axes border
cla	Clear current axes
gca	Current axes handle
grid	Grid lines for 2-D and 3-D plots
ishold	Current hold state
makehgtform	Create 4-by-4 transform matrix

Operating on Object Properties

get	Query object properties
linkaxes	Synchronize limits of specified 2-D axes
linkprop	Keep same value for corresponding properties
refreshdata	Refresh data in graph when data source is specified
set	Set object properties

3-D Visualization

Surface and Mesh Plots

Creating Surfaces and Meshes

hidden	Remove hidden lines from mesh plot
mesh, meshc, meshz	Mesh plots
peaks	Example function of two variables
surf, surfc	3-D shaded surface plot
surface	Create surface object
surfl	Surface plot with colormap-based lighting

tetramesh	Tetrahedron mesh plot
trimesh	Triangular mesh plot
triplot	2-D triangular plot
trisurf	Triangular surface plot

Domain Generation

griddata	Data gridding
meshgrid	Generate `X` and `Y` arrays for 3-D plots

Color Operations

brighten	Brighten or darken colormap
caxis	Color axis scaling
colorbar	Colorbar showing color scale
colordef	Set default property values to display different color schemes
colormap	Set and get current colormap
colormapeditor	Start colormap editor
ColorSpec	Color specification
graymon	Set default figure properties for grayscale monitors
hsv2rgb	Convert HSV colormap to RGB colormap
rgb2hsv	Convert RGB colormap to HSV colormap
rgbplot	Plot colormap
shading	Set color shading properties
spinmap	Spin colormap

surfnorm	Compute and display 3-D surface normals
whitebg	Change axes background color

Colormaps

contrast	Grayscale colormap for contrast enhancement

View Control

Controlling the Camera Viewpoint (p. 1-99)	Orbiting, dollying, pointing, rotating camera positions and setting fields of view
Setting the Aspect Ratio and Axis Limits (p. 1-100)	Specifying what portions of axes to view and how to scale them
Object Manipulation (p. 1-100)	Panning, rotating, and zooming views
Selecting Region of Interest (p. 1-101)	Interactively identifying rectangular regions

Controlling the Camera Viewpoint

camdolly	Move camera position and target
cameratoolbar	Control camera toolbar programmatically
camlookat	Position camera to view object or group of objects
camorbit	Rotate camera position around camera target
campan	Rotate camera target around camera position

campos	Set or query camera position
camproj	Set or query projection type
camroll	Rotate camera about view axis
camtarget	Set or query location of camera target
camup	Set or query camera up vector
camva	Set or query camera view angle
camzoom	Zoom in and out on scene
makehgtform	Create 4-by-4 transform matrix
view	Viewpoint specification
viewmtx	View transformation matrices

Setting the Aspect Ratio and Axis Limits

daspect	Set or query axes data aspect ratio
pbaspect	Set or query plot box aspect ratio
xlim, ylim, zlim	Set or query axis limits

Object Manipulation

pan	Pan view of graph interactively
reset	Reset graphics object properties to their defaults
rotate	Rotate object in specified direction
rotate3d	Rotate 3-D view using mouse
selectmoveresize	Select, move, resize, or copy axes and uicontrol graphics objects
zoom	Turn zooming on or off or magnify by factor

Selecting Region of Interest

dragrect	Drag rectangles with mouse
rbbox	Create rubberband box for area selection

Lighting

camlight	Create or move light object in camera coordinates
diffuse	Calculate diffuse reflectance
light	Create light object
lightangle	Create or position `light` object in spherical coordinates
lighting	Specify lighting algorithm
material	Control reflectance properties of surfaces and patches
specular	Calculate specular reflectance

Transparency

alim	Set or query axes alpha limits
alpha	Set transparency properties for objects in current axes
alphamap	Specify figure alphamap (transparency)

Volume Visualization

coneplot	Plot velocity vectors as cones in 3-D vector field
contourslice	Draw contours in volume slice planes
curl	Compute curl and angular velocity of vector field
divergence	Compute divergence of vector field
flow	Simple function of three variables
interpstreamspeed	Interpolate stream-line vertices from flow speed
isocaps	Compute isosurface end-cap geometry
isocolors	Calculate isosurface and patch colors
isonormals	Compute normals of isosurface vertices
isosurface	Extract isosurface data from volume data
reducepatch	Reduce number of patch faces
reducevolume	Reduce number of elements in volume data set
shrinkfaces	Reduce size of patch faces
slice	Volumetric slice plot
smooth3	Smooth 3-D data
stream2	Compute 2-D streamline data
stream3	Compute 3-D streamline data
streamline	Plot streamlines from 2-D or 3-D vector data
streamparticles	Plot stream particles
streamribbon	3-D stream ribbon plot from vector volume data

streamslice	Plot streamlines in slice planes
streamtube	Create 3-D stream tube plot
subvolume	Extract subset of volume data set
surf2patch	Convert surface data to patch data
volumebounds	Coordinate and color limits for volume data

Creating Graphical User Interfaces

Predefined Dialog Boxes

dialog	Create and display dialog box
errordlg	Create and open error dialog box
export2wsdlg	Export variables to workspace
helpdlg	Create and open help dialog box
inputdlg	Create and open input dialog box
listdlg	Create and open list-selection dialog box
msgbox	Create and open message box
printdlg	Print dialog box
printpreview	Preview figure to print
questdlg	Create and open question dialog box
uigetdir	Open standard dialog box for selecting a directory

uigetfile	Open standard dialog box for retrieving files
uigetpref	Open dialog box for retrieving preferences
uiopen	Open file selection dialog box with appropriate file filters
uiputfile	Open standard dialog box for saving files
uisave	Open standard dialog box for saving workspace variables
uisetcolor	Open standard dialog box for setting object's `ColorSpec`
uisetfont	Open standard dialog box for setting object's font characteristics
waitbar	Open waitbar
warndlg	Open warning dialog box

Deploying User Interfaces

guidata	Store or retrieve GUI data
guihandles	Create structure of handles
movegui	Move GUI figure to specified location on screen
openfig	Open new copy or raise existing copy of saved figure

Developing User Interfaces

addpref	Add preference
getappdata	Value of application-defined data
getpref	Preference

ginput	Graphical input from mouse or cursor
guidata	Store or retrieve GUI data
guide	Open GUI Layout Editor
inspect	Open Property Inspector
isappdata	True if application-defined data exists
ispref	Test for existence of preference
rmappdata	Remove application-defined data
rmpref	Remove preference
setappdata	Specify application-defined data
setpref	Set preference
uigetpref	Open dialog box for retrieving preferences
uisetpref	Manage preferences used in `uigetpref`
waitfor	Wait for condition before resuming execution
waitforbuttonpress	Wait for key press or mouse-button click

User Interface Objects

menu	Generate menu of choices for user input
uibuttongroup	Create container object to exclusively manage radio buttons and toggle buttons
uicontextmenu	Create context menu
uicontrol	Create user interface control object

uimenu	Create menus on figure windows
uipanel	Create panel container object
uipushtool	Create push button on toolbar
uitoggletool	Create toggle button on toolbar
uitoolbar	Create toolbar on figure

Finding Objects from Callbacks

findall	Find all graphics objects
findfigs	Find visible offscreen figures
findobj	Locate graphics objects with specific properties
gcbf	Handle of figure containing object whose callback is executing
gcbo	Handle of object whose callback is executing

GUI Utility Functions

align	Align user interface controls (uicontrols) and axes
getpixelposition	Get component position in pixels
listfonts	List available system fonts
selectmoveresize	Select, move, resize, or copy axes and uicontrol graphics objects
setpixelposition	Set component position in pixels
textwrap	Wrapped string matrix for given uicontrol
uistack	Reorder visual stacking order of objects

Controlling Program Execution

uiresume, uiwait	Control program execution

External Interfaces

Dynamic Link Libraries (p. 1-109)	Access functions stored in external shared library (.dll) files
Java (p. 1-110)	Work with objects constructed from Java API and third-party class packages
Component Object Model and ActiveX (p. 1-111)	Integrate COM components into your application
Web Services (p. 1-113)	Communicate between applications over a network using SOAP and WSDL
Serial Port Devices (p. 1-113)	Read and write to devices connected to your computer's serial port

See also MATLAB C and Fortran API Reference for functions you can use in external routines that interact with MATLAB programs and the data in MATLAB workspaces.

Dynamic Link Libraries

calllib	Call function in external library
libfunctions	Information on functions in external library
libfunctionsview	Create window displaying information on functions in external library
libisloaded	Determine whether external library is loaded
libpointer	Create pointer object for use with external libraries
libstruct	Construct structure as defined in external library

loadlibrary	Load external library into MATLAB
unloadlibrary	Unload external library from memory

Java

class	Create object or return class of object
fieldnames	Field names of structure, or public fields of object
import	Add package or class to current Java import list
inspect	Open Property Inspector
isa	Determine whether input is object of given class
isjava	Determine whether input is Java object
ismethod	Determine whether input is object method
isprop	Determine whether input is object property
javaaddpath	Add entries to dynamic Java class path
javaArray	Construct Java array
javachk	Generate error message based on Java feature support
javaclasspath	Set and get dynamic Java class path
javaMethod	Invoke Java method
javaObject	Construct Java object
javarmpath	Remove entries from dynamic Java class path
methods	Information on class methods

methodsview	Information on class methods in separate window
usejava	Determine whether Java feature is supported in MATLAB

Component Object Model and ActiveX

actxcontrol	Create ActiveX control in figure window
actxcontrollist	List all currently installed ActiveX controls
actxcontrolselect	Open GUI to create ActiveX control
actxGetRunningServer	Get handle to running instance of Automation server
actxserver	Create COM server
addproperty	Add custom property to object
class	Create object or return class of object
delete (COM)	Remove COM control or server
deleteproperty	Remove custom property from object
enableservice	Enable, disable, or report status of Automation server
eventlisteners	List of events attached to listeners
events	List of events control can trigger
Execute	Execute MATLAB command in server
Feval (COM)	Evaluate MATLAB function in server
fieldnames	Field names of structure, or public fields of object
get (COM)	Get property value from interface, or display properties

GetCharArray	Get character array from server
GetFullMatrix	Get matrix from server
GetVariable	Get data from variable in server workspace
GetWorkspaceData	Get data from server workspace
inspect	Open Property Inspector
interfaces	List custom interfaces to COM server
invoke	Invoke method on object or interface, or display methods
isa	Determine whether input is object of given class
iscom	Is input COM object
isevent	Is input event
isinterface	Is input COM interface
ismethod	Determine whether input is object method
isprop	Determine whether input is object property
load (COM)	Initialize control object from file
MaximizeCommandWindow	Open server window on Windows desktop
methods	Information on class methods
methodsview	Information on class methods in separate window
MinimizeCommandWindow	Minimize size of server window
move	Move or resize control in parent window
propedit (COM)	Open built-in property page for control
PutCharArray	Store character array in server

PutFullMatrix	Store matrix in server
PutWorkspaceData	Store data in server workspace
Quit (COM)	Terminate MATLAB server
registerevent	Register event handler with control's event
release	Release interface
save (COM)	Serialize control object to file
set (COM)	Set object or interface property to specified value
unregisterallevents	Unregister all events for control
unregisterevent	Unregister event handler with control's event

Web Services

callSoapService	Send SOAP message off to endpoint
createClassFromWsdl	Create MATLAB object based on WSDL file
createSoapMessage	Create SOAP message to send to server
parseSoapResponse	Convert response string from SOAP server into MATLAB data types

Serial Port Devices

clear (serial)	Remove serial port object from MATLAB workspace
delete (serial)	Remove serial port object from memory
disp (serial)	Serial port object summary information

fclose (serial)	Disconnect serial port object from device
fgetl (serial)	Read line of text from device and discard terminator
fgets (serial)	Read line of text from device and include terminator
fopen (serial)	Connect serial port object to device
fprintf (serial)	Write text to device
fread (serial)	Read binary data from device
fscanf (serial)	Read data from device, and format as text
fwrite (serial)	Write binary data to device
get (serial)	Serial port object properties
instrcallback	Event information when event occurs
instrfind	Read serial port objects from memory to MATLAB workspace
instrfindall	Find visible and hidden serial port objects
isvalid (serial)	Determine whether serial port objects are valid
length (serial)	Length of serial port object array
load (serial)	Load serial port objects and variables into MATLAB workspace
readasync	Read data asynchronously from device
record	Record data and event information to file
save (serial)	Save serial port objects and variables to MAT-file
serial	Create serial port object

serialbreak	Send break to device connected to serial port
set (serial)	Configure or display serial port object properties
size (serial)	Size of serial port object array
stopasync	Stop asynchronous read and write operations

Purpose

Matrix and array arithmetic

Syntax

```
A+B
A-B
A*B
A.*B
A/B
A./B
A\B
A.\B
A^B
A.^B
A'
A.'
```

Description

MATLAB has two different types of arithmetic operations. Matrix arithmetic operations are defined by the rules of linear algebra. Array arithmetic operations are carried out element by element, and can be used with multidimensional arrays. The period character (`.`) distinguishes the array operations from the matrix operations. However, since the matrix and array operations are the same for addition and subtraction, the character pairs `.+` and `.-` are not used.

`+` Addition or unary plus. `A+B` adds `A` and `B`. `A` and `B` must have the same size, unless one is a scalar. A scalar can be added to a matrix of any size.

`-` Subtraction or unary minus. `A-B` subtracts `B` from `A`. `A` and `B` must have the same size, unless one is a scalar. A scalar can be subtracted from a matrix of any size.

`*` Matrix multiplication. `C = A*B` is the linear algebraic product of the matrices `A` and `B`. More precisely,

$$C(i,j) = \sum_{k=1}^{n} A(i,k)B(k,j)$$

For nonscalar `A` and `B`, the number of columns of `A` must equal the number of rows of `B`. A scalar can multiply a matrix of any size.

`.*` Array multiplication. `A.*B` is the element-by-element product of the arrays `A` and `B`. `A` and `B` must have the same size, unless one of them is a scalar.

`/` Slash or matrix right division. `B/A` is roughly the same as `B*inv(A)`. More precisely, `B/A = (A'\B')'`. See the reference page for `mrdivide` for more information.

`./` Array right division. `A./B` is the matrix with elements `A(i,j)/B(i,j)`. `A` and `B` must have the same size, unless one of them is a scalar.

`\` Backslash or matrix left division. If `A` is a square matrix, `A\B` is roughly the same as `inv(A)*B`, except it is computed in a different way. If `A` is an `n`-by-`n` matrix and `B` is a column vector with `n` components, or a matrix with several such columns, then `X = A\B` is the solution to the equation $AX = B$ computed by Gaussian elimination. A warning message is displayed if `A` is badly scaled or nearly singular. See the reference page for `mldivide` for more information.

If A is an m-by-n matrix with `m ~= n` and B is a column vector with m components, or a matrix with several such columns, then `X = A\B` is the solution in the least squares sense to the under- or overdetermined system of equations $AX = B$. The effective rank, k, of A is determined from the QR decomposition with pivoting (see "Algorithm" on page 2-2183 for details). A solution X is computed that has at most k nonzero components per column. If `k < n`, this is usually not the same solution as `pinv(A)*B`, which is the least squares solution with the smallest norm $\|X\|$.

`.\` Array left division. `A.\B` is the matrix with elements `B(i,j)/A(i,j)`. A and B must have the same size, unless one of them is a scalar.

`^` Matrix power. `X^p` is X to the power p, if p is a scalar. If p is an integer, the power is computed by repeated squaring. If the integer is negative, X is inverted first. For other values of p, the calculation involves eigenvalues and eigenvectors, such that if `[V,D] = eig(X)`, then `X^p = V*D.^p/V`.

If x is a scalar and P is a matrix, `x^P` is x raised to the matrix power P using eigenvalues and eigenvectors. `X^P`, where X and P are both matrices, is an error.

`.^` Array power. `A.^B` is the matrix with elements `A(i,j)` to the `B(i,j)` power. A and B must have the same size, unless one of them is a scalar.

`'` Matrix transpose. `A'` is the linear algebraic transpose of A. For complex matrices, this is the complex conjugate transpose.

`.'` Array transpose. `A.'` is the array transpose of A. For complex matrices, this does not involve conjugation.

Nondouble Data Type Support

This section describes the arithmetic operators' support for data types other than `double`.

Data Type single

You can apply any of the arithmetic operators to arrays of type `single` and MATLAB returns an answer of type `single`. You can also combine an array of type `double` with an array of type `single`, and the result has type `single`.

Integer Data Types

You can apply most of the arithmetic operators to real arrays of the following integer data types:

- `int8` and `uint8`
- `int16` and `uint16`
- `int32` and `uint32`

All operands must have the same integer data type and MATLAB returns an answer of that type.

Note The arithmetic operators do not support operations on the data types `int64` or `uint64`. Except for the unary operators `+A` and `A.'`, the arithmetic operators do not support operations on complex arrays of any integer data type.

For example,

```
x = int8(3) + int8(4);
class(x)

ans =

int8
```

The following table lists the binary arithmetic operators that you can apply to arrays of the same integer data type. In the table, `A` and `B` are arrays of the same integer data type and `c` is a scalar of type `double` or the same type as `A` and `B`.

Operation	Support when A and B Have Same Integer Type
`+A, -A`	Yes
`A+B, A+c, c+B`	Yes
`A-B, A-c, c-B`	Yes
`A.*B`	Yes
`A*c, c*B`	Yes
`A*B`	No
`A/c, c/B`	Yes
`A.\B, A./B`	Yes
`A\B, A/B`	No
`A.^B`	Yes, if `B` has nonnegative integer values.
`c^k`	Yes, for a scalar `c` and a nonnegative scalar integer `k`, which have the same integer data type or one of which has type `double`
`A.', A'`	Yes

Combining Integer Data Types with Type Double

For the operations that support integer data types, you can combine a scalar or array of an integer data type with a scalar, but not an array, of type `double` and the result has the same integer data type as the input of integer type. For example,

```
y = 5 + int32(7);
class(y)
```

```
ans =

int32
```

However, you cannot combine an array of an integer data type with either of the following:

- A scalar or array of a different integer data type
- A scalar or array of type `single`

The section "Numeric Types", under "Data Types" in the MATLAB Programming documentation, provides more information about operations on nondouble data types.

Remarks

The arithmetic operators have M-file function equivalents, as shown:

Binary addition	`A+B`	`plus(A,B)`
Unary plus	`+A`	`uplus(A)`
Binary subtraction	`A-B`	`minus(A,B)`
Unary minus	`-A`	`uminus(A)`
Matrix multiplication	`A*B`	`mtimes(A,B)`
Arraywise multiplication	`A.*B`	`times(A,B)`
Matrix right division	`A/B`	`mrdivide(A,B)`
Arraywise right division	`A./B`	`rdivide(A,B)`
Matrix left division	`A\B`	`mldivide(A,B)`
Arraywise left division	`A.\B`	`ldivide(A,B)`

Matrix power	`A^B`	`mpower(A,B)`
Arraywise power	`A.^B`	`power(A,B)`
Complex transpose	`A'`	`ctranspose(A)`
Matrix transpose	`A.'`	`transpose(A)`

Note For some toolboxes, the arithmetic operators are overloaded, that is, they perform differently in the context of that toolbox. To see the toolboxes that overload a given operator, type `help` followed by the operator name. For example, type `help plus`. The toolboxes that overload `plus` (`+`) are listed. For information about using the operator in that toolbox, see the documentation for the toolbox.

Examples

Here are two vectors, and the results of various matrix and array operations on them, printed with `format rat`.

Matrix Operations		Array Operations	
`x`	1 2 3	`y`	4 5 6
`x'`	`1 2 3`	`y'`	`4 5 6`
`x+y`	5 7 9	`x-y`	`-3` `-3` `-3`
`x + 2`	3 4 5	`x-2`	`-1` 0 1

Matrix Operations		Array Operations	
`x * y`	Error	`x.*y`	4 10 18
`x'*y`	32	`x'.*y`	Error
`x*y'`	4 5 6 8 10 12 12 15 18	`x.*y'`	Error
`x*2`	2 4 6	`x.*2`	2 4 6
`x\y`	16/7	`x.\y`	4 5/2 2
`2\x`	1/2 1 3/2	`2./x`	2 1 2/3
`x/y`	0 0 1/6 0 0 1/3 0 0 1/2	`x./y`	1/4 2/5 1/2
`x/2`	1/2 1 3/2	`x./2`	1/2 1 3/2

Matrix Operations		Array Operations	

`x^y`	Error	`x.^y`	`1`
			`32`
			`729`

`x^2`	Error	`x.^2`	`1`
			`4`
			`9`

`2^x`	Error	`2.^x`	`2`
			`4`
			`8`

`(x+i*y)'`	`1 - 4i 2 - 5i` `3 - 6i`		
`(x+i*y).'`	`1 + 4i 2 + 5i` `3 + 6i`		

Diagnostics

- From matrix division, if a square `A` is singular,

  ```
  Warning: Matrix is singular to working precision.
  ```

- From elementwise division, if the divisor has zero elements,

  ```
  Warning: Divide by zero.
  ```

  Matrix division and elementwise division can produce `NaN`s or `Inf`s where appropriate.

- If the inverse was found, but is not reliable,

  ```
  Warning: Matrix is close to singular or badly scaled.
      Results may be inaccurate.  RCOND = xxx
  ```

- From matrix division, if a nonsquare `A` is rank deficient,

```
Warning: Rank deficient, rank = xxx tol = xxx
```

Purpose

Relational operations

Syntax

```
A < B
A > B
A <= B
A >= B
A == B
A ~= B
```

Description

The relational operators are <, >, <=, >=, ==, and ~=. Relational operators perform element-by-element comparisons between two arrays. They return a `logical` array of the same size, with elements set to logical `1` (`true`) where the relation is true, and elements set to logical `0` (`false`) where it is not.

The operators <, >, <=, and >= use only the real part of their operands for the comparison. The operators == and ~= test real and imaginary parts.

To test if two strings are equivalent, use `strcmp`, which allows vectors of dissimilar length to be compared.

Note For some toolboxes, the relational operators are overloaded, that is, they perform differently in the context of that toolbox. To see the toolboxes that overload a given operator, type `help` followed by the operator name. For example, type `help lt`. The toolboxes that overload `lt (<)` are listed. For information about using the operator in that toolbox, see the documentation for the toolbox.

Examples

If one of the operands is a scalar and the other a matrix, the scalar expands to the size of the matrix. For example, the two pairs of statements

```
X = 5; X >= [1 2 3; 4 5 6; 7 8 10]
X = 5*ones(3,3); X >= [1 2 3; 4 5 6; 7 8 10]
```

produce the same result:

```
ans =

     1     1     1
     1     1     0
     0     0     0
```

See Also

all, any, find, strcmp

Logical Operators: Elementwise & | ~, Logical Operators: Short-circuit && ||

Purpose

Elementwise logical operations on arrays

Syntax

```
A & B
A | B
~A
```

Description

The symbols `&`, `|`, and `~` are the logical array operators `AND`, `OR`, and `NOT`. They work element by element on arrays, with logical `0` representing `false`, and logical `1` or any nonzero element representing `true`. The logical operators return a `logical` array with elements set to `1` (`true`) or `0` (`false`), as appropriate.

The `&` operator does a logical `AND`, the `|` operator does a logical `OR`, and `~A` complements the elements of `A`. The function `xor(A,B)` implements the exclusive `OR` operation. The truth table for these operators and functions is shown below.

Inputs		and	or	not	xor
A	B	A & B	A | B	~A	xor(A,B)
0	0	0	0	1	0
0	1	0	1	1	1
1	0	0	1	0	1
1	1	1	1	0	0

The precedence for the logical operators with respect to each other is

Operator	Operation	Priority
~	NOT	Highest
&	Elementwise AND	
|	Elementwise OR	
&&	Short-circuit AND	
||	Short-circuit OR	Lowest

Remarks

MATLAB always gives the & operator precedence over the | operator. Although MATLAB typically evaluates expressions from left to right, the expression `a|b&c` is evaluated as `a|(b&c)`. It is a good idea to use parentheses to explicitly specify the intended precedence of statements containing combinations of & and |.

These logical operators have M-file function equivalents, as shown.

Logical Operation	Equivalent Function
`A & B`	`and(A,B)`
`A | B`	`or(A,B)`
`~A`	`not(A)`

Short-Circuiting in Elementwise Operators

When used in the context of an `if` or `while` expression, and only in this context, the elementwise | and & operators use short-circuiting in evaluating their expressions. That is, `A|B` and `A&B` ignore the second operand, `B`, if the first operand, `A`, is sufficient to determine the result.

So, although the statement `1|[]` evaluates to `false`, the same statement evaluates to `true` when used in either an `if` or `while` expression:

```
A = 1;   B = [];
if(A|B) disp 'The statement is true',  end;
   The statement is true
```

while the reverse logical expression, which does not short-circuit, evaluates to `false`

```
if(B|A) disp 'The statement is true',  end;
```

Another example of short-circuiting with elementwise operators shows that a logical expression such as the following, which under most circumstances is invalid due to a size mismatch between `A` and `B`,

```
A = [1 1];   B = [2 0 1];
```

```
A|B        % This generates an error.
```

works within the context of an `if` or `while` expression:

```
if (A|B) disp 'The statement is true',  end;
   The statement is true
```

Examples

This example shows the logical `OR` of the elements in the vector `u` with the corresponding elements in the vector `v`:

```
u = [0 0 1 1 0 1];
v = [0 1 1 0 0 1];
u | v

ans =
   0   1   1   1   0   1
```

`Logical Operators:  Short-circuit && ||`

`Relational Operators < > <= >= == ~=`

Logical Operators: Short-circuit && ||

Purpose

Logical operations, with short-circuiting capability

Syntax

```
expr1 && expr2
expr1 || expr2
```

Description

`expr1 && expr2` represents a logical `AND` operation that employs short-circuiting behavior. With short-circuiting, the second operand `expr2` is evaluated only when the result is not fully determined by the first operand `expr1`. For example, if `A = 0`, then the following statement evaluates to `false`, regardless of the value of `B`, so MATLAB does not evaluate `B`:

```
A && B
```

These two expressions must each be a valid MATLAB statement that evaluates to a scalar logical result.

`expr1 || expr2` represents a logical `OR` operation that employs short-circuiting behavior.

Note Always use the `&&` and `||` operators when short-circuiting is required. Using the elementwise operators (`&` and `|`) for short-circuiting can yield unexpected results.

Examples

In the following statement, it doesn't make sense to evaluate the relation on the right if the divisor, `b`, is zero. The test on the left is put in to avoid generating a warning under these circumstances:

```
x = (b ~= 0) && (a/b > 18.5)
```

By definition, if any operands of an `AND` expression are `false`, the entire expression must be `false`. So, if `(b ~= 0)` evaluates to `false`, MATLAB assumes the entire expression to be `false` and terminates its evaluation of the expression early. This avoids the warning that would be generated if MATLAB were to evaluate the operand on the right.

Special Characters [ ] ( ) {} = ' . ... , ; : % ! @

Purpose

Special characters

Syntax

```
[ ]
{ }
( )
=
'
.
.
.( )
..
...
,
;
:
%
%{ %}
!
@
```

Description

`[ ]` Brackets are used to form vectors and matrices. `[6.9 9.64 sqrt(-1)]` is a vector with three elements separated by blanks. `[6.9, 9.64, i]` is the same thing. `[1+j 2-j 3]` and `[1 +j 2 -j 3]` are not the same. The first has three elements, the second has five.

`[11 12 13; 21 22 23]` is a 2-by-3 matrix. The semicolon ends the first row.

Vectors and matrices can be used inside `[ ]` brackets. `[A B;C]` is allowed if the number of rows of `A` equals the number of rows of `B` and the number of columns of `A` plus the number of columns of `B` equals the number of columns of `C`. This rule generalizes in a hopefully obvious way to allow fairly complicated constructions.

`A = [ ]` stores an empty matrix in `A`. `A(m,:) = [ ]` deletes row `m` of `A`. `A(:,n) = [ ]` deletes column `n` of `A`. `A(n) = [ ]` reshapes `A` into a column vector and deletes the third element.

`[A1,A2,A3...] = function` assigns function output to multiple variables.

For the use of `[` and `]` on the left of an "=" in multiple assignment statements, see `lu`, `eig`, `svd`, and so on.

`{ }` Curly braces are used in cell array assignment statements. For example, `A(2,1) = {[1 2 3; 4 5 6]}`, or `A{2,2} = 'str'`. See `help paren` for more information about `{ }`.

`( )` Parentheses are used to indicate precedence in arithmetic expressions in the usual way. They are used to enclose arguments of functions in the usual way. They are also used to enclose subscripts of vectors and matrices in a manner somewhat more general than usual. If `X` and `V` are vectors, then `X(V)` is `[X(V(1)), X(V(2)), ..., X(V(n))]`. The components of `V` must be integers to be used as subscripts. An error occurs if any such subscript is less than 1 or greater than the size of `X`. Some examples are

- `X(3)` is the third element of `X`.
- `X([1 2 3])` is the first three elements of `X`.

See `help paren` for more information about `( )`.

If `X` has `n` components, `X(n: 1:1)` reverses them. The same indirect subscripting works in matrices. If `V` has `m` components and `W` has `n` components, then `A(V,W)` is the `m`-by-`n` matrix formed from the elements of `A` whose subscripts are the elements of `V` and `W`. For example, `A([1,5],:) = A([5,1],:)` interchanges rows 1 and 5 of `A`.

`=` Used in assignment statements. `B = A` stores the elements of `A` in `B`. == is the relational equals operator. See the `Relational Operators < > <= >= == ~=` page.

`'` Matrix transpose. `X'` is the complex conjugate transpose of `X`. `X.'` is the nonconjugate transpose.

Quotation mark. `'any text'` is a vector whose components are the ASCII codes for the characters. A quotation mark within the text is indicated by two quotation marks.

`.` Decimal point. `314/100`, `3.14`, and `.314e1` are all the same.

Element-by-element operations. These are obtained using `.*`, `.^`, `./`, or `.\`. See the Arithmetic Operators page.

`.` Field access. `S(m).f` when `S` is a structure, accesses the contents of field `f` of that structure.

`.(` `)` Dynamic Field access. `S.(df)` when `A` is a structure, accesses the contents of dynamic field `df` of that structure. Dynamic field names are defined at runtime.

`..` Parent directory. See `cd`.

`...` Continuation. Three or more periods at the end of a line continue the current function on the next line. Three or more periods before the end of a line cause MATLAB to ignore the remaining text on the current line and continue the function on the next line. This effectively makes a comment out of anything on the current line that follows the three periods. See "Entering Long Statements (Line Continuation)" for more information.

`,` Comma. Used to separate matrix subscripts and function arguments. Used to separate statements in multistatement lines. For multistatement lines, the comma can be replaced by a semicolon to suppress printing.

`;` Semicolon. Used inside brackets to end rows. Used after an expression or statement to suppress printing or to separate statements.

`:` Colon. Create vectors, array subscripting, and `for` loop iterations. See `colon (:)` for details.

`%` Percent. The percent symbol denotes a comment; it indicates a logical end of line. Any following text is ignored. MATLAB displays the first contiguous comment lines in a M-file in response to a `help` command.

`%{` `%}` Percent-brace. The text enclosed within the `%{` and `%}` symbols is a comment block. Use these symbols to insert comments that take up more than a single line in your M-file code. Any text between these two symbols is ignored by MATLAB.

With the exception of whitespace characters, the %{ and %} operators must appear alone on the lines that immediately precede and follow the block of help text. Do not include any other text on these lines.

`!`	Exclamation point. Indicates that the rest of the input line is issued as a command to the operating system. See "Running External Programs" for more information.
`@`	Function handle. MATLAB data type that is a handle to a function. See `function_handle (@)` for details.

Remarks

Some uses of special characters have M-file function equivalents, as shown:

Horizontal concatenation	`[A,B,C...]`	`horzcat(A,B,C...)`
Vertical concatenation	`[A;B;C...]`	`vertcat(A,B,C...)`
Subscript reference	`A(i,j,k...)`	`subsref(A,S)`. See help `subsref`.
Subscript assignment	`A(i,j,k...)=B`	`subsasgn(A,S,B)`. See help `subsasgn`.

Note For some toolboxes, the special characters are overloaded, that is, they perform differently in the context of that toolbox. To see the toolboxes that overload a given character, type `help` followed by the character name. For example, type `help transpose`. The toolboxes that overload `transpose (.')` are listed. For information about using the character in that toolbox, see the documentation for the toolbox.

`Relational Operators < > <= >= == ~=`

`Logical Operators:  Elementwise & | ~,`

Purpose

Create vectors, array subscripting, and `for`-loop iterators

Description

The colon is one of the most useful operators in MATLAB. It can create vectors, subscript arrays, and specify `for` iterations.

The colon operator uses the following rules to create regularly spaced vectors:

`j:k`	is the same as `[j,j+1,...,k]`
`j:k`	is empty if `j > k`
`j:i:k`	is the same as `[j,j+i,j+2i, ...,k]`
`j:i:k`	is empty if `i == 0`, if `i > 0` and `j > k`, or if `i < 0` and `j < k`

where `i`, `j`, and `k` are all scalars.

Below are the definitions that govern the use of the colon to pick out selected rows, columns, and elements of vectors, matrices, and higher-dimensional arrays:

`A(:,j)`	is the `j`th column of `A`
`A(i,:)`	is the `i`th row of `A`
`A(:,:)`	is the equivalent two-dimensional array. For matrices this is the same as `A`.
`A(j:k)`	is `A(j), A(j+1),...,A(k)`
`A(:,j:k)`	is `A(:,j), A(:,j+1),...,A(:,k)`
`A(:,:,k)`	is the `k`th page of three-dimensional array `A`.
`A(i,j,k,:)`	is a vector in four-dimensional array `A`. The vector includes `A(i,j,k,1)`, `A(i,j,k,2)`, `A(i,j,k,3)`, and so on.
`A(:)`	is all the elements of `A`, regarded as a single column. On the left side of an assignment statement, `A(:)` fills `A`, preserving its shape from before. In this case, the right side must contain the same number of elements as `A`.

Examples

Using the colon with integers,

```
D = 1:4
```

results in

```
D =
    1    2    3    4
```

Using two colons to create a vector with arbitrary real increments between the elements,

```
E = 0:.1:.5
```

results in

```
E =
    0    0.1000    0.2000    0.3000    0.4000    0.5000
```

The command

```
A(:,:,2) = pascal(3)
```

generates a three-dimensional array whose first page is all zeros.

```
A(:,:,1) =
     0     0     0
     0     0     0
     0     0     0

A(:,:,2) =
     1     1     1
     1     2     3
     1     3     6
```

Using a colon with characters to iterate a for-loop,

```
for x='a':'d',x,end
```

results in

```
x =
     a
x =
     b
x =
     c
x =
     d
```

`for`, `linspace`, `logspace`, `reshape`

abs

Purpose

Absolute value and complex magnitude

Syntax

```
abs(X)
```

Description

`abs(X)` returns an array `Y` such that each element of `Y` is the absolute value of the corresponding element of `X`.

If `X` is complex, `abs(X)` returns the complex modulus (magnitude), which is the same as

```
sqrt(real(X).^2 + imag(X).^2)
```

Examples

```
abs(-5)
ans =
     5

abs(3+4i)
ans =
     5
```

See Also

`angle`, `sign`, `unwrap`

Purpose

Construct array with accumulation

Syntax

```
A = accumarray(subs, val)
A = accumarray(subs,val,sz)
A = accumarray(subs,val,sz,fun)
A = accumarray(subs,val,sz,fun,fillval)
A = accumarray(subs,val,sz,fun,fillval,issparse)
A = accumarray({subs1, subs2, ...}, val, ...)
```

Description

`A = accumarray(subs, val)` creates an array `A` by accumulating elements of the vector `val` using the subscript in `subs`. Each row of the `m`-by-`n` matrix `subs` defines an N-dimensional subscript into the output `A`. Each element of `val` has a corresponding row in `subs`. `accumarray` collects all elements of `val` that correspond to identical subscripts in `subs`, sums those values, and stores the result in the element of `A` that corresponds to the subscript. Elements of `A` that are not referred to by any row of `subs` contain zero.

If `subs` is a nonempty matrix with N>1 columns, then `A` is an N-dimensional array of size `max(subs,[],1)`. If `subs` is empty with N>1 columns, then `A` is an N-dimensional empty array with size 0-by-0-by-`...`-by-0. `subs` can also be a column vector, in which case a second column of ones is implied, and `A` is a column vector. `subs` must contain positive integers.

`subs` can also be a cell vector with one or more elements, each element a vector of positive integers. All the vectors must have the same length. In this case, `subs` is treated as if the vectors formed columns of an index matrix.

`val` must be a numeric, logical, or character vector with the same length as the number of rows in `subs`. `val` can also be a scalar whose value is repeated for all the rows of `subs`.

`accumarray` sums values from `val` using the default behavior of `sum`.

`A = accumarray(subs,val,sz)` creates an array `A` with size `sz`, where `sz` is a vector of positive integers. If `subs` is nonempty with N>1 columns, then `sz` must have N elements, where `all(sz >=`

`max(subs,[],1))`. If `subs` is a nonempty column vector, then `sz` must be `[M 1]`, where `M >= MAX(subs)`. Specify `sz` as `[]` for the default behavior.

`A = accumarray(subs,val,sz,fun)` applies function `fun` to each subset of elements of `val`. You must specify the `fun` input using the `@` symbol (e.g., `@sin`). The function `fun` must accept a column vector and return a numeric, logical, or character scalar, or a scalar cell. Return value `A` has the same class as the values returned by `fun`. Specify `fun` as `[]` for the default behavior. `fun` is `@sum` by default.

Note If the subscripts in `subs` are not sorted, `fun` should not depend on the order of the values in its input data.

`A = accumarray(subs,val,sz,fun,fillval)` puts the scalar value `fillval` in elements of `A` that are not referred to by any row of `subs`. For example, if `subs` is empty, then `A` is `repmat(fillval,sz)`. `fillval` and the values returned by `fun` must belong to the same class.

`A = accumarray(subs,val,sz,fun,fillval,issparse)` creates an array `A` that is sparse if the scalar input `issparse` is equal to logical 1 (i.e., `true`), or full if `issparse` is equal to logical 0 (`false`). `A` is full by default. If `issparse` is `true`, then `fillval` must be zero or `[]`, and `val` and the output of `fun` must be double.

`A = accumarray({subs1, subs2, ...}, val, ...)` passes multiple `subs` vectors in a cell array. You can use any of the four optional inputs (`sz`, `fun`, `fillval`, or `issparse`) with this syntax.

Examples

Example 1

Create a 5-by-1 vector, and sum values for repeated 1-dimensional subscripts:

```
val = 101:105;
subs = [1; 2; 4; 2; 4]
subs =
```

```
     1       % Subscript 1 of result <= val(1)
     2       % Subscript 2 of result <= val(2)
     4       % Subscript 4 of result <= val(3)
     2       % Subscript 2 of result <= val(4)
     4       % Subscript 4 of result <= val(5)

A = accumarray(subs, val)
A =
   101       % A(1) = val(1) = 101
   206       % A(2) = val(2)+val(4) = 102+104 = 206
     0       % A(3) = 0
   208       % A(4) = val(3)+val(5) = 103+105 = 208
```

Example 2

Create a 2-by-3-by-2 array, and sum values for repeated three-dimensional subscripts:

```
val = 101:105;
subs = [1 1 1; 2 1 2; 2 3 2; 2 1 2; 2 3 2];

A = accumarray(subs, val)
A(:,:,1) =
   101     0     0
     0     0     0
A(:,:,2) =
     0     0     0
   206     0   208
```

Example 3

Create a 2-by-3-by-2 array, and sum values natively:

```
val = 101:105;
subs = [1 1 1; 2 1 2; 2 3 2; 2 1 2; 2 3 2];

A = accumarray(subs, int8(val), [], @(x) sum(x,'native'))
A(:,:,1) =
  101    0    0
```

```
    0    0    0
A(:,:,2) =
    0    0    0
  127    0  127

class(A)
ans =
    int8
```

Example 4

Pass multiple subscript arguments in a cell array.

Create a 12-element vector `V`:

```
V = 101:112;
```

Create three 12-element vectors, one for each dimension of the resulting array `A`. Note how the indices of these vectors determine which elements of `V` are accumulated in `A`:

```
%        index 1   index 6 => V(1)+V(6) => A(1,3,1)
%          |         |
rowsubs = [1 3 3 2 3 1 2 2 3 3 1 2];
colsubs = [3 4 2 1 4 3 4 2 2 4 3 4];
pagsubs = [1 1 2 2 1 1 2 1 1 1 2 2];
%               |
%             index 4 => V(4) => A(2,1,2)
%
% A(1,3,1) = V(1) + V(6) = 101 + 106 = 207
% A(2,1,2) = V(4) = 104
```

Call `accumarray`, passing the subscript vectors in a cell array:

```
A = accumarray({rowsubs colsubs pagsubs}, V)
A(:,:,1) =
     0     0   207     0        % A(1,3,1) is 207
     0   108     0     0
     0   109     0   317
```

```
A(:,:,2) =
     0     0   111     0
   104     0     0   219        % A(2,1,2) is 104
     0   103     0     0
```

Example 5

Create an array with the `max` function, and fill all empty elements of that array with `NaN`:

```
val = 101:105;
subs = [1 1; 2 1; 2 3; 2 1; 2 3];

A = accumarray(subs, val, [2 4], @max, NaN)
A =
   101   NaN   NaN   NaN
   104   NaN   105   NaN
```

Example 6

Create a sparse matrix using the `prod` function:

```
val = 101:105;
subs = [1 1; 2 1; 2 3; 2 1; 2 3];

A = accumarray(subs, val, [2 4], @prod, 0, true)
A =
   (1,1)           101
   (2,1)         10608
   (2,3)         10815
```

Example 7

Count the number of subscripts for each bin:

```
val = 1;
subs = [1 1; 2 1; 2 3; 2 1; 2 3];

A = accumarray(subs, val, [2 4])
A =
```

```
     1     0     0     0
     2     0     2     0
```

Example 8

Create a logical array that shows which bins have two or more values:

```
val = 101:105;
subs = [1 1; 2 1; 2 3; 2 1; 2 3];

A = accumarray(subs, val, [2 4], @(x) length(x) > 1)
A =
     0     0     0     0
     1     0     1     0
```

Example 9

Group values in a cell array:

```
val = 101:105;
subs = [1 1; 2 1; 2 3; 2 1; 2 3];

A = accumarray(subs, val, [2 4], @(x) {x})
A =
    [       101]     []               []     []
    [2x1 double]     []    [2x1 double]     []

A{2}
ans =
   104
   102
```

See Also

`full`, `sparse`, `sum`

Purpose

Inverse cosine; result in radians

Syntax

```
Y = acos(X)
```

Description

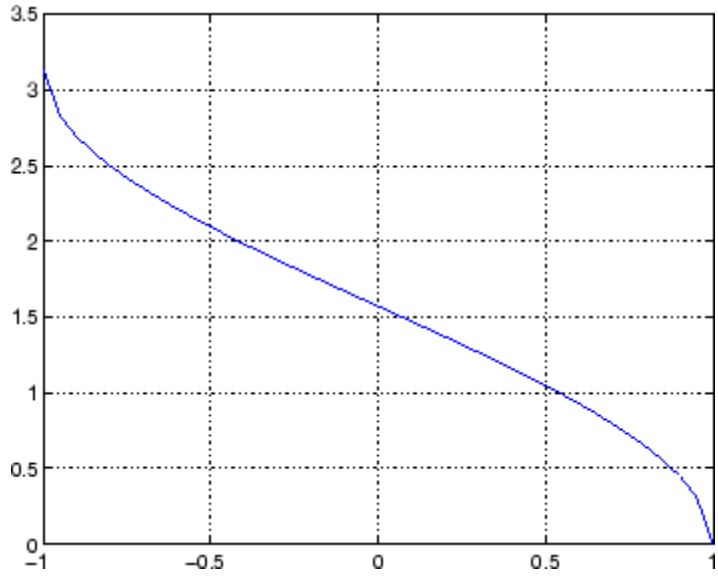
`Y = acos(X)` returns the inverse cosine (arccosine) for each element of `X`. For real elements of `X` in the domain $[-1, 1]$, `acos(X)` is real and in the range $[0, \pi]$. For real elements of `X` outside the domain $[-1, 1]$, `acos(X)` is complex.

The `acos` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

Examples

Graph the inverse cosine function over the domain $-1 \le x \le 1$.

```
x = -1:.05:1;
plot(x,acos(x)), grid on
```



Definition

The inverse cosine can be defined as

$$\cos^{-1}(z) = -i \log\left[z + i(1 - z^2)^{\frac{1}{2}} \right]$$

Algorithm

`acos` uses FDLIBM, which was developed at SunSoft, a Sun Microsystems, Inc., business, by Kwok C. Ng, and others. For information about FDLIBM, see `http://www.netlib.org`.

See Also

`acosd`, `acosh`, `cos`

Purpose

Inverse cosine; result in degrees

Syntax

```
Y = acosd(X)
```

Description

`Y = acosd(X)` is the inverse cosine, expressed in degrees, of the elements of `X`.

See Also

`cosd`, `acos`

Purpose

Inverse hyperbolic cosine

Syntax

```
Y = acosh(X)
```

Description

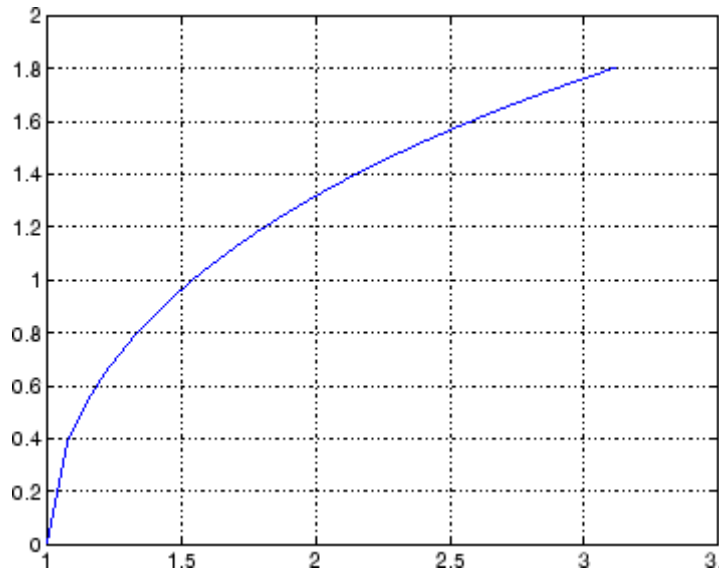
`Y = acosh(X)` returns the inverse hyperbolic cosine for each element of `X`.

The `acosh` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

Examples

Graph the inverse hyperbolic cosine function over the domain $1 \le x \le \pi$.

```
x = 1:pi/40:pi;
plot(x,acosh(x)), grid on
```



Definition

The hyperbolic inverse cosine can be defined as

$$\cosh^{-1}(z) = \log\left[z + (z^2 - 1)^{\frac{1}{2}} \right]$$

Algorithm

`acosh` uses FDLIBM, which was developed at SunSoft, a Sun Microsystems, Inc., business, by Kwok C. Ng, and others. For information about FDLIBM, see `http://www.netlib.org`.

See Also

`acos`, `cosh`

Purpose

Inverse cotangent; result in radians

Syntax

```
Y = acot(X)
```

Description

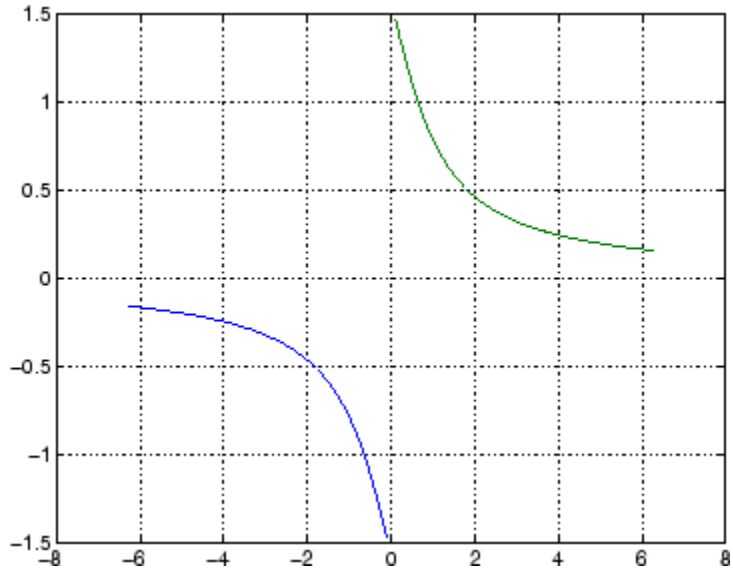
`Y = acot(X)` returns the inverse cotangent (arccotangent) for each element of `X`.

The `acot` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

Examples

Graph the inverse cotangent over the domains $-2\pi \le x < 0$ and $0 < x \le 2\pi$.

```
x1 = -2*pi:pi/30:-0.1;
x2 = 0.1:pi/30:2*pi;
plot(x1,acot(x1),x2,acot(x2)), grid on
```



Definition

The inverse cotangent can be defined as

$$\cot^{-1}(z) = \tan^{-1}\left(\frac{1}{z}\right)$$

Algorithm

`acot` uses FDLIBM, which was developed at SunSoft, a Sun Microsystems, Inc., business, by Kwok C. Ng, and others. For information about FDLIBM, see `http://www.netlib.org`.

`cot`, `acotd`, `acoth`

acotd

Purpose

Inverse cotangent; result in degrees

Syntax

```
Y = acosd(X)
```

Description

`Y = acosd(X)` is the inverse cotangent, expressed in degrees, of the elements of `X`.

See Also

`cotd`, `acot`

Purpose

Inverse hyperbolic cotangent

Syntax

```
Y = acoth(X)
```

Description

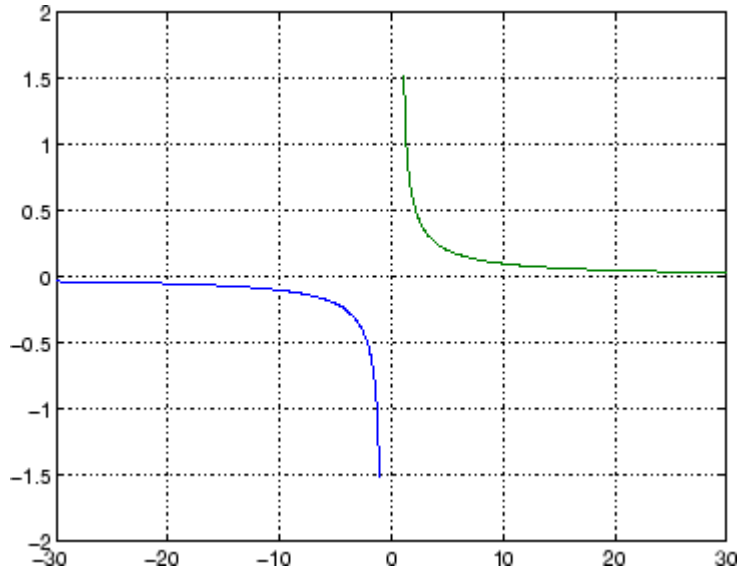
`Y = acoth(X)` returns the inverse hyperbolic cotangent for each element of `X`.

The `acoth` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

Examples

Graph the inverse hyperbolic cotangent over the domains $-30 \le x < -1$ and $1 < x \le 30$.

```
x1 = -30:0.1:-1.1;
x2 = 1.1:0.1:30;
plot(x1,acoth(x1),x2,acoth(x2)), grid on
```



Definition

The hyperbolic inverse cotangent can be defined as

$$\coth^{-1}(z) = \tanh^{-1}\left(\frac{1}{z}\right)$$

Algorithm

`acoth` uses FDLIBM, which was developed at SunSoft, a Sun Microsystems, Inc. business, by Kwok C. Ng, and others. For information about FDLIBM, see `http://www.netlib.org`.

See Also

`acot`, `coth`

Purpose

Inverse cosecant; result in radians

Syntax

```
Y = acsc(X)
```

Description

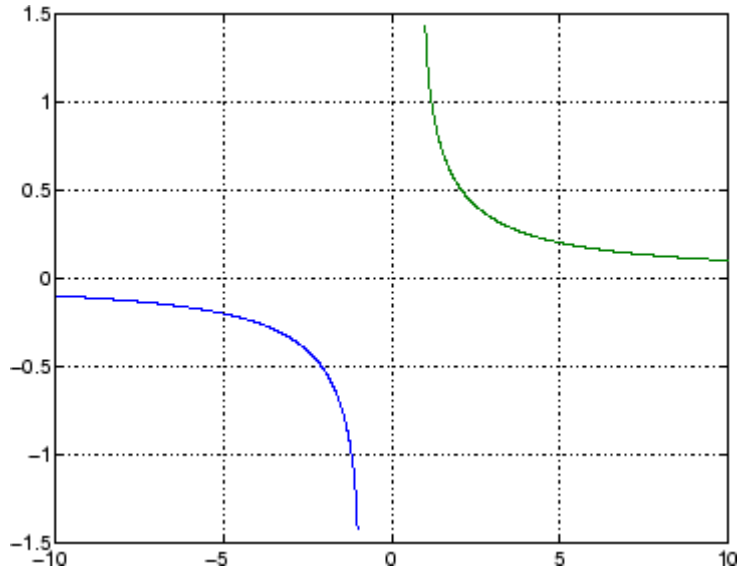
`Y = acsc(X)` returns the inverse cosecant (arccosecant) for each element of `X`.

The `acsc` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

Examples

Graph the inverse cosecant over the domains $-10 \le x < -1$ and $1 < x \le 10$.

```
x1 = -10:0.01:-1.01;
x2 = 1.01:0.01:10;
plot(x1,acsc(x1),x2,acsc(x2)), grid on
```



Definition

The inverse cosecant can be defined as

$$\csc^{-1}(z) = \sin^{-1}\left(\frac{1}{z}\right)$$

Algorithm

`acsc` uses FDLIBM, which was developed at SunSoft, a Sun Microsystems, Inc. business, by Kwok C. Ng, and others. For information about FDLIBM, see `http://www.netlib.org`.

See Also

`csc`, `acscd`, `acsch`

Purpose

Inverse cosecant; result in degrees

Syntax

```
Y = acscd(X)
```

Description

`Y = acscd(X)` is the inverse cotangent, expressed in degrees, of the elements of `X`.

See Also

`cscd`, `acsc`

Purpose

Inverse hyperbolic cosecant

Syntax

```
Y = acsch(X)
```

Description

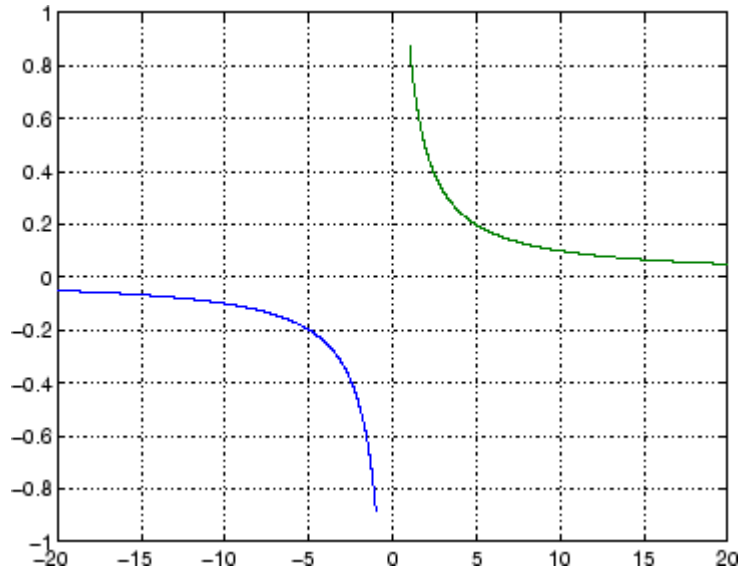
`Y = acsch(X)` returns the inverse hyperbolic cosecant for each element of `X`.

The `acsch` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

Examples

Graph the inverse hyperbolic cosecant over the domains $-20 \le x \le -1$ and $1 \le x \le 20$.

```
x1 = -20:0.01:-1;
x2 = 1:0.01:20;
plot(x1,acsch(x1),x2,acsch(x2)), grid on
```



Definition

The hyperbolic inverse cosecant can be defined as

$$\operatorname{csch}^{-1}(z) = \operatorname{sinh}^{-1}\left(\frac{1}{z}\right)$$

Algorithm

`acsc` uses FDLIBM, which was developed at SunSoft, a Sun Microsystems, Inc. business, by Kwok C. Ng, and others. For information about FDLIBM, see `http://www.netlib.org`.

`acsc`, `csch`

Purpose

Create ActiveX control in figure window

Syntax

```
h = actxcontrol('progid')
h = actxcontrol('progid','param1',value1,...)
h = actxcontrol('progid', position)
h = actxcontrol('progid', position, fig_handle)
h = actxcontrol('progid',position,fig_handle,event_handler)
h = actxcontrol('progid',position,fig_handle,event_handler,
   'filename')
```

Description

`h = actxcontrol('progid')` creates an ActiveX control in a figure window. The type of control created is determined by the string `progid`, the programmatic identifier (`progid`) for the control. (See the documentation provided by the control vendor to get this string.) The returned object, `h`, represents the default interface for the control.

Note that `progid` cannot be an ActiveX server because MATLAB cannot insert ActiveX servers in a figure. See `actxserver` for use with ActiveX servers.

`h = actxcontrol('progid','param1',value1,...)` creates an ActiveX control using the optional parameter name/value pairs. Parameter names include:

- `position` — MATLAB position vector specifying the control's position. The format is [left, bottom, width, height] using pixel units.
- `parent` — Handle to parent figure, model, or command window.
- `callback` — Name of event handler. Specify a single name to use the same handler for all events. Specify a cell array of event name/event handler pairs to handle specific events.
- `filename` — Sets the control's initial conditions to those in the previously saved control.
- `licensekey` — License key to create licensed ActiveX controls that require design-time licenses. See "Deploying ActiveX Controls Requiring Run-Time Licenses" for information on how to use controls that require run-time licenses.

For example:

```
h = actxcontrol('progid','position',[0 0 200 200],...
 'parent',gcf,...
 'callback',{`Click' 'myClickHandler';...
 'DblClick' 'myDblClickHandler';...
 'MouseDown' 'myMouseDownHandler'});
```

The following syntaxes are deprecated and will not become obsolete. They are included for reference, but the above syntaxes are preferred.

`h = actxcontrol('progid', position)` creates an ActiveX control having the location and size specified in the vector, `position`. The format of this vector is

```
[x y width height]
```

The first two elements of the vector determine where the control is placed in the figure window, with `x` and `y` being offsets, in pixels, from the bottom left corner of the figure window to the same corner of the control. The last two elements, `width` and `height`, determine the size of the control itself.

The default `position` vector is `[20 20 60 60]`.

`h = actxcontrol('progid', position, fig_handle)` creates an ActiveX control at the specified `position` in an existing figure window. This window is identified by the Handle Graphics handle, `fig_handle`.

The current figure handle is returned by the `gcf` command.

Note If the figure window designated by `fig_handle` is invisible, the control is invisible. If you want the control you are creating to be invisible, use the handle of an invisible figure window.

`h = actxcontrol('progid',position,fig_handle,event_handler)` creates an ActiveX control that responds to events. Controls respond to events by invoking an M-file function whenever an event (such

as clicking a mouse button) is fired. The `event_handler` argument identifies one or more M-file functions to be used in handling events (see "Specifying Event Handlers" on page 2-86 below).

```
h =
actxcontrol('progid',position,fig_handle,event_handler,'filename')
```

creates an ActiveX control with the first four arguments, and sets its initial state to that of a previously saved control. MATLAB loads the initial state from the file specified in the string `filename`.

If you don't want to specify an `event_handler`, you can use an empty string (`''`) as the fourth argument.

The `progid` argument must match the `progid` of the saved control.

Specifying Event Handlers

There is more than one valid format for the `event_handler` argument. Use this argument to specify one of the following:

- A different event handler routine for each event supported by the control
- One common routine to handle selected events
- One common routine to handle all events

In the first case, use a cell array for the `event_handler` argument, with each row of the array specifying an event and handler pair:

```
{'event' 'eventhandler'; 'event2' 'eventhandler2'; ...}
```

`event` can be either a string containing the event name or a numeric event identifier (see Example 2 below), and `eventhandler` is a string identifying the M-file function you want the control to use in handling the event. Include only those events that you want enabled.

In the second case, use the same cell array syntax just described, but specify the same `eventhandler` for each event. Again, include only those events that you want enabled.

In the third case, make `event_handler` a string (instead of a cell array) that contains the name of the one M-file function that is to handle all events for the control.

There is no limit to the number of event and handler pairs you can specify in the `event_handler` cell array.

Event handler functions should accept a variable number of arguments.

Strings used in the `event_handler` argument are not case sensitive.

Note Although using a single handler for all events may be easier in some cases, specifying an individual handler for each event creates more efficient code that results in better performance.

Remarks

If the control implements any custom interfaces, use the `interfaces` function to list them, and the `invoke` function to get a handle to a selected interface.

When you no longer need the control, call `release` to release the interface and free memory and other resources used by the interface. Note that releasing the interface does not delete the control itself. Use the `delete` function to do this.

For more information on handling control events, see the section, "Writing Event Handlers" in the External Interfaces documentation.

For an example event handler, see the file `sampev.m` in the `toolbox\matlab\winfun\comcli` directory.

Note If you encounter problems creating Microsoft Forms 2.0 controls in MATLAB or other non-VBA container applications, see "Using Microsoft Forms 2.0 Controls" in the External Interfaces documentation.

Examples

Example 1 — Basic Control Methods

Start by creating a `figure` window to contain the control. Then create a control to run a Microsoft Calendar application in the window. Position the control at a `[0 0]` x-y offset from the bottom left of the figure window, and make it the same size (600 x 500 pixels) as the figure window.

```
f = figure('position', [300 300 600 500]);
cal = actxcontrol('mscal.calendar', [0 0 600 500], f)
cal =
    COM.mscal.calendar
```

Call the `get` method on `cal` to list all properties of the calendar:

```
cal.get
        BackColor: 2.1475e+009
              Day: 23
          DayFont: [1x1 Interface.Standard_OLE_Types.Font]
            Value: '8/20/2001'
                  .
                  .
```

Read just one property to record today's date:

```
date = cal.Value
date =
   8/23/2001
```

Set the `Day` property to a new value:

```
cal.Day = 5;
date = cal.Value
date =
   8/5/2001
```

Call `invoke` with no arguments to list all available methods:

```
meth = cal.invoke
meth =
```

```
          NextDay: 'HRESULT NextDay(handle)'
        NextMonth: 'HRESULT NextMonth(handle)'
         NextWeek: 'HRESULT NextWeek(handle)'
         NextYear: 'HRESULT NextYear(handle)'
            .
            .
```

Invoke the `NextWeek` method to advance the current date by one week:

```
cal.NextWeek;
date = cal.Value
date =
   8/12/2001
```

Call `events` to list all calendar events that can be triggered:

```
cal.events
ans =
   Click = void Click()
   DblClick = void DblClick()
   KeyDown = void KeyDown(int16 KeyCode, int16 Shift)
   KeyPress = void KeyPress(int16 KeyAscii)
   KeyUp = void KeyUp(int16 KeyCode, int16 Shift)
   BeforeUpdate = void BeforeUpdate(int16 Cancel)
   AfterUpdate = void AfterUpdate()
   NewMonth = void NewMonth()
   NewYear = void NewYear()
```

Example 2 — Event Handling

The `event_handler` argument specifies how you want the control to handle any events that occur. The control can handle all events with one common handler function, selected events with a common handler function, or each type of event can be handled by a separate function.

This command creates an `mwsamp` control that uses one event handler, `sampev`, to respond to all events:

```
h = actxcontrol('mwsamp.mwsampctrl.2', [0 0 200 200], ...
```

```
    gcf, 'sampev')
```

The next command also uses a common event handler, but will only invoke the handler when selected events, `Click` and `DblClick` are fired:

```
h = actxcontrol('mwsamp.mwsampctrl.2', [0 0 200 200], ...
   gcf, {'Click' 'sampev'; 'DblClick' 'sampev'})
```

This command assigns a different handler routine to each event. For example, `Click` is an event, and `myclick` is the routine that executes whenever a `Click` event is fired:

```
h = actxcontrol('mwsamp.mwsampctrl.2', [0 0 200 200], ...
   gcf, {'Click', 'myclick'; 'DblClick' 'my2click'; ...
   'MouseDown' 'mymoused'});
```

The next command does the same thing, but specifies the events using numeric event identifiers:

```
h = actxcontrol('mwsamp.mwsampctrl.2', [0 0 200 200], ...
gcf, {-600, 'myclick'; -601 'my2click'; -605 'mymoused'});
```

See the section, “Sample Event Handlers” in the External Interfaces documentation for examples of event handler functions and how to register them with MATLAB.

See Also

`actxserver`, `release`, `delete`, `save`, `load`, `interfaces`

Purpose

List all currently installed ActiveX controls

Syntax

```
C = actxcontrollist
```

Description

`C = actxcontrollist` returns a list of each control, including its name, programmatic identifier (or ProgID), and filename, in output cell array `C`.

Examples

Here is an example of the information that might be returned for several controls:

```
list = actxcontrollist;

for k = 1:2
   sprintf(' Name = %s\n ProgID = %s\n File = %s\n', ...
           list{k,:})
end

ans =
   Name = ActiveXPlugin Object
   ProgID = Microsoft.ActiveXPlugin.1
   File = C:\WINNT\System32\plugin.ocx

ans =
   Name = Adaptec CD Guide
   ProgID = Adaptec.EasyCDGuide
   File = D:\APPLIC~1\Adaptec\Shared\CDGuide\CDGuide.ocx
```

See Also

`actxcontrolselect`, `actxcontrol`

actxcontrolselect

Purpose

Open GUI to create ActiveX control

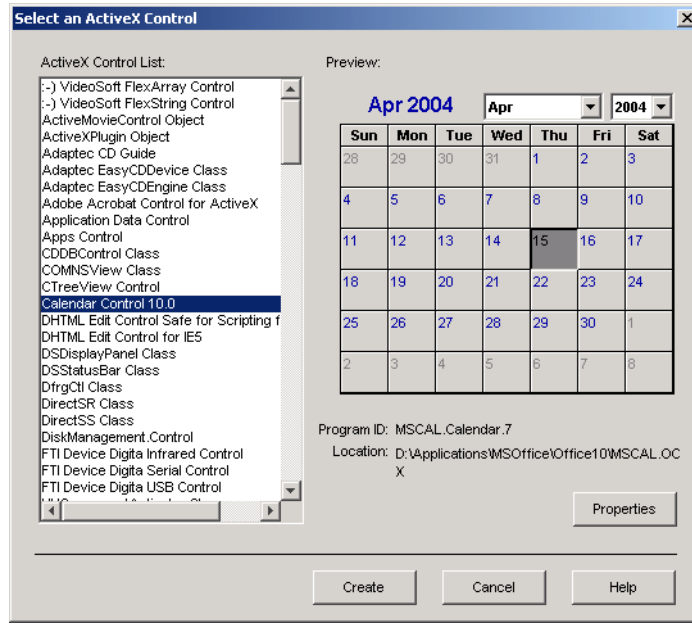
Syntax

```
h = actxcontrolselect
[h, info] = actxcontrolselect
```

Description

`h = actxcontrolselect` displays a graphical interface that lists all ActiveX controls installed on the system and creates the one that you select from the list. The function returns a handle `h` for the object. Use the handle to identify this particular control object when calling other MATLAB COM functions.

`[h, info] = actxcontrolselect` returns the handle `h` and also the 1-by-3 cell array `info` containing information about the control. The information returned in the cell array shows the name, programmatic identifier (or ProgID), and filename for the control.

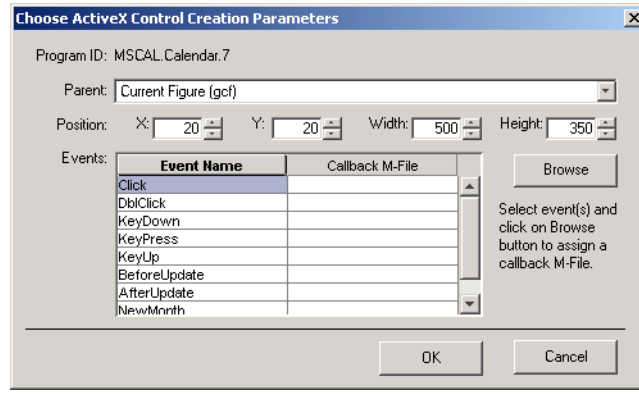


The `actxcontrolselect` interface has a selection panel at the left of the window and a preview panel at the right. Click on one of the control names in the selection panel to see a preview of the control displayed. (If MATLAB cannot create the control, an error message is displayed in the preview panel.) Select an item from the list and click the **Create** button at the bottom.

Remarks

Click the **Properties** button on the `actxcontrolselect` window to enter nondefault values for properties when creating the control. You can select which figure window to put the control in (**Parent** field), where to position it in the window (**X** and **Y** fields), and what size to make the control (**Width** and **Height**).

You can also register any events you want the control to respond to and what event handling routines to use when any of these events fire. Do this by entering the name of the appropriate event handling routine to the right of the event, or clicking the **Browse** button to search for the event handler file.



Note If you encounter problems creating Microsoft Forms 2.0 controls in MATLAB or other non-VBA container applications, see “Using Microsoft Forms 2.0 Controls” in the External Interfaces documentation.

Examples

Select `Calendar Control 9.0` in the `actxcontrolselect` window and then click **Properties** to open the window shown above. Enter new values for the size of the control, setting **Width** to `500` and **Height** to `350`, then click **OK**. Click **Create** in the `actxcontrolselect` window to create the control.

The control appears in a MATLAB figure window and the `actxcontrolselect` function returns these values:

```
h =
   COM.mscal.calendar.7
info =
    [1x20 char]    'MSCAL.Calendar.7'    [1x41 char]
```

Expand the `info` cell array to show the control name, ProgID, and filename:

```
info{:}
ans =
   Calendar Control 9.0
ans =
   MSCAL.Calendar.7
ans =
   D:\Applications\MSOffice\Office\MSCAL.OCX
```

See Also

`actxcontrollist`, `actxcontrol`

Purpose

Get handle to running instance of Automation server

Syntax

```
h = actxGetRunningServer('progid')
```

Description

`h = actxGetRunningServer('progid')` gets a reference to a running instance of the OLE Automation server, where `progid` is the programmatic identifier of the Automation server object and `h` is the handle to the server object's default interface.

The function issues an error if the server specified by `progid` is not currently running or if the server object is not registered. When there are multiple instances of the Automation server already running, the behavior of this function is controlled by the operating system.

Example

```
h = actxGetRunningServer('Excel.Application')
```

See Also

`actxcontrol`, `actxserver`

Purpose

Create COM server

Syntax

```
h = actxserver('progid')
h = actxserver('progid', 'machine', 'machineName')
h = actxserver('progid', 'interface', 'interfaceName')
h = actxserver('progid', 'machine', 'machineName',
   'interface', 'interfaceName')
h = actxserver('progid', machine)
```

Description

`h = actxserver('progid')` creates a local OLE Automation server, where `progid` is the programmatic identifier of the COM server, and `h` is the handle of the server's default interface.

Get `progid` from the control or server vendor's documentation. To see the `progid` values for MATLAB, refer to "Programmatic Identifiers" in the MATLAB External Interfaces documentation.

`h = actxserver('progid', 'machine', 'machineName')` creates an OLE Automation server on a remote machine, where `machineName` is a string specifying the name of the machine on which to launch the server.

`h = actxserver('progid', 'interface', 'interfaceName')` creates a Custom interface server, where `interfaceName` is a string specifying the interface name of the COM object. Values for `interfaceName` are

- `IUnknown` — Use the IUnknown interface.
- The Custom interface name

You must know the name of the interface and have the server vendor's documentation in order to use the `interfaceName` value. See "COM Server Types" in the MATLAB External Interfaces documentation for information about Custom COM servers and interfaces.

`h = actxserver('progid', 'machine', 'machineName', 'interface', 'interfaceName')` creates a Custom interface server on a remote machine.

The following syntaxes are deprecated and will not become obsolete. They are included for reference, but the syntaxes described earlier are preferred:

`h = actxserver('progid', machine)` creates a COM server running on the remote system named by the `machine` argument. This can be an IP address or a DNS name. Use this syntax only in environments that support Distributed Component Object Model (DCOM).

Remarks

For components implemented in a dynamic link library (DLL), `actxserver` creates an in-process server. For components implemented as an executable (EXE), `actxserver` creates an out-of-process server. Out-of-process servers can be created either on the client system or on any other system on a network that supports DCOM.

If the control implements any Custom interfaces, use the `interfaces` function to list them, and the `invoke` function to get a handle to a selected interface.

You can register events for COM servers.

Run Microsoft Excel Example

This example creates an OLE Automation server, Microsoft Excel version 9.0, and manipulates a workbook in the application:

```
%  Create a COM server running Microsoft Excel
e = actxserver ('Excel.Application')

% e =
%     COM.excel.application

% Make the Excel frame window visible
e.Visible = 1;

% Use the get method on the Excel object "e"
% to list all properties of the application:
e.get

% ans =
```

```
%        Application: [1x1Interface.Microsoft_Excel_9.0_
%Object_Library._Application]
%            Creator: 'xlCreatorCode'
%          Workbooks: [1x1 Interface.Microsoft_Excel_9.0_
%Object_Library.Workbooks]
%            Caption: 'Microsoft Excel - Book1'
%    CellDragAndDrop: 0
%   ClipboardFormats: {3x1 cell}
%             Cursor: 'xlNorthwestArrow'
%               .
%               .

% Create an interface "eWorkBooks"
eWorkbooks = e.Workbooks

% eWorkbooks =
%    Interface.Microsoft_Excel_9.0_Object_Library.Workbooks

% List all methods for that interface
eWorkbooks.invoke

% ans =
%       Add: 'handle Add(handle, [Optional]Variant)'
%     Close: 'void Close(handle)'
%      Item: 'handle Item(handle, Variant)'
%      Open: 'handle Open(handle, string, [Optional]Variant)'
%  OpenText: 'void OpenText(handle, string, [Optional]Variant)'

% Add a new workbook "w",
% also creating a new interface
w = eWorkbooks.Add

% w =
%    Interface.Microsoft_Excel_9.0_Object_Library._Workbook

% Close Excel and delete the object
e.Quit;
```

```
e.delete;
```

See Also

actxcontrol, release, delete, save, load, interfaces

addCause (MException)

Purpose

Append MException objects

Syntax

```
new_ME = addCause(base_ME, cause_ME)
base_ME = addCause(base_ME, cause_ME)
```

Description

`new_ME = addCause(base_ME, cause_ME)` creates a new `MException` object `new_ME` from two existing `MException` objects, `base_ME` and `cause_ME`. `addCause` constructs `new_ME` by making a copy of the `base_ME` object and appending `cause_ME` to the `cause` property of that object.

If other errors have contributed to the exception currently being thrown, you can add the `MException` objects that represent these errors to the `cause` field of the current `MException` to provide further information for diagnosing the error at hand. All objects of the `MException` class have a property called `cause` which is defined as a vector of additional `MException` objects that can be added onto a base object of that class.

`base_ME = addCause(base_ME, cause_ME)` modifies existing `MException` object `base_ME` by appending `cause_ME` to the `cause` property of that object.

Examples

Example 1

This example attempts to assign data from array `D`. If `D` does not exist, the code attempts to recreate `D` by loading it from a MAT-file. The code constructs a new `MException` object `new_ME` to store the causes of the first two errors, `cause1_ME` and `cause2_ME`:

```
try
    x = D(1:25);
catch cause1_ME
    try
        filename = 'test2O4';
        testdata = load(filename);
        x = testdata.D(1:25)
    catch cause2_ME
        base_ME = MException('MATLAB:LoadErr', ...
               'Unable to load from file %s', filename);
```

```
        new_ME = addCause(base_ME, cause1_ME);
        new_ME = addCause(new_ME, cause2_ME);
        throw(new_ME);
    end
end
```

When you run the code, MATLAB displays the following message:

```
??? Unable to load from file test204
```

There are two exceptions in the cause field of `new_ME`:

```
new_ME.cause
ans =
    [1x1 MException]
    [1x1 MException]
```

Examine the `cause` field of `new_ME` to see the related errors:

```
new_ME.cause{:}
ans =

 MException object with properties:

    identifier: 'MATLAB:UndefinedFunction'
       message: 'Undefined function or method 'D' for input
            arguments of type 'double'.'
         stack: [0x1 struct]
         cause: {}
ans =

 MException object with properties:

    identifier: 'MATLAB:load:couldNotReadFile'
       message: 'Unable to read file test204: No such file
            or directory.'
         stack: [0x1 struct]
         cause: {}
```

Example 2

This example attempts to open a file in a directory that is not on the MATLAB path. It uses a nested `try-catch` block to give the user the opportunity to extend the path. If the still cannot be found, the program issues an exception with the first error appended to the second using `addCause`:

```
function data = read_it(filename);
try
   fid = fopen(filename, 'r');
   data = fread(fid);
catch ME1
   if strcmp(ME1.identifier, 'MATLAB:FileIO:InvalidFid')
      msg = sprintf('\n%s%s%s', 'Cannot open file ', ...
         filename, '. Try another location?  ');
      reply = input(msg, 's')
      if reply(1) == 'y'
          newdir = input('Enter directory name:  ', 's');
      else
          throw(ME1);
      end
      addpath(newdir);
      try
         fid = fopen(filename, 'r');
         data = fread(fid);
      catch ME2
         ME3 = addCause(ME2, ME1)
         throw(ME3);
      end
      rmpath(newdir);
   end
end
fclose(fid);
```

If you run this function in a `try-catch` block at the command line, you can look at the `MException` object by assigning it to a variable (`e`) with the `catch` command.

```
try
   d = read_it('anytextfile.txt');
catch e
end

e
e =
 MException object with properties:

    identifier: 'MATLAB:FileIO:InvalidFid'
       message: 'Invalid file identifier.  Use fopen to
generate a valid file identifier.'
         stack: [1x1 struct]
         cause: {[1x1 MException]}

  Cannot open file anytextfile.txt. Try another location?y
Enter directory name:  xxxxxxx
Warning: Name is nonexistent or not a directory: xxxxxxx.
> In path at 110
  In addpath at 89
```

addevent

Purpose

Add event to timeseries object

Syntax

```
ts = addevent(ts,e)
ts = addevent(ts,Name,Time)
```

Description

`ts = addevent(ts,e)` adds one or more `tsdata.event` objects, `e`, to the `timeseries` object `ts`. `e` is either a single `tsdata.event` object or an array of `tsdata.event` objects.

`ts = addevent(ts,Name,Time)` constructs one or more `tsdata.event` objects and adds them to the `Events` property of `ts`. `Name` is a cell array of event name strings. `Time` is a cell array of event times.

Examples

Create a time-series object and add an event to this object.

```
%% Import the sample data
load count.dat

%% Create time-series object
count1=timeseries(count(:,1),1:24,'name', 'data');

%% Modify the time units to be 'hours' ('seconds' is default)
count1.TimeInfo.Units = 'hours';

%% Construct and add the first event at 8 AM
e1 = tsdata.event('AMCommute',8);

%% Specify the time units of the time
e1.Units = 'hours';
```

View the properties (`EventData`, `Name`, `Time`, `Units`, and `StartDate`) of the event object.

```
get(e1)
```

MATLAB responds with

```
    EventData: []
```

```
           Name: 'AMCommute'
           Time: 8
          Units: 'hours'
      StartDate: ''
  %% Add the event to count1
  count1 = addevent(count1,e1);
```

An alternative syntax for adding two events to the time series `count1` is as follows:

```
count1 = addevent(count1,{'AMCommute' 'PMCommute'},{8 18})
```

See Also

`timeseries`, `tsdata.event`, `tsprops`

addframe

Purpose

Add frame to Audio/Video Interleaved (AVI) file

Syntax

```
aviobj = addframe(aviobj,frame)
aviobj = addframe(aviobj,frame1,frame2,frame3,...)
aviobj = addframe(aviobj,mov)
aviobj = addframe(aviobj,h)
```

Description

`aviobj = addframe(aviobj,frame)` appends the data in `frame` to the AVI file identified by `aviobj`, which was created by a previous call to `avifile`. `frame` can be either an indexed image (`m`-by-`n`) or a truecolor image (`m`-by-`n`-by-3) of `double` or `uint8` precision. If `frame` is not the first frame added to the AVI file, it must be consistent with the dimensions of the previous frames.

`addframe` returns a handle to the updated AVI file object, `aviobj`. For example, `addframe` updates the `TotalFrames` property of the AVI file object each time it adds a frame to the AVI file.

`aviobj = addframe(aviobj,frame1,frame2,frame3,...)` adds multiple frames to an AVI file.

`aviobj = addframe(aviobj,mov)` appends the frames contained in the MATLAB movie `mov` to the AVI file `aviobj`. MATLAB movies that store frames as indexed images use the colormap in the first frame as the colormap for the AVI file, unless the colormap has been previously set.

`aviobj = addframe(aviobj,h)` captures a frame from the figure or axis handle `h` and appends this frame to the AVI file. `addframe` renders the figure into an offscreen array before appending it to the AVI file. This ensures that the figure is written correctly to the AVI file even if the figure is obscured on the screen by another window or screen saver.

Note If an animation uses XOR graphics, you must use `getframe` to capture the graphics into a frame of a MATLAB movie. You can then add the frame to an AVI movie using the `addframe` syntax `aviobj = addframe(aviobj,mov)`. See the example for an illustration.

Example

This example calls `addframe` to add frames to the AVI file object `aviobj`.

```
fig=figure;
set(fig,'DoubleBuffer','on');
set(gca,'xlim',[-80 80],'ylim',[-80 80],...
 'nextplot','replace','Visible','off')

aviobj = avifile('example.avi')

x = -pi:.1:pi;
radius = 0:length(x);
for i=1:length(x)
 h = patch(sin(x)*radius(i),cos(x)*radius(i),...
   [abs(cos(x(i))) 0 0]);
 set(h,'EraseMode','xor');
 frame = getframe(gca);
 aviobj = addframe(aviobj,frame);
end

aviobj = close(aviobj);
```

See Also

`avifile`, `close`, `movie2avi`

addOptional (inputParser)

Purpose

Add optional argument to `inputParser` schema

Syntax

```
p.addOptional(argname, default, validator)
addOptional(p, argname, default, validator)
```

Description

`p.addOptional(argname, default, validator)` updates the schema for `inputParser` object `p` by adding an optional argument, `argname`. Specify the argument name in a string enclosed within single quotation marks. The `default` input specifies the value to use when the optional argument `argname` is not present in the actual inputs to the function. The optional `validator` input is a handle to a function that MATLAB uses during parsing to validate the input arguments. If the validator function returns `false` or errors, the parsing fails and MATLAB throws an error.

MATLAB parses parameter-value arguments after required arguments and optional arguments.

`addOptional(p, argname, default, validator)` is functionally the same as the syntax above.

Note For more information on the `inputParser` class, see Parsing Inputs with inputParser in the MATLAB Programming documentation.

Examples

Write an M-file function called `publish_ip`, based on the MATLAB `publish` function, to illustrate the use of the `inputParser` class.

There are three calling syntaxes for this function:

```
publish_ip('script')
publish_ip('script', 'format')
publish_ip('script', options)
```

From these three syntaxes, you can see that there is one required argument (`script`), one optional argument (`format`), and some number

of optional arguments that are specified as parameter-value pairs (`options`).

Begin writing the example `publish_ip` M-file by entering the following two statements. The second statement calls the class constructor for `inputParser` to create an instance of the class. This class instance, or object, gives you access to all of the methods and properties of the class:

```
function x = publish_ip(script, varargin)
p = inputParser;   % Create an instance of the class.
```

Following the constructor, add this block of code to the M-file. This code uses the `addRequired(inputParser)`, `addOptional`, and `addParamValue(inputParser)` methods to define the input arguments to the function:

```
p.addRequired('script', @ischar);
p.addOptional('format', 'html', ...
    @(x)any(strcmpi(x,{'html','ppt','xml','latex'})));
p.addParamValue('outputDir', pwd, @ischar);
p.addParamValue('maxHeight', [], @(x)x>0 && mod(x,1)==0);
p.addParamValue('maxWidth', [], @(x)x>0 && mod(x,1)==0);
```

Also add the next two lines to the M-file. The `Parameters` property of `inputParser` lists all of the arguments that belong to the object `p`:

```
disp 'The input parameters for this program are
disp(p.Parameters)'
```

Save the M-file using the **Save** option on the MATLAB **File** menu, and then run it to see the following list displayed:

```
The input parameters for this program are
    'format'
    'maxHeight'
    'maxWidth'
    'outputDir'
    'script'
```

See Also

`inputParser`, `addRequired(inputParser)`, `addParamValue(inputParser)`, `parse(inputParser)`, `createCopy(inputParser)`

Purpose

Add parameter-value argument to `inputParser` schema

Syntax

```
p.addParamValue(argname, default, validator)
addParamValue(p, argname, default, validator)
```

Description

`p.addParamValue(argname, default, validator)` updates the schema for `inputParser` object `p` by adding a parameter-value argument, `argname`. Specify the argument name in a string enclosed within single quotation marks. The `default` input specifies the value to use when the optional argument name is not present in the actual inputs to the function. The optional `validator` is a handle to a function that MATLAB uses during parsing to validate the input arguments. If the validator function returns `false` or errors, the parsing fails and MATLAB throws an error.

MATLAB parses parameter-value arguments after required arguments and optional arguments.

`addParamValue(p, argname, default, validator)` is functionally the same as the syntax above.

Note For more information on the `inputParser` class, see Parsing Inputs with inputParser in the MATLAB Programming documentation.

Examples

Write an M-file function called `publish_ip`, based on the MATLAB `publish` function, to illustrate the use of the `inputParser` class. There are three calling syntaxes for this function:

```
publish_ip('script')
publish_ip('script', 'format')
publish_ip('script', options)
```

From these calling syntaxes, you can see that there is one required argument (`script`), one optional argument (`format`), and a number of optional arguments that are specified as parameter-value pairs (`options`).

Begin writing the example `publish_ip` M-file by entering the following two statements. Call the class constructor for `inputParser` to create an instance of the class. This class instance, or object, gives you access to all of the methods and properties of the class:

```
function x = publish_ip(script, varargin)
p = inputParser;   % Create an instance of the class.
```

After calling the constructor, add the following lines to the M-file. This code uses the `addRequired(inputParser)`, `addOptional(inputParser)`, and `addParamValue` methods to define the input arguments to the function:

```
p.addRequired('script', @ischar);
p.addOptional('format', 'html', ...
    @(x)any(strcmpi(x,{'html','ppt','xml','latex'})));
p.addParamValue('outputDir', pwd, @ischar);
p.addParamValue('maxHeight', [], @(x)x>0 && mod(x,1)==0);
p.addParamValue('maxWidth', [], @(x)x>0 && mod(x,1)==0);
```

Also add the next two lines to the M-file. The `Parameters` property of `inputParser` lists all of the arguments that belong to the object `p`:

```
disp 'The input parameters for this program are
disp(p.Parameters)'
```

Save the M-file using the **Save** option on the MATLAB **File** menu, and then run it to see the following list displayed:

```
The input parameters for this program are
    'format'
    'maxHeight'
    'maxWidth'
    'outputDir'
    'script'
```

See Also

`inputParser`, `addRequired(inputParser)`, `addOptional(inputParser)`, `parse(inputParser)`, `createCopy(inputParser)`

addpath

Purpose

Add directories to MATLAB search path

GUI Alternatives

As an alternative to the `addpath` function, use **File > Set Path** to open the Set Path dialog box.

Syntax

```
addpath('directory')
addpath('dir','dir2','dir3' ...)
addpath('dir','dir2','dir3' ...'-flag')
addpath dir1 dir2 dir3 ... -flag
```

Description

`addpath('directory')` adds the specified directory to the top (also called front) of the current MATLAB search path. Use the full pathname for `directory`.

`addpath('dir','dir2','dir3' ...)` adds all the specified directories to the top of the path. Use the full pathname for each `dir`.

`addpath('dir','dir2','dir3' ...'-flag')` adds the specified directories to either the top or bottom of the path, depending on the value of `flag`.

flag Argument	Result
`0` or `begin`	Add specified directories to the top of the path
`1` or `end`	Add specified directories to the bottom (also called end) of the path

`addpath dir1 dir2 dir3 ... -flag` is the unquoted form of the syntax.

Remarks

To recursively add subdirectories of your directory in addition to the directory itself, run

```
addpath(genpath('directory'))
```

Use addpath statements in your startup.m file to use the modified path in future sessions. For details, see "Modifying the Path in a startup.m File" in the MATLAB Desktop Tools and Development Environment Documentation.

Examples

For the current path, viewed by typing path,

```
MATLABPATH
c:\matlab\toolbox\general
c:\matlab\toolbox\ops
c:\matlab\toolbox\strfun
```

you can add c:/matlab/mymfiles to the front of the path by typing

```
addpath('c:/matlab/mymfiles')
```

Verify that the files were added to the path by typing

```
path
```

and MATLAB returns

```
MATLABPATH
c:\matlab\mymfiles
c:\matlab\toolbox\general
c:\matlab\toolbox\ops
c:\matlab\toolbox\strfun
```

You can also use genpath in conjunction with addpath to add subdirectories to the path from the command line. For example, to add /control and its subdirectories to the path, use

```
addpath(genpath(fullfile(matlabroot,'toolbox/control')))
```

See Also

genpath, path, pathdef, pathsep, pathtool, rehash, restoredefaultpath, rmpath, savepath, startup

"Search Path" in the MATLAB Desktop Tools and Development Environment Documentation

addpref

Purpose

Add preference

Syntax

```
addpref('group','pref',val)
addpref('group',{'pref1','pref2',...'prefn'},{val1,val2,
   ...valn})
```

Description

`addpref('group','pref',val)` creates the preference specified by `group` and `pref` and sets its value to `val`. It is an error to add a preference that already exists.

`group` labels a related collection of preferences. You can choose any name that is a legal variable name, and is descriptive enough to be unique, e.g. `'ApplicationOnePrefs'`. The input argument `pref` identifies an individual preference in that group, and must be a legal variable name.

`addpref('group',{'pref1','pref2',...'prefn'},{val1,val2,...valn})` creates the preferences specified by the cell array of names `'pref1'`, `'pref2'`,`...`,`'prefn'`, setting each to the corresponding value.

Note Preference values are persistent and maintain their values between MATLAB sessions. Where they are stored is system dependent.

Examples

This example adds a preference called `version` to the `mytoolbox` group of preferences and sets its value to the string `1.0`.

```
addpref('mytoolbox','version','1.0')
```

See Also

`getpref`, `ispref`, `rmpref`, `setpref`, `uigetpref`, `uisetpref`

Purpose

Add custom property to object

Syntax

```
h.addproperty('propertyname')
addproperty(h, 'propertyname')
```

Description

`h.addproperty('propertyname')` adds the custom property specified in the string, `propertyname`, to the object or interface, `h`. Use `set` to assign a value to the property.

`addproperty(h, 'propertyname')` is an alternate syntax for the same operation.

Examples

Create an `mwsamp` control and add a new property named `Position` to it. Assign an array value to the property:

```
f = figure('position', [100 200 200 200]);
h = actxcontrol('mwsamp.mwsampctrl.2', [0 0 200 200], f);
h.get
     Label: 'Label'
    Radius: 20

h.addproperty('Position');
h.Position = [200 120];
h.get
     Label: 'Label'
    Radius: 20
  Position: [200 120]

h.get('Position')
ans =
   200   120
```

Delete the custom `Position` property:

```
h.deleteproperty('Position');
h.get
     Label: 'Label'
    Radius: 20
```

See Also deleteproperty, get, set, inspect

Purpose

Add required argument to `inputParser` schema

Syntax

```
p.addRequired(argname, validator)
addRequired(p, argname, validator)
```

Description

`p.addRequired(argname, validator)` updates the schema for `inputParser` object `p` by adding a required argument, `argname`. Specify the argument name in a string enclosed within single quotation marks. The optional `validator` is a handle to a function that MATLAB uses during parsing to validate the input arguments. If the validator function returns `false` or errors, the parsing fails and MATLAB throws an error.

MATLAB parses required arguments before optional or parameter-value arguments.

`addRequired(p, argname, validator)` is functionally the same as the syntax above.

Note For more information on the `inputParser` class, see Parsing Inputs with inputParser in the MATLAB Programming documentation.

Examples

Write an M-file function called `publish_ip`, based on the MATLAB `publish` function, to illustrate the use of the `inputParser` class. There are three calling syntaxes for this function:

```
publish_ip('script')
publish_ip('script', 'format')
publish_ip('script', options)
```

From these calling syntaxes, you can see that there is one required argument (`script`), one optional argument (`format`), and a number of optional arguments that are specified as parameter-value pairs (`options`).

Begin writing the example `publish_ip` M-file by entering the following two statements. Call the class constructor for `inputParser` to create an

instance of the class. This class instance, or object, gives you access to all of the methods and properties of the class:

```
function x = publish_ip(script, varargin)
p = inputParser;   % Create an instance of the class.
```

After calling the constructor, add the following lines to the M-file. This code uses the `addRequired`, `addOptional(inputParser)`, and `addParamValue(inputParser)` methods to define the input arguments to the function:

```
p.addRequired('script', @ischar);
p.addOptional('format', 'html', ...
    @(x)any(strcmpi(x,{'html','ppt','xml','latex'})));
p.addParamValue('outputDir', pwd, @ischar);
p.addParamValue('maxHeight', [], @(x)x>0 && mod(x,1)==0);
p.addParamValue('maxWidth', [], @(x)x>0 && mod(x,1)==0);
```

Also add the next two lines to the M-file. The `Parameters` property of `inputParser` lists all of the arguments that belong to the object `p`:

```
disp 'The input parameters for this program are
disp(p.Parameters)'
```

Save the M-file using the **Save** option on the MATLAB **File** menu, and then run it to see the following list displayed:

```
The input parameters for this program are
    'format'
    'maxHeight'
    'maxWidth'
    'outputDir'
    'script'
```

See Also

`inputParser`, `addOptional(inputParser)`, `addParamValue(inputParser)`, `parse(inputParser)`, `createCopy(inputParser)`

Purpose

Add data sample to `timeseries` object

Syntax

```
ts = addsample(ts,'Field1',Value1,'Field2',Value2,...)
ts = addsample(ts,s)
```

Description

`ts = addsample(ts,'Field1',Value1,'Field2',Value2,...)` adds one or more data samples to the `timeseries` object `ts`, where one field must specify `Time` and another must specify `Data`. You can also specify the following optional property-value pairs:

- `'Quality'` — Array of data quality codes
- `'OverwriteFlag'` — Logical value that controls whether to overwrite a data sample at the same time with the new sample you are adding to your `timeseries` object. When set to `true`, the new sample overwrites the old sample at the same time.

`ts = addsample(ts,s)` adds one or more new samples stored in a structure `s` to the `timeseries` object `ts`. You must define the fields of the structure `s` before passing it as an argument to `addsample` by assigning values to the following optional `s` fields:

- `s.data`
- `s.time`
- `s.quality`
- `s.overwriteflag`

Remarks

A time-series *data sample* consists of one or more values recorded at a specific time. The number of data samples in a time series is the same as the length of the time vector.

The `Time` value must be a valid time vector.

Suppose that `N` is the number of samples. The sample size of each time series is given by `SampleSize = getsamplesize(ts)`. When

`ts.IsTimeFirst` is `true`, the size of the data is `N`-by-`SampleSize`. When `ts.IsTimeFirst` is `false`, the size of the data is `SampleSize`-by-`N`.

Examples

Add a data value of `420` at time `3`.

```
ts = ts.addsample('Time',3,'Data',420);
```

Add a data value of `420` at time `3` and specify quality code `1` for this data value. Set the flag to overwrite an existing value at time `3`.

```
ts = ts.addsample('Data',3.2,'Quality',1,'OverwriteFlag',...
        true,'Time',3);
```

See Also

`delsample`, `getdatasamplesize`, `tsprops`

Purpose

Add sample to tscollection object

Syntax

```
tsc = addsampletocollection(tsc,'time',Time,TS1Name,TS1Data,
   TSnName,TSnData)
```

Description

`tsc = addsampletocollection(tsc,'time',Time,TS1Name,TS1Data, TSnName,TSnData)` adds data samples `TSnData` to the collection member `TSnName` in the `tscollection` object `tsc` at one or more `Time` values. Here, `TSnName` is the string that represents the name of a time series in `tsc`, and `TSnData` is an array containing data samples.

Remarks

If you do not specify data samples for a time-series member in tsc, that time-series member will contain missing data at the times given by Time (for numerical time-series data), `NaN` values, or (for logical time-series data) `false` values.

When a time-series member requires `Quality` values, you can specify data quality codes together with the data samples by using the following syntax:

```
tsc = addsampletocollection(tsc,'time',time,TS1Name,...
          ts1cellarray,TS2Name,ts2cellarray,...)
```

Specify data in the first cell array element and `Quality` in the second cell array element.

Note If a time-series member already has `Quality` values but you only provide data samples, `0`s are added to the existing `Quality` array at the times given by `Time`.

Examples

The following example shows how to create a `tscollection` that consists of two `timeseries` objects, where one `timeseries` does not have quality codes and the other does. The final step of the example adds a sample to the `tscollection`.

1 Create two `timeseries` objects, `ts1` and `ts2`.

```
ts1 = timeseries([1.1 2.9 3.7 4.0 3.0],1:5,...
                 'name','acceleration');
ts2 = timeseries([3.2 4.2 6.2 8.5 1.1],1:5,...
                 'name','speed');
```

2 Define a dictionary of quality codes and descriptions for `ts2`.

```
ts2.QualityInfo.Code = [0 1];
ts2.QualityInfo.Description = {'bad','good'};
```

3 Assign a quality of code of `1`, which is equivalent to `'good'`, to each data value in `ts2`.

```
ts2.Quality = ones(5,1);
```

4 Create a time-series collection `tsc`, which includes time series `ts1` and `ts2`.

```
tsc = tscollection({ts1,ts2});
```

5 Add a data sample to the collection `tsc` at `3.5` seconds.

```
tsc = addsampletocollection(tsc,'time',3.5,'acceleration',10,
        'speed',{5 1});
```

The cell array for the `timeseries` object `'speed'` specifies both the data value 5 and the quality code `1`.

Note If you do not specify a quality code when adding a data sample to a time series that has quality codes, then the lowest quality code is assigned to the new sample by default.

See Also

`delsamplefromcollection`, `tscollection`, `tsprops`

Purpose

Modify date number by field

Syntax

```
R = addtodate(D, Q, F)
```

Description

`R = addtodate(D, Q, F)` adds quantity `Q` to the indicated date field `F` of a scalar serial date number `D`, returning the updated date number `R`.

The quantity `Q` to be added must be a double scalar whole number, and can be either positive or negative. The date field `F` must be a 1-by-`N` character array equal to one of the following: `'year'`, `'month'`, or `'day'`.

If the addition to the date field causes the field to roll over, MATLAB adjusts the next more significant fields accordingly. Adding a negative quantity to the indicated date field rolls back the calender on the indicated field. If the addition causes the field to roll back, MATLAB adjusts the next less significant fields accordingly.

Examples

Adding 20 days to the given date in late December causes the calendar to roll over to January of the next year:

```
R = addtodate(datenum('12/24/1984 12:45'), 20, 'day');

datestr(R)
ans =
   13-Jan-1985 12:45:00
```

See Also

`date`, `datenum`, `datestr`, `datevec`

addts

Purpose

Add timeseries object to tscollection object

Syntax

```
tsc = addts(tsc,ts)
tsc = addts(tsc,ts)
tsc = addts(tsc,ts,Name)
tsc = addts(tsc,Data,Name)
```

Description

`tsc = addts(tsc,ts)` adds the `timeseries` object ts to `tscollection` object tsc.

`tsc = addts(tsc,ts)` adds a cell array of `timeseries` objects ts to the `tscollection` tsc.

`tsc = addts(tsc,ts,Name)` adds a cell array of `timeseries` objects ts to `tscollection` tsc. Name is a cell array of strings that gives the names of the `timeseries` objects in `ts`.

`tsc = addts(tsc,Data,Name)` creates a new `timeseries` object from Data with the name Name and adds it to the `tscollection` object tsc. Data is a numerical array and Name is a string.

Remarks

The `timeseries` objects you add to the collection must have the same time vector as the collection. That is, the time vectors must have the same time values and units.

Suppose that the time vector of a `timeseries` object is associated with calendar dates. When you add this `timeseries` to a collection with a time vector without calendar dates, the time vectors are compared based on the units and the values relative to the `StartDate` property. For more information about properties, see the `timeseries` reference page.

Examples

The following example shows how to add a time series to a time-series collection:

1. Create two `timeseries` objects, `ts1` and `ts2`.

```
ts1 = timeseries([1.1 2.9 3.7 4.0 3.0],1:5,...
                 'name','acceleration');
```

```
ts2 = timeseries([3.2 4.2 6.2 8.5 1.1],1:5,...
                 'name','speed');
```

2 Create a time-series collection `tsc`, which includes `ts1`.

```
tsc = tscollection(ts1);
```

3 Add `ts2` to the `tsc` collection.

```
tsc = addts(tsc, ts2);
```

4 To view the members of `tsc`, type

```
tsc
```

at the MATLAB prompt. MATLAB responds with

```
Time Series Collection Object: unnamed

Time vector characteristics

      Start time            1 seconds
      End time              5 seconds

Member Time Series Objects:

      acceleration
      speed
```

The members of `tsc` are listed by name at the bottom: `acceleration` and `speed`. These are the `Name` properties of the `timeseries` objects `ts1` and `ts2`, respectively.

See Also

`removets`, `tscollection`

Purpose

Airy functions

Syntax

```
W = airy(Z)
W = airy(k,Z)
[W,ierr] = airy(k,Z)
```

Definition

The Airy functions form a pair of linearly independent solutions to

$$\frac{d^2W}{dZ^2} - ZW = 0$$

The relationship between the Airy and modified Bessel functions is

$$Ai(Z) = \left[\frac{1}{\pi}\sqrt{Z/3}\right] K_{1/3}(\zeta)$$

$$Bi(Z) = \sqrt{Z/3}\ \ [I_{-1/3}(\zeta) + I_{1/3}(\zeta)]$$

where

$$\zeta = \frac{2}{3}Z^{3/2}$$

Description

`W = airy(Z)` returns the Airy function, $Ai(Z)$, for each element of the complex array `Z`.

`W = airy(k,Z)` returns different results depending on the value of `k`.

k	Returns
0	The same result as `airy(Z)`
1	The derivative, $Ai'(Z)$

k	Returns
2	The Airy function of the second kind, $Bi(Z)$
3	The derivative, $Bi'(Z)$

`[W,ierr] = airy(k,Z)` also returns completion flags in an array the same size as `W`.

ierr	Description
0	`airy` successfully computed the Airy function for this element.
1	Illegal arguments
2	Overflow. Returns `Inf`
3	Some loss of accuracy in argument reduction
4	Unacceptable loss of accuracy, `Z` too large
5	No convergence. Returns `NaN`

align

Purpose

Align user interface controls (uicontrols) and axes

Syntax

```
align(HandleList,'HorizontalAlignment','VerticalAlignment')
Positions = align(HandleList,'HorizontalAlignment',
   'VerticalAlignment')
Positions = align(CurPositions,'HorizontalAlignment',
   'VerticalAlignment')
```

Description

`align(HandleList,'HorizontalAlignment','VerticalAlignment')` aligns the `uicontrol` and `axes` objects in `HandleList`, a vector of handles, according to the options `HorizontalAlignment` and `VerticalAlignment`. The following table shows the possible values for `HorizontalAlignment` and `VerticalAlignment`.

Argument	Possible Values
HorizontalAlignment	`None`, `Left`, `Center`, `Right`, `Distribute`, `Fixed`
VerticalAlignment	`None`, `Top`, `Middle`, `Bottom`, `Distribute`, `Fixed`

All alignment options align the objects within the bounding box that encloses the objects. `Distribute` and `Fixed` align objects to the bottom left of the bounding box. `Distribute` evenly distributes the objects while `Fixed` distributes the objects with a fixed distance (in points) between them.

If you use `Fixed` for `Horizontal Alignment` or `Vertical Alignment`, then you must specify the distance, in points, as an extra argument. These are some examples:

```
align(HandleList,'Fixed',Distance,'VerticalAlignment')
```

distributes the specified components `Distance` points horizontally and aligns them vertically as specified.

```
align(HandleList,'HorizontalAlignment','Fixed',Distance)
```

aligns the specified components horizontally as specified and distributes them `Distance` points vertically.

```
align(HandleList,'Fixed','HorizontalDistance',...
      'Fixed','VerticalDistance')
```

distributes the specified components `HorizontalDistance` points horizontally and distributes them `VerticalDistance` points vertically.

Note 72 points equals 1 inch.

`Positions = align(HandleList,'HorizontalAlignment', 'VerticalAlignment')` returns updated positions for the specified objects as a vector of `Position` vectors. The position of the objects on the figure does not change.

`Positions = align(CurPositions,'HorizontalAlignment', 'VerticalAlignment')` returns updated positions for the objects whose positions are contained in `CurPositions`, where `CurPositions` is a vector of `Position` vectors. The position of the objects on the figure does not change.

alim

Purpose

Set or query axes alpha limits

Syntax

```
alpha_limits = alim
alim([amin amax])
alim_mode = alim('mode')
alim('alim_mode')
alim(axes_handle,...)
```

Description

`alpha_limits = alim` returns the alpha limits (the axes `ALim` property) of the current axes.

`alim([amin amax])` sets the alpha limits to the specified values. `amin` is the value of the data mapped to the first alpha value in the alphamap, and `amax` is the value of the data mapped to the last alpha value in the alphamap. Data values in between are linearly interpolated across the alphamap, while data values outside are clamped to either the first or last alphamap value, whichever is closest.

`alim_mode = alim('mode')` returns the alpha limits mode (the axes `ALimMode` property) of the current axes.

`alim('alim_mode')` sets the alpha limits mode on the current axes. `alim_mode` can be

- auto — MATLAB automatically sets the alpha limits based on the alpha data of the objects in the axes.
- `manual` — MATLAB does not change the alpha limits.

`alim(axes_handle,...)` operates on the specified axes.

Axes `ALim` and `ALimMode` properties

Patch `FaceVertexAlphaData` property

Image and surface `AlphaData` properties

Transparency for related functions

"Transparency" in 3-D Visualization for examples

Purpose

Determine whether all array elements are nonzero

Syntax

```
B = all(A)
B = all(A, dim)
```

Description

`B = all(A)` tests whether *all* the elements along various dimensions of an array are nonzero or logical `1` (`true`).

If `A` is a vector, `all(A)` returns logical `1` (`true`) if all the elements are nonzero and returns logical `0` (`false`) if one or more elements are zero.

If `A` is a matrix, `all(A)` treats the columns of `A` as vectors, returning a row vector of logical 1's and 0's.

If `A` is a multidimensional array, `all(A)` treats the values along the first nonsingleton dimension as vectors, returning a logical condition for each vector.

`B = all(A, dim)` tests along the dimension of `A` specified by scalar *`dim`*.

Examples

Given

```
A = [0.53 0.67 0.01 0.38 0.07 0.42 0.69]
```

then `B = (A < 0.5)` returns logical `1` (`true`) only where `A` is less than one half:

```
0    0    1    1    1    1    0
```

The `all` function reduces such a vector of logical conditions to a single condition. In this case, `all(B)` yields `0`.

This makes `all` particularly useful in `if` statements:

```
if all(A < 0.5)
    do something
end
```

where code is executed depending on a single condition, not a vector of possibly conflicting conditions.

Applying the `all` function twice to a matrix, as in `all(all(A))`, always reduces it to a scalar condition.

```
all(all(eye(3)))
ans =
   0
```

Other functions that collapse an array's dimensions include `max`, `mean`, `median`, `min`, `prod`, `std`, `sum`, and `trapz`.

allchild

Purpose

Find all children of specified objects

Syntax

```
child_handles = allchild(handle_list)
```

Description

`child_handles = allchild(handle_list)` returns the list of all children (including ones with hidden handles) for each handle. If `handle_list` is a single element, `allchild` returns the output in a vector. Otherwise, the output is a cell array.

Examples

Compare the results returned by these two statements.

```
get(gca,'Children')
allchild(gca)
```

`findall`, `findobj`

Purpose

Set transparency properties for objects in current axes

Syntax

```
alpha
alpha(face_alpha)
alpha(alpha_data)
alpha(alpha_data)
alpha(alpha_data)
alpha(alpha_data_mapping)
alpha(object_handle,value)
```

Description

`alpha` sets one of three transparency properties, depending on what arguments you specify with the call to this function.

FaceAlpha

`alpha(face_alpha)` sets the `FaceAlpha` property of all image, patch, and surface objects in the current axes. You can set `face_alpha` to

- A scalar — Set the `FaceAlpha` property to the specified value (for images, set the `AlphaData` property to the specified value).
- `'flat'` — Set the `FaceAlpha` property to `flat`.
- `'interp'` — Set the `FaceAlpha` property to `interp`.
- `'texture'` — Set the `FaceAlpha` property to `texture`.
- `'opaque'` — Set the `FaceAlpha` property to `1`.
- `'clear'` — Set the `FaceAlpha` property to `0`.

See for more information.

AlphaData (Surface Objects)

`alpha(alpha_data)` sets the `AlphaData` property of all surface objects in the current axes. You can set `alpha_data` to

- A matrix the same size as `CData` — Set the `AlphaData` property to the specified values.
- `'x'` — Set the `AlphaData` property to be the same as `XData`.

- `'y'` — Set the `AlphaData` property to be the same as `YData`.
- `'z'` — Set the `AlphaData` property to be the same as `ZData`.
- `'color'` — Set the `AlphaData` property to be the same as `CData`.
- `'rand'` — Set the `AlphaData` property to a matrix of random values equal in size to `CData`.

AlphaData (Image Objects)

`alpha(alpha_data)` sets the `AlphaData` property of all image objects in the current axes. You can set `alpha_data` to

- A matrix the same size as `CData` — Set the `AlphaData` property to the specified value.
- `'x'` — Ignored.
- `'y'` — Ignored.
- `'z'` — Ignored.
- `'color'` — Set the `AlphaData` property to be the same as `CData`.
- `'rand'` — Set the `AlphaData` property to a matrix of random values equal in size to `CData`.

FaceVertexAlphaData (Patch Objects)

`alpha(alpha_data)` sets the `FaceVertexAlphaData` property of all patch objects in the current axes. You can set `alpha_data` to

- A matrix the same size as `FaceVertexCData` — Set the `FaceVertexAlphaData` property to the specified value.
- `'x'` — Set the `FaceVertexAlphaData` property to be the same as `Vertices(:,1)`.
- `'y'` — Set the `FaceVertexAlphaData` property to be the same as `Vertices(:,2)`.
- `'z'` — Set the `FaceVertexAlphaData` property to be the same as `Vertices(:,3)`.

- `'color'` — Set the `FaceVertexAlphaData` property to be the same as `FaceVertexCData`.
- `'rand'` — Set the `FaceVertexAlphaData` property to random values.

See Mapping Data to Transparency for more information.

AlphaDataMapping

`alpha(alpha_data_mapping)` sets the `AlphaDataMapping` property of all image, patch, and surface objects in the current axes. You can set `alpha_data_mapping` to

- `'scaled'` — Set the `AlphaDataMapping` property to `scaled`.
- `'direct'` — Set the `AlphaDataMapping` property to `direct`.
- `'none'` — Set the `AlphaDataMapping` property to `none`.

`alpha(object_handle,value)` sets the transparency property only on the object identified by `object_handle`.

Transparency for related functions

“Transparency” in 3-D Visualization for examples

alphamap

Purpose

Specify figure alphamap (transparency)

Syntax

```
alphamap
alphamap(alpha_map)
alphamap('parameter')
alphamap('parameter',length)
alphamap('parameter',delta)
alphamap(figure_handle,...)
alpha_map = alphamap
alpha_map = alphamap(figure_handle)
alpha_map = alphamap('parameter')
```

Description

`alphamap` enables you to set or modify a figure's `Alphamap` property. Unless you specify a figure handle as the first argument, `alphamap` operates on the current figure.

`alphamap(alpha_map)` sets the `AlphaMap` of the current figure to the specified m-by-1 array of alpha values.

`alphamap('parameter')` creates a new alphamap or modifies the current alphamap. You can specify the following parameters:

- `default` — Set the `AlphaMap` property to the figure's default alphamap.
- `rampup` — Create a linear alphamap with increasing opacity (default `length` equals the current alphamap length).
- `rampdown` — Create a linear alphamap with decreasing opacity (default `length` equals the current alphamap length).
- `vup` — Create an alphamap that is opaque in the center and becomes more transparent linearly towards the beginning and end (default `length` equals the current alphamap length).
- `vdown` — Create an alphamap that is transparent in the center and becomes more opaque linearly towards the beginning and end (default `length` equals the current alphamap length).

- `increase` — Modify the alphamap making it more opaque (default `delta` is `.1`, which is added to the current values).
- `decrease` — Modify the alphamap making it more transparent (default `delta` is `.1`, which is subtracted from the current values).
- `spin` — Rotate the current alphamap (default `delta` is 1; note that `delta` must be an integer).

`alphamap('parameter',length)` creates a new alphamap with the length specified by `length` (used with parameters `rampup`, `rampdown`, `vup`, `vdown`).

`alphamap('parameter',delta)` modifies the existing alphamap using the value specified by `delta` (used with parameters `increase`, `decrease`, `spin`).

`alphamap(figure_handle,...)` performs the operation on the alphamap of the figure identified by `figure_handle`.

`alpha_map = alphamap` returns the current alphamap.

`alpha_map = alphamap(figure_handle)` returns the current alphamap from the figure identified by `figure_handle`.

`alpha_map = alphamap('parameter')` returns the alphamap modified by the `parameter`, but does not set the `AlphaMap` property.

Transparency for related functions

“Transparency” in 3-D Visualization for examples

Purpose

Approximate minimum degree permutation

Syntax

```
P = amd(A)
P = amd(A,opts)
```

Description

`P = amd(A)` returns the approximate minimum degree permutation vector for the sparse matrix `C = A + A'`. The Cholesky factorization of `C(P,P)` or `A(P,P)` tends to be sparser than that of `C` or `A`. The `amd` function tends to be faster than `symamd`, and also tends to return better orderings than `symamd`. Matrix `A` must be square. If `A` is a full matrix, then `amd(A)` is equivalent to `amd(sparse(A))`.

`P = amd(A,opts)` allows additional options for the reordering. The `opts` input is a structure with the two fields shown below. You only need to set the fields of interest:

- **dense** — A nonnegative scalar value that indicates what is considered to be dense. If A is n-by-n, then rows and columns with more than `max(16,(dense*sqrt(n)))` entries in `A + A'` are considered to be "dense" and are ignored during the ordering. MATLAB places these rows and columns last in the output permutation. The default value for this field is 10.0 if this option is not present.
- **aggressive** — A scalar value controlling aggressive absorption. If this field is set to a nonzero value, then aggressive absorption is performed. This is the default if this option is not present.

MATLAB performs an assembly tree post-ordering, which is typically the same as an elimination tree post-ordering. It is not always identical because of the approximate degree update used, and because “dense” rows and columns do not take part in the post-order. It well-suited for a subsequent `chol` operation, however, If you require a precise elimination tree post-ordering, you can use the following code:

```
P = amd(S);
C = spones(S)+spones(S'); % Skip this line if S is already symmetric
[ignore, Q] = etree(C(P,P));
P = P(Q);
```

Examples

This example constructs a sparse matrix and computes a two Cholesky factors: one of the original matrix and one of the original matrix preordered by `amd`. Note how much sparser the Cholesky factor of the preordered matrix is compared to the factor of the matrix in its natural ordering:

```
A = gallery('wathen',50,50);
p = amd(A);
L = chol(A,'lower');
Lp = chol(A(p,p),'lower');

figure;
subplot(2,2,1);    spy(A);
title('Sparsity structure of A');

subplot(2,2,2); spy(A(p,p));
title('Sparsity structure of AMD ordered A');

subplot(2,2,3); spy(L);
title('Sparsity structure of Cholesky factor of A');

subplot(2,2,4); spy(Lp);
title('Sparsity structure of Cholesky factor of AMD ordered A');

set(gcf,'Position',[100 100 800 700]);
```

Sparse Matrix Algorithms Research at the University of Florida:
`http://www.cise.ufl.edu/research/sparse/`

Purpose

Ancestor of graphics object

Syntax

```
p = ancestor(h,type)
p = ancestor(h,type,'toplevel')
```

Description

`p = ancestor(h,type)` returns the handle of the closest ancestor of `h`, if the ancestor is one of the types of graphics objects specified by `type`. `type` can be:

- a string that is the name of a single type of object. For example, `'figure'`
- a cell array containing the names of multiple objects. For example, `{'hgtransform','hggroup','axes'}`

If MATLAB cannot find an ancestor of `h` that is one of the specified types, then `ancestor` returns `p` as empty.

Note that `ancestor` returns `p` as empty but does not issue an error if `h` is not the handle of a Handle Graphics object.

`p = ancestor(h,type,'toplevel')` returns the highest-level ancestor of `h`, if this type appears in the `type` argument.

Examples

Create some line objects and parent them to an hggroup object.

```
hgg = hggroup;
hgl = line(randn(5),randn(5),'Parent',hgg);
```

Now get the ancestor of the lines.

```
p = ancestor(hgg,{'figure','axes','hggroup'});
get(p,'Type')
ans =

hggroup
```

Now get the top-level ancestor

```
p=ancestor(hgg,{'figure','axes','hggroup'},'toplevel');
get(p,'type')
ans =

figure
```

See Also

findobj

Purpose

Find logical AND of array or scalar inputs

Syntax

```
A & B & ...
and(A, B)
```

Description

`A & B & ...` performs a logical AND of all input arrays `A`, `B`, etc., and returns an array containing elements set to either logical 1 (`true`) or logical 0 (`false`). An element of the output array is set to 1 if all input arrays contain a nonzero element at that same array location. Otherwise, that element is set to 0.

Each input of the expression can be an array or can be a scalar value. All nonscalar input arrays must have equal dimensions. If one or more inputs are an array, then the output is an array of the same dimensions. If all inputs are scalar, then the output is scalar.

If the expression contains both scalar and nonscalar inputs, then each scalar input is treated as if it were an array having the same dimensions as the other input arrays. In other words, if input `A` is a 3-by-5 matrix and input `B` is the number 1, then `B` is treated as if it were a 3-by-5 matrix of ones.

`and(A, B)` is called for the syntax `A & B` when either `A` or `B` is an object.

Note The symbols `&` and `&&` perform different operations in MATLAB. The element-wise AND operator described here is `&`. The short-circuit AND operator is `&&`.

Examples

If matrix `A` is

```
    0.4235    0.5798         0    0.7942         0
    0.5155         0    0.7833    0.0592    0.8744
    0.3340         0         0         0    0.0150
    0.4329    0.6405    0.6808    0.0503         0
```

and matrix `B` is

```
     0     1     0     1     0
     1     1     1     0     1
     0     1     1     1     0
     0     1     0     0     1
```

then

```
A & B
ans =
     0     1     0     1     0
     1     0     1     0     1
     0     0     0     0     0
     0     1     0     0     0
```

See Also

Purpose

Phase angle

Syntax

```
P = angle(Z)
```

Description

`P = angle(Z)` returns the phase angles, in radians, for each element of complex array `Z`. The angles lie between $\pm\pi$.

For complex `Z`, the magnitude `R` and phase angle `theta` are given by

```
R = abs(Z)
theta = angle(Z)
```

and the statement

```
Z = R.*exp(i*theta)
```

converts back to the original complex `Z`.

Examples

```
Z = [ 1 - 1i   2 + 1i   3 - 1i   4 + 1i
      1 + 2i   2 - 2i   3 + 2i   4 - 2i
      1 - 3i   2 + 3i   3 - 3i   4 + 3i
      1 + 4i   2 - 4i   3 + 4i   4 - 4i ]

P = angle(Z)

P =
   -0.7854    0.4636   -0.3218    0.2450
    1.1071   -0.7854    0.5880   -0.4636
   -1.2490    0.9828   -0.7854    0.6435
    1.3258   -1.1071    0.9273   -0.7854
```

Algorithm

The `angle` function can be expressed as `angle(z) = imag(log(z)) = atan2(imag(z),real(z))`.

See Also

`abs`, `atan2`, `unwrap`

Purpose

Create annotation objects

GUI Alternatives

Create several types of annotations with the Figure Palette and modify annotations with the Property Editor, components of the plotting tools. Directly manipulate annotations in *plot edit* mode. For details, see "How to Annotate Graphs" and "Working in Plot Edit Mode" in the MATLAB Graphics documentation.

Syntax

```
annotation(annotation_type)
annotation('line',x,y)
annotation('arrow',x,y)
annotation('doublearrow',x,y)
annotation('textarrow',x,y)
annotation('textbox',[x y w h])
annotation('ellipse',[x y w h])
annotation('rectangle',[x y w h])
annotation(figure_handle,...)
annotation(...,'PropertyName',PropertyValue,...)
anno_obj_handle = annotation(...)
```

Description

`annotation(annotation_type)` creates the specified annotation type using default values for all properties. *`annotation_type`* can be one of the following strings:

- `'line'`
- `'arrow'`
- `'doublearrow'` (two-headed arrow),
- `'textarrow'` (arrow with attached text box),
- `'textbox'`
- `'ellipse'`
- `'rectangle'`

`annotation('line',x,y)` creates a line annotation object that extends from the point defined by `x(1),y(1)` to the point defined by `x(2),y(2)`, specified in normalized figure units.

`annotation('arrow',x,y)` creates an arrow annotation object that extends from the point defined by `x(1),y(1)` to the point defined by `x(2),y(2)`, specified in normalized figure units.

`annotation('doublearrow',x,y)` creates a two-headed annotation object that extends from the point defined by `x(1),y(1)` to the point defined by `x(2),y(2)`, specified in normalized figure units.

`annotation('textarrow',x,y)` creates a textarrow annotation object that extends from the point defined by `x(1),y(1)` to the point defined by `x(2),y(2)`, specified in normalized figure units. The tail end of the arrow is attached to an editable text box.

`annotation('textbox',[x y w h])` creates an editable text box annotation with its lower left corner at the point `x,y`, a width `w`, and a height `h`, specified in normalized figure units. Specify `x`, `y`, `w`, and `h` in a single vector.

To type in the text box, enable plot edit mode (`plotedit`) and double-click within the box.

`annotation('ellipse',[x y w h])` creates an ellipse annotation with the lower left corner of the bounding rectangle at the point `x,y`, a width `w`, and a height `h`, specified in normalized figure units. Specify `x`, `y`, `w`, and `h` in a single vector.

`annotation('rectangle',[x y w h])` creates a rectangle annotation with the lower left corner of the rectangle at the point `x,y`, a width `w`, and a height `h`, specified in normalized figure units. Specify `x`, `y`, `w`, and `h` in a single vector.

`annotation(figure_handle,...)` creates the annotation in the specified figure.

`annotation(...,'`*`PropertyName`*`',PropertyValue,...)` creates the annotation and sets the specified properties to the specified values.

`anno_obj_handle = annotation(...)` returns the handle to the annotation object that is created.

Annotation Layer

All annotation objects are displayed in an overlay axes that covers the figure. This layer is designed to display only annotation objects. You should not parent objects to this axes nor set any properties of this axes. See the See Also section for information on the properties of annotation objects that you can set.

Objects in the Plotting Axes

You can create lines, text, rectangles, and ellipses in data coordinates in the axes of a graph using the `line`, `text`, and `rectangle` functions. These objects are not placed in the annotation axes and must be located inside their parent axes.

Deleting Annotations

Existing annotations persist on a plot when you replace its data. This might not be what you want to do. If it is not, or if you want to remove annotation objects for any reason, you can do so manually, or sometimes programmatically, in several ways:

- To manually delete, click the **Edit Plot** tool or invoke `plottools`, select the annotation(s) you want to remove, and do one of the following:
  - Press the **Delete** key.
  - Press the **Backspace** key.
  - Select **Clear** from the **Edit** menu.
  - Select **Delete** from the context menu (one annotation at a time).
- If you obtained a handle for the annotation when you created it, use the `delete` function:

  ```
  delete(anno_obj_handle)
  ```

  There is no reliable way to obtain handles for annotations from a figure's property set; you must keep track of them yourself.

- To delete all annotations at once (as well as all plot contents), type

```
clf
```

Normalized Coordinates

By default, annotation objects use normalized coordinates to specify locations within the figure. In normalized coordinates, the point 0,0 is always the lower left corner and the point 1,1 is always the upper right corner of the figure window, regardless of the figure size and proportions. Set the `Units` property of annotation objects to change their coordinates from `normalized` to `inches`, `centimeters`, `points`, `pixels`, or `characters`.

When their `Units` property is other than `normalized`, annotation objects have absolute positions with respect to the figure's origin, and fixed sizes. Therefore, they will shift position with respect to axes when you resize figures. When units are normalized, annotations shrink and grow when you resize figures; this can cause lines of text in textbox annotations to wrap. However, if you set the `FontUnits` property of an annotation textbox object to `normalized`, the text changes size rather than wraps if the textbox size changes.

You can use either the `set` command or the Inspector to change a selected annotation object's `Units` property:

```
set(gco,'Units','inches')  % or
inspect(gco)
```

See Also

See "Annotating Graphs" and "Annotation Objects" for more information.

Annotation Arrow Properties

Purpose

Define annotation arrow properties

Modifying Properties

You can set and query annotation object properties using the `set` and `get` functions and the Property Editor (displayed with the `propertyeditor` command).

Use the `annotation` function to create annotation objects and obtain their handles. For an example of its use, see "Positioning Annotations in Data Space" in the MATLAB Graphics documentation.

Annotation Arrow Property Descriptions

Properties You Can Modify

This section lists the properties you can modify on an annotation arrow object.

`Color`
ColorSpec

Color of the object. A three-element RGB vector or one of the MATLAB predefined names, specifying the object's color.

See the `ColorSpec` reference page for more information on specifying color.

`HeadLength`
scalar value in points

Length of the arrowhead. Specify this property in points (1 point = 1/72 inch). See also `HeadWidth`.

`HeadStyle`
select string from list

Style of the arrowhead. Specify this property as one of the strings from the following table.

Head Style String	Head	Head Style String	Head
none		star4	
plain		rectangle	
ellipse		diamond	
vback1		rose	
vback2 (Default)		hypocycloid	
vback3		astroid	
cback1		deltoid	
cback2			
cback3			

`HeadWidth`
scalar value in points

Width of the arrowhead. Specify this property in points (1 point = 1/72 inch). See also `HeadLength`.

`LineStyle`
`{-} | -- | : | -. | none`

Line style. This property specifies the line style of the object. Available line styles are shown in the following table.

Specifier String	Line Style
`-`	Solid line (default)
`--`	Dashed line
`:`	Dotted line
`-.`	Dash-dot line
`none`	No line

You can use `LineStyle none` when you want to place a marker at each point but do not want the points connected with a line (see the `Marker` property).

`LineWidth`
scalar

The width of linear objects and edges of filled areas. Specify this value in points (1 point = $^1/_{72}$ inch). The default `LineWidth` is 0.5 points.

`Position`
four-element vector [x, y, width, height]

Size and location of the object. Specify the lower left corner of the object with the first two elements of the vector defining the point *x, y* in units normalized to the figure (when `Units` property is `normalized`). The third and fourth elements specify the object's *dx* and *dy*, respectively, in units normalized to the figure.

`Units`
`{normalized} | inches | centimeters | points | pixels`

position units. MATLAB uses this property to determine the units used by the `Position` property. All positions are measured

from the lower left corner of the figure window. Normalized units interpret `Position` as a fraction of the width and height of the parent axes. When you resize the axes, MATLAB modifies the size of the object accordingly. `pixels`, `inches`, `centimeters`, and `points` are absolute units (1 point = 1/72 inch).

`X`

vector $[X_{begin}\ X_{end}]$

X-coordinates of the beginning and ending points for line. Specify this property as a vector of *x*-axis (horizontal) values that specify the beginning and ending points of the line, units normalized to the figure.

`Y`

vector $[Y_{begin}\ Y_{end}]$

Y-coordinates of the beginning and ending points for line. Specify this property as a vector of *y*-axis (vertical) values that specify the beginning and ending points of the line, units normalized to the figure.

Annotation Doublearrow Properties

Purpose

Define annotation doublearrow properties

Modifying Properties

You can set and query annotation object properties using the `set` and `get` functions and the Property Editor (displayed with the `propertyeditor` command).

Use the `annotation` function to create annotation objects and obtain their handles. For an example of its use, see "Positioning Annotations in Data Space" in the MATLAB Graphics documentation.

Annotation Doublearrow Property Descriptions

Properties You Can Modify

This section lists the properties you can modify on an annotation doublearrow object.

`Color`
ColorSpec

Color of the object. A three-element RGB vector or one of the MATLAB predefined names, specifying the object's color.

See the `ColorSpec` reference page for more information on specifying color.

`Head1Length`
scalar value in points

Length of the first arrowhead. Specify this property in points (1 point = 1/72 inch). See also `Head1Width`.

The first arrowhead is located at the end defined by the point `x(1)`, `y(1)`. See also the `X` and `Y` properties.

`Head2Length`
scalar value in points

Length of the second arrowhead. Specify this property in points (1 point = 1/72 inch). See also `Head1Width`.

The first arrowhead is located at the end defined by the point `x(end)`, `y(end)`. See also the `X` and `Y` properties.

`Head1Style`
select string from list

Style of the first arrowhead. Specify this property as one of the strings from the following table

`Head2Style`
select string from list

Style of the second arrowhead. Specify this property as one of the strings from the following table.

Head Style String	Head	Head Style String	Head
`none`		`star4`	
`plain`		`rectangle`	
`ellipse`		`diamond`	
`vback1`		`rose`	
`vback2` (Default)		`hypocycloid`	
`vback3`		`astroid`	
`cback1`		`deltoid`	

Head Style String	Head	Head Style String	Head
`cback2`			
`cback3`			

`Head1Width`
scalar value in points

Width of the first arrowhead. Specify this property in points (1 point = 1/72 inch). See also Head1Length.

`Head2Width`
scalar value in points

Width of the second arrowhead. Specify this property in points (1 point = 1/72 inch). See also Head2Length.

`LineStyle`
`{-} | -- | : | -. | none`

Line style. This property specifies the line style of the object. Available line styles are shown in the following table.

Specifier String	Line Style
`-`	Solid line (default)
`--`	Dashed line
`:`	Dotted line
`-.`	Dash-dot line
`none`	No line

You can use `LineStyle none` when you want to place a marker at each point but do not want the points connected with a line (see the `Marker` property).

`LineWidth`
scalar

The width of linear objects and edges of filled areas. Specify this value in points (1 point = $^1/_{72}$ inch). The default `LineWidth` is 0.5 points.

`Position`
four-element vector [x, y, width, height]

Size and location of the object. Specify the lower left corner of the object with the first two elements of the vector defining the point *x, y* in units normalized to the figure (when `Units` property is `normalized`). The third and fourth elements specify the object's *dx* and *dy*, respectively, in units normalized to the figure.

`Units`
`{normalized} | inches | centimeters | points | pixels`

position units. MATLAB uses this property to determine the units used by the `Position` property. All positions are measured from the lower left corner of the figure window. Normalized units interpret `Position` as a fraction of the width and height of the parent axes. When you resize the axes, MATLAB modifies the size of the object accordingly. `pixels`, `inches`, `centimeters`, and `points` are absolute units (1 point = 1/72 inch).

`X`
vector [X_{begin} X_{end}]

X-coordinates of the beginning and ending points for line. Specify this property as a vector of *x*-axis (horizontal) values that specify the beginning and ending points of the line, units normalized to the figure.

Y

vector [Y_{begin} Y_{end}]

Y-coordinates of the beginning and ending points for line. Specify this property as a vector of *y*-axis (vertical) values that specify the beginning and ending points of the line, units normalized to the figure.

Purpose

Define annotation ellipse properties

Modifying Properties

You can set and query annotation object properties using the `set` and `get` functions and the Property Editor (displayed with the `propertyeditor` command).

Use the `annotation` function to create annotation objects and obtain their handles. For an example of its use, see "Positioning Annotations in Data Space" in the MATLAB Graphics documentation.

Annotation Ellipse Property Descriptions

Properties You Can Modify

This section lists the properties you can modify on an annotation ellipse object.

`EdgeColor`

ColorSpec `{[0 0 0]} | none |`

Color of the object's edges. A three-element RGB vector or one of the MATLAB predefined names, specifying the edge color.

See the `ColorSpec` reference page for more information on specifying color.

`FaceColor`

`{flat} | none | ColorSpec`

Color of filled areas. This property can be any of the following:

- `ColorSpec` — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for all filled areas. See `ColorSpec` for more information on specifying color.
- `none` — Do not draw faces. Note that `EdgeColor` is drawn independently of `FaceColor`
- `flat` — The color of the filled areas is determined by the figure colormap. See `colormap` for information on setting the colormap.

See the `ColorSpec` reference page for more information on specifying color.

`LineStyle`

`{-} | -- | : | -. | none`

Line style. This property specifies the line style of the object. Available line styles are shown in the following table.

Specifier String	Line Style
`-`	Solid line (default)
`--`	Dashed line
`:`	Dotted line
`-.`	Dash-dot line
`none`	No line

You can use `LineStyle none` when you want to place a marker at each point but do not want the points connected with a line (see the `Marker` property).

`LineWidth`

scalar

The width of linear objects and edges of filled areas. Specify this value in points (1 point = $^1/_{72}$ inch). The default `LineWidth` is 0.5 points.

`Position`

four-element vector [x, y, width, height]

Size and location of the object. Specify the lower left corner of the object with the first two elements of the vector defining the point *x, y* in units normalized to the figure (when `Units` property is `normalized`). The third and fourth elements specify the object's *dx* and *dy*, respectively, in units normalized to the figure.

`Units`

`{normalized} | inches | centimeters | points | pixels`

position units. MATLAB uses this property to determine the units used by the `Position` property. All positions are measured from the lower left corner of the figure window. Normalized units interpret `Position` as a fraction of the width and height of the parent axes. When you resize the axes, MATLAB modifies the size of the object accordingly. `pixels`, `inches`, `centimeters`, and `points` are absolute units (1 point = 1/72 inch).

Annotation Line Properties

Purpose

Define annotation line properties

Modifying Properties

You can set and query annotation object properties using the `set` and `get` functions and the Property Editor (displayed with the `propertyeditor` command).

Use the `annotation` function to create annotation objects and obtain their handles. For an example of its use, see "Positioning Annotations in Data Space" in the MATLAB Graphics documentation.

Annotation Line Property Descriptions

Properties You Can Modify

This section lists the properties you can modify on an annotation line object.

`Color`
ColorSpec

Color of the object. A three-element RGB vector or one of the MATLAB predefined names, specifying the object's color.

See the `ColorSpec` reference page for more information on specifying color.

`LineStyle`
`{-} | -- | : | -. | none`

Line style. This property specifies the line style of the object. Available line styles are shown in the following table.

Specifier String	Line Style
`-`	Solid line (default)
`--`	Dashed line
`:`	Dotted line

Specifier String	Line Style
`-.`	Dash-dot line
`none`	No line

You can use `LineStyle` `none` when you want to place a marker at each point but do not want the points connected with a line (see the `Marker` property).

`LineWidth`
scalar

The width of linear objects and edges of filled areas. Specify this value in points (1 point = $^1/_{72}$ inch). The default `LineWidth` is 0.5 points.

`Position`
four-element vector [x, y, width, height]

Size and location of the object. Specify the lower left corner of the object with the first two elements of the vector defining the point *x, y* in units normalized to the figure (when `Units` property is `normalized`). The third and fourth elements specify the object's *dx* and *dy*, respectively, in units normalized to the figure.

`Units`
`{normalized} | inches | centimeters | points | pixels`

position units. MATLAB uses this property to determine the units used by the `Position` property. All positions are measured from the lower left corner of the figure window. Normalized units interpret `Position` as a fraction of the width and height of the parent axes. When you resize the axes, MATLAB modifies the size of the object accordingly. `pixels`, `inches`, `centimeters`, and `points` are absolute units (1 point = 1/72 inch).

X

vector [X_{begin} X_{end}]

X-coordinates of the beginning and ending points for line. Specify this property as a vector of *x*-axis (horizontal) values that specify the beginning and ending points of the line, units normalized to the figure.

Y

vector [Y_{begin} Y_{end}]

Y-coordinates of the beginning and ending points for line. Specify this property as a vector of *y*-axis (vertical) values that specify the beginning and ending points of the line, units normalized to the figure.

Purpose

Define annotation rectangle properties

Modifying Properties

You can set and query annotation object properties using the `set` and `get` functions and the Property Editor (displayed with the `propertyeditor` command).

Use the `annotation` function to create annotation objects and obtain their handles. For an example of its use, see "Positioning Annotations in Data Space" in the MATLAB Graphics documentation.

Annotation Rectangle Property Descriptions

Properties You Can Modify

This section lists the properties you can modify on an annotation rectangle object.

`EdgeColor`
ColorSpec `{[0 0 0]} | none |`

Color of the object's edges. A three-element RGB vector or one of the MATLAB predefined names, specifying the edge color.

See the `ColorSpec` reference page for more information on specifying color.

`FaceAlpha`
Scalar alpha value in range [0 1]

Transparency of object background. This property defines the degree to which the object's background color is transparent. A value of `1` (the default) makes to color opaque, a value of `0` makes the background completely transparent (i.e., invisible). The default FaceAlpha is `1`.

`FaceColor`
`{flat} | none | ColorSpec`

Color of filled areas. This property can be any of the following:

- `ColorSpec` — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for all filled areas. See `ColorSpec` for more information on specifying color.
- `none` — Do not draw faces. Note that `EdgeColor` is drawn independently of `FaceColor`
- `flat` — The color of the filled areas is determined by the figure colormap. See `colormap` for information on setting the colormap.

  See the `ColorSpec` reference page for more information on specifying color.

`LineStyle`

```
{-} | -- | :  | -.  | none
```

Line style. This property specifies the line style of the object. Available line styles are shown in the following table.

Specifier String	Line Style
`-`	Solid line (default)
`--`	Dashed line
`:`	Dotted line
`-.`	Dash-dot line
`none`	No line

You can use `LineStyle none` when you want to place a marker at each point but do not want the points connected with a line (see the `Marker` property).

`LineWidth`

scalar

The width of linear objects and edges of filled areas. Specify this value in points (1 point = $^{1}/_{72}$ inch). The default `LineWidth` is 0.5 points.

`Position`

four-element vector [x, y, width, height]

Size and location of the object. Specify the lower left corner of the object with the first two elements of the vector defining the point *x, y* in units normalized to the figure (when `Units` property is `normalized`). The third and fourth elements specify the object's *dx* and *dy*, respectively, in units normalized to the figure.

`Units`

`{normalized} | inches | centimeters | points | pixels`

position units. MATLAB uses this property to determine the units used by the `Position` property. All positions are measured from the lower left corner of the figure window. Normalized units interpret `Position` as a fraction of the width and height of the parent axes. When you resize the axes, MATLAB modifies the size of the object accordingly. `pixels`, `inches`, `centimeters`, and `points` are absolute units (1 point = 1/72 inch).

Annotation Textarrow Properties

Purpose

Define annotation textarrow properties

Modifying Properties

You can set and query annotation object properties using the `set` and `get` functions and the Property Editor (displayed with the `propertyeditor` command).

Use the `annotation` function to create annotation objects and obtain their handles. For an example of its use, see "Positioning Annotations in Data Space" in the MATLAB Graphics documentation.

Annotation Textarrow Property Descriptions

Properties You Can Modify

This section lists the properties you can modify on an annotation textarrow object.

`Color`

ColorSpec Default: [0 0 0]

Color of the arrow, text and text border. A three-element RGB vector or one of the MATLAB predefined names, specifying the color of the arrow, the color of the text (`TextColor` property), and the rectangle enclosing the text (`TextEdgeColor` property).

Setting the `Color` property also sets the `TextColor` and `TextEdgeColor` properties to the same color. However, if the value of the `TextEdgeColor` is `none`, it remains `none` and the text box is not displayed. You can set `TextColor` or `TextEdgeColor` independently without affecting other properties.

For example, if you want to create a textarrow with a red arrow and black text in a black box, you must

1. Set the `Color` property to red — `set(h,'Color','r')`
2. Set the `TextColor` to black — `set(h,'TextColor','k')`
3. Set the `TextEdgeColor` to black .— `set(h,'TextEdgeColor','k')`

If you do not want display the text box, set the `TextEdgeColor` to `none`.

See the `ColorSpec` reference page for more information on specifying color.

`FontAngle`
`{normal} | italic | oblique`

Character slant. MATLAB uses this property to select a font from those available on your particular system. Generally, setting this property to `italic` or `oblique` selects a slanted font.

`FontName`
A name, such as `Helvetica`

Font family. A string specifying the name of the font to use for the text. To display and print properly, this font must be supported on your system. The default font is `Helvetica`.

`FontSize`
size in points

Approximate size of text characters. A value specifying the font size to use in points. The default size is 10 (1 point = 1/72 inch).

`FontUnits`
`{points} | normalized | inches | centimeters | pixels`

Font size units. MATLAB uses this property to determine the units used by the `FontSize` property. Normalized units interpret `FontSize` as a fraction of the height of the parent axes. When you resize the axes, MATLAB modifies the screen `FontSize` accordingly. `pixels`, `inches`, `centimeters`, and `points` are absolute units (1 point = 1/72 inch).

`FontWeight`
`light | {normal} | demi | bold`

Weight of text characters. MATLAB uses this property to select a font from those available on your system. Generally, setting this property to `bold` or `demi` causes MATLAB to use a bold font.

`HeadLength`
scalar value in points

Length of the arrowhead. Specify this property in points (1 point = 1/72 inch). See also `HeadWidth`.

`HeadStyle`
select string from list

Style of the arrowhead. Specify this property as one of the strings from the following table.

Head Style String	Head	Head Style String	Head
`none`		`star4`	
`plain`		`rectangle`	
`ellipse`		`diamond`	
`vback1`		`rose`	
`vback2` (Default)		`hypocycloid`	
`vback3`		`astroid`	
`cback1`		`deltoid`	

Head Style String	Head	Head Style String	Head
`cback2`			
`cback3`			

`HeadWidth`
scalar value in points

Width of the arrowhead. Specify this property in points (1 point = 1/72 inch). See also `HeadLength`.

`HorizontalAlignment`
`{left} | center | right`

Horizontal alignment of text. This property specifies the horizontal justification of the text string. It determines where MATLAB places the string with regard to the point specified by the `Position` property. The following picture illustrates the alignment options.

`HorizontalAlignment` viewed with the `VerticalAlignment` set to middle (the default).

See the `Extent` property for related information.

`Interpreter`
latex | `{tex}` | `none`

Interpret T_EX instructions. This property controls whether MATLAB interprets certain characters in the `String` property as T_EX instructions (default) or displays all characters literally. The options are:

- `latex` — Supports the full L_AT_EX markup language.
- `tex` — Supports a subset of plain T_EX markup language. See the `String` property for a list of supported T_EX instructions.
- `none` — Displays literal characters.

`LineStyle`

`{-} | -- | : | -. | none`

Line style. This property specifies the line style of the object. Available line styles are shown in the following table.

Specifier String	Line Style
`-`	Solid line (default)
`--`	Dashed line
`:`	Dotted line
`-.`	Dash-dot line
`none`	No line

You can use `LineStyle none` when you want to place a marker at each point but do not want the points connected with a line (see the `Marker` property).

`LineWidth`

scalar

The width of linear objects and edges of filled areas. Specify this value in points (1 point = $^1/_{72}$ inch). The default `LineWidth` is 0.5 points.

`Position`
four-element vector [x, y, width, height]

Size and location of the object. Specify the lower left corner of the object with the first two elements of the vector defining the point *x, y* in units normalized to the figure (when `Units` property is `normalized`). The third and fourth elements specify the object's *dx* and *dy*, respectively, in units normalized to the figure.

`String`
string

The text string. Specify this property as a quoted string for single-line strings, or as a cell array of strings, or a padded string matrix for multiline strings. MATLAB displays this string at the specified location. Vertical slash characters are not interpreted as line breaks in text strings, and are drawn as part of the text string. See Mathematical Symbols, Greek Letters, and TeX Characters for an example.

When the text `Interpreter` property is set to `Tex` (the default), you can use a subset of TeX commands embedded in the string to produce special characters such as Greek letters and mathematical symbols. The following table lists these characters and the character sequences used to define them.

Character Sequence	Symbol	Character Sequence	Symbol	Character Sequence	Symbol
`\alpha`	α	`\upsilon`	υ	`\sim`	~
`\beta`	β	`\phi`	Φ	`\leq`	≤
`\gamma`	γ	`\chi`	χ	`\infty`	∞
`\delta`	δ	`\psi`	ψ	`\clubsuit`	♣
`\epsilon`	ε	`\omega`	ω	`\diamondsuit`	♦
`\zeta`	ζ	`\Gamma`	Γ	`\heartsuit`	♥

Character Sequence	Symbol	Character Sequence	Symbol	Character Sequence	Symbol
\eta	η	\Delta	Δ	\spadesuit	♠
\theta	θ	\Theta	Θ	\leftrightarrow	↔
\vartheta	ϑ	\Lambda	Λ	\leftarrow	→
\iota	ι	\Xi	Ξ	\uparrow	↑
\kappa	κ	\Pi	Π	\rightarrow	↔
\lambda	λ	\Sigma	Σ	\downarrow	↓
\mu	μ	\Upsilon	ϒ	\circ	º
\nu	ν	\Phi	Φ	\pm	±
\xi	ξ	\Psi	Ψ	\geq	≥
\pi	π	\Omega	Ω	\propto	∝
\rho	ρ	\forall	∀	\partial	∂
\sigma	σ	\exists	∃	\bullet	•
\varsigma	ς	\ni	∍	\div	÷
\tau	τ	\cong	≅	\neq	≠
\equiv	≡	\approx	∼	\aleph	
\Im	ℑ	\Re	ℜ	\wp	℘
\otimes	⊗	\oplus	⊕	\oslash	∅
\cap	∩	\cup	∪	\supseteq	⊇
\supset	⊃	\subseteq	⊆	\subset	⊂
\int	∫	\in		\o	o
\rfloor	⌋	\lceil	⌈	\nabla	∇
\lfloor	⌊	\cdot	·	\ldots	...

Character Sequence	Symbol	Character Sequence	Symbol	Character Sequence	Symbol
\perp	⊥	\neg	¬	\prime	´
\wedge	∧	\times	x	\0	∅
\rceil	⌉	\surd	√	\mid	|
\vee	∨	\varpi	ϖ	\copyright	©
\langle	∠	\rangle	∠		

You can also specify stream modifiers that control font type and color. The first four modifiers are mutually exclusive. However, you can use `\fontname` in combination with one of the other modifiers:

`TextBackgroundColor`
`ColorSpec` Default: `none`

Color of text background rectangle. A three-element RGB vector or one of the MATLAB predefined names, specifying the arrow color.

See the `ColorSpec` reference page for more information on specifying color.

`TextColor`
`ColorSpec` Default: `[0 0 0]`

Color of text. A three-element RGB vector or one of the MATLAB predefined names, specifying the arrow color.

See the `ColorSpec` reference page for more information on specifying color. Setting the `Color` property also sets this property.

`TextEdgeColor`
`ColorSpec` or `none` Default: `none`

Color of edge of text rectangle. A three-element RGB vector or one of the MATLAB predefined names, specifying the color of the rectangle that encloses the text.

See the `ColorSpec` reference page for more information on specifying color. Setting the `Color` property also sets this property.

`TextLineWidth`
width in points

The width of the text rectangle edge. Specify this value in points (1 point = $^1/_{72}$ inch). The default `TextLineWidth` is 0.5 points.

`TextMargin`
dimension in pixels default: 5

Space around text. Specify a value in pixels that defines the space around the text string, but within the rectangle.

`TextRotation`
rotation angle in degrees (default = 0)

Text orientation. This property determines the orientation of the text string. Specify values of rotation in degrees (positive angles cause counterclockwise rotation). Angles are absolute and not relative to previous rotations; a rotation of 0 degrees is always horizontal.

`Units`
`{normalized} | inches | centimeters | points | pixels`

position units. MATLAB uses this property to determine the units used by the `Position` property. All positions are measured from the lower left corner of the figure window. Normalized units interpret `Position` as a fraction of the width and height of the parent axes. When you resize the axes, MATLAB modifies the size of the object accordingly. `pixels`, `inches`, `centimeters`, and `points` are absolute units (1 point = 1/72 inch).

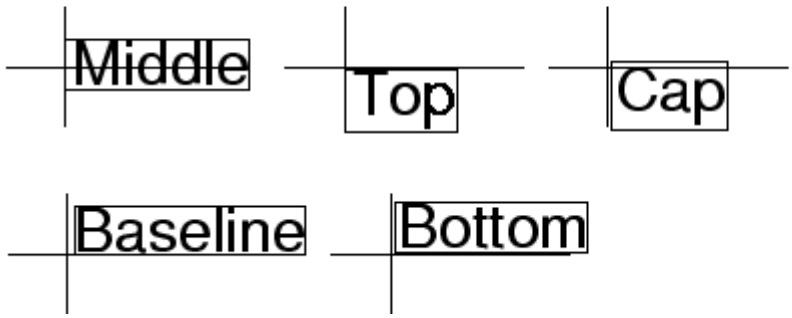
```
VerticalAlignment
     top | cap | {middle} | baseline |
     bottom
```

Vertical alignment of text. This property specifies the vertical justification of the text string. It determines where MATLAB places the string with regard to the value of the `Position` property. The possible values mean

- top — Place the top of the string' s `Extent` rectangle at the specified *y*-position.
- `cap` — Place the string so that the top of a capital letter is at the specified *y*-position.
- `middle` — Place the middle of the string at the specified *y*-position.
- `baseline` — Place font baseline at the specified *y*-position.
- `bottom` — Place the bottom of the string's `Extent` rectangle at the specified *y*-position.

The following picture illustrates the alignment options.

Text `VerticalAlignment` property viewed with the `HorizontalAlignment` property set to `left` (the default).



X

vector [X_{begin} X_{end}]

X-coordinates of the beginning and ending points for line. Specify this property as a vector of *x*-axis (horizontal) values that specify the beginning and ending points of the line, units normalized to the figure.

Y

vector [Y_{begin} Y_{end}]

Y-coordinates of the beginning and ending points for line. Specify this property as a vector of *y*-axis (vertical) values that specify the beginning and ending points of the line, units normalized to the figure.

Purpose

Define annotation textbox properties

Modifying Properties

You can set and query annotation object properties using the `set` and `get` functions and the Property Editor (displayed with the `propertyeditor` command).

Use the `annotation` function to create annotation objects and obtain their handles. For an example of its use, see "Positioning Annotations in Data Space" in the MATLAB Graphics documentation.

Annotation Textbox Property Descriptions

Properties You Can Modify

This section lists the properties you can modify on an annotation textbox object.

`BackgroundColor`
`ColorSpec` Default: `none`

Color of text background rectangle. A three-element RGB vector or one of the MATLAB predefined names, specifying the arrow color.

See the `ColorSpec` reference page for more information on specifying color.

`Color`
`ColorSpec` Default: `[0 0 0]`

Color of text. A three-element RGB vector or one of the MATLAB predefined names, specifying the arrow color.

See the `ColorSpec` reference page for more information on specifying color. Setting the `Color` property also sets this property.

`EdgeColor`
`ColorSpec` or `none` Default: `none`

Color of edge of text rectangle. A three-element RGB vector or one of the MATLAB predefined names, specifying the color of the rectangle that encloses the text.

See the `ColorSpec` reference page for more information on specifying color. Setting the `Color` property also sets this property.

`FaceAlpha`
Scalar alpha value in range [0 1]

Transparency of object background. This property defines the degree to which the object's background color is transparent. A value of `1` (the default) makes to color opaque, a value of `0` makes the background completely transparent (i.e., invisible). The default FaceAlpha is `1`.

`FitBoxToText`
`on | off`

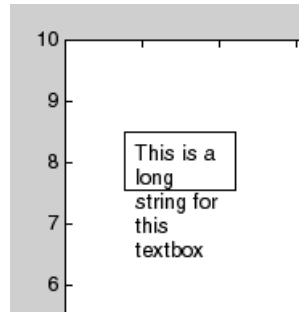
Automatically adjust text box width and height to fit text. When this property is `on` (the default), MATLAB automatically resizes textboxes to fit the *x*-extents and *y*-extents of the text strings they contain. When it is `off`, text strings are wrapped to fit the width of their textboxes, which can cause them to extend below the bottom of the box.

If you resize a textbox in plot edit mode or change the width or height of its `position` property directly, MATLAB sets the object's `FitBoxToText` property to `'off'`. You can toggle this property with `set`, with the Property Inspector, or in plot edit mode via the object's context menu.

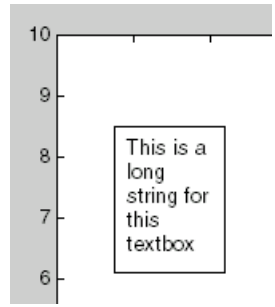
`FitHeightToText`
`on | off`

Automatically adjust text box width and height to fit text. MATLAB automatically wraps text strings to fit the width of the text box. However, if the text string is long enough, it can extend beyond the bottom of the text box.

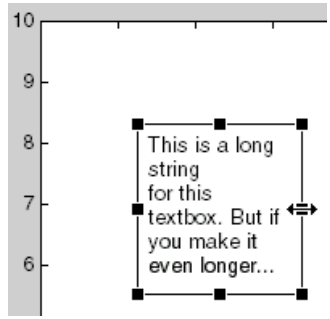
Note The `FitHeightToText` property is obsolete. To control line wrapping behavior in textboxes, use `fitBoxToText` instead.



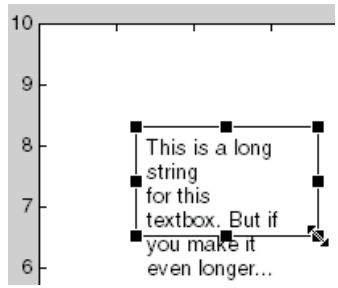
When you set this mode to `on`, MATLAB automatically adjusts the height of the text box to accommodate the string, doing so as you create or edit the string.



The fit-size-to-text behavior turns off if you resize the text box programmatically or manually in plot edit mode.



However, if you resize the text box from any other handles, the position you set is honored without regard to how the text fits the box.



`FontAngle`

`{normal} | italic | oblique`

Character slant. MATLAB uses this property to select a font from those available on your particular system. Generally, setting this property to `italic` or `oblique` selects a slanted font.

`FontName`

A name, such as `Helvetica`

Font family. A string specifying the name of the font to use for the text. To display and print properly, this font must be supported on your system. The default font is `Helvetica`.

`FontSize`
size in points

Approximate size of text characters. A value specifying the font size to use in points. The default size is 10 (1 point = 1/72 inch).

`FontUnits`
`{points} | normalized | inches | centimeters | pixels`

Font size units. MATLAB uses this property to determine the units used by the `FontSize` property. Normalized units interpret `FontSize` as a fraction of the height of the parent axes. When you resize the axes, MATLAB modifies the screen `FontSize` accordingly. `pixels`, `inches`, `centimeters`, and `points` are absolute units (1 point = 1/72 inch).

`FontWeight`
`light | {normal} | demi | bold`

Weight of text characters. MATLAB uses this property to select a font from those available on your system. Generally, setting this property to `bold` or `demi` causes MATLAB to use a bold font.

`HorizontalAlignment`
`{left} | center | right`

Horizontal alignment of text. This property specifies the horizontal justification of the text string. It determines where MATLAB places the string with regard to the point specified by the `Position` property. The following picture illustrates the alignment options.

`HorizontalAlignment` viewed with the `VerticalAlignment` set to middle (the default).

See the `Extent` property for related information.

`Interpreter`
latex | {tex} | none

Interpret T_EX instructions. This property controls whether MATLAB interprets certain characters in the `String` property as T_EX instructions (default) or displays all characters literally. The options are:

- `latex` — Supports the full L_AT_EX markup language.
- `tex` — Supports a subset of plain T_EX markup language. See the `String` property for a list of supported T_EX instructions.
- `none` — Displays literal characters.

`LineStyle`
{-} | -- | : | -. | none

Line style. This property specifies the line style of the object. Available line styles are shown in the following table.

Specifier String	Line Style
`-`	Solid line (default)
`--`	Dashed line
`:`	Dotted line
`-.`	Dash-dot line
`none`	No line

You can use `LineStyle none` when you want to place a marker at each point but do not want the points connected with a line (see the `Marker` property).

`LineWidth`
scalar

The width of linear objects and edges of filled areas. Specify this value in points (1 point = $^{1}/_{72}$ inch). The default `LineWidth` is 0.5 points.

`Margin`

dimension in pixels default: 5

Space around text. Specify a value in pixels that defines the space around the text string, but within the rectangle.

`Position`

four-element vector [x, y, width, height]

Size and location of the object. Specify the lower left corner of the object with the first two elements of the vector defining the point *x, y* in units normalized to the figure (when `Units` property is `normalized`). The third and fourth elements specify the object's *dx* and *dy*, respectively, in units normalized to the figure.

`String`

string

The text string. Specify this property as a quoted string for single-line strings, or as a cell array of strings, or a padded string matrix for multiline strings. MATLAB displays this string at the specified location. Vertical slash characters are not interpreted as line breaks in text strings, and are drawn as part of the text string. See Mathematical Symbols, Greek Letters, and TeX Characters for an example.

When the text `Interpreter` property is set to `Tex` (the default), you can use a subset of TeX commands embedded in the string to produce special characters such as Greek letters and mathematical symbols. The following table lists these characters and the character sequences used to define them.

Character Sequence	Symbol	Character Sequence	Symbol	Character Sequence	Symbol
\alpha	α	\upsilon	υ	\sim	~
\beta	β	\phi	Φ	\leq	≤
\gamma	γ	\chi	χ	\infty	∞
\delta	δ	\psi	ψ	\clubsuit	♣
\epsilon	ε	\omega	ω	\diamondsuit	♦
\zeta	ζ	\Gamma	Γ	\heartsuit	♥
\eta	η	\Delta	Δ	\spadesuit	♠
\theta	Θ	\Theta	Θ	\leftrightarrow	↔
\vartheta	ϑ	\Lambda	Λ	\leftarrow	→
\iota	ι	\Xi	Ξ	\uparrow	↑
\kappa	κ	\Pi	Π	\rightarrow	↔
\lambda	λ	\Sigma	Σ	\downarrow	↓
\mu	μ	\Upsilon	ϒ	\circ	º
\nu	ν	\Phi	Φ	\pm	±
\xi	ξ	\Psi	Ψ	\geq	≥
\pi	π	\Omega	Ω	\propto	∝
\rho	ρ	\forall	∀	\partial	∂
\sigma	σ	\exists	∃	\bullet	•
\varsigma	ς	\ni	∍	\div	÷
\tau	τ	\cong	≅	\neq	≠
\equiv	≡	\approx	≈	\aleph	
\Im	ℑ	\Re	ℜ	\wp	℘

Character Sequence	Symbol	Character Sequence	Symbol	Character Sequence	Symbol
\otimes	⊗	\oplus	⊕	\oslash	∅
\cap	∩	\cup	∪	\supseteq	⊇
\supset	⊃	\subseteq	⊆	\subset	⊂
\int	∫	\in		\o	o
\rfloor	⌋	\lceil	⌈	\nabla	∇
\lfloor	⌊	\cdot	·	\ldots	...
\perp	⊥	\neg	¬	\prime	´
\wedge	∧	\times	x	\0	∅
\rceil	⌉	\surd	√	\mid	|
\vee	∨	\varpi	ϖ	\copyright	©
\langle	∠	\rangle	∠		

You can also specify stream modifiers that control font type and color. The first four modifiers are mutually exclusive. However, you can use `\fontname` in combination with one of the other modifiers:

`Units`

`{normalized} | inches | centimeters | points | pixels`

position units. MATLAB uses this property to determine the units used by the `Position` property. All positions are measured from the lower left corner of the figure window. Normalized units interpret `Position` as a fraction of the width and height of the parent axes. When you resize the axes, MATLAB modifies the size of the object accordingly. `pixels`, `inches`, `centimeters`, and `points` are absolute units (1 point = 1/72 inch).

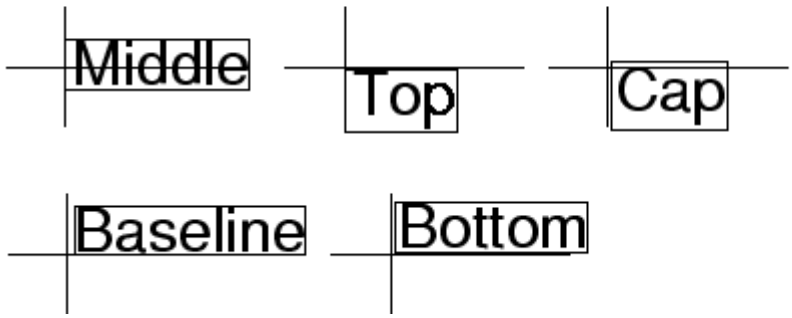
```
VerticalAlignment
     top | cap | {middle} | baseline |
     bottom
```

Vertical alignment of text. This property specifies the vertical justification of the text string. It determines where MATLAB places the string with regard to the value of the `Position` property. The possible values mean

- top — Place the top of the string' s `Extent` rectangle at the specified *y*-position.
- `cap` — Place the string so that the top of a capital letter is at the specified *y*-position.
- `middle` — Place the middle of the string at the specified *y*-position.
- `baseline` — Place font baseline at the specified *y*-position.
- `bottom` — Place the bottom of the string's `Extent` rectangle at the specified *y*-position.

The following picture illustrates the alignment options.

Text `VerticalAlignment` property viewed with the `HorizontalAlignment` property set to `left` (the default).



Purpose

Most recent answer

Syntax

```
ans
```

Description

MATLAB creates the ans variable automatically when you specify no output argument.

Examples

The statement

```
2+2
```

is the same as

```
ans = 2+2
```

See Also

display

Purpose

Determine whether any array elements are nonzero

Syntax

```
B = any(A)
B = any(A,dim)
```

Description

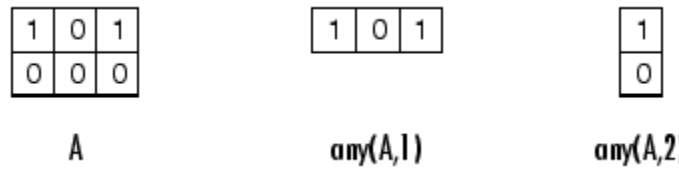
`B = any(A)` tests whether *any* of the elements along various dimensions of an array is a nonzero number or is logical `1` (`true`). `any` ignores entries that are `NaN` (Not a Number).

If `A` is a vector, `any(A)` returns logical `1` (`true`) if any of the elements of `A` is a nonzero number or is logical `1` (`true`), and returns logical `0` (`false`) if all the elements are zero.

If `A` is a matrix, `any(A)` treats the columns of `A` as vectors, returning a row vector of logical 1's and 0's.

If `A` is a multidimensional array, `any(A)` treats the values along the first nonsingleton dimension as vectors, returning a logical condition for each vector.

`B = any(A,dim)` tests along the dimension of `A` specified by scalar *`dim`*.



Examples

Example 1 – Reducing a Logical Vector to a Scalar Condition

Given

```
A = [0.53 0.67 0.01 0.38 0.07 0.42 0.69]
```

then `B = (A < 0.5)` returns logical `1` (`true`) only where `A` is less than one half:

```
0    0    1    1    1    1    0
```

The any function reduces such a vector of logical conditions to a single condition. In this case, any(B) yields logical 1.

This makes any particularly useful in if statements:

```
if any(A < 0.5)do something
end
```

where code is executed depending on a single condition, not a vector of possibly conflicting conditions.

Example 2– Reducing a Logical Matrix to a Scalar Condition

Applying the any function twice to a matrix, as in any(any(A)), always reduces it to a scalar condition.

```
any(any(eye(3)))
ans =
   1
```

Example 3 – Testing Arrays of Any Dimension

You can use the following type of statement on an array of any dimensions. This example tests a 3-D array to see if any of its elements are greater than 3:

```
x = rand(3,7,5) * 5;

any(x(:) > 3)
ans =
     1
```

or less than zero:

```
any(x(:) < 0)
ans =
     0
```

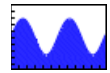
all, logical operators (elementwise and short-circuit), relational operators, colon

Other functions that collapse an array's dimensions include `max`, `mean`, `median`, `min`, `prod`, `std`, `sum`, and `trapz`.

Purpose

Filled area 2-D plot



GUI Alternatives

To graph selected variables, use the Plot Selector in the Workspace Browser, or use the Figure Palette Plot Catalog. Manipulate graphs in *plot edit* mode with the Property Editor. For details, see Plotting Tools — Interactive Plotting in the MATLAB Graphics documentation and Creating Graphics from the Workspace Browser in the MATLAB Desktop Tools documentation.

Syntax

```
area(Y)
area(X,Y)
area(...,basevalue)
area(...,'PropertyName',PropertyValue,...)
area(axes_handle,...)
h = area(...)
hpatches = area('v6',...)
```

Description

An area graph displays elements in `Y` as one or more curves and fills the area beneath each curve. When `Y` is a matrix, the curves are stacked showing the relative contribution of each row element to the total height of the curve at each x interval.

`area(Y)` plots the vector `Y` or the sum of each column in matrix `Y`. The *x*-axis automatically scales to `1:size(Y,1)`.

`area(X,Y)` For vectors `X` and `Y`, `area(X,Y)` is the same as `plot(X,Y)` except that the area between `0` and `Y` is filled. When `Y` is a matrix, `area(X,Y)` plots the columns of `Y` as filled areas. For each `X`, the net result is the sum of corresponding values from the columns of `Y`.

If `X` is a vector, `length(X)` must equal `length(Y)`. If `X` is a matrix, `size(X)` must equal `size(Y)`.

`area(...,basevalue)` specifies the base value for the area fill. The default `basevalue` is `0`. See the `BaseValue` property for more information.

`area(...,'PropertyName',PropertyValue,...)` specifies property name and property value pairs for the patch graphics object created by `area`.

`area(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = area(...)` returns handles of `areaseries` graphics objects.

Backward-Compatible Version

`hpatches = area('v6',...)` returns the handles of patch objects instead of areaseries objects for compatibility with MATLAB 6.5 and earlier.

Note The `v6` option enables users of Version 7.x of MATLAB to create FIG-files that previous versions can open. It is obsolete and will be removed in a future version of MATLAB.

See Plot Objects and Backward Compatibility for more information.

Areaseries Objects

Creating an area graph of an *m*-by-*n* matrix creates *n* areaseries objects (i.e., one per column), whereas a 1-by-*n* vector creates one area object.

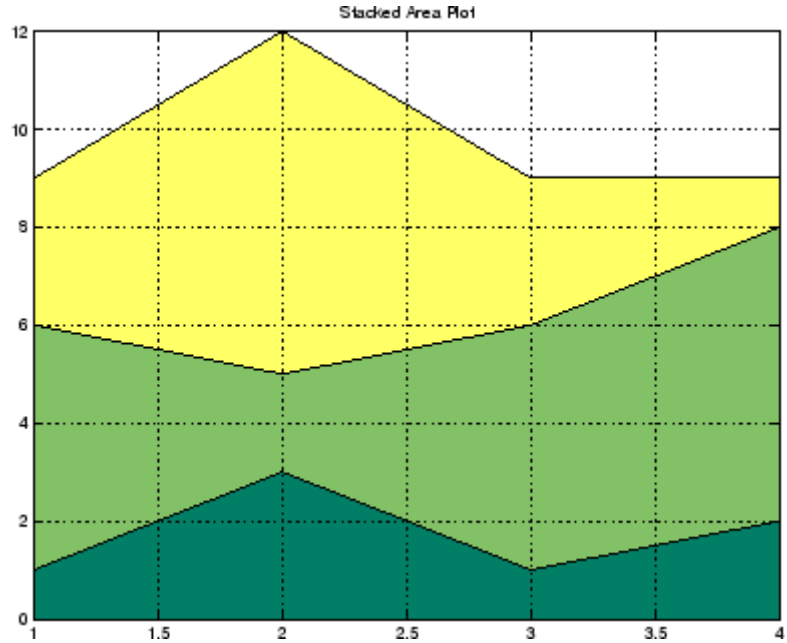
Some areaseries object properties that you set on an individual areaseries object set the values for all areaseries objects in the graph. See the property descriptions for information on specific properties.

Examples

Stacked Area Graph

This example plots the data in the variable `Y` as an area graph. Each subsequent column of `Y` is stacked on top of the previous data. The figure colormap controls the coloring of the individual areas. You can explicitly set the color of an area using the `EdgeColor` and `FaceColor` properties.

```
Y = [1, 5, 3;
 3, 2, 7;
 1, 5, 3;
 2, 6, 1];
area(Y)
grid on
colormap summer
set(gca,'Layer','top')
title 'Stacked Area Plot'
```

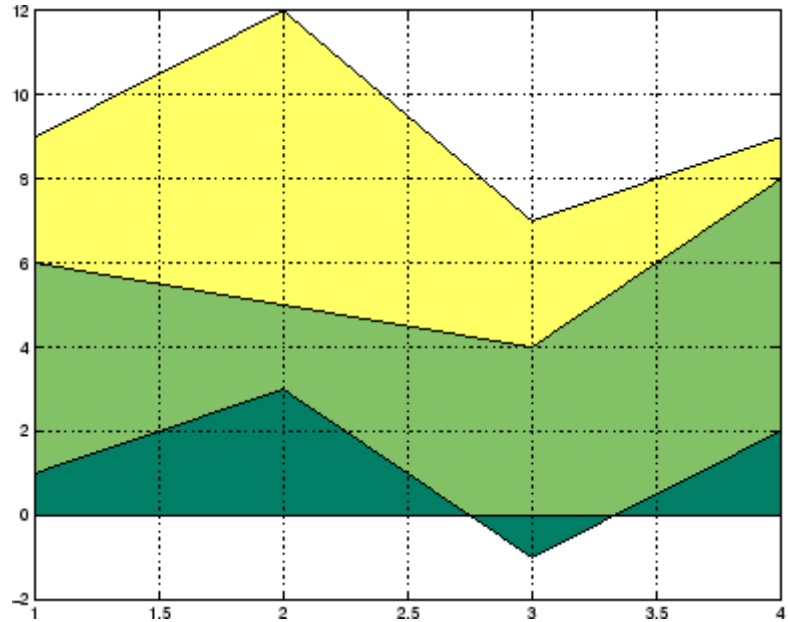


Adjusting the Base Value

The area function uses a *y*-axis value of 0 as the base of the filled areas. You can change this value by setting the area `BaseValue` property. For example, negate one of the values of Y from the previous example and replot the data.

```
Y(3,1) = -1; % Was 1
h = area(Y);
set(gca,'Layer','top')
grid on
colormap summer
```

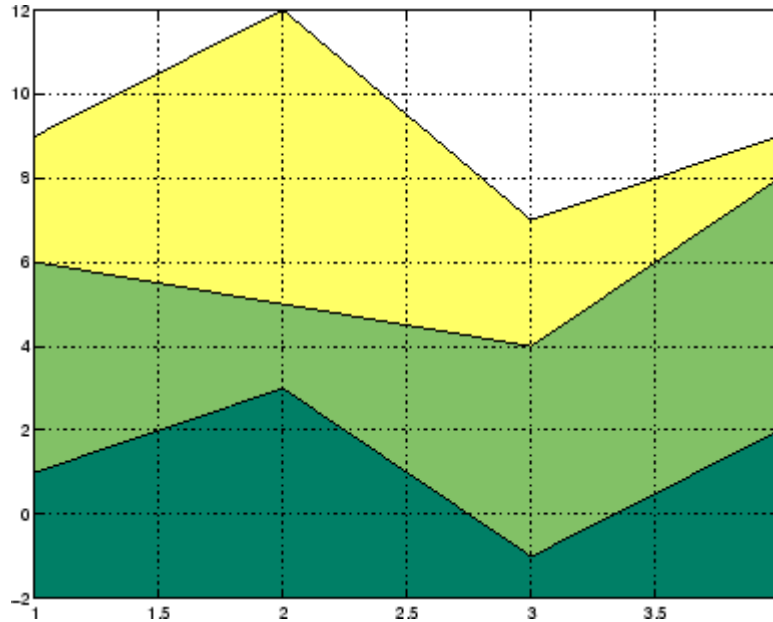
The area graph now looks like this:



Adjusting the `BaseValue` property improves the appearance of the graph:

```
set(h,'BaseValue',-2)
```

Setting the `BaseValue` property on one areaseries object sets the values of all objects.



Specifying Colors and Line Styles

You can specify the colors of the filled areas and the type of lines used to separate them.

```
h = area(Y,-2); % Set BaseValue via argument
set(h(1),'FaceColor',[.5 0 0])
set(h(2),'FaceColor',[.7 0 0])
set(h(3),'FaceColor',[1 0 0])
set(h,'LineStyle',':','LineWidth',2) % Set
all to same value
```

`Areaseries Properties` for property descriptions

Purpose

Define areaseries properties

Modifying Properties

You can set and query graphics object properties using the `set` and `get` commands or with the property editor (`propertyeditor`).

Note that you cannot define default properties for areaseries objects.

See "Plot Objects" for more information on areaseries objects.

Areaseries Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

`Annotation`

`hg.Annotation` object Read Only

Control the display of areaseries objects in legends. The `Annotation` property enables you to specify whether this areaseries object is represented in a figure legend.

Querying the `Annotation` property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the areaseries object is displayed in a figure legend:

IconDisplayStyle Value	Purpose
`on`	Include the areaseries object in a legend as one entry, but not its children objects
`off`	Do not include the areaseries or its children in a legend (default)
`children`	Include only the children of the areaseries as separate entries in the legend

Setting the `IconDisplayStyle` property

These commands set the `IconDisplayStyle` of a graphics object with handle `hobj` to `children`, which causes each child object to have an entry in the legend:

```
hAnnotation = get(hobj,'Annotation');
hLegendEntry = get(hAnnotation','LegendInformation');
set(hLegendEntry,'IconDisplayStyle','children')
```

Using the `IconDisplayStyle` property

See “Controlling Legends” for more information and examples.

`BaseValue`
double: *y*-axis value

Value where filled area base is drawn. Specify the value along the *y*-axis at which MATLAB draws the baseline of the bottommost filled area.

`BeingDeleted`
`on | {off}` Read Only

This object is being deleted. The `BeingDeleted` property provides a mechanism that you can use to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object's delete function might call other functions that act on a number of different objects. These functions might not need to perform actions on objects if the objects are going to be deleted, and therefore, can check the object's `BeingDeleted` property before acting.

`BusyAction`
`cancel | {queue}`

Callback routine interruption. The `BusyAction` property enables you to control how MATLAB handles events that potentially interrupt executing callbacks. If there is a callback function executing, callbacks invoked subsequently always attempt to interrupt it.

If the `Interruptible` property of the object whose callback is executing is set to `on` (the default), then interruption occurs at the next point where the event queue is processed. If the `Interruptible` property is `off`, the `BusyAction` property (of the object owning the executing callback) determines how MATLAB handles the event. The choices are

- `cancel` — Discard the event that attempted to execute a second callback routine.
- `queue` — Queue the event that attempted to execute a second callback routine until the current callback finishes.

`ButtonDownFcn`

string or function handle

Button press callback function. A callback that executes whenever you press a mouse button while the pointer is over this object, but not over another graphics object. See the `HitTestArea` property for information about selecting objects of this type.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

This property can be

- A string that is a valid MATLAB expression
- The name of an M-file
- A function handle

Set this property to a function handle that references the callback. The expressions execute in the MATLAB workspace.

See “Function Handle Callbacks” for information on how to use function handles to define the callbacks.

`Children`
array of graphics object handles

Children of this object. The handle of a patch object that is the child of this object (whether visible or not).

Note that if a child object's `HandleVisibility` property is set to `callback` or `off`, its handle does not show up in this object's `Children` property unless you set the root `ShowHiddenHandles` property to `on`:

```
set(0,'ShowHiddenHandles','on')
```

`Clipping`
`{on} | off`

Clipping mode. MATLAB clips graphs to the axes plot box by default. If you set `Clipping` to `off`, portions of graphs can be displayed outside the axes plot box. This can occur if you create a plot object, set `hold` to `on`, freeze axis scaling (`axis manual`), and then create a larger plot object.

`CreateFcn`
string or function handle

Callback routine executed during object creation. This property defines a callback that executes when MATLAB creates an object. You must specify the callback during the creation of the object. For example,

```
area(y,'CreateFcn',@CallbackFcn)
```

where `@CallbackFcn` is a function handle that references the callback function.

MATLAB executes this routine after setting all other object properties. Setting this property on an existing object has no effect.

The handle of the object whose `CreateFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

`DeleteFcn`

string or function handle

Callback executed during object deletion. A callback that executes when this object is deleted (e.g., this might happen when you issue a `delete` command on the object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object’s properties so the callback routine can query these values.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which can be queried using `gcbo`.

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

See the `BeingDeleted` property for related information.

`DisplayName`

string (default is empty string)

String used by legend for this areaseries object. The `legend` function uses the string defined by the `DisplayName` property to label this areaseries object in the legend.

- If you specify string arguments with the `legend` function, `DisplayName` is set to this areaseries object's corresponding string and that string is used for the legend.
- If `DisplayName` is empty, legend creates a string of the form, `['data' n]`, where *n* is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, `DisplayName` is set to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add programmatically a legend that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See "Controlling Legends" for more examples.

`EdgeColor`

`{[0 0 0]} | none | ColorSpec`

Color of line that separates filled areas. You can set the color of the edges of filled areas to a three-element RGB vector or one of the MATLAB predefined names, including the string `none`. The default edge color is black. See `ColorSpec` for more information on specifying color.

`EraseMode`

`{normal} | none | xor | background`

Erase mode. This property controls the technique MATLAB uses to draw and erase objects and their children. Alternative erase modes are useful for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to ensure that all objects are rendered correctly. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- `none` — Do not erase objects when they are moved or destroyed. While the objects are still visible on the screen after erasing with `EraseMode` `none`, you cannot print these objects because MATLAB stores no information about their former locations.
- `xor` — Draw and erase the object by performing an exclusive OR (XOR) with each pixel index of the screen behind it. Erasing the object does not damage the color of the objects behind it. However, the color of the erased object depends on the color of the screen behind it and it is correctly colored only when it is over the axes background color (or the figure background color if the axes `Color` property is set to `none`). That is, it isn't erased correctly if there are objects behind it.
- `background` — Erase the graphics objects by redrawing them in the axes background color, (or the figure background color if the axes `Color` property is set to `none`). This damages other graphics objects that are behind the erased object, but the erased object is always properly colored.

Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB can mathematically combine layers of colors (e.g., performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

Set the axes background color with the axes `Color` property. Set the figure background color with the figure `Color` property.

You can use the MATLAB `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

`FaceColor`
`{flat} | none | ColorSpec`

Color of filled areas. This property can be any of the following:

- `ColorSpec` — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for all filled areas. See `ColorSpec` for more information on specifying color.
- `none` — Do not draw faces. Note that `EdgeColor` is drawn independently of `FaceColor`
- `flat` — The color of the filled areas is determined by the figure colormap. See `colormap` for information on setting the colormap.

  See the `ColorSpec` reference page for more information on specifying color.

`HandleVisibility`
`{on} | callback | off`

Control access to object's handle by command-line users and GUIs. This property determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally accessing objects that you need to protect for some reason.

- `on` — Handles are always visible when `HandleVisibility` is `on`.
- `callback` — Setting `HandleVisibility` to `callback` causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions

invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.

- `off` — Setting `HandleVisibility` to `off` makes handles invisible at all times. This might be necessary when a callback invokes a function that might potentially damage the GUI (such as evaluating a user-typed string) and so temporarily hides its own handles during the execution of that function.

Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Properties Affected by Handle Visibility

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

Overriding Handle Visibility

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings (this does not affect the values of the `HandleVisibility` properties). See also `findall`.

Handle Validity

Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

`HitTest`

`{on} | off`

Selectable by mouse click. `HitTest` determines whether this object can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the objects that compose the area graph. If `HitTest` is `off`, clicking this object selects the object below it (which is usually the axes containing it).

`HitTestArea`

`on | {off}`

Select areaseries object on filled area or extent of graph. This property enables you to select areaseries objects in two ways:

- Select by clicking bars (default).
- Select by clicking anywhere in the extent of the area plot.

  When `HitTestArea` is `off`, you must click the bars to select the bar object. When `HitTestArea` is `on`, you can select the bar object by clicking anywhere within the extent of the bar graph (i.e., anywhere within a rectangle that encloses all the bars).

`Interruptible`

`{on} | off`

Callback routine interruption mode. The `Interruptible` property controls whether an object's callback can be interrupted by callbacks invoked subsequently.

Only callbacks defined for the `ButtonDownFcn` property are affected by the `Interruptible` property. MATLAB checks for events that can interrupt a callback only when it encounters a `drawnow`, `figure`, `getframe`, or `pause` command in the routine. See the `BusyAction` property for related information.

Setting `Interruptible` to `on` allows any graphics object's callback to interrupt callback routines originating from a bar property. Note that MATLAB does not save the state of variables or the display (e.g., the handle returned by the `gca` or `gcf` command) when an interruption occurs.

`LineStyle`

`{-} | -- | :  | -.  | none`

Line style. This property specifies the line style of the object. Available line styles are shown in the following table.

Specifier String	Line Style
`-`	Solid line (default)
`--`	Dashed line
`:`	Dotted line
`-.`	Dash-dot line
`none`	No line

You can use `LineStyle none` when you want to place a marker at each point but do not want the points connected with a line (see the `Marker` property).

`LineWidth`
scalar

The width of linear objects and edges of filled areas. Specify this value in points (1 point = $^1/_{72}$ inch). The default `LineWidth` is 0.5 points.

`Parent`
handle of parent axes, hggroup, or hgtransform

Parent of this object. This property contains the handle of the object's parent. The parent is normally the axes, hggroup, or hgtransform object that contains the object.

See "Objects That Can Contain Other Objects" for more information on parenting graphics objects.

`Selected`
`on | {off}`

Is object selected? When you set this property to `on`, MATLAB displays selection "handles" at the corners and midpoints if the `SelectionHighlight` property is also `on` (the default). You can, for example, define the `ButtonDownFcn` callback to set this property to `on`, thereby indicating that this particular object is selected. This property is also set to `on` when an object is manually selected in plot edit mode.

`SelectionHighlight`
`{on} | off`

Objects are highlighted when selected. When the `Selected` property is `on`, MATLAB indicates the selected state by drawing four edge handles and four corner handles. When `SelectionHighlight` is `off`, MATLAB does not draw the handles except when in plot edit mode and objects are selected manually.

`Tag`
string

User-specified object label. The `Tag` property provides a means to identify graphics objects with a user-specified label. This is particularly useful when you are constructing interactive graphics programs that would otherwise need to define object handles as global variables or pass them as arguments between callbacks. You can define `Tag` as any string.

For example, you might create an areaseries object and set the `Tag` property.

```
t = area(Y,'Tag','area1')
```

When you want to access objects of a given type, you can use `findobj` to find the object's handle. The following statement changes the `FaceColor` property of the object whose `Tag` is `area1`.

```
set(findobj('Tag','area1'),'FaceColor','red')
```

`Type`

string (read only)

Type of graphics object. This property contains a string that identifies the class of the graphics object. For areaseries objects, `Type` is 'hggroup'.

The following statement finds all the hggroup objects in the current axes.

```
t = findobj(gca,'Type','hggroup');
```

`UIContextMenu`

handle of a uicontextmenu object

Associate a context menu with this object. Assign this property the handle of a uicontextmenu object created in the object's parent figure. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the object.

`UserData`
array

User-specified data. This property can be any data you want to associate with this object (including cell arrays and structures). The object does not set values for this property, but you can access it using the `set` and `get` functions.

`Visible`
`{on} | off`

Visibility of this object and its children. By default, a new object's visibility is `on`. This means all children of the object are visible unless the child object's `Visible` property is set to `off`. Setting an object's `Visible` property to `off` prevents the object from being displayed. However, the object still exists and you can set and query its properties.

`XData`
vector or matrix

The x-axis values for a graph. The *x*-axis values for graphs are specified by the `X` input argument. If `XData` is a vector, `length(XData)` must equal `length(YData)` and must be monotonic. If `XData` is a matrix, `size(XData)` must equal `size(YData)` and each column must be monotonic.

You can use `XData` to define meaningful coordinates for an underlying surface whose topography is being mapped. See "Setting the Axis Limits on Contour Plots" on page 2-640 for more information.

`XDataMode`
{auto} | manual

Use automatic or user-specified x-axis values. If you specify `XData` (by setting the `XData` property or specifying the `x` input

argument), MATLAB sets this property to `manual` and uses the specified values to label the *x*-axis.

If you set `XDataMode` to `auto` after having specified `XData`, MATLAB resets the *x*-axis ticks to `1:size(YData,1)` or to the column indices of the `ZData`, overwriting any previous values for `XData`.

`XDataSource`
string (MATLAB variable)

Link `XData` to MATLAB variable. Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `XData`.

MATLAB reevaluates this property only when you set it. Therefore, a change to workspace variables appearing in an expression does not change `XData`.

You can use the `refreshdata` function to force an update of the object's data. `refreshdata` also enables you to specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

See the `refreshdata` reference page for more information.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

`YData`
vector or matrix

Area plot data. `YData` contains the data plotted as filled areas (the `Y` input argument). If `YData` is a vector, `area` creates a single filled area whose upper boundary is defined by the elements of `YData`. If `YData` is a matrix, `area` creates one filled area per column, stacking each on the previous plot.

The input argument `Y` in the `area` function calling syntax assigns values to `YData`.

`YDataSource`
string (MATLAB variable)

Link `YData` to MATLAB variable. Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `YData`.

MATLAB reevaluates this property only when you set it. Therefore, a change to workspace variables appearing in an expression does not change `YData`.

You can use the `refreshdata` function to force an update of the object's data. `refreshdata` also enables you to specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

See the `refreshdata` reference page for more information.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

Purpose

Apply function to each element of array

Syntax

```
A = arrayfun(fun, S)
A = arrayfun(fun, S, T, ...)
[A, B, ...] = arrayfun(fun, S, ...)
[A, ...] = arrayfun(fun, S, ..., 'param1', value1, ...)
```

Description

`A = arrayfun(fun, S)` applies the function specified by `fun` to each element of array `S`, and returns the results in array `A`. The value `A` returned by `arrayfun` is the same size as `S`, and the `(I,J,...)`th element of `A` is equal to `fun(S(I,J,...))`. The first input argument `fun` is a function handle to a function that takes one input argument and returns a scalar value. `fun` must return values of the same class each time it is called.

If `fun` is bound to more than one built-in or M-file (that is, if it represents a set of overloaded functions), then the class of the values that `arrayfun` actually provides as input arguments to `fun` determines which functions are executed.

The order in which `arrayfun` computes elements of `A` is not specified and should not be relied upon.

`A = arrayfun(fun, S, T, ...)` evaluates `fun` using elements of the arrays `S`, `T`, `...` as input arguments. The `(I,J,...)`th element of `A` is equal to `fun(S(I,J,...), T(I,J,...), ...)`. All input arguments must be of the same size.

`[A, B, ...] = arrayfun(fun, S, ...)` evaluates `fun`, which is a function handle to a function that returns multiple outputs, and returns arrays `A`, `B`, `...`, each corresponding to one of the output arguments of `fun`. `arrayfun` calls `fun` each time with as many outputs as there are in the call to `arrayfun`. `fun` can return output arguments having different classes, but the class of each output must be the same each time `fun` is called.

`[A, ...] = arrayfun(fun, S, ..., 'param1', value1, ...)` enables you to specify optional parameter name and value pairs.

Parameters recognized by arrayfun are shown below. Enclose each parameter name with single quotes.

Parameter Name	Parameter Value
UniformOutput	A logical 1 (true) or 0 (false), indicating whether or not the outputs of fun can be returned without encapsulation in a cell array. If true (the default), fun must return scalar values that can be concatenated into an array. These values can also be a cell array. If false, arrayfun returns a cell array (or multiple cell arrays), where the (I,J,...)th cell contains the value fun(S(I,J,...), ...).
ErrorHandler	A function handle, specifying the function that arrayfun is to call if the call to fun fails. If an error handler is not specified, arrayfun rethrows the error from the call to fun.

Remarks

MATLAB provides two functions that are similar to arrayfun; these are structfun and cellfun. With structfun, you can apply a given function to all fields of one or more structures. With cellfun, you apply the function to all cells of one or more cell arrays.

Examples

Example 1 — Operating on a Single Input.

Create a 1-by-15 structure array with fields f1 and f2, each field containing an array of a different size. Make each f1 field be unequal to the f2 field at that same array index:

```
for k=1:15
   s(k).f1 = rand(k+3,k+7) * 10;
   s(k).f2 = rand(k+3,k+7) * 10;
```

```
end
```

Set three `f1` fields to be equal to the `f2` field at that array index:

```
s(3).f2 = s(3).f1;
s(9).f2 = s(9).f1;
s(12).f2 = s(12).f1;
```

Use `arrayfun` to compare the fields at each array index. This compares the array of `s(1).f1` with that of `s(1).f2`, the array of `s(2).f1` with that of `s(2).f2`, and so on through the entire structure array.

The first argument in the call to `arrayfun` is an anonymous function. Anonymous functions return a function handle, which is the required first input to `arrayfun`:

```
z = arrayfun(@(x)isequal(x.f1, x.f2), s)
z =
   0  0  1  0  0  0  0  0  1  0  0  1  0  0  0
```

Example 2 — Operating on Multiple Inputs.

This example performs the same array comparison as in the previous example, except that it compares the some field of more than one structure array rather than different fields of the same structure array. This shows how you can use more than one array input with `arrayfun`.

Make copies of array `s`, created in the last example, to arrays `t` and `u`.

```
t = s;   u = s;
```

Make one element of structure array `t` unequal to the same element of `s`. Do the same with structure array `u`:

```
t(4).f1(12)=0;
u(14).f1(6)=0;
```

Compare field `f1` of the three arrays `s`, `t`, and `u`:

```
z = arrayfun(@(a,b,c)isequal(a.f1, b.f1, c.f1), s, t, u)
z =
```

```
     1   1   1   0   1   1   1   1   1   1   1   1   1   0   1
```

Example 3 — Generating Nonuniform Output.

Generate a 1-by-3 structure array `s` having random matrices in field `f1`:

```
rand('state', 0);
s(1).f1 = rand(7,4) * 10;
s(2).f1 = rand(3,7) * 10;
s(3).f1 = rand(5,5) * 10;
```

Find the maximum for each `f1` vector. Because the output is nonscalar, specify the `UniformOutput` option as `false`:

```
sMax = arrayfun(@(x) max(x.f1), s, 'UniformOutput', false)
sMax =
    [1x4 double]    [1x7 double]    [1x5 double]

sMax{:}
ans =
  9.5013  9.2181  9.3547  8.1317
ans =
  2.7219  9.3181  8.4622  6.7214  8.3812   8.318  7.0947
ans =
  6.8222  8.6001  8.9977  8.1797  8.385
```

Find the mean for each `f1` vector:

```
sMean = arrayfun(@(x) mean(x.f1), s, ...
                 'UniformOutput', false)
sMean =
    [1x4 double]    [1x7 double]    [1x5 double]

sMean{:}
ans =
  6.2628  6.2171  5.4231  3.3144
ans =
  1.6209   7.079  5.7696  4.6665  5.1301  5.7136  4.8099
ans =
```

```
    3.8195  5.8816  6.9128  4.9022  5.9541
```

Example 4 — Assigning to More Than One Output Variable.

The next example uses the `lu` function on the same structure array, returning three outputs from `arrayfun`:

```
[l u p] = arrayfun(@(x)lu(x.f1), s, 'UniformOutput', false)
l =
    [7x4 double]    [3x3 double]    [5x5 double]
u =
    [4x4 double]    [3x7 double]    [5x5 double]
p =
    [7x7 double]    [3x3 double]    [5x5 double]

l{3}
ans =
       1          0          0          0          0
 0.44379          1          0          0          0
 0.79398    0.79936          1          0          0
 0.27799   0.066014   -0.77517          1          0
 0.28353    0.85338    0.29223    0.67036          1

u{3}
ans =
   6.8222     3.7837     8.9977     3.4197     3.0929
        0     6.9209     4.2232     1.3796     7.0124
        0          0    -4.0708   -0.40607    -2.3804
        0          0          0     6.8232     2.1729
        0          0          0          0   -0.35098

p{3}
ans =
     0     0     1     0     0
     0     0     0     1     0
     0     0     0     0     1
     1     0     0     0     0
     0     1     0     0     0
```

See Also `structfun`, `cellfun`, `spfun`, `function_handle`, `cell2mat`

Purpose

Set FTP transfer type to ASCII

Syntax

```
ascii(f)
```

Description

`ascii(f)` sets the download and upload FTP mode to ASCII, which converts new lines, where `f` was created using `ftp`. Use this function for text files only, including HTML pages and Rich Text Format (RTF) files.

Examples

Connect to the MathWorks FTP server, and display the FTP object.

```
tmw=ftp('ftp.mathworks.com');
disp(tmw)
FTP Object
  host: ftp.mathworks.com
  user: anonymous
   dir: /
  mode: binary
```

Note that the FTP object defaults to binary mode.

Use the `ascii` function to set the FTP mode to ASCII, and use the `disp` function to display the FTP object.

```
ascii(tmw)
disp(tmw)
FTP Object
  host: ftp.mathworks.com
  user: anonymous
   dir: /
  mode: ascii
```

Note that the FTP object is now set to ASCII mode.

See Also

`ftp`, `binary`

Purpose

Inverse secant; result in radians

Syntax

```
Y = asec(X)
```

Description

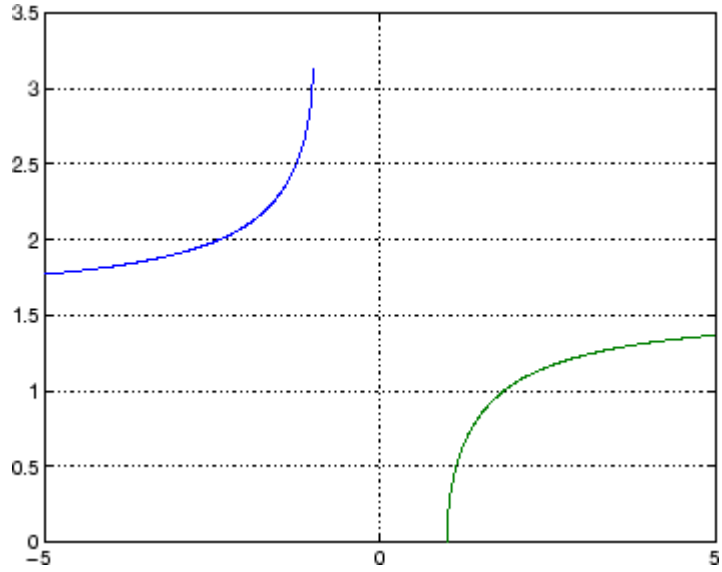
`Y = asec(X)` returns the inverse secant (arcsecant) for each element of `X`.

The `asec` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

Examples

Graph the inverse secant over the domains $1 \le x \le 5$ and $-5 \le x \le -1$.

```
x1 = -5:0.01:-1;
x2 = 1:0.01:5;
plot(x1,asec(x1),x2,asec(x2)), grid on
```



Definition

The inverse secant can be defined as

$$\sec^{-1}(z) = \cos^{-1}\left(\frac{1}{z}\right)$$

Algorithm

`asec` uses FDLIBM, which was developed at SunSoft, a Sun Microsystems, Inc. business, by Kwok C. Ng, and others. For information about FDLIBM, see `http://www.netlib.org`.

See Also

`asecd`, `asech`, `sec`

asecd

Purpose Inverse secant; result in degrees

Syntax `Y = asecd(X)`

Description `Y = asecd(X)` is the inverse secant, expressed in degrees, of the elements of `X`.

See Also `secd`, `asec`

Purpose

Inverse hyperbolic secant

Syntax

```
Y = asech(X)
```

Description

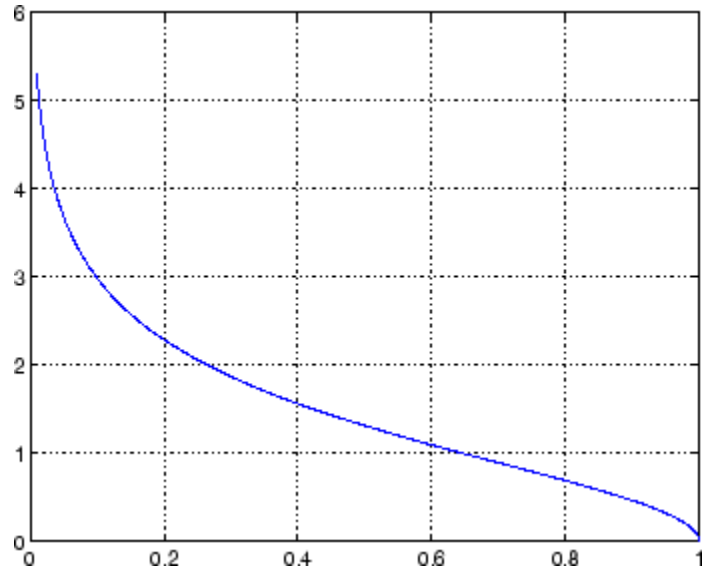
`Y = asech(X)` returns the inverse hyperbolic secant for each element of `X`.

The `asech` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

Examples

Graph the inverse hyperbolic secant over the domain $0.01 \le x \le 1$.

```
x = 0.01:0.001:1;
plot(x,asech(x)), grid on
```



Definition

The hyperbolic inverse secant can be defined as

$$\operatorname{sech}^{-1}(z) = \cosh^{-1}\left(\frac{1}{z}\right)$$

Algorithm

`asech` uses FDLIBM, which was developed at SunSoft, a Sun Microsystems, Inc. business, by Kwok C. Ng, and others. For information about FDLIBM, see http://www.netlib.org.

See Also

`asec`, `sech`

Purpose

Inverse sine; result in radians

Syntax

```
Y = asin(X)
```

Description

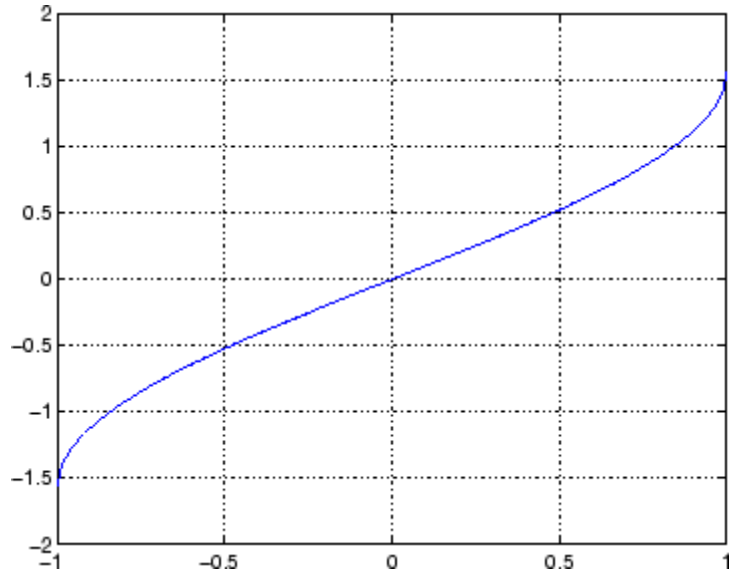
`Y = asin(X)` returns the inverse sine (arcsine) for each element of `X`. For real elements of `X` in the domain $[-1, 1]$, `asin(X)` is in the range $[-\pi/2, \pi/2]$. For real elements of `x` outside the range $[-1, 1]$, `asin(X)` is complex.

The `asin` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

Examples

Graph the inverse sine function over the domain $-1 \le x \le 1$.

```
x = -1:.01:1;
plot(x,asin(x)), grid on
```



Definition

The inverse sine can be defined as

$$\sin^{-1}(z) = -i \log\left[iz + (1 - z^2)^{\frac{1}{2}} \right]$$

Algorithm

`asin` uses FDLIBM, which was developed at SunSoft, a Sun Microsystems, Inc. business, by Kwok C. Ng, and others. For information about FDLIBM, see `http://www.netlib.org`.

See Also

`asind`, `asinh`, `sin`, `sind`, `sinh`

Purpose

Inverse sine; result in degrees

Syntax

Description

`Y = asind(X)` is the inverse sine, expressed in degrees, of the elements of `X`.

See Also

`asin`, `asinh`, `sin`, `sind`, `sinh`

Purpose

Inverse hyperbolic sine

Syntax

```
Y = asinh(X)
```

Description

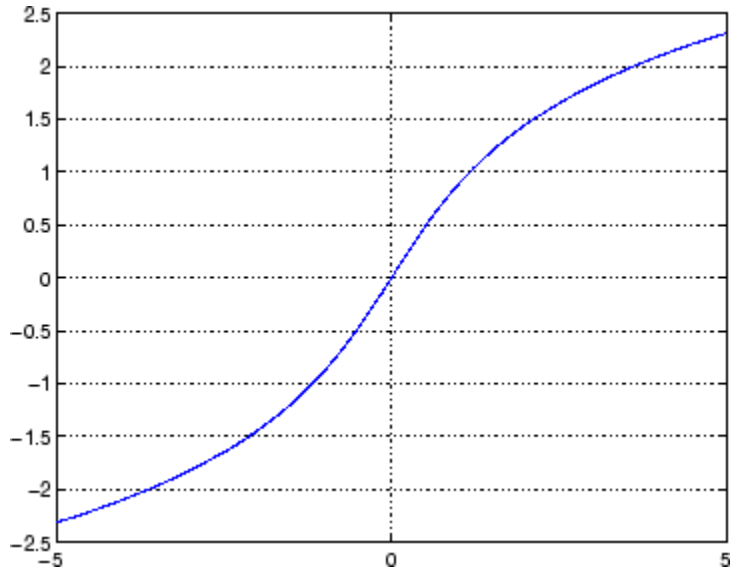
`Y = asinh(X)` returns the inverse hyperbolic sine for each element of `X`.

The `asinh` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

Examples

Graph the inverse hyperbolic sine function over the domain $-5 \le x \le 5$.

```
x = -5:.01:5;
plot(x,asinh(x)), grid on
```



Definition

The hyperbolic inverse sine can be defined as

$$\sinh^{-1}(z) = \log\left[z + (z^2 + 1)^{\frac{1}{2}} \right]$$

Algorithm

`asinh` uses FDLIBM, which was developed at SunSoft, a Sun Microsystems, Inc. business, by Kwok C. Ng, and others. For information about FDLIBM, see `http://www.netlib.org`.

See Also

`asin`, `asind`, `sin`, `sinh`, `sind`

Purpose

Generate error when condition is violated

Syntax

```
assert(expression)
assert(expression, 'errmsg')
assert(expression, 'errmsg', value1, value2, ...)
assert(expression, 'msg_id', 'errmsg', value1, value2, ...)
```

Description

`assert(expression)` evaluates `expression` and, if it is `false`, displays the error message: `Assertion Failed`.

`assert(expression, 'errmsg')` evaluates `expression` and, if it is `false`, displays the string contained in `errmsg`. This string must be enclosed in single quotation marks. When `errmsg` is the last input to `assert`, MATLAB displays it literally, without performing any substitutions on the characters in `errmsg`.

`assert(expression, 'errmsg', value1, value2, ...)` evaluates `expression` and, if it is `false`, displays the formatted string contained in `errmsg`. The `errmsg` string can include escape sequences such as `\t` or `\n`, as well as any of the C language conversion operators supported by the `sprintf` function (e.g., `%s` or `%d`). Additional arguments `value1`, `value2`, etc. provide values that correspond to and replace the conversion operators.

See “Formatting Strings” in the MATLAB Programming documentation for more detailed information on using string formatting commands.

MATLAB makes substitutions for escape sequences and conversion operators in `errmsg` in the same way that it does for the `sprintf` function.

`assert(expression, 'msg_id', 'errmsg', value1, value2, ...)` evaluates `expression` and, if it is `false`, displays the formatted string `errmsg`, also tagging the error with the message identifier `msg_id`. See in the MATLAB Programming documentation for information.

Examples

This function tests input arguments using `assert`:

```
function write2file(varargin)
```

```
min_inputs = 3;
assert(nargin >= min_inputs, ...
  'You must call function %s with at least %d inputs', ...
  mfilename, min_inputs)

infile = varargin{1};
assert(ischar(infile), ...
      'First argument must be a filename.')
assert(exist(infile)~=0, 'File %s not found.', infile)

fid = fopen(infile, 'w');
assert(fid > 0, 'Cannot open file %s for writing', infile)

fwrite(fid, varargin{2}, varargin{3});
```

See Also

`error`, `eval`, `sprintf`

assignin

Purpose

Assign value to variable in specified workspace

Syntax

```
assignin(ws, 'var', val)
```

Description

`assignin(ws, 'var', val)` assigns the value `val` to the variable *`var`* in the workspace `ws`. *`var`* is created if it doesn't exist. `ws` can have a value of `'base'` or `'caller'` to denote the MATLAB base workspace or the workspace of the caller function.

The `assignin` function is particularly useful for these tasks:

- Exporting data from a function to the MATLAB workspace
- Within a function, changing the value of a variable that is defined in the workspace of the caller function (such as a variable in the function argument list)

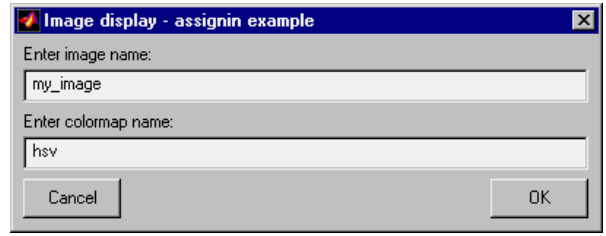
Remarks

The MATLAB base workspace is the workspace that is seen from the MATLAB command line (when not in the debugger). The caller workspace is the workspace of the function that called the M-file. Note that the base and caller workspaces are equivalent in the context of an M-file that is invoked from the MATLAB command line.

Examples

This example creates a dialog box for the image display function, prompting a user for an image name and a colormap name. The `assignin` function is used to export the user-entered values to the MATLAB workspace variables `imfile` and `cmap`.

```
prompt = {'Enter image name:','Enter colormap name:'};
title = 'Image display - assignin example';
lines = 1;
def = {'my_image','hsv'};
answer = inputdlg(prompt,title,lines,def);
assignin('base','imfile',answer{1});
assignin('base','cmap',answer{2});
```



See Also

`evalin`

Purpose

Inverse tangent; result in radians

Syntax

```
Y = atan(X)
```

Description

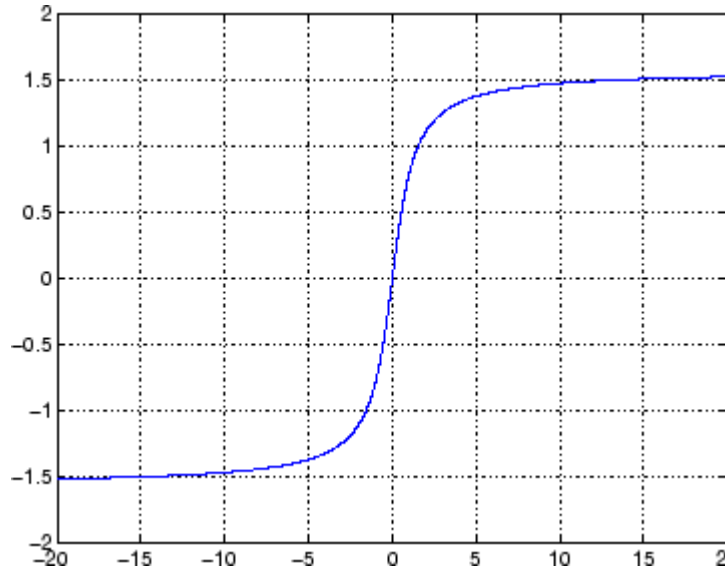
`Y = atan(X)` returns the inverse tangent (arctangent) for each element of `X`. For real elements of `X`, `atan(X)` is in the range $[-\pi/2, \pi/2]$.

The `atan` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

Examples

Graph the inverse tangent function over the domain $-20 \le x \le 20$.

```
x = -20:0.01:20;
plot(x,atan(x)), grid on
```



Definition

The inverse tangent can be defined as

$$\tan^{-1}(z) = \frac{i}{2}\log\left(\frac{i+z}{i-z}\right)$$

Algorithm

`atan` uses FDLIBM, which was developed at SunSoft, a Sun Microsystems, Inc. business, by Kwok C. Ng, and others. For information about FDLIBM, see `http://www.netlib.org`.

See Also

`atan2`, `tan`, `atand`, `atanh`

Purpose

Four-quadrant inverse tangent

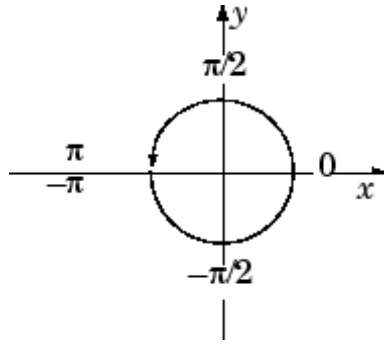
Syntax

```
P = atan2(Y,X)
```

Description

`P = atan2(Y,X)` returns an array `P` the same size as `X` and `Y` containing the element-by-element, four-quadrant inverse tangent (arctangent) of the real parts of `Y` and `X`. Any imaginary parts of the inputs are ignored.

Elements of `P` lie in the closed interval `[-pi,pi]`, where `pi` is the MATLAB floating-point representation of π. `atan` uses `sign(Y)` and `sign(X)` to determine the specific quadrant.



`atan2(Y,X)` contrasts with `atan(Y/X)`, whose results are limited to the interval $[-\pi/2, \pi/2]$, or the right side of this diagram.

Examples

Any complex number $z = x + iy$ is converted to polar coordinates with

```
r = abs(z)
theta = atan2(imag(z),real(z))
```

For example,

```
z = 4 + 3i;
r = abs(z)
theta = atan2(imag(z),real(z))
```

```
r =
     5

theta =
    0.6435
```

This is a common operation, so MATLAB provides a function, `angle(z)`, that computes `theta = atan2(imag(z),real(z))`.

To convert back to the original complex number

```
z = r *exp(i *theta)
z =

   4.0000 + 3.0000i
```

Algorithm

`atan2` uses FDLIBM, which was developed at SunSoft, a Sun Microsystems, Inc. business, by Kwok C. Ng, and others. For information about FDLIBM, see `http://www.netlib.org`.

See Also

`angle`, `atan`, `atanh`

atand

Purpose

Inverse tangent; result in degrees

Syntax

```
Y = atand(X)
```

Description

`Y = atand(X)` is the inverse tangent, expressed in degrees, of the elements of `X`.

See Also

`tand`, `atan`

Purpose

Inverse hyperbolic tangent

Syntax

```
Y = atanh(X)
```

Description

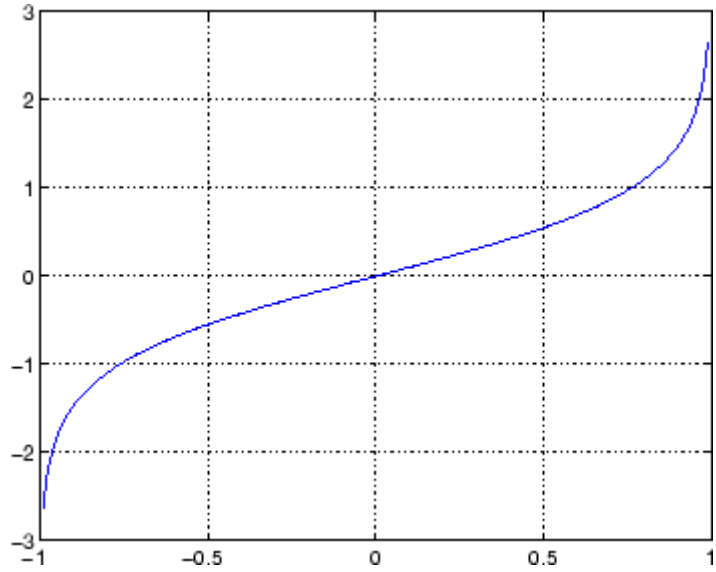
The `atanh` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

`Y = atanh(X)` returns the inverse hyperbolic tangent for each element of `X`.

Examples

Graph the inverse hyperbolic tangent function over the domain $-1 < x < 1$.

```
x = -0.99:0.01:0.99;
plot(x,atanh(x)), grid on
```



Definition

The hyperbolic inverse tangent can be defined as

$$\tanh^{-1}(z) = \frac{1}{2}\log\left(\frac{1+z}{1-z}\right)$$

Algorithm

`atanh` uses FDLIBM, which was developed at SunSoft, a Sun Microsystems, Inc. business, by Kwok C. Ng, and others. For information about FDLIBM, see `http://www.netlib.org`.

See Also

`atan2`, `atan`, `tanh`

Purpose

Create audio player object

Syntax

```
player = audioplayer(Y, Fs)
player = audioplayer(Y, Fs, nBits)
player = audioplayer(Y, Fs, nBits, ID)
player = audioplayer(R)
player = audioplayer(R, ID)
```

Description

Note To use all of the features of the audio player object, your system needs a properly installed and configured sound card with 8- and 16-bit I/O, two channels, and support for sampling rates of up to 48 kHz.

`player = audioplayer(Y, Fs)` creates an audio player object for signal `Y`, using sample rate `Fs`. The function returns `player`, a handle to the audio player object. The audio player object supports methods and properties that you can use to control how the audio data is played.

The input signal `Y` can be a vector or two-dimensional array containing `single`, `double`, `int8`, `uint8`, or `int16` MATLAB data types. `Fs` is the sampling rate in Hz to use for playback. Valid values for `Fs` depend on the specific audio hardware installed. Typical values supported by most sound cards are 8000, 11025, 22050, and 44100 Hz.

`player = audioplayer(Y, Fs, nBits)` creates an audio player object and uses `nBits` bits per sample for floating point signal `Y`. Valid values for `nBits` are 8, 16, and 24 on Windows, 8 and 16 on UNIX. The default number of bits per sample for floating point signals is 16.

`player = audioplayer(Y, Fs, nBits, ID)` creates an audio player object using audio device identifier `ID` for output. If `ID` equals -1, the default output device will be used. This option is only available on Windows.

`player = audioplayer(R)` creates an audio player object using audio recorder object `R`.

`player = audioplayer(R, ID)` creates an audio player object from audio recorder object `R` using audio device identifier `ID` for output. This option is only available on Windows.

Remarks

The value range of the input sample depends on the MATLAB data type. The following table lists these ranges.

Data Type	Input Sample Value Range
`int8`	-128 to 127
`uint8`	0 to 255
`int16`	-32768 to 32767
`single`	-1 to 1
`double`	-1 to 1

Example

Load a sample audio file of Handel's Hallelujah Chorus, create an audio player object, and play back only the first three seconds. `y` contains the audio samples and `Fs` is the sampling rate. You can use any of the `audioplayer` functions listed above on the player:

```
load handel;
player = audioplayer(y, Fs);
play(player,[1 (get(player, 'SampleRate')*3)]);
```

To stop the playback, use this command:

```
stop(player); % Equivalent to player.stop
```

Methods

After you create an audio player object, you can use the methods listed below on that object. `player` represents a handle to the audio player object.

Method	Description

`play(player)`
`play(player, start)`
`play(player, [start stop])`
`play(player, range)`
	Starts playback from the beginning and plays to the end of audio player object `player`. Play audio from the sample indicated by `start` to the end, or from the sample indicated by `start` up to the sample indicated by `stop`. The values of `start` and `stop` can also be specified in a two-element vector `range`.

`playblocking(player)`
`playblocking(player, start)`
`playblocking(player, [start stop])`
`playblocking(player, range)`
	Same as play, but does not return control until playback completes.

`stop(player)`	Stops playback.
`pause(player)`	Pauses playback.
`resume(player)`	Restarts playback from where playback was paused.
`isplaying(player)`	Indicates whether playback is in progress. If `0`, playback is not in progress. If `1`, playback is in progress.

`display(player)`
`disp(player)`
`get(player)`
	Displays all property information about audio player `player`.

Properties

Audio player objects have the properties listed below. To set a user-settable property, use this syntax:

```
set(player, 'property1', value,'property2',value,...)
```

To view a read-only property,

```
get(player,'property')  % Displays 'property' setting.
```

Property	Description	Type
`Type`	Name of the object's class.	Read-only
`SampleRate`	Sampling frequency in Hz.	User-settable
`BitsPerSample`	Number of bits per sample.	Read-only
`NumberOfChannels`	Number of channels.	Read-only
`TotalSamples`	Total length, in samples, of the audio data.	Read-only
`Running`	Status of the audio player (`'on'` or `'off'`).	Read-only
`CurrentSample`	Current sample being played by the audio output device (if it is not playing, `CurrentSample` is the next sample to be played with `play` or `resume`).	Read-only
`UserData`	User data of any type.	User-settable
`Tag`	User-specified object label string.	User-settable
For information on using the following four properties, see Creating Timer Callback Functions in the MATLAB documentation. Note that for audio player object callbacks, `eventStruct (event)` is currently empty (`[]`).		

Property	Description	Type
`TimerFcn`	Handle to a user-specified callback function that is executed repeatedly (at `TimerPeriod` intervals) during playback.	User-settable
`TimerPeriod`	Time, in seconds, between `TimerFcn` callbacks.	User-settable
`StartFcn`	Handle to a user-specified callback function that is executed once when playback starts.	User-settable
`StopFcn`	Handle to a user-specified callback function that is executed once when playback stops.	User-settable

audiorecorder

Purpose

Create audio recorder object

Syntax

```
y = audiorecorder
y = audiorecorder(Fs, nbits, nchans)
y = audiorecorder(Fs, nbits, channels, id)
```

Description

Note To use all of the features of the audiorecorder object, your system must have a properly installed and configured sound card with 8- and 16-bit I/O and support for sampling rates of up to 48 kHz.

`y = audiorecorder` creates an 8000 Hz, 8-bit, 1 channel audiorecorder object. `y` is a handle to the object. The audiorecorder object supports methods and properties that you can use to record audio data.

`y = audiorecorder(Fs, nbits, nchans)` creates an audiorecorder object using the sampling rate `Fs` (in Hz), the sample size `nbits`, and the number of channels`nchans`. `Fs` can be any sampling rate supported by the audio hardware. Common sampling rates are 8000, 11025, 22050, and 44100 (only 44100, 48000, and 96000 on a Macintosh). The value of `nbits` must be `8`, `16`, or `24`, on Windows, and `8` or `16` on UNIX. The number of channels, `nchans` must be `1` (mono) or `2` (stereo).

`y = audiorecorder(Fs, nbits, channels, id)` creates an audiorecorder object using the audio device specified by its `id` for input. If `id` equals -1, the default input device will be used. This option is only available on Windows.

Examples

Example 1

Using a microphone, record your voice, using a sample rate of 44100 Hz, 16 bits per sample, and one channel. Speak into the microphone, then pause the recording. Play back what you've recorded so far. Record some more, then stop the recording. Finally, return the recorded data to MATLAB as an int16 array.

```
r = audiorecorder(44100, 16, 1);
```

```
record(r);     % speak into microphone...
pause(r);
p = play(r);   % listen
resume(r);     % speak again
stop(r);
p = play(r);   % listen to complete recording
mySpeech = getaudiodata(r, 'int16'); % get data as int16 array
```

Remarks

The current implementation of `audiorecorder` is not intended for long, high-sample-rate recording because it uses system memory for storage and does not use disk buffering. When large recordings are attempted, MATLAB performance may degrade.

Methods

After you create an audiorecorder object, you can use the methods listed below on that object. `y` represents the name of the returned audiorecorder object

Method	Description
`record(y)` `record(y,length)`	Starts recording. Records for `length` number of seconds.
`recordblocking(y,length)`	Same as record, but does not return control until recording completes.
`stop(y)`	Stops recording.
`pause(y)`	Pauses recording.
`resume(y)`	Restarts recording from where recording was paused.
`isrecording(y)`	Indicates the status of recording. If `0`, recording is not in progress. If `1`, recording is in progress.
`play(y)`	Creates an `audioplayer`, plays the recorded audio data, and returns a handle to the created `audioplayer`.

Method	Description
`getplayer(y)`	Creates an `audioplayer` and returns a handle to the created `audioplayer`.
`getaudiodata(y)` `getaudiodata(y,'type')`	Returns the recorded audio data to the MATLAB workspace. `type` is a string containing the desired data type. Supported data types are `double`, `single`, `int16`, `int8`, or `uint8`. If `type` is omitted, it defaults to `'double'`. For `double` and `single`, the array contains values between -1 and 1. For `int8`, values are between -128 to 127. For `uint8`, values are from 0 to 255. For `int16`, values are from -32768 to 32767. If the recording is in mono, the returned array has one column. If it is in stereo, the array has two columns, one for each channel.

`display(y)`
`disp(y)`
`get(y)`
	Displays all property information about audio recorder `y`.

Properties

Audio recorder objects have the properties listed below. To set a user-settable property, use this syntax:

```
set(y, 'property1', value,'property2',value,...)
```

To view a read-only property,

```
get(y,'property')  %displays 'property' setting.
```

Property	Description	Type
`Type`	Name of the object's class.	Read-only
`SampleRate`	Sampling frequency in Hz.	Read-only
`BitsPerSample`	Number of bits per recorded sample.	Read-only
`NumberOfChannels`	Number of channels of recorded audio.	Read-only
`TotalSamples`	Total length, in samples, of the recording.	Read-only
`Running`	Status of the audio recorder (`'on'` or `'off'`).	Read-only
`CurrentSample`	Current sample being recorded by the audio output device (if it is not recording, `currentsample` is the next sample to be recorded with `record` or `resume`).	Read-only
`UserData`	User data of any type.	User-settable
For information on using the following four properties, see Creating Timer Callback Functions in the MATLAB documentation. Note that for audio object callbacks, `eventStruct` (`event`) is currently empty (`[]`).		
`TimerFcn`	Handle to a user-specified callback function that is executed repeatedly (at TimerPeriod intervals) during recording.	User-settable
`TimerPeriod`	Time, in seconds, between `TimerFcn` callbacks.	User-settable

Property	Description	Type
`StartFcn`	Handle to a user-specified callback function that is executed once when recording starts.	User-settable
`StopFcn`	Handle to a user-specified callback function that is executed once when recording stops.	User-settable
`NumberOfBuffers`	Number of buffers used for recording (you should adjust this only if you have skips, dropouts, etc., in your recording).	User-settable
`BufferLength`	Length in seconds of buffer (you should adjust this only if you have skips, dropouts, etc., in your recording).	User-settable
`Tag`	User-specified object label string.	User-settable

See Also

`audioplayer`, `wavread`, `wavrecord`, `wavwrite`, `get`, `set`, `methods`

Purpose

Information about NeXT/SUN (`.au`) sound file

Syntax

```
[m d] = aufinfo(aufile)
```

Description

`[m d] = aufinfo(aufile)` returns information about the contents of the AU sound file specified by the string `aufile`.

`m` is the string `'Sound (AU) file'`, if `filename` is an AU file. Otherwise, it contains an empty string (`''`).

`d` is a string that reports the number of samples in the file and the number of channels of audio data. If `filename` is not an AU file, it contains the string `'Not an AU file'`.

See Also

`auread`

auread

Purpose

Read NeXT/SUN (`.au`) sound file

Graphical Interface

As an alternative to `auread`, use the Import Wizard. To activate the Import Wizard, select **Import data** from the **File** menu.

Syntax

```
y = auread('aufile')
[y,Fs,bits] = auread('aufile')
[...] = auread('aufile',N)
[...] = auread('aufile',[N1 N2])
siz = auread('aufile','size')
```

Description

`y = auread('aufile')` loads a sound file specified by the string `aufile`, returning the sampled data in `y`. The `.au` extension is appended if no extension is given. Amplitude values are in the range `[-1,+1]`. `auread` supports multichannel data in the following formats:

- 8-bit mu-law
- 8-, 16-, and 32-bit linear
- Floating-point

`[y,Fs,bits] = auread('aufile')` returns the sample rate (`Fs`) in Hertz and the number of bits per sample (`bits`) used to encode the data in the file.

`[...] = auread('aufile',N)` returns only the first `N` samples from each channel in the file.

`[...] = auread('aufile',[N1 N2])` returns only samples `N1` through `N2` from each channel in the file.

`siz = auread('aufile','size')` returns the size of the audio data contained in the file in place of the actual audio data, returning the vector `siz = [samples channels]`.

See Also

`auwrite`, `wavread`

Purpose

Write NeXT/SUN (.au) sound file

Syntax

```
auwrite(y,'aufile')
auwrite(y,Fs,'aufile')
auwrite(y,Fs,N,'aufile')
auwrite(y,Fs,N,'method','aufile')
```

Description

`auwrite(y,'aufile')` writes a sound file specified by the string `aufile`. The data should be arranged with one channel per column. Amplitude values outside the range `[-1,+1]` are clipped prior to writing. `auwrite` supports multichannel data for 8-bit mu-law and 8- and 16-bit linear formats.

`auwrite(y,Fs,'aufile')` specifies the sample rate of the data in Hertz.

`auwrite(y,Fs,N,'aufile')` selects the number of bits in the encoder. Allowable settings are `N = 8` and `N = 16`.

`auwrite(y,Fs,N,'method','aufile')` allows selection of the encoding method, which can be either `mu` or `linear`. Note that mu-law files must be 8-bit. By default, `method = 'mu'`.

`auread`, `wavwrite`

Purpose

Create new Audio/Video Interleaved (AVI) file

Syntax

```
aviobj = avifile(filename)
aviobj = avifile(filename, 'Param1', Val1, 'Param2', Val2,
   ...)
```

Description

`aviobj = avifile(filename)` creates an `avifile` object, giving it the name specified in `filename`, using default values for all `avifile` object properties. AVI is a file format for storing audio and video data. If `filename` does not include an extension, `avifile` appends `.avi` to the filename. To close all open AVI files, use the `clear mex` command.

`avifile` returns a handle to an AVI file object `aviobj`. You use this object to refer to the AVI file in other functions. An AVI file object supports properties and methods that control aspects of the AVI file created.

`aviobj = avifile(filename, 'Param1', Val1, 'Param2', Val2,...)` creates an `avifile` object with the property values specified by parameter/value pairs. This table lists available parameters.

Parameter	Value	Default
`'colormap'`	An `m`-by-3 matrix defining the colormap to be used for indexed AVI movies, where `m` must be no greater than 256 (236 if using `Indeo` compression). You must set this parameter before calling `addframe`, unless you are using `addframe` with the MATLAB movie syntax.	There is no default colormap.
`'compression'`	A text string specifying the compression codec to use.	

Parameter	Value		Default

	On Windows:
	`'Indeo3'`
	`'Indeo5'`
	`'Cinepak'`
	`'MSVC'`
	`'RLE'`
	`'None'`
		On UNIX:
		`'None'`
			`'Indeo5'` on Windows.
			`'None'` on UNIX.

	To use a custom compression codec, specify the four-character code that identifies the codec (typically included in the codec documentation). The `addframe` function reports an error if it cannot find the specified custom compressor. You must set this parameter before calling `addframe`.		
`'fps'`	A scalar value specifying the speed of the AVI movie in frames per second (fps).		15 fps
`'keyframe'`	For compressors that support temporal compression, this is the number of key frames per second.		2.1429 key frames per second.

Parameter	Value	Default
'quality'	A number between 0 and 100. This parameter has no effect on uncompressed movies. Higher quality numbers result in higher video quality and larger file sizes. Lower quality numbers result in lower video quality and smaller file sizes. You must set this parameter before calling addframe.	75
'videoname'	A descriptive name for the video stream. This parameter must be no greater than 64 characters long and must be set before using addframe.	The default is the filename.

You can also use structure syntax (also called dot notation) to set avifile object properties. The property name must be typed in full, however it is not case sensitive. For example, to set the quality property to 100, use the following syntax:

```
aviobj = avifile('myavifile');
aviobj.quality = 100;
```

All the field names of an avifile object are the same as the parameter names listed in the table, except for the keyframe parameter. To set this property using dot notation, specify the KeyFramePerSec property. For example, to change the value of keyframe to 2.5, type

```
aviobj.KeyFramePerSec = 2.5;
```

Example

This example shows how to use the avifile function to create the AVI file example.avi.

```
fig=figure;
set(fig,'DoubleBuffer','on');
```

```
set(gca,'xlim',[-80 80],'ylim',[-80 80],...
    'NextPlot','replace','Visible','off')
mov = avifile('example.avi')
x = -pi:.1:pi;
radius = 0:length(x);
for k=1:length(x)
 h = patch(sin(x)*radius(k),cos(x)*radius(k),...
    [abs(cos(x(k))) 0 0]);
 set(h,'EraseMode','xor');
 F = getframe(gca);
 mov = addframe(mov,F);
end
mov = close(mov);
```

See Also

addframe, close, movie2avi

Purpose

Information about Audio/Video Interleaved (AVI) file

Syntax

```
fileinfo = aviinfo(filename)
```

Description

`fileinfo = aviinfo(filename)` returns a structure whose fields contain information about the AVI file specified in the string `filename`. If `filename` does not include an extension, then `.avi` is used. The file must be in the current working directory or in a directory on the MATLAB path.

The set of fields in the `fileinfo` structure is shown below.

Field Name	Description
`AudioFormat`	String containing the name of the format used to store the audio data, if audio data is present
`AudioRate`	Integer indicating the sample rate in Hertz of the audio stream, if audio data is present
`Filename`	String specifying the name of the file
`FileModDate`	String containing the modification date of the file
FileSize	Integer indicating the size of the file in bytes
`FramesPerSecond`	Integer indicating the desired frames per second
`Height`	Integer indicating the height of the AVI movie in pixels
`ImageType`	String indicating the type of image. Either `'truecolor'` for a truecolor (RGB) image, or `'indexed'` for an indexed image.

Field Name	Description
`NumAudioChannels`	Integer indicating the number of channels in the audio stream, if audio data is present
`NumFrames`	Integer indicating the total number of frames in the movie
`NumColormapEntries`	Integer specifying the number of colormap entries. For a truecolor image, this value is 0 (zero).
`Quality`	Number between 0 and 100 indicating the video quality in the AVI file. Higher quality numbers indicate higher video quality; lower quality numbers indicate lower video quality. This value is not always set in AVI files and therefore can be inaccurate.
`VideoCompression`	String containing the compressor used to compress the AVI file. If the compressor is not Microsoft Video 1, Run Length Encoding (RLE), Cinepak, or Intel Indeo, `aviinfo` returns the four-character code that identifies the compressor.
`Width`	Integer indicating the width of the AVI movie in pixels

See also

`avifile`, `aviread`

Purpose

Read Audio/Video Interleaved (AVI) file

Syntax

```
mov = aviread(filename)
mov = aviread(filename, index)
```

Description

`mov = aviread(filename)` reads the AVI movie `filename` into the MATLAB movie structure `mov`. If `filename` does not include an extension, then `.avi` is used. Use the `movie` function to view the movie `mov`. On UNIX, `filename` must be an uncompressed AVI file.

`mov` has two fields, `cdata` and `colormap`. The content of these fields varies depending on the type of image.

Image Type	cdata Field	colormap Field
`Truecolor`	Height-by-width-by-3 array of `uint8` values	Empty
`Indexed`	Height-by-width array of `uint8` values	`m`-by-3 array of `double` values

`aviread` supports 8-bit frames, for indexed and grayscale images, 16-bit grayscale images, or 24-bit truecolor images. Note, however, that `movie` only accepts 8-bit image frames; it does not accept 16-bit grayscale image frames.

`mov = aviread(filename, index)` reads only the frames specified by `index`. `index` can be a single index or an array of indices into the video stream. In AVI files, the first frame has the index value 1, the second frame has the index value 2, and so on.

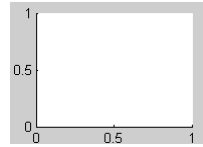
Note If you are using MATLAB on a Windows platform, consider using the new `mmreader` function, which adds support for more video formats and codecs.

See also

`avifile`, `aviinfo`, `mmreader`, `movie`

Purpose

Create axes graphics object



GUI Alternatives

To create a figure select **New > Figure** from the MATLAB Desktop or a figure's **File** menu. To add an axes to a figure, click one of the *New Subplots* icons in the Figure Palette, and slide right to select an arrangement of new axes. For details, see "Plotting Tools — Interactive Plotting" in the MATLAB Graphics documentation.

Syntax

```
axes
axes('PropertyName',propertyvalue,...)
axes(h)
h = axes(...)
```

Description

`axes` is the low-level function for creating axes graphics objects.

`axes` creates an axes graphics object in the current figure using default property values.

`axes('PropertyName',propertyvalue,...)` creates an axes object having the specified property values. MATLAB uses default values for any properties that you do not explicitly define as arguments.

`axes(h)` makes existing axes `h` the current axes and brings the figure containing it into focus. It also makes `h` the first axes listed in the figure's `Children` property and sets the figure's `CurrentAxes` property to `h`. The current axes is the target for functions that draw image, line, patch, rectangle, surface, and text graphics objects.

If you want to make an axes the current axes without changing the state of the parent figure, set the `CurrentAxes` property of the figure containing the axes:

```
set(figure_handle,'CurrentAxes',axes_handle)
```

This is useful if you want a figure to remain minimized or stacked below other figures, but want to specify the current axes.

`h = axes(...)` returns the handle of the created axes object.

Remarks

MATLAB automatically creates an axes, if one does not already exist, when you issue a command that creates a graph.

The `axes` function accepts property name/property value pairs, structure arrays, and cell arrays as input arguments (see the `set` and `get` commands for examples of how to specify these data types). These properties, which control various aspects of the axes object, are described in the `Axes Properties` section.

Use the `set` function to modify the properties of an existing axes or the `get` function to query the current values of axes properties. Use the `gca` command to obtain the handle of the current axes.

The `axis` (not `axes`) function provides simplified access to commonly used properties that control the scaling and appearance of axes.

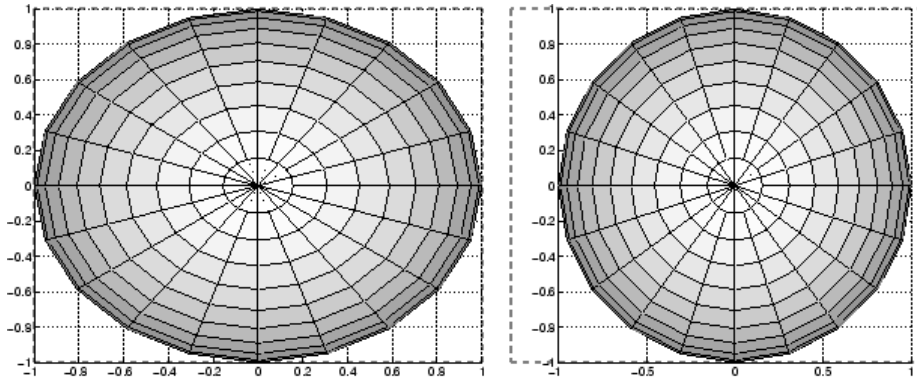
While the basic purpose of an axes object is to provide a coordinate system for plotted data, axes properties provide considerable control over the way MATLAB displays data.

Stretch-to-Fill

By default, MATLAB stretches the axes to fill the axes position rectangle (the rectangle defined by the last two elements in the `Position` property). This results in graphs that use the available space in the rectangle. However, some 3-D graphs (such as a sphere) appear distorted because of this stretching, and are better viewed with a specific three-dimensional aspect ratio.

Stretch-to-fill is active when the `DataAspectRatioMode`, `PlotBoxAspectRatioMode`, and `CameraViewAngleMode` are all `auto` (the default). However, stretch-to-fill is turned off when the `DataAspectRatio`, `PlotBoxAspectRatio`, or `CameraViewAngle` is user-specified, or when one or more of the corresponding modes is set to `manual` (which happens automatically when you set the corresponding property value).

This picture shows the same sphere displayed both with and without the stretch-to-fill. The dotted lines show the axes rectangle.



Stretch-to-fill active | Stretch-to-fill disabled

When stretch-to-fill is disabled, MATLAB sets the size of the axes to be as large as possible within the constraints imposed by the `Position` rectangle without introducing distortion. In the picture above, the height of the rectangle constrains the axes size.

Examples

Zooming

Zoom in using aspect ratio and limits:

```
sphere
set(gca,'DataAspectRatio',[1 1 1],...
        'PlotBoxAspectRatio',[1 1 1],'ZLim',[-0.6 0.6])
```

Zoom in and out using the `CameraViewAngle`:

```
sphere
set(gca,'CameraViewAngle',get(gca,'CameraViewAngle')-5)
set(gca,'CameraViewAngle',get(gca,'CameraViewAngle')+5)
```

Note that both examples disable the MATLAB stretch-to-fill behavior.

Positioning the Axes

The axes `Position` property enables you to define the location of the axes within the figure window. For example,

```
h = axes('Position',position_rectangle)
```

creates an axes object at the specified position within the current figure and returns a handle to it. Specify the location and size of the axes with a rectangle defined by a four-element vector,

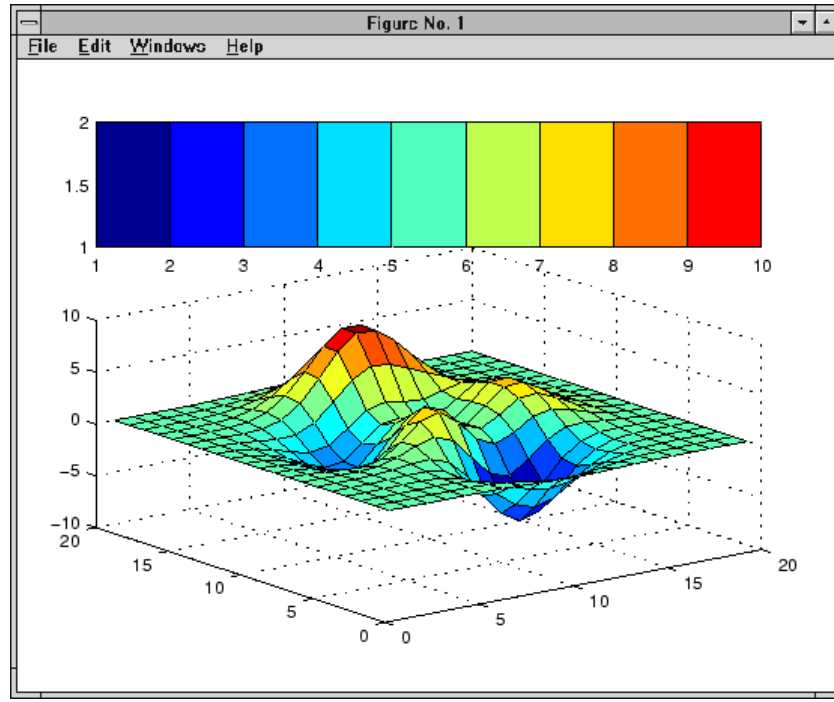
```
position_rectangle = [left, bottom, width, height];
```

The `left` and `bottom` elements of this vector define the distance from the lower left corner of the figure to the lower left corner of the rectangle. The `width` and `height` elements define the dimensions of the rectangle. You specify these values in units determined by the `Units` property. By default, MATLAB uses normalized units where (0,0) is the lower left corner and (1.0,1.0) is the upper right corner of the figure window.

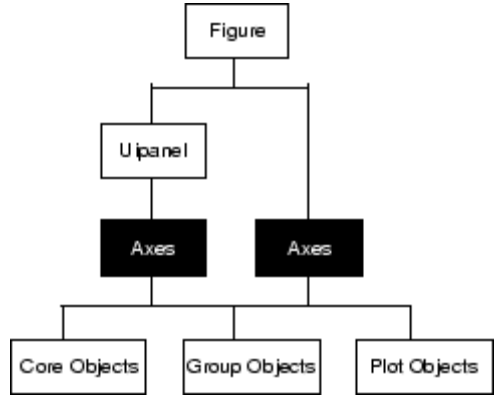
You can define multiple axes in a single figure window:

```
axes('position',[.1  .1  .8  .6])
mesh(peaks(20));
axes('position',[.1  .7  .8  .2])
pcolor([1:10;1:10]);
```

In this example, the first plot occupies the bottom two-thirds of the figure, and the second occupies the top third.



Object Hierarchy



Setting Default Properties

You can set default axes properties on the figure and root levels:

```
set(0,'DefaultAxes<PropertyName>',PropertyValue,...)
set(gcf,'DefaultAxes<PropertyName>',PropertyValue,...)
```

where *PropertyName* is the name of the axes property and `PropertyValue` is the value you are specifying. Use `set` and `get` to access axes properties.

“Axes Operations” on page 1-96 for related functions

“Axes Properties” for more examples

See “Types of Graphics Objects” for information on core, group, plot, and annotation objects.

Purpose

Axes properties

Modifying Properties

You can set and query graphics object properties in two ways:

- The Property Editor is an interactive tool that enables you to see and change object property values.
- The `set` and `get` commands enable you to set and query the values of properties.

To change the default values of properties, see Setting Default Property Values.

Axes Property Descriptions

This section lists property names along with the types of values each accepts. Curly braces { } enclose default values.

`ActivePositionProperty`

`{outerposition} | position`

Use `OuterPosition` or `Position` property for resize. `ActivePositionProperty` specifies which property MATLAB uses to determine the size of the axes when the figure is resized (interactively or during a printing or exporting operation).

See `OuterPosition` and `Position` for related properties.

See Automatic Axes Resize for a discussion of how to use axes positioning properties.

`ALim`

`[amin, amax]`

Alpha axis limits. A two-element vector that determines how MATLAB maps the `AlphaData` values of surface, patch, and image objects to the figure's alphamap. `amin` is the value of the data mapped to the first alpha value in the alphamap, and `amax` is the value of the data mapped to the last alpha value in the alphamap. Data values in between are linearly interpolated

across the alphamap, while data values outside are clamped to either the first or last alphamap value, whichever is closest.

When `ALimMode` is `auto` (the default), MATLAB assigns `amin` the minimum data value and `amax` the maximum data value in the graphics object's `AlphaData`. This maps `AlphaData` elements with minimum data values to the first alphamap entry and those with maximum data values to the last alphamap entry. Data values in between are mapped linearly to the values

If the axes contains multiple graphics objects, MATLAB sets `ALim` to span the range of all objects' `AlphaData` (or `FaceVertexAlphaData` for patch objects).

See the `alpha` function reference page for additional information.

`ALimMode`

`{auto} | manual`

Alpha axis limits mode. In `auto` mode, MATLAB sets the `ALim` property to span the `AlphaData` limits of the graphics objects displayed in the axes. If `ALimMode` is `manual`, MATLAB does not change the value of `ALim` when the `AlphaData` limits of axes children change. Setting the `ALim` property sets `ALimMode` to `manual`.

`AmbientLightColor`

`ColorSpec`

The background light in a scene. Ambient light is a directionless light that shines uniformly on all objects in the axes. However, if there are no visible light objects in the axes, MATLAB does not use `AmbientLightColor`. If there are light objects in the axes, the `AmbientLightColor` is added to the other light sources.

`AspectRatio`

(Obsolete)

This property produces a warning message when queried or changed. It has been superseded by the `DataAspectRatio[Mode]` and `PlotBoxAspectRatio[Mode]` properties.

`BeingDeleted`

`on | {off}`

This object is being deleted. The `BeingDeleted` property provides a mechanism that you can use to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object's delete function might call other functions that act on a number of different objects. These functions might not need to perform actions on objects if the objects are going to be deleted, and therefore, can check the object's `BeingDeleted` property before acting.

See the `close` and `delete` function reference pages for related information.

`Box`

`on | {off}`

Axes box mode. This property specifies whether to enclose the axes extent in a box for 2-D views or a cube for 3-D views. The default is to not display the box.

`BusyAction`

`cancel | {queue}`

Callback routine interruption. The `BusyAction` property enables you to control how MATLAB handles events that potentially interrupt executing callbacks. If there is a callback executing, callback invoked subsequently always attempt to interrupt it. If the `Interruptible` property of the object whose callback is

executing is set to `on` (the default), then interruption occurs at the next point where the event queue is processed.

If the `Interruptible` property is `off`, the `BusyAction` property (of the object owning the executing callback) determines how MATLAB handles the event. The choices are

- `cancel` — Discard the event that attempted to execute a second callback routine.
- `queue` — Queue the event that attempted to execute a second callback routine until the current callback finishes.

`ButtonDownFcn`

functional handle, cell array containing function handle and additional arguments, or string (not recommended)

Button press callback function. A callback that executes whenever you press a mouse button while the pointer is within the axes, but not over another graphics object parented to the axes. For 3-D views, the active area is defined by a rectangle that encloses the axes.

See the figure's `SelectionType` property to determine whether modifier keys were also pressed.

Set this property to a function handle that references the callback. The function must define at least two input arguments (handle of axes associated with the button down event and an event structure, which is empty for this property)

See Function Handle Callbacks for information on how to use function handles to define the callback function.

Some Plotting Functions Reset the ButtonDownFcn

Most MATLAB plotting functions clear the axes and reset a number of axes properties, including the `ButtonDownFcn` before

plotting data. If you want to create an interface that enables users to plot data interactively, consider using a control device such as a push button (`uicontrol`), which is not affected by plotting functions. See "Example — Using Function Handles in GUIs" for an example.

If you must use the axes `ButtonDownFcn` to plot data, then you should use low-level functions such as `line` `patch`, and `surface` and manage the process with the figure and axes `NextPlot` properties.

See "High-Level Versus Low-Level" for information on how plotting functions behave.

See "Preparing Figures and Axes for Graphics" for more information.

Camera Properties

See View Control with the Camera Toolbar for information related to the Camera properties

`CameraPosition`
`[x, y, z]` axes coordinates

The location of the camera. This property defines the position from which the camera views the scene. Specify the point in axes coordinates.

If you fix `CameraViewAngle`, you can zoom in and out on the scene by changing the `CameraPosition`, moving the camera closer to the `CameraTarget` to zoom in and farther away from the `CameraTarget` to zoom out. As you change the `CameraPosition`, the amount of perspective also changes, if `Projection` is `perspective`. You can also zoom by changing the `CameraViewAngle`; however, this does not change the amount of perspective in the scene.

`CameraPositionMode`
`{auto} | manual`

Auto or manual `CameraPosition`. When set to `auto`, MATLAB automatically calculates the `CameraPosition` such that the camera lies a fixed distance from the `CameraTarget` along the azimuth and elevation specified by `view`. Setting a value for `CameraPosition` sets this property to manual.

`CameraTarget`
`[x, y, z]` axes coordinates

Camera aiming point. This property specifies the location in the axes that the camera points to. The `CameraTarget` and the `CameraPosition` define the vector (the view axis) along which the camera looks.

`CameraTargetMode`
`{auto} | manual`

Auto or manual `CameraTarget` placement. When this property is `auto`, MATLAB automatically positions the `CameraTarget` at the centroid of the axes plot box. Specifying a value for `CameraTarget` sets this property to `manual`.

`CameraUpVector`
`[x, y, z]` axes coordinates

Camera rotation. This property specifies the rotation of the camera around the viewing axis defined by the `CameraTarget` and the `CameraPosition` properties. Specify `CameraUpVector` as a three-element array containing the *x*, *y*, and *z* components of the vector. For example, `[0 1 0]` specifies the positive *y*-axis as the up direction.

The default `CameraUpVector` is `[0 0 1]`, which defines the positive *z*-axis as the up direction.

`CameraUpVectorMode`
`auto} | manual`

Default or user-specified up vector. When `CameraUpVectorMode` is `auto`, MATLAB uses a value of `[0 0 1]` (positive *z*-direction is up) for 3-D views and `[0 1 0]` (positive *y*-direction is up) for 2-D views. Setting a value for `CameraUpVector` sets this property to `manual`.

`CameraViewAngle`
scalar greater than 0 and less than or equal to 180 (angle in degrees)

The field of view. This property determines the camera field of view. Changing this value affects the size of graphics objects displayed in the axes, but does not affect the degree of perspective distortion. The greater the angle, the larger the field of view, and the smaller objects appear in the scene.

`CameraViewAngleMode`
`{auto} | manual`

Auto or manual `CameraViewAngle`. When in `auto` mode, MATLAB sets `CameraViewAngle` to the minimum angle that captures the entire scene (up to 180°).

The following table summarizes MATLAB automatic camera behavior.

CameraViewAngle	Camera Target	Camera Position	Behavior
auto	auto	auto	CameraTarget is set to plot box centroid, CameraViewAngle is set to capture entire scene, CameraPosition is set along the view axis.
auto	auto	manual	CameraTarget is set to plot box centroid, CameraViewAngle is set to capture entire scene.
auto	manual	auto	CameraViewAngle is set to capture entire scene, CameraPosition is set along the view axis.
auto	manual	manual	CameraViewAngle is set to capture entire scene.
manual	auto	auto	CameraTarget is set to plot box centroid, CameraPosition is set along the view axis.
manual	auto	manual	CameraTarget is set to plot box centroid

CameraViewAngle	Camera Target	Camera Position	Behavior
manual	manual	auto	CameraPosition is set along the view axis.
manual	manual	manual	All camera properties are user-specified.

`Children`

vector of graphics object handles

. A vector containing the handles of all graphics objects rendered within the axes (whether visible or not). The graphics objects that can be children of axes are `image`, `light`, `line`, `patch`, `rectangle`, `surface`, and `text`. You can change the order of the handles and thereby change the stacking of the objects on the display.

The text objects used to label the *x*-, *y*-, and *z*-axes and the title are also children of axes, but their `HandleVisibility` properties are set to `off`. This means their handles do not show up in the axes `Children` property unless you set the Root `ShowHiddenHandles` property to `on`.

When an object's `HandleVisibility` property is set to `off`, it is not listed in its parent's `Children` property. See `HandleVisibility` for more information.

`CLim`

`[cmin, cmax]`

Color axis limits. A two-element vector that determines how MATLAB maps the `CData` values of surface and patch objects to the figure's colormap. `cmin` is the value of the data mapped to the first color in the colormap, and `cmax` is the value of the data mapped to the last color in the colormap. Data values in between are linearly interpolated across the colormap, while data

values outside are clamped to either the first or last colormap color, whichever is closest.

When `CLimMode` is `auto` (the default), MATLAB assigns `cmin` the minimum data value and `cmax` the maximum data value in the graphics object's `CData`. This maps `CData` elements with minimum data value to the first colormap entry and with maximum data value to the last colormap entry.

If the axes contains multiple graphics objects, MATLAB sets `CLim` to span the range of all objects' `CData`.

See the `caxis` function reference page for related information.

`CLimMode`

`{auto} | manual`

Color axis limits mode. In `auto` mode, MATLAB sets the `CLim` property to span the `CData` limits of the graphics objects displayed in the axes. If `CLimMode` is `manual`, MATLAB does not change the value of `CLim` when the `CData` limits of axes children change. Setting the `CLim` property sets this property to `manual`.

`Clipping`

`{on} | off`

This property has no effect on axes.

`Color`

`{none} | ColorSpec`

Color of the axes back planes. Setting this property to `none` means the axes is transparent and the figure color shows through. A `ColorSpec` is a three-element RGB vector or one of the MATLAB predefined names. Note that while the default value is `none`, the `matlabrc.m` file may set the axes `color` to a specific color.

`ColorOrder`

m-by-3 matrix of RGB values

Colors to use for multiline plots. `ColorOrder` is an *m*-by-3 matrix of RGB values that define the colors used by the `plot` and `plot3` functions to color each line plotted. If you do not specify a line color with `plot` and `plot3`, these functions cycle through the `ColorOrder` to obtain the color for each line plotted. To obtain the current `ColorOrder`, which may be set during startup, get the property value:

```
get(gca,'ColorOrder')
```

Note that if the axes `NextPlot` property is set to `replace` (the default), high-level functions like `plot` reset the `ColorOrder` property before determining the colors to use. If you want MATLAB to use a `ColorOrder` that is different from the default, set `NextPlot` to `replacechildren`. You can also specify your own default `ColorOrder`.

`CreateFcn`

functional handle, cell array containing function handle and additional arguments, or string (not recommended)

Callback function executed during object creation. A callback function that executes when MATLAB creates an axes object. You must define this property as a default value for axes. For example, the statement

```
set(0,'DefaultAxesCreateFcn',@ax_create)
```

defines a default value on the `Root` level that sets axes properties whenever you (or MATLAB) create an axes.

```
function ax_create(src,evnt)
 set(src,'Color','b',...
 'XLim',[1 10],...
 'YLim',[0 100])
end
```

MATLAB executes this function after setting all properties for the axes. Setting the `CreateFcn` property on an existing axes object has no effect.

The handle of the object whose `CreateFcn` is being executed is passed by MATLAB as the first argument to the callback function and is also accessible through the Root `CallbackObject` property, which can be queried using `gcbo`.

See "Function Handle Callbacks" for information on how to use function handles to define the callback function.

`CurrentPoint`
2-by-3 matrix

Location of last button click, in axes data units. A 2-by-3 matrix containing the coordinates of two points defined by the location of the pointer when the mouse was last clicked. MATLAB returns the coordinates with respect to the requested axes.

Clicking Within the Axes — Orthogonal Projection

The two points lie on the line that is perpendicular to the plane of the screen and passes through the pointer. This is true for both 2-D and 3-D views.

The 3-D coordinates are the points, in the axes coordinate system, where this line intersects the front and back surfaces of the axes volume (which is defined by the axes x, y, and z limits).

The returned matrix is of the form:

$$\begin{bmatrix} x_{front} & y_{front} & z_{front} \\ x_{back} & y_{back} & z_{back} \end{bmatrix}$$

where *front* defines the point nearest to the camera position. Therefore, if cp is the matrix returned by the CurrentPoint property, then the first row,

```
cp(1,:)
```

specifies the point nearest the viewer and the second row,

```
cp(2,:)
```

specifies the point furthest from the viewer.

Clicking Outside the Axes — Orthogonal Projection

When you click outside the axes volume, but within the figure, the values returned are:

- Back point — a point in the plane of the camera target (which is perpendicular to the viewing axis).
- Front point — a point in the camera position plane (which is perpendicular to the viewing axis).

These points lie on a line that passes through the pointer and is perpendicular to the camera target and camera position planes.

Clicking Within the Axes — Perspective Projection

The values of the current point when using perspective project can be different from the same point in orthographic projection because the shape of the axes volume can be different.

Clicking Outside the Axes — Perspective Projection

Clicking outside of the axes volume causes the front point to be returned as the current camera position at all times. Only the back point updates with the coordinates of a point that lies on a line extending from the camera position through the pointer and intersecting the camera target at the point.

Related Information

See Defining Scenes with Camera Graphics for information on the camera properties.

See View Projection Types for information on orthogonal and perspective projections.

`DataAspectRatio`
`[dx dy dz]`

Relative scaling of data units. A three-element vector controlling the relative scaling of data units in the *x*, *y*, and *z* directions. For example, setting this property to `[1 2 1]` causes the length of one unit of data in the *x* direction to be the same length as two units of data in the *y* direction and one unit of data in the *z* direction.

Note that the `DataAspectRatio` property interacts with the `PlotBoxAspectRatio`, `XLimMode`, `YLimMode`, and `ZLimMode` properties to control how MATLAB scales the *x*-, *y*-, and *z*-axis. Setting the `DataAspectRatio` will disable the stretch-to-fill behavior if `DataAspectRatioMode`, `PlotBoxAspectRatioMode`, and `CameraViewAngleMode` are all `auto`. The following table describes the interaction between properties when `stretch-to-fill` behavior is disabled.

X-, Y-, Z-Limits	DataAspect Ratio	PlotBox AspectRatio	Behavior
`auto`	`auto`	`auto`	Limits chosen to span data range in all dimensions.

X-, Y-, Z-Limits	DataAspect Ratio	PlotBox AspectRatio	Behavior
`auto`	`auto`	`manual`	Limits chosen to span data range in all dimensions. `DataAspectRatio` is modified to achieve the requested `PlotBoxAspectRatio` within the limits selected by MATLAB.
`auto`	`manual`	`auto`	Limits chosen to span data range in all dimensions. `PlotBoxAspectRatio` is modified to achieve the requested `DataAspectRatio` within the limits selected by MATLAB.
`auto`	`manual`	`manual`	Limits chosen to completely fit and center the plot within the requested `PlotBoxAspectRatio` given the requested `DataAspectRatio` (this may produce empty space around 2 of the 3 dimensions).

X-, Y-, Z-Limits	DataAspect Ratio	PlotBox AspectRatio	Behavior
`manual`	`auto`	`auto`	Limits are honored. The `DataAspectRatio` and `PlotBoxAspectRatio` are modified as necessary.
`manual`	`auto`	`manual`	Limits and `PlotBoxAspectRatio` are honored. The `DataAspectRatio` is modified as necessary.
`manual`	`manual`	`auto`	Limits and `DataAspectRatio` are honored. The `PlotBoxAspectRatio` is modified as necessary.
`1 manual` `2 auto`	`manual`	`manual`	The 2 automatic limits are selected to honor the specified aspect ratios and limit. See "Examples."
`2 or 3 manual`	`manual`	`manual`	Limits and `DataAspectRatio` are honored; the `PlotBoxAspectRatio` is ignored.

See “Understanding Axes Aspect Ratio” for more information.

`DataAspectRatioMode`
`{auto} | manual`

User or MATLAB controlled data scaling. This property controls whether the values of the `DataAspectRatio` property are user defined or selected automatically by MATLAB. Setting values for the `DataAspectRatio` property automatically sets this property to `manual`. Changing `DataAspectRatioMode` to `manual` disables the stretch-to-fill behavior if `DataAspectRatioMode`, `PlotBoxAspectRatioMode`, and `CameraViewAngleMode` are all auto.

`DeleteFcn`
functional handle, cell array containing function handle and additional arguments, or string (not recommended)

Delete axes callback function. A callback function that executes when the axes object is deleted (e.g., when you issue a `delete` or `clf` command). MATLAB executes the routine before destroying the object's properties so the callback can query these values.

The handle of the object whose `DeleteFcn` is being executed is passed by MATLAB as the first argument to the callback function and is also accessible through the Root `CallbackObject` property, which can be queried using `gcbo`.

See "Function Handle Callbacks" for information on how to use function handles to define the callback function.

`DrawMode`
`{normal} | fast`

Rendering mode. This property controls the way MATLAB renders graphics objects displayed in the axes when the figure `Renderer` property is `painters`.

- `normal` mode draws objects in back to front ordering based on the current view in order to handle hidden surface elimination and object intersections.
- `fast` mode draws objects in the order in which you specify the drawing commands, without considering the relationships of the objects in three dimensions. This results in faster rendering because it requires no sorting of objects according to location in the view, but can produce undesirable results because it bypasses the hidden surface elimination and object intersection handling provided by `normal DrawMode`.

When the figure `Renderer` is `zbuffer`, `DrawMode` is ignored, and hidden surface elimination and object intersection handling are always provided.

`FontAngle`

`{normal} | italic | oblique`

Select italic or normal font. This property selects the character slant for axes text. `normal` specifies a nonitalic font. `italic` and `oblique` specify italic font.

`FontName`

A name such as `Courier` or the string `FixedWidth`

Font family name. The font family name specifying the font to use for axes labels. To display and print properly, `FontName` must be a font that your system supports. Note that the *x*-, *y*-, and *z*-axis labels are not displayed in a new font until you manually reset them (by setting the `XLabel`, `YLabel`, and `ZLabel` properties or by using the `xlabel`, `ylabel`, or `zlabel` command). Tick mark labels change immediately.

Specifying a Fixed-Width Font

If you want an axes to use a fixed-width font that looks good in any locale, you should set `FontName` to the string `FixedWidth`:

```
set(axes_handle,'FontName','FixedWidth')
```

This eliminates the need to hardcode the name of a fixed-width font, which might not display text properly on systems that do not use ASCII character encoding (such as in Japan, where multibyte character sets are used). A properly written MATLAB application that needs to use a fixed-width font should set `FontName` to `FixedWidth` (note that this string is case sensitive) and rely on `FixedWidthFontName` to be set correctly in the end user's environment.

End users can adapt a MATLAB application to different locales or personal environments by setting the root `FixedWidthFontName` property to the appropriate value for that locale from `startup.m`.

Note that setting the root `FixedWidthFontName` property causes an immediate update of the display to use the new font.

`FontSize`

Font size specified in `FontUnits`

Font size. An integer specifying the font size to use for axes labels and titles, in units determined by the `FontUnits` property. The default point size is 12. The *x*-, *y*-, and *z*-axis text labels are not displayed in a new font size until you manually reset them (by setting the `XLabel`, `YLabel`, or `ZLabel` properties or by using the `xlabel`, `ylabel`, or `zlabel` command). Tick mark labels change immediately.

`FontUnits`

`{points} | normalized | inches | centimeters | pixels`

Units used to interpret the `FontSize` property. When set to `normalized`, MATLAB interprets the value of `FontSize` as a fraction of the height of the axes. For example, a `normalized` `FontSize` of 0.1 sets the text characters to a font whose height is one tenth of the axes' height. The default units (`points`), are equal to 1/72 of an inch.

Note that if you are setting both the `FontSize` and the `FontUnits` in one function call, you must set the `FontUnits` property first so that MATLAB can correctly interpret the specified `FontSize`.

`FontWeight`

`{normal} | bold | light | demi`

Select bold or normal font. The character weight for axes text. The *x*-, *y*-, and *z*-axis text labels are not displayed in bold until you manually reset them (by setting the `XLabel`, `YLabel`, and `ZLabel` properties or by using the `xlabel`, `ylabel`, or `zlabel` commands). Tick mark labels change immediately.

`GridLineStyle`

`- | --| {:} | -.  | none`

Line style used to draw grid lines. The line style is a string consisting of a character, in quotes, specifying solid lines (-), dashed lines (--), dotted lines(`:`), or dash-dot lines (-.). The default grid line style is dotted. To turn on grid lines, use the `grid` command.

`HandleVisibility`

`{on} | callback | off`

Control access to object's handle by command-line users and GUIs. This property determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally drawing into or deleting a figure that contains only user interface devices (such as a dialog box).

Handles are always visible when `HandleVisibility` is `on`.

Setting `HandleVisibility` to `callback` causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from

command-line users, while allowing callback routines to have complete access to object handles.

Setting `HandleVisibility` to `off` makes handles invisible at all times. This may be necessary when a callback routine invokes a function that might potentially damage the GUI (such as evaluating a user-typed string) and so temporarily hides its own handles during the execution of that function.

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the Root's `CurrentFigure` property, objects do not appear in the Root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

You can set the Root `ShowHiddenHandles` property to on to make all handles visible regardless of their `HandleVisibility` settings (this does not affect the values of the `HandleVisibility` properties).

Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

`HitTest`

`{on} | off`

Selectable by mouse click. `HitTest` determines if the axes can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click

on the axes. If `HitTest` is `off`, clicking the axes selects the object below it (which is usually the figure containing it).

`Interruptible`
`{on} | off`

Callback routine interruption mode. The `Interruptible` property controls whether an axes callback routine can be interrupted by subsequently invoked callback routines. Only callback routines defined for the `ButtonDownFcn` are affected by the `Interruptible` property. MATLAB checks for events that can interrupt a callback routine only when it encounters a `drawnow`, `figure`, `getframe`, or `pause` command in the routine. See the `BusyAction` property for related information.

Setting `Interruptible` to `on` allows any graphics object's callback routine to interrupt callback routines originating from an axes property. Note that MATLAB does not save the state of variables or the display (e.g., the handle returned by the `gca` or `gcf` command) when an interruption occurs.

`Layer`
`{bottom} | top`

Draw axis lines below or above graphics objects. This property determines if axis lines and tick marks are drawn on top or below axes children objects for any 2-D view (i.e., when you are looking along the *x*-, *y*-, or *z*-axis). This is useful for placing grid lines and tick marks on top of images.

`LineStyleOrder`
`LineSpec` (default: a solid line '-')

Order of line styles and markers used in a plot. This property specifies which line styles and markers to use and in what order when creating multiple-line plots. For example,

```
set(gca,'LineStyleOrder', '-*|:|o')
```

sets LineStyleOrder to solid line with asterisk marker, dotted line, and hollow circle marker. The default is (-), which specifies a solid line for all data plotted. Alternatively, you can create a cell array of character strings to define the line styles:

```
set(gca,'LineStyleOrder',{'-*',':','o'})
```

MATLAB supports four line styles, which you can specify any number of times in any order. MATLAB cycles through the line styles only after using all colors defined by the ColorOrder property. For example, the first eight lines plotted use the different colors defined by ColorOrder with the first line style. MATLAB then cycles through the colors again, using the second line style specified, and so on.

You can also specify line style and color directly with the plot and plot3 functions or by altering the properties of theline or lineseries objects after creating the graph.

High-Level Functions and LineStyleOrder

Note that, if the axes NextPlot property is set to replace (the default), high-level functions like plot reset the LineStyleOrder property before determining the line style to use. If you want MATLAB to use a LineStyleOrder that is different from the default, set NextPlot to replacechildren.

Specifying a Default LineStyleOrder

You can also specify your own default LineStyleOrder. For example, this statement

```
set(0,'DefaultAxesLineStyleOrder',{'-*',':','o'})
```

creates a default value for the axes LineStyleOrder that is not reset by high-level plotting functions.

`LineWidth`
line width in points

Width of axis lines. This property specifies the width, in points, of the *x*-, *y*-, and *z*-axis lines. The default line width is 0.5 points (1 point = $^1/_{72}$ inch).

`MinorGridLineStyle`
`- | --| {:} | -. | none`

Line style used to draw minor grid lines. The line style is a string consisting of one or more characters, in quotes, specifying solid lines (-), dashed lines (--), dotted lines (:), or dash-dot lines (-.). The default minor grid line style is dotted. To turn on minor grid lines, use the `grid minor` command.

`NextPlot`
`add | {replace} | replacechildren`

Where to draw the next plot. This property determines how high-level plotting functions draw into an existing axes.

- `add` — Use the existing axes to draw graphics objects.
- `replace` — Reset all axes properties except `Position` to their defaults and delete all axes children before displaying graphics (equivalent to `cla reset`).
- `replacechildren` — Remove all child objects, but do not reset axes properties (equivalent to `cla`).

The `newplot` function simplifies the use of the `NextPlot` property and is used by M-file functions that draw graphs using only low-level object creation routines. See the M-file `pcolor.m` for an example. Note that figure graphics objects also have a `NextPlot` property.

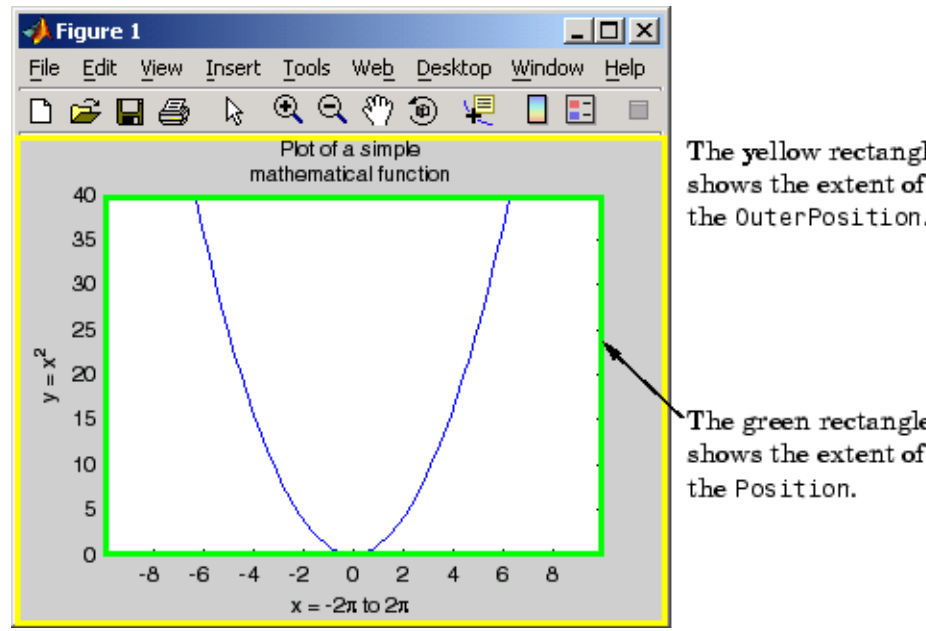
`OuterPosition`
four-element vector

Position of axes including labels, title, and a margin. A four-element vector specifying a rectangle that locates the outer bounds of the axes, including axis labels, the title, and a margin. The vector is defined as follows:

```
[left bottom width height]
```

where `left` and `bottom` define the distance from the lower-left corner of the figure window to the lower-left corner of the rectangle. `width` and `height` are the dimensions of the rectangle

The following picture shows the region defined by the `OuterPosition` enclosed in a yellow rectangle.



When `ActivePositionProperty` is set to `OuterPosition` (the default), none of the text is clipped when you resize the figure.

The default value of `[0 0 1 1]` (normalized units) includes the interior of the figure.

All measurements are in units specified by the `Units` property.

See the `TightInset` property for related information.

See "Automatic Axes Resize" for a discussion of how to use axes positioning properties.

`Parent`
figure or uipanel handle

Axes parent. The handle of the axes' parent object. The parent of an axes object is the figure in which it is displayed or the uipanel object that contains it. The utility function `gcf` returns the handle of the current axes `Parent`. You can reparent axes to other figure or uipanel objects.

See "Objects That Can Contain Other Objects" for more information on parenting graphics objects.

`PlotBoxAspectRatio`
`[px py pz]`

Relative scaling of axes plot box. A three-element vector controlling the relative scaling of the plot box in the *x*, *y*, and *z* directions. The plot box is a box enclosing the axes data region as defined by the *x*-, *y*-, and *z*-axis limits.

Note that the `PlotBoxAspectRatio` property interacts with the `DataAspectRatio`, `XLimMode`, `YLimMode`, and `ZLimMode` properties to control the way graphics objects are displayed in the axes. Setting the `PlotBoxAspectRatio` disables stretch-to-fill behavior, if `DataAspectRatioMode`, `PlotBoxAspectRatioMode`, and `CameraViewAngleMode` are all `auto`.

`PlotBoxAspectRatioMode`
`{auto} | manual`

User or MATLAB controlled axis scaling. This property controls whether the values of the `PlotBoxAspectRatio` property are user defined or selected automatically by MATLAB. Setting values for the `PlotBoxAspectRatio` property automatically sets this property to `manual`. Changing the `PlotBoxAspectRatioMode` to `manual` disables stretch-to-fill behavior if `DataAspectRatioMode`, `PlotBoxAspectRatioMode`, and `CameraViewAngleMode` are all `auto`.

`Position`
four-element vector

Position of axes. A four-element vector specifying a rectangle that locates the axes within its parent container (figure or uipanel). The vector is of the form

```
[left bottom width height]
```

where `left` and `bottom` define the distance from the lower-left corner of the container to the lower-left corner of the rectangle. `width` and `height` are the dimensions of the rectangle. All measurements are in units specified by the `Units` property.

When axes stretch-to-fill behavior is enabled (when `DataAspectRatioMode`, `PlotBoxAspectRatioMode`, and `CameraViewAngleMode` are all `auto`), the axes are stretched to fill the `Position` rectangle. When stretch-to-fill is disabled, the axes are made as large as possible, while obeying all other properties, without extending outside the `Position` rectangle.

See the `OuterPosition` poperty for related information.

See “Automatic Axes Resize” for a discussion of how to use axes positioning properties.

`Projection`
`{orthographic} | perspective`

Type of projection. This property selects between two projection types:

- `orthographic` — This projection maintains the correct relative dimensions of graphics objects with regard to the distance a given point is from the viewer. Parallel lines in the data are drawn parallel on the screen.
- `perspective` — This projection incorporates foreshortening, which allows you to perceive depth in 2-D representations of 3-D objects. Perspective projection does not preserve the relative dimensions of objects; a distant line segment is displayed smaller than a nearer line segment of the same length. Parallel lines in the data may not appear parallel on screen.

`Selected`
`on | {off}`

Is object selected? When you set this property to `on`, MATLAB displays selection "handles" at the corners and midpoints if the `SelectionHighlight` property is also `on` (the default). You can, for example, define the `ButtonDownFcn` callback to set this property to `on`, thereby indicating that the axes has been selected.

`SelectionHighlight`
`{on} | off`

Objects are highlighted when selected. When the `Selected` property is `on`, MATLAB indicates the selected state by drawing four edge handles and four corner handles. When `SelectionHighlight` is `off`, MATLAB does not draw the handles.

`Tag`
string

User-specified object label. The `Tag` property provides a means to identify graphics objects with a user-specified label. This is particularly useful when you are constructing interactive graphics programs that would otherwise need to define object handles as global variables or pass them as arguments between callback routines.

For example, suppose you want to direct all graphics output from an M-file to a particular axes, regardless of user actions that may have changed the current axes. To do this, identify the axes with a `Tag`:

```
axes('Tag','Special Axes')
```

Then make that axes the current axes before drawing by searching for the `Tag` with `findobj`:

```
axes(findobj('Tag','Special Axes'))
```

`TickDir`

```
in | out
```

Direction of tick marks. For 2-D views, the default is to direct tick marks inward from the axis lines; 3-D views direct tick marks outward from the axis line.

`TickDirMode`

```
{auto} | manual
```

Automatic tick direction control. In `auto` mode, MATLAB directs tick marks inward for 2-D views and outward for 3-D views. When you specify a setting for `TickDir`, MATLAB sets `TickDirMode` to `manual`. In `manual` mode, MATLAB does not change the specified tick direction.

`TickLength`

```
[2DLength 3DLength]
```

Length of tick marks. A two-element vector specifying the length of axes tick marks. The first element is the length of tick marks used for 2-D views and the second element is the length of tick marks used for 3-D views. Specify tick mark lengths in units normalized relative to the longest of the visible X-, Y-, or Z-axis annotation lines.

`TightInset`
[left bottom right top] Read only

Margins added to Position to include text labels. The values of this property are the distances between the bounds of the `Position` property and the extent of the axes text labels and title. When added to the `Position` width and height values, the `TightInset` defines the tightest bounding box that encloses the axes and it's labels and title.

See "Automatic Axes Resize" for more information.

`Title`
handle of text object

Axes title. The handle of the `text` object that is used for the axes title. You can use this handle to change the properties of the title text or you can set `Title` to the handle of an existing text object. For example, the following statement changes the color of the current title to red:

```
set(get(gca,'Title'),'Color','r')
```

To create a new title, set this property to the handle of the text object you want to use:

```
set(gca,'Title',text('String','New Title','Color','r'))
```

However, it is generally simpler to use the `title` command to create or replace an axes title:

```
title('New Title','Color','r') % Make text color red
```

```
title({'This title','has 2 lines'}) % Two line title
```

`Type`
string (read only)

Type of graphics object. This property contains a string that identifies the class of graphics object. For axes objects, `Type` is always set to `'axes'`.

`UIContextMenu`
handle of a uicontextmenu object

Associate a context menu with the axes. Assign this property the handle of a uicontextmenu object created in the axes' parent figure. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the axes.

`Units`
`inches | centimeters | {normalized} | points | pixels | characters`

Axes position units. The units used to interpret the `Position` property. All units are measured from the lower left corner of the figure window.

Note The `Units` property controls the positioning of the axes within the figure. This property does not affect the data units used for graphing. See the axes XLim, YLim, and ZLim properties to set the limits of each axis data units.

- `normalized` units map the lower left corner of the figure window to (0,0) and the upper right corner to (1.0, 1.0).
- `inches`, `centimeters`, and `points` are absolute units (one point equals $^1/_{72}$ of an inch).

- `Character` units are defined by characters from the default system font; the width of one character is the width of the letter x, and the height of one character is the distance between the baselines of two lines of text.

When specifying the units as property/value pairs during object creation, you must set the `Units` property before specifying the properties that you want to use these units.

`UserData`
matrix

User-specified data. This property can be any data you want to associate with the axes object. The axes does not use this property, but you can access it using the `set` and `get` functions.

`View`
Obsolete

The functionality provided by the `View` property is now controlled by the axes camera properties — `CameraPosition`, `CameraTarget`, `CameraUpVector`, and `CameraViewAngle`. See the `view` command.

`Visible`
`{on} | off`

Visibility of axes. By default, axes are visible. Setting this property to `off` prevents axis lines, tick marks, and labels from being displayed. The `Visible` property does not affect children of axes.

`XAxisLocation`
`top | {bottom}`

Location of x-axis tick marks and labels. This property controls where MATLAB displays the *x*-axis tick marks and labels. Setting this property to `top` moves the *x*-axis to the top of the plot from its default position at the bottom. This property applies to 2–D views only.

`YAxisLocation`
`right | {left}`

Location of y-axis tick marks and labels. This property controls where MATLAB displays the *y*-axis tick marks and labels. Setting this property to `right` moves the *y*-axis to the right side of the plot from its default position on the left side. This property applies to 2–D views only. See the `plotyy` function for a simple way to use two *y*-axes.

Properties That Control the X-, Y-, or Z-Axis

`XColor`
`YColor`
`ZColor`
`ColorSpec`

Color of axis lines. A three-element vector specifying an RGB triple, or a predefined MATLAB color string. This property determines the color of the axis lines, tick marks, tick mark labels, and the axis grid lines of the respective *x*-, *y*-, and *z*-axis. The default color axis color is black. See`ColorSpec` for details on specifying colors.

`XDir`
`YDir`
`ZDir`
`{normal} | reverse`

Direction of increasing values. A mode controlling the direction of increasing axis values. Axes form a right-hand coordinate system. By default,

- *x*-axis values increase from left to right. To reverse the direction of increasing *x* values, set this property to `reverse`.

```
set(gca,'XDir','reverse')
```

- *y*-axis values increase from bottom to top (2-D view) or front to back (3-D view). To reverse the direction of increasing *y* values, set this property to `reverse`.

  ```
  set(gca,'YDir','reverse')
  ```

- *z*-axis values increase pointing out of the screen (2-D view) or from bottom to top (3-D view). To reverse the direction of increasing *z* values, set this property to `reverse`.

  ```
  set(gca,'ZDir','reverse')
  ```

`XGrid`
`YGrid`
`ZGrid`

`on | {off}`

Axis gridline mode. When you set any of these properties to `on`, MATLAB draws grid lines perpendicular to the respective axis (i.e., along lines of constant *x*, *y*, or *z* values). Use the `grid` command to set all three properties `on` or `off` at once.

```
set(gca,'XGrid','on')
```

`XLabel`
`YLabel`
`ZLabel`

handle of text object

Axis labels. The handle of the `text` object used to label the *x*-, *y*-, or *z*-axis, respectively. To assign values to any of these properties, you must obtain the handle to the text string you want to use as a label. This statement defines a text object and assigns its handle to the `XLabel` property:

```
set(get(gca,'XLabel'),'String','axis label')
```

MATLAB places the string `'axis label'` appropriately for an *x*-axis label. Any text object whose handle you specify as an `XLabel`, `YLabel`, or `ZLabel` property is moved to the appropriate location for the respective label.

Alternatively, you can use the `xlabel`, `ylabel`, and `zlabel` functions, which generally provide a simpler means to label axis lines.

Note that using a bitmapped font (e.g., Courier is usually a bitmapped font) might cause the labels to be rotated improperly. As a workaround, use a TrueType font (e.g., Courier New) for axis labels. See your system documentation to determine the types of fonts installed on your system.

`XLim`
`YLim`
`ZLim`

```
[minimum maximum]
```

Axis limits. A two-element vector specifying the minimum and maximum values of the respective axis. These values are determined by the data you are plotting.

Changing these properties affects the scale of the *x*-, *y*-, or *z*-dimension as well as the placement of labels and tick marks on the axis. The default values for these properties are [0 1].

See the `axis`, `datetick`, `xlim`, `ylim`, and `zlim` commands to set these properties.

`XLimMode`
`YLimMode`
`ZLimMode`

```
{auto} | manual
```

MATLAB or user-controlled limits. The axis limits mode determines whether MATLAB calculates axis limits based on the

data plotted (i.e., the `XData`, `YData`, or `ZData` of the axes children) or uses the values explicitly set with the `XLim`, `YLim`, or `ZLim` property, in which case, the respective limits mode is set to `manual`.

`XMinorGrid`
`YMinorGrid`
`ZMinorGrid`

`on | {off}`

Enable or disable minor gridlines. When set to `on`, MATLAB draws gridlines aligned with the minor tick marks of the respective axis. Note that you do not have to enable minor ticks to display minor grids.

`XMinorTick`
`YMinorTick`
`ZMinorTick`

`on | {off}`

Enable or disable minor tick marks. When set to `on`, MATLAB draws tick marks between the major tick marks of the respective axis. MATLAB automatically determines the number of minor ticks based on the space between the major ticks.

`XScale`
`YScale`
`ZScale`

`{linear} | log`

Axis scaling. Linear or logarithmic scaling for the respective axis. See also `loglog`, `semilogx`, and `semilogy`.

`XTick`
`YTick`
`ZTick`

vector of data values locating tick marks

Tick spacing. A vector of *x*-, *y*-, or *z*-data values that determine the location of tick marks along the respective axis. If you do

not want tick marks displayed, set the respective property to the empty vector, [ ]. These vectors must contain monotonically increasing values.

`XTickLabel`
`YTickLabel`
`ZTickLabel`
string

Tick labels. A matrix of strings to use as labels for tick marks along the respective axis. These labels replace the numeric labels generated by MATLAB. If you do not specify enough text labels for all the tick marks, MATLAB uses all of the labels specified, then reuses the specified labels.

For example, the statement

```
set(gca,'XTickLabel',{'One';'Two';'Three';'Four'})
```

labels the first four tick marks on the *x*-axis and then reuses the labels until all ticks are labeled.

Labels can be specified as cell arrays of strings, padded string matrices, string vectors separated by vertical slash characters, or as numeric vectors (where each number is implicitly converted to the equivalent string using `num2str`). All of the following are equivalent:

```
set(gca,'XTickLabel',{'1';'10';'100'})
set(gca,'XTickLabel','1|10|100')
set(gca,'XTickLabel',[1;10;100])
set(gca,'XTickLabel',['1  ';'10 ';'100'])
```

Note that tick labels do not interpret TeX character sequences (however, the `Title`, `XLabel`, `YLabel`, and `ZLabel` properties do).

`XTickMode`
`YTickMode`
`ZTickMode`
`{auto} | manual`

MATLAB or user-controlled tick spacing. The axis tick modes determine whether MATLAB calculates the tick mark spacing based on the range of data for the respective axis (`auto` mode) or uses the values explicitly set for any of the `XTick`, `YTick`, and `ZTick` properties (`manual` mode). Setting values for the `XTick`, `YTick`, or `ZTick` properties sets the respective axis tick mode to `manual`.

`XTickLabelMode`
`YTickLabelMode`
`ZTickLabelMode`
`{auto} | manual`

MATLAB or user-determined tick labels. The axis tick mark labeling mode determines whether MATLAB uses numeric tick mark labels that span the range of the plotted data (`auto` mode) or uses the tick mark labels specified with the `XTickLabel`, `YTickLabel`, or `ZTickLabel` property (`manual` mode). Setting values for the `XTickLabel`, `YTickLabel`, or `ZTickLabel` property sets the respective axis tick label mode to `manual`.

Purpose

Axis scaling and appearance

Syntax

```
axis([xmin xmax ymin ymax])
axis([xmin xmax ymin ymax zmin zmax cmin cmax])
v = axis
axis auto
axis manual
axis tight
axis fill
axis ij
axis xy
axis equal
axis image
axis square
axis vis3d
axis normal
axis off
axis on
axis(axes_handles,...)
[mode,visibility,direction] = axis('state')
```

Description

`axis` manipulates commonly used axes properties. (See Algorithm section.)

`axis([xmin xmax ymin ymax])` sets the limits for the *x*- and *y*-axis of the current axes.

`axis([xmin xmax ymin ymax zmin zmax cmin cmax])` sets the *x*-, *y*-, and *z*-axis limits and the color scaling limits (see `caxis`) of the current axes.

`v = axis` returns a row vector containing scaling factors for the *x*-, *y*-, and *z*-axis. `v` has four or six components depending on whether the current axes is 2-D or 3-D, respectively. The returned values are the current axes `XLim`, `Ylim`, and `ZLim` properties.

`axis auto` sets MATLAB to its default behavior of computing the current axes limits automatically, based on the minimum and maximum values of *x*, *y*, and *z* data. You can restrict this automatic behavior to

a specific axis. For example, `axis 'auto x'` computes only the *x*-axis limits automatically; `axis 'auto yz'` computes the *y*- and *z*-axis limits automatically.

`axis manual` and axis(axis) freezes the scaling at the current limits, so that if `hold` is `on`, subsequent plots use the same limits. This sets the `XLimMode`, `YLimMode`, and `ZLimMode` properties to `manual`.

`axis tight` sets the axis limits to the range of the data.

`axis fill` sets the axis limits and `PlotBoxAspectRatio` so that the axes fill the position rectangle. This option has an effect only if `PlotBoxAspectRatioMode` or `DataAspectRatioMode` is `manual`.

`axis ij` places the coordinate system origin in the upper left corner. The *i*-axis is vertical, with values increasing from top to bottom. The *j*-axis is horizontal with values increasing from left to right.

`axis xy` draws the graph in the default Cartesian axes format with the coordinate system origin in the lower left corner. The *x*-axis is horizontal with values increasing from left to right. The *y*-axis is vertical with values increasing from bottom to top.

`axis equal` sets the aspect ratio so that the data units are the same in every direction. The aspect ratio of the *x*-, *y*-, and *z*-axis is adjusted automatically according to the range of data units in the *x*, *y*, and *z* directions.

`axis image` is the same as `axis equal` except that the plot box fits tightly around the data.

`axis square` makes the current axes region square (or cubed when three-dimensional). MATLAB adjusts the *x*-axis, *y*-axis, and *z*-axis so that they have equal lengths and adjusts the increments between data units accordingly.

`axis vis3d` freezes aspect ratio properties to enable rotation of 3-D objects and overrides stretch-to-fill.

`axis normal` automatically adjusts the aspect ratio of the axes and the relative scaling of the data units so that the plot fits the figure's shape as well as possible.

`axis off` turns off all axis lines, tick marks, and labels.

`axis on` turns on all axis lines, tick marks, and labels.

`axis(axes_handles,...)` applies the `axis` command to the specified axes. For example, the following statements

```
h1 = subplot(221);
h2 = subplot(222);
axis([h1 h2],'square')
```

set both axes to `square`.

`[mode,visibility,direction] = axis('state')` returns three strings indicating the current setting of axes properties:

Output Argument	Strings Returned
`mode`	`'auto' | 'manual'`
`visibility`	`'on' | 'off'`
`direction`	`'xy' | 'ij'`

`mode` is `auto` if `XLimMode`, `YLimMode`, and `ZLimMode` are all set to `auto`. If `XLimMode`, `YLimMode`, or `ZLimMode` is `manual`, `mode` is `manual`.

Keywords to `axis` can be combined, separated by a space (e.g., `axis tight equal`). These are evaluated from left to right, so subsequent keywords can overwrite properties set by prior ones.

Remarks

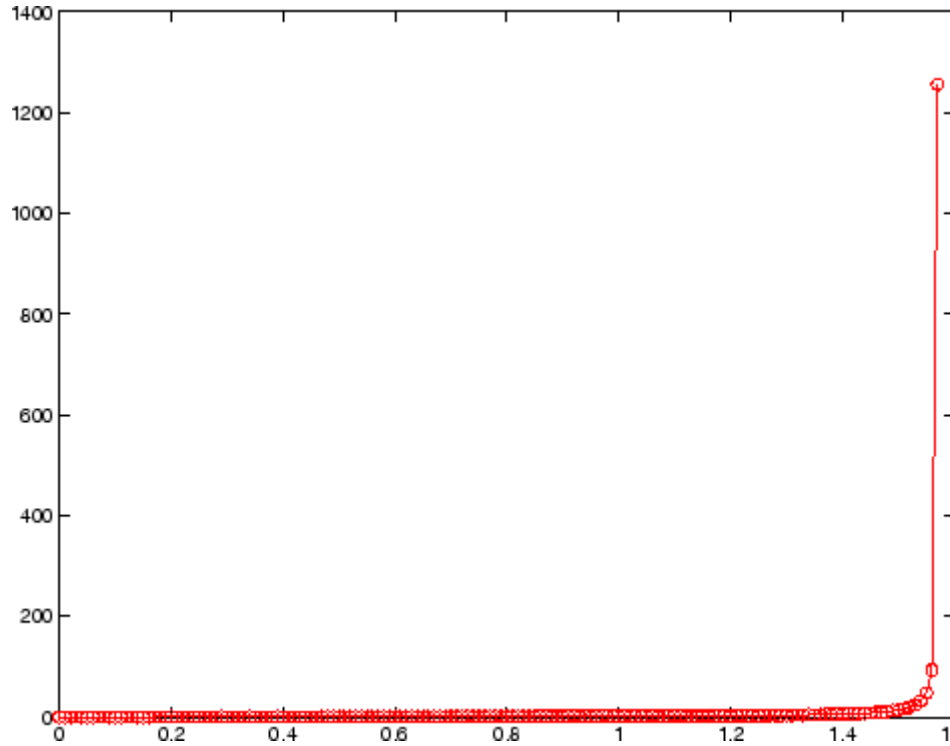
You can create an axes (and a figure for it) if none exists with the `axis` command. However, if you specify non-default limits or formatting for the axes when doing this, such as `[4 8 2 9]`, `square`, `equal`, or `image`, the property is ignored because there are no axis limits to adjust in the absence of plotted data. To use `axis` in this manner, you can set `hold on` to keep preset axes limits from being overridden.

Examples

The statements

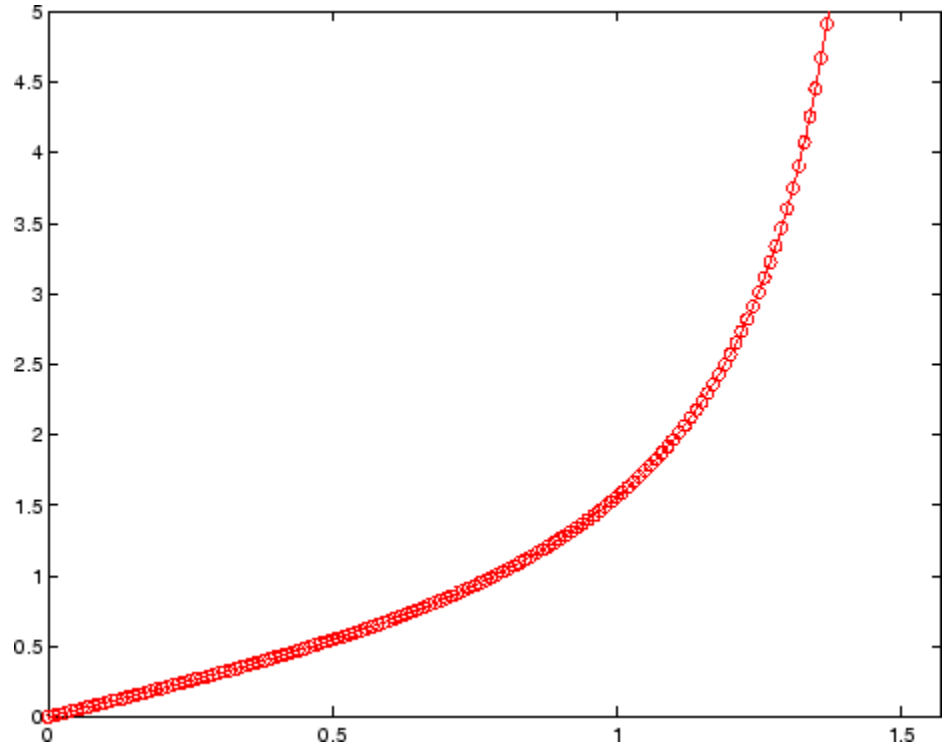
```
x = 0:.025:pi/2;
plot(x,tan(x),'-ro')
```

use the automatic scaling of the *y*-axis based on `ymax = tan(1.57)`, which is well over 1000:



The right figure shows a more satisfactory plot after typing

```
axis([0  pi/2  0  5])
```



Algorithm

When you specify minimum and maximum values for the *x*-, *y*-, and *z*-axes, `axis` sets the `XLim`, `Ylim`, and `ZLim` properties for the current axes to the respective minimum and maximum values in the argument list. Additionally, the `XLimMode`, `YLimMode`, and `ZLimMode` properties for the current axes are set to `manual`.

`axis auto` sets the current axes `XLimMode`, `YLimMode`, and `ZLimMode` properties to `'auto'`.

`axis manual` sets the current axes `XLimMode`, `YLimMode`, and `ZLimMode` properties to `'manual'`.

The following table shows the values of the axes properties set by `axis equal`, `axis normal`, `axis square`, and `axis image`.

Axes Property or Behavior	axis equal	axis normal	axis square	axis image
`DataAspectRatio` property	`[1 1 1]`	`not set`	`not set`	`[1 1 1]`
`DataAspectRatioMode` property	`manual`	`auto`	`auto`	`manual`
`PlotBoxAspectRatio` property	`[3 4 4]`	`not set`	`[1 1 1]`	`auto`
`PlotBoxAspectRatioMode` property	`manual`	`auto`	`manual`	`auto`
Stretch-to-fill behavior;	`disabled`	`active`	`disabled`	`disabled`

Purpose

Diagonal scaling to improve eigenvalue accuracy

Syntax

```
[T,B] = balance(A)
[S,P,B] = balance(A)
B = balance(A)
B = balance(A,'noperm')
```

Description

`[T,B] = balance(A)` returns a similarity transformation `T` such that `B = T\A*T`, and `B` has, as nearly as possible, approximately equal row and column norms. `T` is a permutation of a diagonal matrix whose elements are integer powers of two to prevent the introduction of roundoff error. If `A` is symmetric, then `B == A` and `T` is the identity matrix.

`[S,P,B] = balance(A)` returns the scaling vector `S` and the permutation vector `P` separately. The transformation `T` and balanced matrix `B` are obtained from `A`, `S`, and `P` by `T(:,P) = diag(S)` and `B(P,P) = diag(1./S)*A*diag(S)`.

`B = balance(A)` returns just the balanced matrix `B`.

`B = balance(A,'noperm')` scales `A` without permuting its rows and columns.

Remarks

Nonsymmetric matrices can have poorly conditioned eigenvalues. Small perturbations in the matrix, such as roundoff errors, can lead to large perturbations in the eigenvalues. The condition number of the eigenvector matrix,

```
cond(V) = norm(V)*norm(inv(V))
```

where

```
[V,T] = eig(A)
```

relates the size of the matrix perturbation to the size of the eigenvalue perturbation. Note that the condition number of `A` itself is irrelevant to the eigenvalue problem.

Balancing is an attempt to concentrate any ill conditioning of the eigenvector matrix into a diagonal scaling. Balancing usually cannot turn a nonsymmetric matrix into a symmetric matrix; it only attempts to make the norm of each row equal to the norm of the corresponding column.

Note The MATLAB eigenvalue function, `eig(A)`, automatically balances `A` before computing its eigenvalues. Turn off the balancing with `eig(A,'nobalance')`.

Examples

This example shows the basic idea. The matrix `A` has large elements in the upper right and small elements in the lower left. It is far from being symmetric.

```
A = [1  100  10000; .01  1  100; .0001  .01  1]
A =
   1.0e+04 *
    0.0001    0.0100    1.0000
    0.0000    0.0001    0.0100
    0.0000    0.0000    0.0001
```

Balancing produces a diagonal matrix `T` with elements that are powers of two and a balanced matrix `B` that is closer to symmetric than `A`.

```
[T,B] = balance(A)
T =
   1.0e+03 *
    2.0480         0         0
         0    0.0320         0
         0         0    0.0003
B =
    1.0000    1.5625    1.2207
    0.6400    1.0000    0.7813
    0.8192    1.2800    1.0000
```

To see the effect on eigenvectors, first compute the eigenvectors of A, shown here as the columns of V.

```
[V,E] = eig(A); V
V =
   -1.0000    0.9999    0.9937
    0.0050    0.0100   -0.1120
    0.0000    0.0001    0.0010
```

Note that all three vectors have the first component the largest. This indicates V is badly conditioned; in fact cond(V) is 8.7766e+003. Next, look at the eigenvectors of B.

```
[V,E] = eig(B); V
V =
   -0.8873    0.6933    0.0898
    0.2839    0.4437   -0.6482
    0.3634    0.5679   -0.7561
```

Now the eigenvectors are well behaved and cond(V) is 1.4421. The ill conditioning is concentrated in the scaling matrix; cond(T) is 8192.

This example is small and not really badly scaled, so the computed eigenvalues of A and B agree within roundoff error; balancing has little effect on the computed results.

Algorithm

Inputs of Type Double

For inputs of type double, balance uses the linear algebra package (LAPACK) routines DGEBAL (real) and ZGEBAL (complex). If you request the output T, balance also uses the LAPACK routines DGEBAK (real) and ZGEBAK (complex).

Inputs of Type Single

For inputs of type single, balance uses the LAPACK routines SGEBAL (real) and CGEBAL (complex). If you request the output T, balance also uses the LAPACK routines SGEBAK (real) and CGEBAK (complex).

Limitations

Balancing can destroy the properties of certain matrices; use it with some care. If a matrix contains small elements that are due to roundoff error, balancing might scale them up to make them as significant as the other elements of the original matrix.

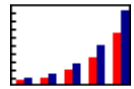
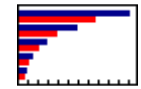
Purpose

Plot bar graph (vertical and horizontal)





GUI Alternatives

To graph selected variables, use the Plot Selector  in the Workspace Browser, or use the Figure Palette Plot Catalog. Manipulate graphs in *plot edit* mode with the Property Editor. For details, see "Plotting Tools — Interactive Plotting" in the MATLAB Graphics documentation and "Creating Plots from the Workspace Browser" in the MATLAB Desktop Tools documentation.

Syntax

```
bar(Y)
bar(x,Y)
bar(...,width)
bar(...,'style')
bar(...,'bar_color')
bar(axes_handle,...)
barh(axes_handle,...)
h = bar(...)
barh(...)
h = barh(...)
hpatches = bar('v6',...)
hpatches = barh('v6',...)
```

Description

A bar graph displays the values in a vector or matrix as horizontal or vertical bars.

`bar(Y)` draws one bar for each element in `Y`. If `Y` is a matrix, `bar` groups the bars produced by the elements in each row. The *x*-axis scale ranges from 1 up to `length(Y)` when `Y` is a vector, and `1` to `size(Y,1)`, which is the number of rows, when `Y` is a matrix. The default is to scale the *x*-axis to the highest x-tick on the plot, (a multiple of 10, 100, etc.). If you want the *x*-axis scale to end exactly at the last bar, you can use the default, and then, for example, type

```
set(gca,'xlim',[1 length(Y)])
```

at the MATLAB prompt.

`bar(x,Y)` draws a bar for each element in `Y` at locations specified in `x`, where `x` is a vector defining the *x*-axis intervals for the vertical bars. The *x*-values can be nonmonotonic, but cannot contain duplicate values. If `Y` is a matrix, `bar` groups the elements of each row in `Y` at corresponding locations in `x`.

`bar(...,width)` sets the relative bar width and controls the separation of bars within a group. The default `width` is `0.8`, so if you do not specify `x`, the bars within a group have a slight separation. If `width` is `1`, the bars within a group touch one another.

`bar(...,'style')` specifies the style of the bars. `'style'` is `'grouped'` or `'stacked'`. `'group'` is the default mode of display.

- `'grouped'` displays *m* groups of *n* vertical bars, where *m* is the number of rows and *n* is the number of columns in `Y`. The group contains one bar per column in `Y`.
- `'stacked'` displays one bar for each row in `Y`. The bar height is the sum of the elements in the row. Each bar is multicolored, with colors corresponding to distinct elements and showing the relative contribution each row element makes to the total sum.

`bar(...,'bar_color')` displays all bars using the color specified by the single-letter abbreviation `'r'`, `'g'`, `'b'`, `'c'`, `'m'`, `'y'`, `'k'`, or `'w'`.

`bar(axes_handle,...)` and `barh(axes_handle,...)` plot into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = bar(...)` returns a vector of handles to barseries graphics objects, one for each created. When `Y` is a matrix, `bar` creates one barseries graphics object per column in `Y`.

`barh(...)` and `h = barh(...)` create horizontal bars. `Y` determines the bar length. The vector `x` is a vector defining the *y*-axis intervals for horizontal bars. The *x*-values can be nonmonotonic, but cannot contain duplicate values.

Backward-Compatible Versions

`hpatches = bar('v6',...)` and `hpatches = barh('v6',...)` return the handles of patch objects instead of barseries objects for compatibility with MATLAB 6.5 and earlier. See patch object properties for a discussion of the properties you can set to control the appearance of these bar graphs.

Note The `v6` option enables users of Version 7.x of MATLAB to create FIG-files that previous versions can open. It is obsolete and will be removed in a future version of MATLAB.

See

Plot Objects and Backward Compatibility for more information.

Barseries Objects

Creating a bar graph of an *m*-by-*n* matrix creates *m* groups of *n* barseries objects. Each barseries object contains the data for corresponding `x` values of each bar group (as indicated by the coloring of the bars).

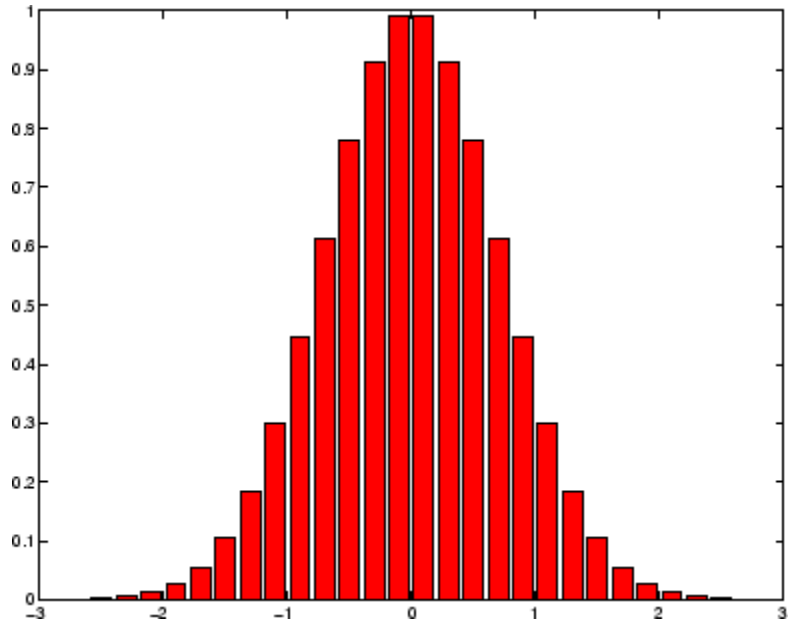
Note that some barseries object properties set on an individual barseries object set the values for all barseries objects in the graph. See the barseries property descriptions for information on specific properties.

Examples

Single Series of Data

This example plots a bell-shaped curve as a bar graph and sets the colors of the bars to red.

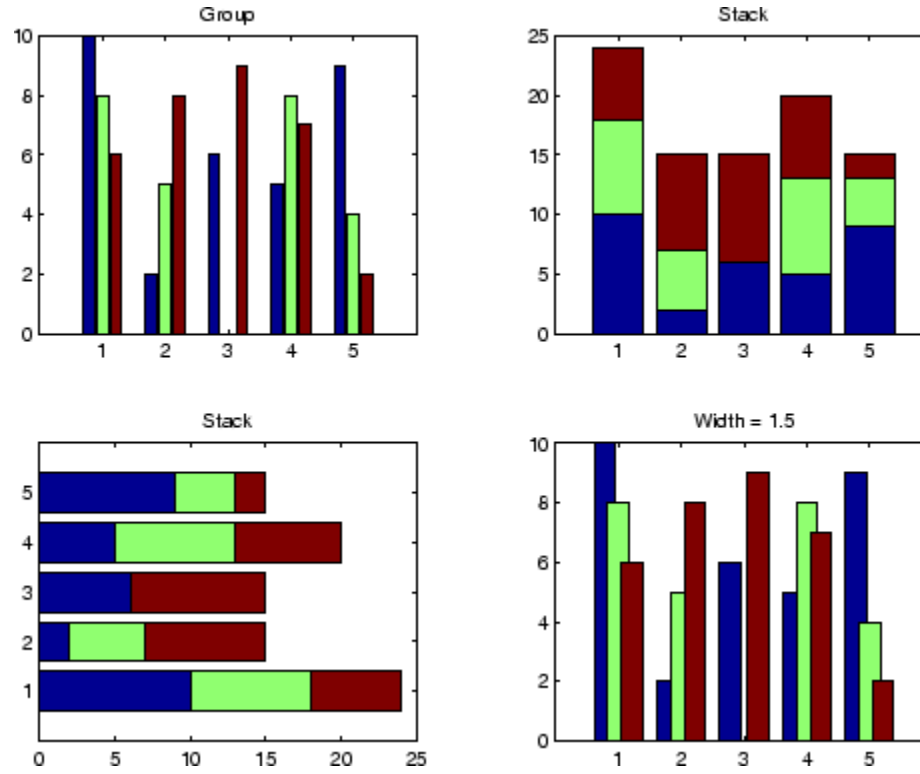
```
x = -2.9:0.2:2.9;
bar(x,exp(-x.*x),'r')
```



Bar Graph Options

This example illustrates some bar graph options.

```
Y = round(rand(5,3)*10);
subplot(2,2,1)
bar(Y,'group')
title 'Group'
subplot(2,2,2)
bar(Y,'stack')
title 'Stack'
subplot(2,2,3)
barh(Y,'stack')
title 'Stack'
subplot(2,2,4)
bar(Y,1.5)
title 'Width = 1.5'
```



Setting Properties with Multiobject Graphs

This example creates a graph that displays three groups of bars and contains five barseries objects. Since all barseries objects in a graph share the same baseline, you can set values using any barseries object's `BaseLine` property. This example uses the first handle returned in `h`.

```
Y = randn(3,5);
h = bar(Y);
set(get(h(1),'BaseLine'),'LineWidth',2,'LineStyle',':')
colormap summer % Change the color scheme
```

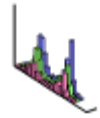
`Barseries Properties`

“Bar and Area Graphs” for more examples

Purpose

Plot 3-D bar chart



GUI Alternatives

To graph selected variables, use the Plot Selector  in the Workspace Browser, or use the Figure Palette Plot Catalog. Manipulate graphs in *plot edit* mode with the Property Editor. For details, see "Plotting Tools — Interactive Plotting" in the MATLAB Graphics documentation and "Creating Graphics from the Workspace Browser" in the MATLAB Desktop Tools documentation.

Syntax

```
bar3(Y)
bar3(x,Y)
bar3(...,width)
bar3(...,'style')
bar3(...,LineSpec)
bar3(axes_handle,...)
h = bar3(...)
bar3h(...)
h = bar3h(...)
```

Description

`bar3` and `bar3h` draw three-dimensional vertical and horizontal bar charts.

`bar3(Y)` draws a three-dimensional bar chart, where each element in `Y` corresponds to one bar. When `Y` is a vector, the *x*-axis scale ranges from `1` to `length(Y)`. When `Y` is a matrix, the *x*-axis scale ranges from `1` to `size(Y,2)`, which is the number of columns, and the elements in each row are grouped together.

`bar3(x,Y)` draws a bar chart of the elements in `Y` at the locations specified in `x`, where `x` is a vector defining the *y*-axis intervals for vertical bars. The *x*-values can be nonmonotonic, but cannot contain duplicate values. If `Y` is a matrix, `bar3` clusters elements from the

same row in `Y` at locations corresponding to an element in `x`. Values of elements in each row are grouped together.

`bar3(...,width)` sets the width of the bars and controls the separation of bars within a group. The default `width` is `0.8`, so if you do not specify `x`, bars within a group have a slight separation. If `width` is `1`, the bars within a group touch one another.

`bar3(...,'style')` specifies the style of the bars. `'style'` is `'detached'`, `'grouped'`, or `'stacked'`. `'detached'` is the default mode of display.

- `'detached'` displays the elements of each row in `Y` as separate blocks behind one another in the *x* direction.
- `'grouped'` displays *n* groups of *m* vertical bars, where *n* is the number of rows and *m* is the number of columns in `Y`. The group contains one bar per column in `Y`.
- `'stacked'` displays one bar for each row in `Y`. The bar height is the sum of the elements in the row. Each bar is multicolored, with colors corresponding to distinct elements and showing the relative contribution each row element makes to the total sum.

`bar3(...,LineSpec)` displays all bars using the color specified by `LineSpec`.

`bar3(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

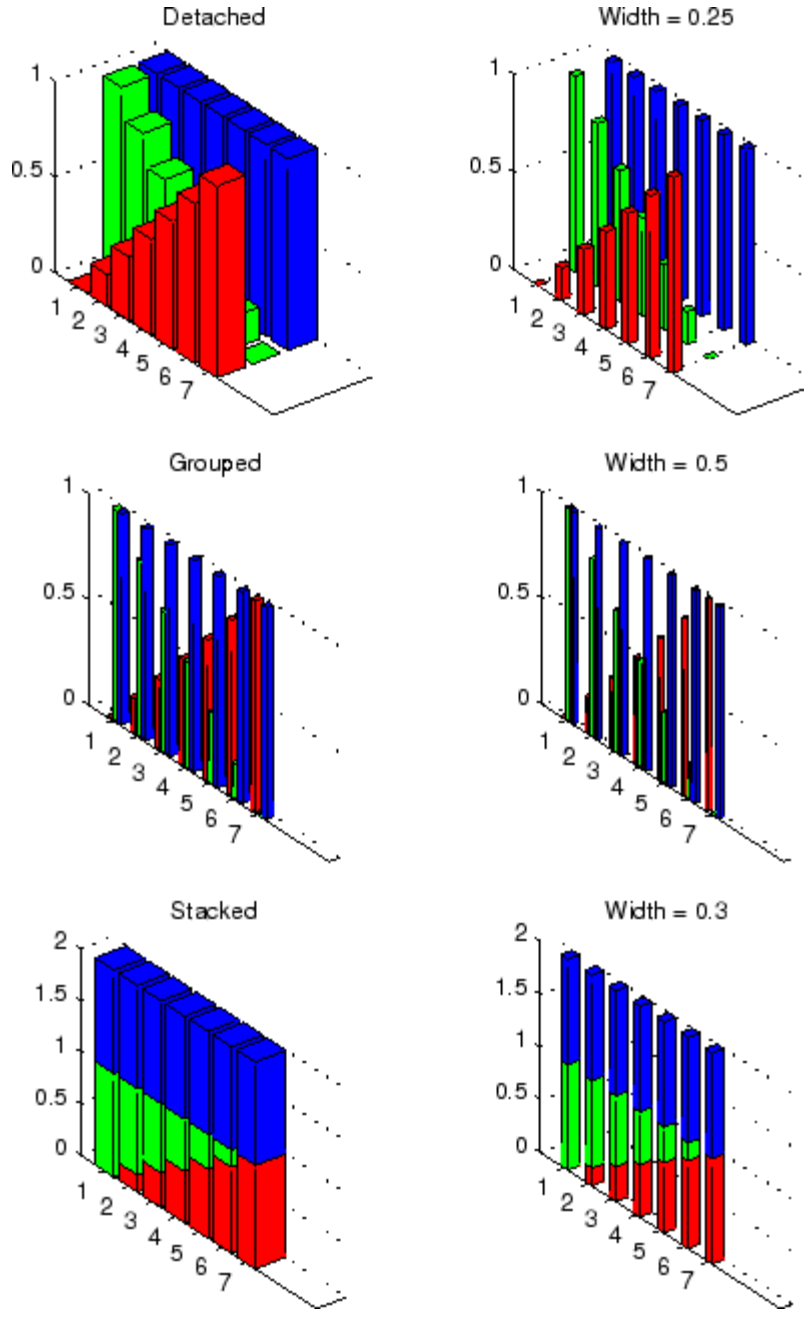
`h = bar3(...)` returns a vector of handles to patch graphics objects, one for each created. `bar3` creates one patch object per column in `Y`. When `Y` is a matrix, `bar3` creates one patch graphics object per column in `Y`.

`bar3h(...)` and `h = bar3h(...)` create horizontal bars. `Y` determines the bar length. The vector `x` is a vector defining the *y*-axis intervals for horizontal bars.

Examples

This example creates six subplots showing the effects of different arguments for `bar3`. The data `Y` is a 7-by-3 matrix generated using the `cool` colormap:

```
Y = cool(7);
subplot(3,2,1)
bar3(Y,'detached')
title('Detached')
subplot(3,2,2)
bar3(Y,0.25,'detached')
title('Width = 0.25')
subplot(3,2,3)
bar3(Y,'grouped')
title('Grouped')
subplot(3,2,4)
bar3(Y,0.5,'grouped')
title('Width = 0.5')
subplot(3,2,5)
bar3(Y,'stacked')
title('Stacked')
subplot(3,2,6)
bar3(Y,0.3,'stacked')
title('Width = 0.3')
colormap([1 0 0;0 1 0;0 0 1])
```



Detached
Width = 0.25
Grouped
Width = 0.5
Stacked
Width = 0.3

Barseries Properties

Purpose

Define barseries properties

Modifying Properties

You can set and query graphics object properties using the `set` and `get` commands or the Property Editor (`propertyeditor`).

Note that you cannot define default properties for barseries objects.

See “Plot Objects” for more information on barseries objects.

Barseries Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

`Annotation`

`hg.Annotation` object Read Only

Control the display of barseries objects in legends. The `Annotation` property enables you to specify whether this barseries object is represented in a figure legend.

Querying the `Annotation` property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the barseries object is displayed in a figure legend:

IconDisplayStyle Value	Purpose
`on`	Include the barseries object in a legend as one entry, but not its children objects
`off`	Do not include the barseries or its children in a legend (default)
`children`	Include only the children of the barseries as separate entries in the legend

Setting the `IconDisplayStyle` property

These commands set the `IconDisplayStyle` of a graphics object with handle `hobj` to `children`, which causes each child object to have an entry in the legend:

```
hAnnotation = get(hobj,'Annotation');
hLegendEntry = get(hAnnotation','LegendInformation');
set(hLegendEntry,'IconDisplayStyle','children')
```

Using the `IconDisplayStyle` property

See “Controlling Legends” for more information and examples.

`BarLayout`

`{grouped} | stacked`

Specify grouped or stacked bars. Grouped bars display *m* groups of *n* vertical bars, where *m* is the number of rows and *n* is the number of columns in the input argument `Y`. The group contains one bar per column in `Y`.

Stacked bars display one bar for each row in the input argument `Y`. The bar height is the sum of the elements in the row. Each bar is multicolored, with colors corresponding to distinct elements and showing the relative contribution each row element makes to the total sum.

`BarWidth`

scalar in range [0 1]

Width of individual bars. `BarWidth` specifies the relative bar width and controls the separation of bars within a group. The default `width` is `0.8`, so if you do not specify `x`, the bars within a group have a slight separation. If `width` is `1`, the bars within a group touch one another.

`BaseLine`

handle of baseline

Handle of the baseline object. This property contains the handle of the line object used as the baseline. You can set the properties of this line using its handle. For example, the following statements create a bar graph, obtain the handle of the baseline from the barseries object, and then set line properties that make the baseline a dashed, red line.

```
bar_handle = bar(randn(10,1));
baseline_handle = get(bar_handle,'BaseLine');
set(baseline_handle,'LineStyle','--','Color','red')
```

`BaseValue`
double: *y*-axis value

Value where baseline is drawn. You can specify the value along the *y*-axis (vertical bars) or *x*-axis (horizontal bars) at which MATLAB draws the baseline.

`BeingDeleted`
`on | {off}` Read Only

This object is being deleted. The `BeingDeleted` property provides a mechanism that you can use to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object's delete function might call other functions that act on a number of different objects. These functions might not need to perform actions on objects if the objects are going to be deleted, and therefore, can check the object's `BeingDeleted` property before acting.

`BusyAction`
`cancel | {queue}`

Callback routine interruption. The `BusyAction` property enables you to control how MATLAB handles events that potentially interrupt executing callbacks. If there is a callback function executing, callbacks invoked subsequently always attempt to interrupt it.

If the `Interruptible` property of the object whose callback is executing is set to `on` (the default), then interruption occurs at the next point where the event queue is processed. If the `Interruptible` property is `off`, the `BusyAction` property (of the object owning the executing callback) determines how MATLAB handles the event. The choices are

- `cancel` — Discard the event that attempted to execute a second callback routine.
- `queue` — Queue the event that attempted to execute a second callback routine until the current callback finishes.

`ButtonDownFcn`

string or function handle

Button press callback function. A callback that executes whenever you press a mouse button while the pointer is over this object, but not over another graphics object. See the `HitTestArea` property for information about selecting objects of this type.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

This property can be

- A string that is a valid MATLAB expression
- The name of an M-file
- A function handle

Set this property to a function handle that references the callback. The expressions execute in the MATLAB workspace.

See “Function Handle Callbacks” for information on how to use function handles to define the callbacks.

`Children`
array of graphics object handles

Children of this object. The handle of a patch object that is the child of this object (whether visible or not).

Note that if a child object's `HandleVisibility` property is set to `callback` or `off`, its handle does not show up in this object's `Children` property unless you set the root `ShowHiddenHandles` property to `on`:

```
set(0,'ShowHiddenHandles','on')
```

`Clipping`
`{on} | off`

Clipping mode. MATLAB clips graphs to the axes plot box by default. If you set `Clipping` to `off`, portions of graphs can be displayed outside the axes plot box. This can occur if you create a plot object, set `hold` to `on`, freeze axis scaling (`axis manual`), and then create a larger plot object.

`CreateFcn`
string or function handle

Callback routine executed during object creation. This property defines a callback that executes when MATLAB creates an object. You must specify the callback during the creation of the object. For example,

```
area(y,'CreateFcn',@CallbackFcn)
```

where `@CallbackFcn` is a function handle that references the callback function.

MATLAB executes this routine after setting all other object properties. Setting this property on an existing object has no effect.

The handle of the object whose `CreateFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

`DeleteFcn`
string or function handle

Callback executed during object deletion. A callback that executes when this object is deleted (e.g., this might happen when you issue a `delete` command on the object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object’s properties so the callback routine can query these values.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which can be queried using `gcbo`.

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

See the `BeingDeleted` property for related information.

`DisplayName`
string (default is empty string)

String used by legend for this barseries object. The `legend` function uses the string defined by the `DisplayName` property to label this barseries object in the legend.

- If you specify string arguments with the `legend` function, `DisplayName` is set to this barseries object's corresponding string and that string is used for the legend.
- If `DisplayName` is empty, legend creates a string of the form, `['data' n]`, where *n* is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, `DisplayName` is set to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add programmatically a legend that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See "Controlling Legends" for more examples.

`EdgeColor`

`{[0 0 0]} | none | ColorSpec`

Color of line that separates filled areas. You can set the color of the edges of filled areas to a three-element RGB vector or one of the MATLAB predefined names, including the string `none`. The default edge color is black. See `ColorSpec` for more information on specifying color.

`EraseMode`

`{normal} | none | xor | background`

Erase mode. This property controls the technique MATLAB uses to draw and erase objects and their children. Alternative erase modes are useful for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to ensure that all objects are rendered correctly. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- `none` — Do not erase objects when they are moved or destroyed. While the objects are still visible on the screen after erasing with `EraseMode` `none`, you cannot print these objects because MATLAB stores no information about their former locations.
- `xor` — Draw and erase the object by performing an exclusive OR (XOR) with each pixel index of the screen behind it. Erasing the object does not damage the color of the objects behind it. However, the color of the erased object depends on the color of the screen behind it and it is correctly colored only when it is over the axes background color (or the figure background color if the axes `Color` property is set to `none`). That is, it isn't erased correctly if there are objects behind it.
- `background` — Erase the graphics objects by redrawing them in the axes background color, (or the figure background color if the axes `Color` property is set to `none`). This damages other graphics objects that are behind the erased object, but the erased object is always properly colored.

Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB can mathematically combine layers of colors (e.g., performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

Set the axes background color with the axes `Color` property. Set the figure background color with the figure `Color` property.

You can use the MATLAB `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

`FaceColor`
`{flat} | none | ColorSpec`

Color of filled areas. This property can be any of the following:

- `ColorSpec` — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for all filled areas. See `ColorSpec` for more information on specifying color.
- `none` — Do not draw faces. Note that `EdgeColor` is drawn independently of `FaceColor`
- `flat` — The color of the filled areas is determined by the figure colormap. See `colormap` for information on setting the colormap.

  See the `ColorSpec` reference page for more information on specifying color.

`HandleVisibility`
`{on} | callback | off`

Control access to object's handle by command-line users and GUIs. This property determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally accessing objects that you need to protect for some reason.

- `on` — Handles are always visible when `HandleVisibility` is `on`.
- `callback` — Setting `HandleVisibility` to `callback` causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions

invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.

- `off` — Setting `HandleVisibility` to `off` makes handles invisible at all times. This might be necessary when a callback invokes a function that might potentially damage the GUI (such as evaluating a user-typed string) and so temporarily hides its own handles during the execution of that function.

Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Properties Affected by Handle Visibility

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

Overriding Handle Visibility

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings (this does not affect the values of the `HandleVisibility` properties). See also `findall`.

Handle Validity

Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

`HitTest`

`{on} | off`

Selectable by mouse click. `HitTest` determines whether this object can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the objects that compose the area graph. If `HitTest` is `off`, clicking this object selects the object below it (which is usually the axes containing it).

`HitTestArea`

`on | {off}`

Select barseries object on bars or area of extent. This property enables you to select barseries objects in two ways:

- Select by clicking bars (default).
- Select by clicking anywhere in the extent of the bar graph.

When `HitTestArea` is `off`, you must click the bars to select the barseries object. When `HitTestArea` is `on`, you can select the barseries object by clicking anywhere within the extent of the bar graph (i.e., anywhere within a rectangle that encloses all the bars).

`Interruptible`

`{on} | off`

Callback routine interruption mode. The `Interruptible` property controls whether an object's callback can be interrupted by callbacks invoked subsequently.

Only callbacks defined for the `ButtonDownFcn` property are affected by the `Interruptible` property. MATLAB checks for events that can interrupt a callback only when it encounters a `drawnow`, `figure`, `getframe`, or `pause` command in the routine. See the `BusyAction` property for related information.

Setting `Interruptible` to `on` allows any graphics object's callback to interrupt callback routines originating from a bar property. Note that MATLAB does not save the state of variables or the display (e.g., the handle returned by the `gca` or `gcf` command) when an interruption occurs.

`LineStyle`

`{-} | -- | :  | -.  | none`

Line style. This property specifies the line style of the object. Available line styles are shown in the following table.

Specifier String	Line Style
`-`	Solid line (default)
`--`	Dashed line
`:`	Dotted line
`-.`	Dash-dot line
`none`	No line

You can use `LineStyle none` when you want to place a marker at each point but do not want the points connected with a line (see the `Marker` property).

`LineWidth`
scalar

The width of linear objects and edges of filled areas. Specify this value in points (1 point = $^1/_{72}$ inch). The default `LineWidth` is 0.5 points.

`Parent`
handle of parent axes, hggroup, or hgtransform

Parent of this object. This property contains the handle of the object's parent. The parent is normally the axes, hggroup, or hgtransform object that contains the object.

See "Objects That Can Contain Other Objects" for more information on parenting graphics objects.

`Selected`
`on | {off}`

Is object selected? When you set this property to `on`, MATLAB displays selection "handles" at the corners and midpoints if the `SelectionHighlight` property is also `on` (the default). You can, for example, define the `ButtonDownFcn` callback to set this property to `on`, thereby indicating that this particular object is selected. This property is also set to `on` when an object is manually selected in plot edit mode.

`SelectionHighlight`
`{on} | off`

Objects are highlighted when selected. When the `Selected` property is `on`, MATLAB indicates the selected state by drawing four edge handles and four corner handles. When `SelectionHighlight` is `off`, MATLAB does not draw the handles except when in plot edit mode and objects are selected manually.

`ShowBaseLine`
`{on} | off`

Turn baseline display on or off. This property determines whether bar plots display a baseline from which the bars are drawn. By default, the baseline is displayed.

`Tag`

string

User-specified object label. The `Tag` property provides a means to identify graphics objects with a user-specified label. This is particularly useful when you are constructing interactive graphics programs that would otherwise need to define object handles as global variables or pass them as arguments between callbacks.

For example, you might create a barseries object and set the `Tag` property:

```
t = bar(Y,'Tag','bar1')
```

When you want to access the barseries object, you can use `findobj` to find the barseries object's handle. The following statement changes the `FaceColor` property of the object whose `Tag` is `bar1`.

```
set(findobj('Tag','bar1'),'FaceColor','red')
```

`Type`

string (read only)

Type of graphics object. This property contains a string that identifies the class of the graphics object. For barseries objects, `Type` is `hggroup`.

The following statement finds all the hggroup objects in the current axes.

```
t = findobj(gca,'Type','hggroup');
```

`UIContextMenu`

handle of a uicontextmenu object

Associate a context menu with this object. Assign this property the handle of a uicontextmenu object created in the object's parent figure. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the object.

`UserData`
array

User-specified data. This property can be any data you want to associate with this object (including cell arrays and structures). The object does not set values for this property, but you can access it using the `set` and `get` functions.

`Visible`
`{on} | off`

Visibility of this object and its children. By default, a new object's visibility is `on`. This means all children of the object are visible unless the child object's `Visible` property is set to `off`. Setting an object's `Visible` property to `off` prevents the object from being displayed. However, the object still exists and you can set and query its properties.

`XData`
array

Location of bars. The *x*-axis intervals for the vertical bars or *y*-axis intervals for horizontal bars (as specified by the `x` input argument). If `YData` is a vector, `XData` must be the same size. If `YData` is a matrix, the length of `XData` must be equal to the number of rows in `YData`.

`XDataMode`
{auto} | manual

Use automatic or user-specified x-axis values. If you specify `XData` (by setting the `XData` property or specifying the `x` input

argument), MATLAB sets this property to `manual` and uses the specified values to label the *x*-axis.

If you set `XDataMode` to `auto` after having specified `XData`, MATLAB resets the *x*-axis ticks to `1:size(YData,1)` or to the column indices of the `ZData`, overwriting any previous values for `XData`.

`XDataSource`
string (MATLAB variable)

Link `XData` to MATLAB variable. Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `XData`.

MATLAB reevaluates this property only when you set it. Therefore, a change to workspace variables appearing in an expression does not change `XData`.

You can use the `refreshdata` function to force an update of the object's data. `refreshdata` also enables you to specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

See the `refreshdata` reference page for more information.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

`YData`
scalar, vector, or matrix

Bar plot data. YData contains the data plotted as bars (the Y input argument). Each value in YData is represented by a bar in the bar graph. If XYData is a matrix, the bar function creates a "group" or a "stack" of bars for each column in the matrix. See “Bar Graph Options” in the bar, barh reference page for examples of grouped and stacked bar graphs.

The input argument Y in the bar function calling syntax assigns values to YData.

YDataSource
string (MATLAB variable)

Link YData to MATLAB variable. Set this property to a MATLAB variable that is evaluated in the base workspace to generate the YData.

MATLAB reevaluates this property only when you set it. Therefore, a change to workspace variables appearing in an expression does not change YData.

You can use the refreshdata function to force an update of the object’s data. refreshdata also enables you to specify that the data source variable be evaluated in the workspace of a function from which you call refreshdata.

See the refreshdata reference page for more information.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

base2dec

Purpose

Convert base N number string to decimal number

Syntax

```
d = base2dec('strn', base)
```

Description

`d = base2dec('strn', base)` converts the string number *strn* of the specified `base` into its decimal (base 10) equivalent. `base` must be an integer between 2 and 36. If `'strn'` is a character array, each row is interpreted as a string in the specified `base`.

Examples

The expression `base2dec('212',3)` converts 212_3 to decimal, returning 23.

See Also

`dec2base`

Purpose

Produce beep sound

Syntax

```
beep
beep on
beep off
s = beep
```

Description

`beep` produces your computer's default beep sound.

`beep on` turns the beep on.

`beep off` turns the beep off.

`s = beep` returns the current beep mode (`on` or `off`).

besselh

Purpose

Bessel function of third kind (Hankel function)

Syntax

```
H = besselh(nu,K,Z)
H = besselh(nu,Z)
H = besselh(nu,K,Z,1)
[H,ierr] = besselh(...)
```

Definitions

The differential equation

$$z^2\frac{d^2y}{dz^2} + z\frac{dy}{dz} + (z^2 - \nu^2)y = 0$$

where ν is a nonnegative constant, is called *Bessel's equation*, and its solutions are known as *Bessel functions*. $J_\nu(z)$ and $J_{-\nu}(z)$ form a fundamental set of solutions of Bessel's equation for noninteger ν. $Y_\nu(z)$ is a second solution of Bessel's equation – linearly independent of $J_\nu(z)$ – defined by

$$Y_\nu(z) = \frac{J_\nu(z)\cos(\nu\pi) - J_{-\nu}(z)}{\sin(\nu\pi)}$$

The relationship between the Hankel and Bessel functions is

$$H_\nu^{(1)}(z) = J_\nu(z) + i\ Y_\nu(z)$$

$$H_\nu^{(2)}(z) = J_\nu(z) - i\ Y_\nu(z)$$

where $J_\nu(z)$ is `besselj`, and $Y_\nu(z)$ is `bessely`.

Description

`H = besselh(nu,K,Z)` computes the Hankel function $H_\nu^{(K)}(z)$, where `K` = 1 or 2, for each element of the complex array `Z`. If `nu` and `Z` are arrays of the same size, the result is also that size. If either input is a scalar, `besselh` expands it to the other input's size. If one input is a row

vector and the other is a column vector, the result is a two-dimensional table of function values.

`H = besselh(nu,Z)` uses `K = 1`.

`H = besselh(nu,K,Z,1)` scales $H_\nu^{(K)}(z)$ by `exp(-i*Z)` if `K = 1`, and by `exp(+i*Z)` if `K = 2`.

`[H,ierr] = besselh(...)` also returns completion flags in an array the same size as `H`.

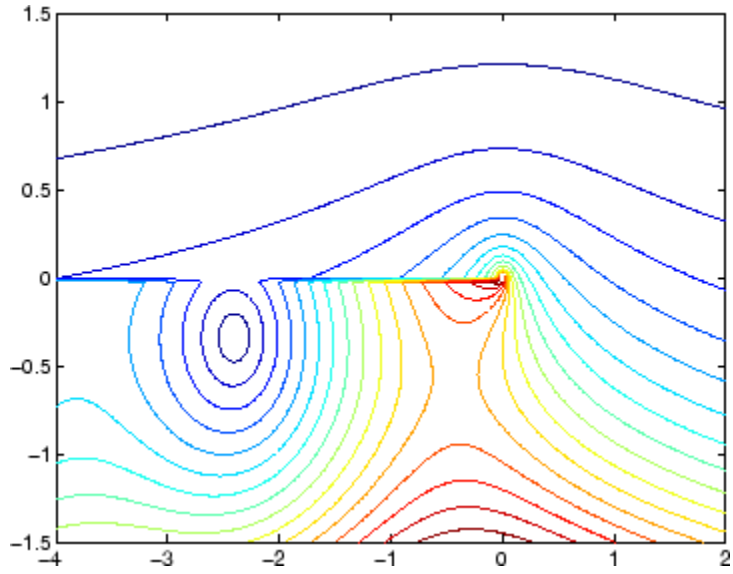
ierr	Description
0	`besselh` successfully computed the Hankel function for this element.
1	Illegal arguments.
2	Overflow. Returns `Inf`.
3	Some loss of accuracy in argument reduction.
4	Unacceptable loss of accuracy, `Z` or `nu` too large.
5	No convergence. Returns `NaN`.

Examples

This example generates the contour plots of the modulus and phase of the Hankel function $H_0^{(1)}(z)$ shown on page 359 of [1] Abramowitz and Stegun, *Handbook of Mathematical Functions*.

It first generates the modulus contour plot

```
[X,Y] = meshgrid(-4:0.025:2,-1.5:0.025:1.5);
H = besselh(0,1,X+i*Y);
contour(X,Y,abs(H),0:0.2:3.2), hold on
```



then adds the contour plot of the phase of the same function.

```
contour(X,Y,(180/pi)*angle(H),-180:10:180); hold off
```

References

[1] Abramowitz, M., and I.A. Stegun, *Handbook of Mathematical Functions*, National Bureau of Standards, Applied Math. Series #55, Dover Publications, 1965.

Purpose

Modified Bessel function of first kind

Syntax

```
I = besseli(nu,Z)
I = besseli(nu,Z,1)
[I,ierr] = besseli(...)
```

Definitions

The differential equation

$$z^2\frac{d^2y}{dz^2} + z\frac{dy}{dz} - (z^2+\nu^2)y = 0$$

where ν is a real constant, is called the *modified Bessel's equation*, and its solutions are known as *modified Bessel functions*.

$I_\nu(z)$ and $I_{-\nu}(z)$ form a fundamental set of solutions of the modified Bessel's equation for noninteger ν. $I_\nu(z)$ is defined by

$$I_\nu(z) = \left(\frac{z}{2}\right)^\nu \sum_{k=0}^{\infty} \frac{\left(\frac{z^2}{4}\right)^k}{k!\ \Gamma(\nu+k+1)}$$

where $\Gamma(a)$ is the gamma function.

$K_\nu(z)$ is a second solution, independent of $I_\nu(z)$. It can be computed using `besselk`.

Description

`I = besseli(nu,Z)` computes the modified Bessel function of the first kind, $I_\nu(z)$, for each element of the array `Z`. The order `nu` need not be an integer, but must be real. The argument `Z` can be complex. The result is real where `Z` is positive.

If `nu` and `Z` are arrays of the same size, the result is also that size. If either input is a scalar, it is expanded to the other input's size. If one input is a row vector and the other is a column vector, the result is a two-dimensional table of function values.

`I = besseli(nu,Z,1)` computes `besseli(nu,Z).*exp(-abs(real(Z)))`.

`[I,ierr] = besseli(...)` also returns completion flags in an array the same size as `I`.

ierr	Description
0	`besseli` successfully computed the modified Bessel function for this element.
1	Illegal arguments.
2	Overflow. Returns `Inf`.
3	Some loss of accuracy in argument reduction.
4	Unacceptable loss of accuracy, `Z` or `nu` too large.
5	No convergence. Returns `NaN`.

Examples

Example 1

```
format long
z = (0:0.2:1)';

besseli(1,z)

ans =
                   0
   0.10050083402813
   0.20402675573357
   0.31370402560492
   0.43286480262064
   0.56515910399249
```

Example 2

`besseli(3:9,(0:.2,10)',1)` generates the entire table on page 423 of [1] Abramowitz and Stegun, *Handbook of Mathematical Functions*

Algorithm

The `besseli` functions use a Fortran MEX-file to call a library developed by D.E. Amos [3] [4].

[4] Amos, D.E., "A Portable Package for Bessel Functions of a Complex Argument and Nonnegative Order," *Trans. Math. Software*, 1986.

Purpose

Bessel function of first kind

Syntax

```
J = besselj(nu,Z)
J = besselj(nu,Z,1)
[J,ierr] = besselj(nu,Z)
```

Definition

The differential equation

$$z^2 \frac{d^2y}{dz^2} + z\frac{dy}{dz} + (z^2 - \nu^2)y = 0$$

where ν is a real constant, is called *Bessel's equation*, and its solutions are known as *Bessel functions*.

$J_\nu(z)$ and $J_{-\nu}(z)$ form a fundamental set of solutions of Bessel's equation for noninteger ν. $J_\nu(z)$ is defined by

$$J_\nu(z) = \left(\frac{z}{2}\right)^\nu \sum_{k=0}^{\infty} \frac{\left(-\frac{z^2}{4}\right)^k}{k!\ \Gamma(\nu + k + 1)}$$

where $\Gamma(a)$ is the gamma function.

$Y_\nu(z)$ is a second solution of Bessel's equation that is linearly independent of $J_\nu(z)$. It can be computed using `bessely`.

Description

`J = besselj(nu,Z)` computes the Bessel function of the first kind, $J_\nu(z)$, for each element of the array `Z`. The order `nu` need not be an integer, but must be real. The argument `Z` can be complex. The result is real where `Z` is positive.

If `nu` and `Z` are arrays of the same size, the result is also that size. If either input is a scalar, it is expanded to the other input's size. If one input is a row vector and the other is a column vector, the result is a two-dimensional table of function values.

`J = besselj(nu,Z,1)` computes
`besselj(nu,Z).*exp(-abs(imag(Z)))`.

`[J,ierr] = besselj(nu,Z)` also returns completion flags in an array the same size as `J`.

ierr	Description
0	`besselj` successfully computed the Bessel function for this element.
1	Illegal arguments.
2	Overflow. Returns `Inf`.
3	Some loss of accuracy in argument reduction.
4	Unacceptable loss of accuracy, `Z` or `nu` too large.
5	No convergence. Returns `NaN`.

Remarks

The Bessel functions are related to the Hankel functions, also called Bessel functions of the third kind,

$$H_\nu^{(1)}(z) = J_\nu(z) + i\ Y_\nu(z)$$

$$H_\nu^{(2)}(z) = J_\nu(z) - i\ Y_\nu(z)$$

where $H_\nu^{(K)}(z)$ is `besselh`, $J_\nu(z)$ is `besselj`, and $Y_\nu(z)$ is `bessely`. The Hankel functions also form a fundamental set of solutions to Bessel's equation (see `besselh`).

Examples

Example 1

```
format long
z = (0:0.2:1)';

besselj(1,z)
```

```
ans =
                    0
   0.09950083263924
   0.19602657795532
   0.28670098806392
   0.36884204609417
   0.44005058574493
```

Example 2

`besselj(3:9,(0:.2:10)')` generates the entire table on page 398 of [1] Abramowitz and Stegun, *Handbook of Mathematical Functions*.

Algorithm

The `besselj` function uses a Fortran MEX-file to call a library developed by D.E. Amos [3] [4].

besselk

Purpose

Modified Bessel function of second kind

Syntax

```
K = besselk(nu,Z)
K = besselk(nu,Z,1)
[K,ierr] = besselk(...)
```

Definitions

The differential equation

$$z^2\frac{d^2y}{dz^2} + z\frac{dy}{dz} - (z^2+\nu^2)y = 0$$

where ν is a real constant, is called the *modified Bessel's equation*, and its solutions are known as *modified Bessel functions*.

A solution $K_\nu(z)$ of the second kind can be expressed as

$$K_\nu(z) = \left(\frac{\pi}{2}\right)\frac{I_{-\nu}(z) - I_\nu(z)}{\sin(\nu\pi)}$$

where $I_\nu(z)$ and $I_{-\nu}(z)$ form a fundamental set of solutions of the modified Bessel's equation for noninteger ν

$$I_\nu(z) = \left(\frac{z}{2}\right)^\nu \sum_{k=0}^{\infty} \frac{\left(\frac{z^2}{4}\right)^k}{k!\ \Gamma(\nu+k+1)}$$

and $\Gamma(a)$ is the gamma function. $K_\nu(z)$ is independent of $I_\nu(z)$. $I_\nu(z)$ can be computed using `besseli`.

Description

`K = besselk(nu,Z)` computes the modified Bessel function of the second kind, $K_\nu(z)$, for each element of the array `Z`. The order `nu` need not be an integer, but must be real. The argument `Z` can be complex. The result is real where `Z` is positive.

If nu and Z are arrays of the same size, the result is also that size. If either input is a scalar, it is expanded to the other input's size. If one input is a row vector and the other is a column vector, the result is a two-dimensional table of function values.

`K = besselk(nu,Z,1)` computes `besselk(nu,Z).*exp(Z)`.

`[K,ierr] = besselk(...)` also returns completion flags in an array the same size as `K`.

ierr	Description
0	`besselk` successfully computed the modified Bessel function for this element.
1	Illegal arguments.
2	Overflow. Returns `Inf`.
3	Some loss of accuracy in argument reduction.
4	Unacceptable loss of accuracy, `Z` or `nu` too large.
5	No convergence. Returns `NaN`.

Examples

Example 1

```
format long
z = (0:0.2:1)';

besselk(1,z)

ans =
                Inf
   4.77597254322047
   2.18435442473269
   1.30283493976350
   0.86178163447218
   0.60190723019723
```

Example 2

`besselk(3:9,(0:.2:10)',1)` generates part of the table on page 424 of [1] Abramowitz and Stegun, *Handbook of Mathematical Functions*.

Algorithm

The `besselk` function uses a Fortran MEX-file to call a library developed by D.E. Amos [3][4].

References

`airy`, `besselh`, `besseli`, `besselj`, `bessely`

Purpose

Bessel function of second kind

Syntax

```
Y = bessely(nu,Z)
Y = bessely(nu,Z,1)
[Y,ierr] = bessely(nu,Z)
```

Definition

The differential equation

$$z^2 \frac{d^2 y}{dz^2} + z \frac{dy}{dz} + (z^2 - \nu^2) y = 0$$

where ν is a real constant, is called *Bessel's equation*, and its solutions are known as *Bessel functions*.

A solution $Y_\nu(z)$ of the second kind can be expressed as

$$Y_\nu(z) = \frac{J_\nu(z)\cos(\nu\pi) - J_{-\nu}(z)}{\sin(\nu\pi)}$$

where $J_\nu(z)$ and $J_{-\nu}(z)$ form a fundamental set of solutions of Bessel's equation for noninteger ν

$$J_\nu(z) = \left(\frac{z}{2}\right)^\nu \sum_{k=0}^{\infty} \frac{\left(-\frac{z^2}{4}\right)^k}{k!\ \Gamma(\nu + k + 1)}$$

and $\Gamma(a)$ is the gamma function. $Y_\nu(z)$ is linearly independent of $J_\nu(z)$.

$J_\nu(z)$ can be computed using `besselj`.

Description

`Y = bessely(nu,Z)` computes Bessel functions of the second kind, $Y_\nu(z)$, for each element of the array `Z`. The order `nu` need not be an integer, but must be real. The argument `Z` can be complex. The result is real where `Z` is positive.

If nu and Z are arrays of the same size, the result is also that size. If either input is a scalar, it is expanded to the other input's size. If one input is a row vector and the other is a column vector, the result is a two-dimensional table of function values.

`Y = bessely(nu,Z,1)` computes `bessely(nu,Z).*exp(-abs(imag(Z)))`.

`[Y,ierr] = bessely(nu,Z)` also returns completion flags in an array the same size as `Y`.

ierr	Description
0	`bessely` successfully computed the Bessel function for this element.
1	Illegal arguments.
2	Overflow. Returns `Inf`.
3	Some loss of accuracy in argument reduction.
4	Unacceptable loss of accuracy, `Z` or `nu` too large.
5	No convergence. Returns `NaN`.

Remarks

The Bessel functions are related to the Hankel functions, also called Bessel functions of the third kind,

$$H_\nu^{(1)}(z) = J_\nu(z) + i\ Y_\nu(z)$$

$$H_\nu^{(2)}(z) = J_\nu(z) - i\ Y_\nu(z)$$

where $H_\nu^{(K)}(z)$ is `besselh`, $J_\nu(z)$ is `besselj`, and $Y_\nu(z)$ is `bessely`. The Hankel functions also form a fundamental set of solutions to Bessel's equation (see `besselh`).

Examples

Example 1

```
format long
z = (0:0.2:1)';

bessely(1,z)

ans =
                -Inf
  -3.32382498811185
  -1.78087204427005
  -1.26039134717739
  -0.97814417668336
  -0.78121282130029
```

Example 2

`bessely(3:9,(0:.2:10)')` generates the entire table on page 399 of [1] Abramowitz and Stegun, *Handbook of Mathematical Functions*.

Algorithm

The `bessely` function uses a Fortran MEX-file to call a library developed by D. E Amos [3] [4].

besselh, besseli, besselj, besselk

Purpose

Beta function

Syntax

```
B = beta(Z,W)
```

Definition

The beta function is

$$B(z, w) = \int_0^1 t^{z-1}(1-t)^{w-1}\,dt = \frac{\Gamma(z)\Gamma(w)}{\Gamma(z+w)}$$

where $\Gamma(z)$ is the gamma function.

Description

`B = beta(Z,W)` computes the beta function for corresponding elements of arrays `Z` and `W`. The arrays must be real and nonnegative. They must be the same size, or either can be scalar.

Examples

In this example, which uses integer arguments,

```
beta(n,3)
   = (n-1)!*2!/(n+2)!
   = 2/(n*(n+1)*(n+2))
```

is the ratio of fairly small integers, and the rational format is able to recover the exact result.

```
format rat
beta((0:10)',3)

ans =

     1/0
     1/3
     1/12
     1/30
     1/60
     1/105
     1/168
     1/252
```

```
1/360
1/495
1/660
```

Algorithm

```
beta(z,w) = exp(gammaln(z)+gammaln(w)-gammaln(z+w))
```

See Also

betainc, betaln, gammaln

Purpose

Incomplete beta function

Syntax

```
I = betainc(X,Z,W)
I = betainc(X,Z,tail)
```

Definition

The incomplete beta function is

$$I_x(z, w) = \frac{1}{B(z, w)} \int_0^x t^{z-1}(1-t)^{w-1}\, dt$$

where $B(z, w)$, the beta function, is defined as

$$B(z, w) = \int_0^1 t^{z-1}(1-t)^{w-1}\, dt = \frac{\Gamma(z)\Gamma(w)}{\Gamma(z+w)}$$

and $\Gamma(z)$ is the gamma function.

Description

`I = betainc(X,Z,W)` computes the incomplete beta function for corresponding elements of the arrays `X`, `Z`, and `W`. The elements of `X` must be in the closed interval $[0,1]$. The arrays `Z` and `W` must be nonnegative and real. All arrays must be the same size, or any of them can be scalar.

`I = betainc(X,Z,tail)` specifies the tail of the incomplete beta function. Choices are:

`'lower'` (the default)	Computes the integral from `0` to `x`
`'upper'`	Computes the integral from `x` to `1`

These functions are related as follows:

```
1-betainc(X,Z,W) = betainc(X,Z,W,'upper')
```

Note that especially when the upper tail value is close to `0`, it is more accurate to use the `'upper'` option than to subtract the `'lower'` value from `1`.

Examples

```
format long
betainc(.5,(0:10)',3)

ans =
   1.00000000000000
   0.87500000000000
   0.68750000000000
   0.50000000000000
   0.34375000000000
   0.22656250000000
   0.14453125000000
   0.08984375000000
   0.05468750000000
   0.03271484375000
   0.01928710937500
```

See Also

beta, betaln

Purpose

Logarithm of beta function

Syntax

```
L = betaln(Z,W)
```

Description

`L = betaln(Z,W)` computes the natural logarithm of the `beta` function `log(beta(Z,W))`, for corresponding elements of arrays `Z` and `W`, without computing `beta(Z,W)`. Since the beta function can range over very large or very small values, its logarithm is sometimes more useful.

`Z` and `W` must be real and nonnegative. They must be the same size, or either can be scalar.

Examples

```
x = 510
betaln(x,x)

ans =
      -708.8616
```

`-708.8616` is slightly less than `log(realmin)`. Computing `beta(x,x)` directly would underflow (or be denormal).

Algorithm

```
betaln(z,w) = gammaln(z)+gammaln(w)-gammaln(z+w)
```

See Also

`beta`, `betainc`, `gammaln`

bicg

Purpose

Biconjugate gradients method

Syntax

```
x = bicg(A,b)
bicg(A,b,tol)
bicg(A,b,tol,maxit)
bicg(A,b,tol,maxit,M)
bicg(A,b,tol,maxit,M1,M2)
bicg(A,b,tol,maxit,M1,M2,x0)
[x,flag] = bicg(A,b,...)
[x,flag,relres] = bicg(A,b,...)
[x,flag,relres,iter] = bicg(A,b,...)
[x,flag,relres,iter,resvec] = bicg(A,b,...)
```

Description

`x = bicg(A,b)` attempts to solve the system of linear equations `A*x = b` for `x`. The `n`-by-`n` coefficient matrix `A` must be square and should be large and sparse. The column vector `b` must have length `n`. `A` can be a function handle `afun` such that `afun(x,'notransp')` returns `A*x` and `afun(x,'transp')` returns `A'*x`. See "Function Handles" in the MATLAB Programming documentation for more information.

"Parameterizing Functions Called by Function Functions", in the MATLAB Mathematics documentation, explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `bicg` converges, it displays a message to that effect. If `bicg` fails to converge after the maximum number of iterations or halts for any reason, it prints a warning message that includes the relative residual `norm(b-A*x)/norm(b)` and the iteration number at which the method stopped or failed.

`bicg(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `bicg` uses the default, `1e-6`.

`bicg(A,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]`, then `bicg` uses the default, `min(n,20)`.

`bicg(A,b,tol,maxit,M)` and `bicg(A,b,tol,maxit,M1,M2)` use the preconditioner `M` or `M = M1*M2` and effectively solve the system

`inv(M)*A*x = inv(M)*b` for `x`. If `M` is `[]` then `bicg` applies no preconditioner. `M` can be a function handle `mfun` such that `mfun(x,'notransp')` returns `M\x` and `mfun(x,'transp')` returns `M'\x`.

`bicg(A,b,tol,maxit,M1,M2,x0)` specifies the initial guess. If `x0` is `[]`, then `bicg` uses the default, an all-zero vector.

`[x,flag] = bicg(A,b,...)` also returns a convergence flag.

Flag	Convergence
0	`bicg` converged to the desired tolerance `tol` within `maxit` iterations.
1	`bicg` iterated `maxit` times but did not converge.
2	Preconditioner `M` was ill-conditioned.
3	`bicg` stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during `bicg` became too small or too large to continue computing.

Whenever `flag` is not `0`, the solution `x` returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = bicg(A,b,...)` also returns the relative residual `norm(b-A*x)/norm(b)`. If `flag` is `0`, `relres <= tol`.

`[x,flag,relres,iter] = bicg(A,b,...)` also returns the iteration number at which `x` was computed, where `0 <= iter <= maxit`.

`[x,flag,relres,iter,resvec] = bicg(A,b,...)` also returns a vector of the residual norms at each iteration including `norm(b-A*x0)`.

Examples

Example 1

```
n = 100;
on = ones(n,1);
A = spdiags([-2*on 4*on -on],-1:1,n,n);
```

```
b = sum(A,2);
tol = 1e-8;
maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);

x = bicg(A,b,tol,maxit,M1,M2);
```

displays this message:

```
bicg converged at iteration 9 to a solution with relative
residual 5.3e-009
```

Example 2

This example replaces the matrix `A` in Example 1 with a handle to a matrix-vector product function `afun`. The example is contained in an M-file `run_bicg` that

- Calls `bicg` with the function handle `@afun` as its first argument.
- Contains `afun` as a nested function, so that all variables in `run_bicg` are available to `afun`.

The following shows the code for `run_bicg`:

```
function x1 = run_bicg
n = 100;
on = ones(n,1);
A = spdiags([-2*on 4*on -on],-1:1,n,n);
b = sum(A,2);
tol = 1e-8;
maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);
x1 = bicg(@afun,b,tol,maxit,M1,M2);

    function y = afun(x,transp_flag)
       if strcmp(transp_flag,'transp')      % y = A'*x
```

```
            y = 4 * x;
            y(1:n-1) = y(1:n-1) - 2 * x(2:n);
            y(2:n) = y(2:n) - x(1:n-1);
         elseif strcmp(transp_flag,'notransp') % y = A*x
            y = 4 * x;
            y(2:n) = y(2:n) - 2 * x(1:n-1);
            y(1:n-1) = y(1:n-1) - x(2:n);
         end
      end
   end
```

When you enter

```
x1=run_bicg;
```

MATLAB displays the message

```
bicg converged at iteration 9 to a solution with ...
relative residual
5.3e-009
```

Example 3

This example demonstrates the use of a preconditioner. Start with `A = west0479`, a real 479-by-479 sparse matrix, and define `b` so that the true solution is a vector of all ones.

```
load west0479;
A = west0479;
b = sum(A,2);
```

You can accurately solve `A*x = b` using backslash since `A` is not so large.

```
x = A \ b;
norm(b-A*x) / norm(b)

ans =
    8.3154e-017
```

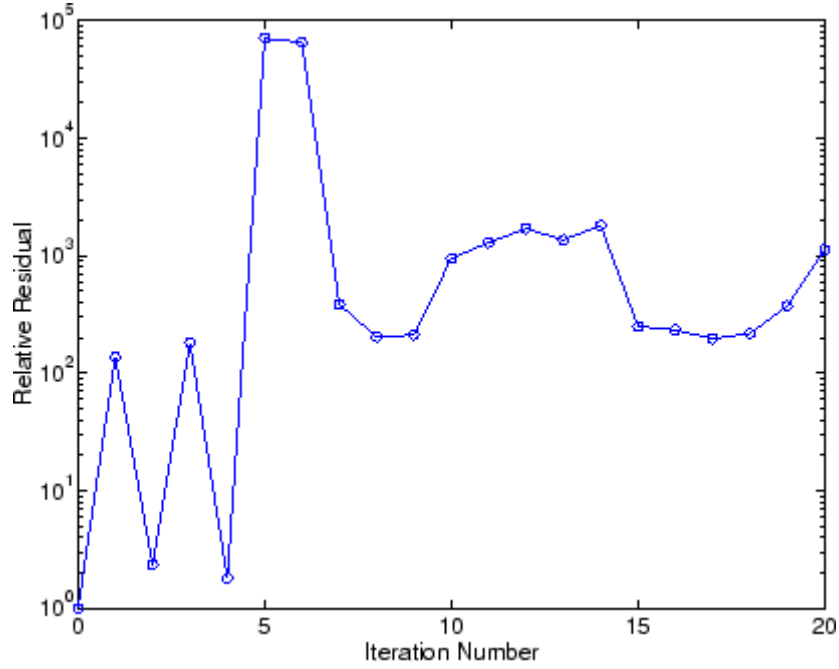
Now try to solve `A*x = b` with `bicg`.

```
[x,flag,relres,iter,resvec] = bicg(A,b)

flag =
          1
relres =
          1
iter =
          0
```

The value of `flag` indicates that `bicg` iterated the default 20 times without converging. The value of `iter` shows that the method behaved so badly that the initial all-zero guess was better than all the subsequent iterates. The value of `relres` supports this: `relres = norm(b-A*x)/norm(b) = norm(b)/norm(b) = 1`. You can confirm that the unpreconditioned method oscillates rather wildly by plotting the relative residuals at each iteration.

```
semilogy(0:20,resvec/norm(b),'-o')
xlabel('Iteration Number')
ylabel('Relative Residual')
```



Now, try an incomplete LU factorization with a drop tolerance of `1e-5` for the preconditioner.

```
[L1,U1] = luinc(A,1e-5);
Warning: Incomplete upper triangular factor has 1 zero diagonal.
         It cannot be used as a preconditioner for an iterative
         method.

nnz(A), nnz(L1), nnz(U1)

ans =
         1887
ans =
         5562
ans =
         4320
```

The zero on the main diagonal of the upper triangular `U1` indicates that `U1` is singular. If you try to use it as a preconditioner,

```
[x,flag,relres,iter,resvec] = bicg(A,b,1e-6,20,L1,U1)

flag =
         2
relres =
         1
iter =
         0
resvec =
         7.0557e+005
```

the method fails in the very first iteration when it tries to solve a system of equations involving the singular `U1` using backslash. `bicg` is forced to return the initial estimate since no other iterates were produced.

Try again with a slightly less sparse preconditioner.

```
[L2,U2] = luinc(A,1e-6);

nnz(L2), nnz(U2)

ans =
         6231
ans =
         4559
```

This time `U2` is nonsingular and may be an appropriate preconditioner.

```
[x,flag,relres,iter,resvec] = bicg(A,b,1e-15,10,L2,U2)

flag =
         0
relres =
         2.8664e-016
iter =
```

```
     8
```

and `bicg` converges to within the desired tolerance at iteration number 8. Decreasing the value of the drop tolerance increases the fill-in of the incomplete factors but also increases the accuracy of the approximation to the original matrix. Thus, the preconditioned system becomes closer to `inv(U)*inv(L)*L*U*x = inv(U)*inv(L)*b`, where `L` and `U` are the true LU factors, and closer to being solved within a single iteration.

The next graph shows the progress of `bicg` using six different incomplete LU factors as preconditioners. Each line in the graph is labeled with the drop tolerance of the preconditioner used in `bicg`.

Purpose

Biconjugate gradients stabilized method

Syntax

```
x = bicgstab(A,b)
bicgstab(A,b,tol)
bicgstab(A,b,tol,maxit)
bicgstab(A,b,tol,maxit,M)
bicgstab(A,b,tol,maxit,M1,M2)
bicgstab(A,b,tol,maxit,M1,M2,x0)
[x,flag] = bicgstab(A,b,...)
[x,flag,relres] = bicgstab(A,b,...)
[x,flag,relres,iter] = bicgstab(A,b,...)
[x,flag,relres,iter,resvec] = bicgstab(A,b,...)
```

Description

`x = bicgstab(A,b)` attempts to solve the system of linear equations `A*x=b` for `x`. The `n`-by-`n` coefficient matrix `A` must be square and should be large and sparse. The column vector `b` must have length `n`. `A` can be a function handle `afun` such that `afun(x)` returns `A*x`. See "Function Handles" in the MATLAB Programming documentation for more information.

"Parameterizing Functions Called by Function Functions", in the MATLAB Mathematics documentation, explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `bicgstab` converges, a message to that effect is displayed. If `bicgstab` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual `norm(b-A*x)/norm(b)` and the iteration number at which the method stopped or failed.

`bicgstab(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `bicgstab` uses the default, `1e-6`.

`bicgstab(A,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]`, then `bicgstab` uses the default, `min(n,20)`.

`bicgstab(A,b,tol,maxit,M)` and `bicgstab(A,b,tol,maxit,M1,M2)` use preconditioner `M` or `M = M1*M2` and effectively solve the system

`inv(M)*A*x = inv(M)*b` for `x`. If `M` is `[]` then `bicgstab` applies no preconditioner. `M` can be a function handle `mfun` such that `mfun(x)` returns `M\x`.

`bicgstab(A,b,tol,maxit,M1,M2,x0)` specifies the initial guess. If `x0` is `[]`, then `bicgstab` uses the default, an all zero vector.

`[x,flag] = bicgstab(A,b,...)` also returns a convergence flag.

Flag	Convergence
0	`bicgstab` converged to the desired tolerance `tol` within `maxit` iterations.
1	`bicgstab` iterated `maxit` times but did not converge.
2	Preconditioner `M` was ill-conditioned.
3	`bicgstab` stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during `bicgstab` became too small or too large to continue computing.

Whenever `flag` is not `0`, the solution `x` returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = bicgstab(A,b,...)` also returns the relative residual `norm(b-A*x)/norm(b)`. If `flag` is `0`, `relres <= tol`.

`[x,flag,relres,iter] = bicgstab(A,b,...)` also returns the iteration number at which `x` was computed, where `0 <= iter <= maxit`. `iter` can be an integer + 0.5, indicating convergence halfway through an iteration.

`[x,flag,relres,iter,resvec] = bicgstab(A,b,...)` also returns a vector of the residual norms at each half iteration, including `norm(b-A*x0)`.

Example

Example 1

This example first solves `Ax = b` by providing `A` and the preconditioner `M1` directly as arguments.

```
A = gallery('wilk',21);
b = sum(A,2);
tol = 1e-12;
maxit = 15;
M1 = diag([10:-1:1 1 1:10]);

x = bicgstab(A,b,tol,maxit,M1);
```

displays the message

```
bicgstab converged at iteration 12.5 to a solution with relative
residual 6.7e-014
```

Example 2

This example replaces the matrix `A` in Example 1 with a handle to a matrix-vector product function `afun`, and the preconditioner `M1` with a handle to a backsolve function `mfun`. The example is contained in an M-file `run_bicgstab` that

- Calls `bicgstab` with the function handle `@afun` as its first argument.
- Contains `afun` and `mfun` as nested functions, so that all variables in `run_bicgstab` are available to `afun` and `mfun`.

The following shows the code for `run_bicgstab`:

```
function x1 = run_bicgstab
n = 21;
A = gallery('wilk',n);
b = sum(A,2);
tol = 1e-12;
maxit = 15;
M1 = diag([10:-1:1 1 1:10]);
x1 = bicgstab(@afun,b,tol,maxit,@mfun);
```

```
    function y = afun(x)
       y = [0; x(1:n-1)] + ...
           [((n-1)/2:-1:0)'; (1:(n-1)/2)'].*x + ...
           [x(2:n); 0];
    end

    function y = mfun(r)
        y = r ./ [((n-1)/2:-1:1)'; 1; (1:(n-1)/2)'];
    end
end
```

When you enter

```
x1 = run_bicgstab;
```

MATLAB displays the message

```
bicgstab converged at iteration 12.5 to a solution with relative
residual 6.7e-014
```

Example 3

This examples demonstrates the use of a preconditioner. Start with `A = west0479`, a real 479-by-479 sparse matrix, and define `b` so that the true solution is a vector of all ones.

```
load west0479;
A = west0479;
b = sum(A,2);
[x,flag] = bicgstab(A,b)
```

`flag` is `1` because `bicgstab` does not converge to the default tolerance `1e-6` within the default 20 iterations.

```
[L1,U1] = luinc(A,1e-5);
[x1,flag1] = bicgstab(A,b,1e-6,20,L1,U1)
```

`flag1` is `2` because the upper triangular `U1` has a zero on its diagonal. This causes `bicgstab` to fail in the first iteration when it tries to solve a system such as `U1*y = r` using backslash.

```
[L2,U2] = luinc(A,1e-6);
[x2,flag2,relres2,iter2,resvec2] = bicgstab(A,b,1e-15,10,L2,U2)
```

`flag2` is `0` because `bicgstab` converges to the tolerance of `3.1757e-016` (the value of `relres2`) at the sixth iteration (the value of `iter2`) when preconditioned by the incomplete LU factorization with a drop tolerance of `1e-6`. `resvec2(1) = norm(b)` and `resvec2(13) = norm(b-A*x2)`. You can follow the progress of `bicgstab` by plotting the relative residuals at the halfway point and end of each iteration starting from the initial estimate (iterate number 0).

```
semilogy(0:0.5:iter2,resvec2/norm(b),'-o')
xlabel('iteration number')
ylabel('relative residual')
```

Purpose

Convert binary number string to decimal number

Syntax

```
bin2dec(binarystr)
```

Description

`bin2dec(binarystr)` interprets the binary string *`binarystr`* and returns the equivalent decimal number.

`bin2dec` ignores any space (`' '`) characters in the input string.

Examples

Binary `010111` converts to decimal `23`:

```
bin2dec('010111')
ans =
    23
```

Because space characters are ignored, this string yields the same result:

```
bin2dec(' 010   111 ')
ans =
    23
```

See Also

`dec2bin`

binary

Purpose

Set FTP transfer type to binary

Syntax

```
binary(f)
```

Description

`binary(f)` sets the FTP download and upload mode to binary, which does not convert new lines, where `f` was created using `ftp`. Use this function when downloading or uploading any nontext file, such as an executable or ZIP archive.

Examples

Connect to the MathWorks FTP server, and display the FTP object.

```
tmw=ftp('ftp.mathworks.com');
disp(tmw)
FTP Object
  host: ftp.mathworks.com
  user: anonymous
   dir: /
  mode: binary
```

Note that the FTP object defaults to binary mode.

Use the `ascii` function to set the FTP mode to ASCII, and use the `disp` function to display the FTP object.

```
ascii(tmw)
disp(tmw)
FTP Object
  host: ftp.mathworks.com
  user: anonymous
   dir: /
  mode: ascii
```

Note that the FTP object is now set to ASCII mode.

Use the `binary` function to set the FTP mode to binary, and use the `disp` function to display the FTP object.

```
binary(tmw)
```

```
disp(tmw)
FTP Object
  host: ftp.mathworks.com
  user: anonymous
   dir: /
  mode: binary
```

Note that the FTP object's mode is again set to binary.

See Also

`ftp`, `ascii`

bitand

Purpose

Bitwise AND

Syntax

```
C = bitand(A, B)
```

Description

`C = bitand(A, B)` returns the bitwise AND of arguments `A` and `B`, where `A` and `B` are unsigned integers or arrays of unsigned integers.

Examples

Example 1

The five-bit binary representations of the integers 13 and 27 are 01101 and 11011, respectively. Performing a bitwise AND on these numbers yields 01001, or 9:

```
C = bitand(uint8(13), uint8(27))
C =
    9
```

Example 2

Create a truth table for a logical AND operation:

```
A = uint8([0 1; 0 1]);
B = uint8([0 0; 1 1]);

TT = bitand(A, B)
TT =
    0    0
    0    1
```

See Also

`bitcmp`, `bitget`, `bitmax`, `bitor`, `bitset`, `bitshift`, `bitxor`

Purpose

Bitwise complement

Syntax

```
C = bitcmp(A)
C = bitcmp(A, n)
```

Description

`C = bitcmp(A)` returns the bitwise complement of `A`, where `A` is an unsigned integer or an array of unsigned integers.

`C = bitcmp(A, n)` returns the bitwise complement of `A` as an `n`-bit unsigned integer `C`. Input `A` may not have any bits set higher than `n` (that is, `A` may not have a value greater than `2^n-1`). The value of `n` can be no greater than the number of bits in the unsigned integer class of `A`. For example, if the class of `A` is `uint32`, then `n` must be a positive integer less than 32.

Examples

Example 1

With eight-bit arithmetic, the one's complement of 01100011 (decimal 99) is 10011100 (decimal 156):

```
C = bitcmp(uint8(99))
C =
   156
```

Example 2

The complement of hexadecimal A5 (decimal 165) is 5A:

```
x = hex2dec('A5')
x =
   165

dec2hex(bitcmp(x, 8))
ans =
5A
```

Next, find the complement of hexadecimal 000000A5:

```
dec2hex(bitcmp(x, 32))
```

```
ans =
FFFFFF5A
```

See Also

bitand, bitget, bitmax, bitor, bitset, bitshift, bitxor

Purpose

Bit at specified position

Syntax

```
C = bitget(A, bit)
```

Description

`C = bitget(A, bit)` returns the value of the bit at position *`bit`* in `A`. Operand `A` must be an unsigned integer or an array of unsigned integers, and *`bit`* must be a number between 1 and the number of bits in the unsigned integer class of `A` (e.g., 32 for the `uint32` class).

Examples

Example 1

The `dec2bin` function converts decimal numbers to binary. However, you can also use the `bitget` function to show the binary representation of a decimal number. Just test successive bits from most to least significant:

```
disp(dec2bin(13))
1101

C = bitget(uint8(13), 4:-1:1)
C =
     1     1     0     1
```

Example 2

Prove that `intmax` sets all the bits to 1:

```
a = intmax('uint8');
if all(bitget(a, 1:8))
   disp('All the bits have value 1.')
   end

All the bits have value 1.
```

See Also

`bitand`, `bitcmp`, `bitmax`, `bitor`, `bitset`, `bitshift`, `bitxor`

bitmax

Purpose

Maximum double-precision floating-point integer

Syntax

```
bitmax
```

Description

`bitmax` returns the maximum unsigned double-precision floating-point integer for your computer. It is the value when all bits are set, namely the value $2^{53} - 1$.

Note Instead of integer-valued double-precision variables, use unsigned integers for bit manipulations and replace `bitmax` with `intmax`.

Examples

Display in different formats the largest floating point integer and the largest 32 bit unsigned integer:

```
format long e
bitmax
ans =
   9.007199254740991e+015

intmax('uint32')
ans =
   4294967295

format hex
bitmax
ans =
   433fffffffffffff

intmax('uint32')
ans =
   ffffffff
```

In the second bitmax statement, the last 13 hex digits of `bitmax` are `f`, corresponding to 52 1's (all 1's) in the mantissa of the binary

representation. The first 3 hex digits correspond to the sign bit 0 and the 11 bit biased exponent 10000110011 in binary (1075 in decimal), and the actual exponent is (1075-1023) = 52. Thus the binary value of bitmax is 1.111...111 x 2^52 with 52 trailing 1's, or 2^53-1.

See Also

bitand, bitcmp, bitget, bitor, bitset, bitshift, bitxor

bitor

Purpose

Bitwise OR

Syntax

```
C = bitor(A, B)
```

Description

`C = bitor(A, B)` returns the bitwise OR of arguments `A` and `B`, where `A` and `B` are unsigned integers or arrays of unsigned integers.

Examples

Example 1

The five-bit binary representations of the integers 13 and 27 are 01101 and 11011, respectively. Performing a bitwise OR on these numbers yields 11111, or 31.

```
C = bitor(uint8(13), uint8(27))
C =
    31
```

Example 2

Create a truth table for a logical OR operation:

```
A = uint8([0 1; 0 1]);
B = uint8([0 0; 1 1]);

TT = bitor(A, B)
TT =
    0    1
    1    1
```

See Also

`bitand`, `bitcmp`, `bitget`, `bitmax`, `bitset`, `bitshift`, `bitxor`

Purpose

Set bit at specified position

Syntax

```
C = bitset(A, bit)
C = bitset(A, bit, v)
```

Description

`C = bitset(A, bit)` sets bit position *`bit`* in `A` to 1 (on). `A` must be an unsigned integer or an array of unsigned integers, and *`bit`* must be a number between 1 and the number of bits in the unsigned integer class of `A` (e.g., 32 for the `uint32` class).

`C = bitset(A, bit, v)` sets the bit at position *`bit`* to the value `v`, which must be either 0 or 1.

Examples

Example 1

Setting the fifth bit in the five-bit binary representation of the integer 9 (01001) yields 11001, or 25:

```
C = bitset(uint8(9), 5)
C =
    25
```

Example 2

Repeatedly subtract powers of 2 from the largest `uint32` value:

```
a = intmax('uint32')
for k = 1:32
   a = bitset(a, 32-k+1, 0)
   end
```

See Also

`bitand`, `bitcmp`, `bitget`, `bitmax`, `bitor`, `bitshift`, `bitxor`

bitshift

Purpose

Shift bits specified number of places

Syntax

```
C = bitshift(A, k)
C = bitshift(A, k, n)
```

Description

`C = bitshift(A, k)` returns the value of `A` shifted by `k` bits. Input argument `A` must be an unsigned integer or an array of unsigned integers. Shifting by `k` is the same as multiplication by `2^k`. Negative values of `k` are allowed and this corresponds to shifting to the right, or dividing by `2^abs(k)` and truncating to an integer. If the shift causes `C` to overflow the number of bits in the unsigned integer class of `A`, then the overflowing bits are dropped.

`C = bitshift(A, k, n)` causes any bits that overflow `n` bits to be dropped. The value of `n` must be less than or equal to the length in bits of the unsigned integer class of `A` (e.g., `n <= 32` for `uint32`).

Instead of using `bitshift(A, k, 8)` or another power of 2 for `n`, consider using `bitshift(uint8(A), k)` or the appropriate unsigned integer class for `A`.

Examples

Example 1

Shifting 1100 (12, decimal) to the left two bits yields 110000 (48, decimal).

```
C = bitshift(12, 2)
C =
    48
```

Example 2

Repeatedly shift the bits of an unsigned 16 bit value to the left until all the nonzero bits overflow. Track the progress in binary:

```
a = intmax('uint16');
disp(sprintf( ...
   'Initial uint16 value %5d is %16s in binary', ...
   a, dec2bin(a)))
```

```
for k = 1:16
   a = bitshift(a, 1);
   disp(sprintf( ...
      'Shifted uint16 value %5d is %16s in binary',...
      a, dec2bin(a)))
end
```

See Also

bitand, bitcmp, bitget, bitmax, bitor, bitset, bitxor, fix

bitxor

Purpose

Bitwise XOR

Syntax

```
C = bitxor(A, B)
```

Description

`C = bitxor(A, B)` returns the bitwise XOR of arguments `A` and `B`, where `A` and `B` are unsigned integers or arrays of unsigned integers.

Examples

Example 1

The five-bit binary representations of the integers 13 and 27 are 01101 and 11011, respectively. Performing a bitwise XOR on these numbers yields 10110, or 22.

```
C = bitxor(uint8(13), uint8(27))
C =
    22
```

Example 2

Create a truth table for a logical XOR operation:

```
A = uint8([0 1; 0 1]);
B = uint8([0 0; 1 1]);

TT = bitxor(A, B)
TT =
    0    1
    1    0
```

See Also

`bitand`, `bitcmp`, `bitget`, `bitmax`, `bitor`, `bitset`, `bitshift`

Purpose

Create string of blank characters

Syntax

```
blanks(n)
```

Description

`blanks(n)` is a string of `n` blanks.

Examples

`blanks` is useful with the `display` function. For example,

```
disp(['xxx' blanks(20) 'yyy'])
```

displays twenty blanks between the strings `'xxx'` and `'yyy'`.

`disp(blanks(n)')` moves the cursor down `n` lines.

See Also

`clc`, `format`, `home`

blkdiag

Purpose

Construct block diagonal matrix from input arguments

Syntax

```
out = blkdiag(a,b,c,d,...)
```

Description

`out = blkdiag(a,b,c,d,...)`, where `a`, `b`, `c`, `d`, `...` are matrices, outputs a block diagonal matrix of the form

$$\begin{bmatrix} a & 0 & 0 & 0 & 0 \\ 0 & b & 0 & 0 & 0 \\ 0 & 0 & c & 0 & 0 \\ 0 & 0 & 0 & d & 0 \\ 0 & 0 & 0 & 0 & \ldots \end{bmatrix}$$

The input matrices do not have to be square, nor do they have to be of equal size.

See Also

`diag`, `horzcat`, `vertcat`

Purpose

Axes border

Syntax

```
box on
box off
box
box(axes_handle,...)
```

Description

`box on` displays the boundary of the current axes.

`box off` does not display the boundary of the current axes.

`box` toggles the visible state of the current axes boundary.

`box(axes_handle,...)` uses the axes specified by `axes_handle` instead of the current axes.

Algorithm

The `box` function sets the axes `Box` property to `on` or `off`.

See Also

`axes`, `grid`

"Axes Operations" on page 1-96 for related functions

break

Purpose

Terminate execution of `for` or `while` loop

Syntax

```
break
```

Description

`break` terminates the execution of a `for` or `while` loop. Statements in the loop that appear after the `break` statement are not executed.

In nested loops, `break` exits only from the loop in which it occurs. Control passes to the statement that follows the `end` of that loop.

Remarks

`break` is not defined outside a `for` or `while` loop. Use `return` in this context instead.

Examples

The example below shows a `while` loop that reads the contents of the file `fft.m` into a MATLAB character array. A `break` statement is used to exit the `while` loop when the first empty line is encountered. The resulting character array contains the M-file help for the `fft` program.

```
fid = fopen('fft.m','r');
s = '';
while ~feof(fid)
   line = fgetl(fid);
   if isempty(line), break, end
   s = strvcat(s,line);
end
disp(s)
```

See Also

`for`, `while`, `end`, `continue`, `return`

Purpose

Brighten or darken colormap

Syntax

```
brighten(beta)
brighten(h,beta)
newmap = brighten(beta)
newmap = brighten(cmap,beta)
```

Description

`brighten` increases or decreases the color intensities in a colormap. The modified colormap is brighter if `0 < beta < 1` and darker if `1 < beta < 0`.

`brighten(beta)` replaces the current colormap with a brighter or darker colormap of essentially the same colors. `brighten(beta)`, followed by `brighten(-beta)`, where `beta < 1`, restores the original map.

`brighten(h,beta)` brightens all objects that are children of the figure having the handle `h`.

`newmap = brighten(beta)` returns a brighter or darker version of the current colormap without changing the display.

`newmap = brighten(cmap,beta)` returns a brighter or darker version of the colormap `cmap` without changing the display.

Examples

Brighten and then darken the current colormap:

```
beta = .5; brighten(beta);
beta = -.5; brighten(beta);
```

Algorithm

The values in the colormap are raised to the power of gamma, where gamma is

$$\gamma = \begin{cases} 1-\beta, & \beta > 0 \\ \dfrac{1}{1+\beta}, & \beta \le 0 \end{cases}$$

`brighten` has no effect on graphics objects defined with true color.

Purpose

Build searchable documentation database

Syntax

```
builddocsearchdb help_location
```

Description

`builddocsearchdb help_location` builds a searchable database of user-added HTML and related help files in the specified help location. The `help_location` argument is the full path to the directory containing the help files. The database enables the Help browser to search for content within the help files.

`builddocsearchdb` creates a directory named `helpsearch` under `help_location`. The `helpsearch` directory contains the search database files. Add the location of the `helpsearch` directory to your `info.xml` file.

The `helpsearch` directory works only with the version of MATLAB used to create it.

For a full discussion of this process, refer to "Adding HTML Help Files for Your Own Toolboxes to the Help Browser".

Examples

Build a search database for the documentation files found at `D:\work\mytoolbox\help`.

```
builddocsearchdb D:\work\mytoolbox\help
```

See Also

`doc`, `help`

builtin

Purpose

Execute built-in function from overloaded method

Syntax

```
builtin(function, x1, ..., xn)
[y1, ..., yn] = builtin(function, x1, ..., xn)
```

Description

`builtin` is used in methods that overload built-in functions to execute the original built-in function. If *`function`* is a string containing the name of a built-in function, then

`builtin(`*`function`*`, x1, ..., xn)` evaluates the specified `function` at the given arguments `x1` through `xn`. The `function` argument must be a string containing a valid function name. `function` cannot be a function handle.

`[y1, ..., yn] = builtin(`*`function`*`, x1, ..., xn)` returns multiple output arguments.

Remarks

`builtin(...)` is the same as `feval(...)` except that it calls the original built-in version of the function even if an overloaded one exists. (For this to work you must never overload `builtin`.)

See Also

`feval`

Purpose

Apply element-by-element binary operation to two arrays with singleton expansion enabled

Syntax

```
C = bsxfun(fun,A,B)
```

Description

`C = bsxfun(fun,A,B)` applies an element-by-element binary operation to arrays `A` and `B`, with singleton expansion enabled. `fun` is a function handle, and can either be an M-file function or one of the following built-in functions:

`@plus`	Plus
`@minus`	Minus
`@times`	Array multiply
`@rdivide`	Right array divide
`@ldivide`	Left array divide
`@power`	Array power
`@max`	Binary maximum
`@min`	Binary minimum
`@rem`	Remainder after division
`@mod`	Modulus after division
`@atan2`	Four quadrant inverse tangent
`@hypot`	Square root of sum of squares
`@eq`	Equal
`@ne`	Not equal
`@lt`	Less than
`@le`	Less than or equal to
`@gt`	Greater than
`@ge`	Greater than or equal to

`@and`	Element-wise logical AND
`@or`	Element-wise logical OR
`@xor`	Logical exclusive OR

If an M-file function is specified, it must be able to accept either two column vectors of the same size, or one column vector and one scalar, and return as output a column vector of the size as the input values.

Each dimension of `A` and `B` must either be equal to each other, or equal to `1`. Whenever a dimension of `A` or `B` is singleton (equal to `1`), the array is virtually replicated along the dimension to match the other array. The array may be diminished if the corresponding dimension of the other array is `0`.

The size of the output array `C` is equal to: `max(size(A),size(B)).*(size(A)>0 & size(B)>0)`.

Examples

In this example, `bsxfun` is used to subtract the column means from the matrix `A`.

```
A = magic(5);
A = bsxfun(@minus, A, mean(A))
A =

     4    11   -12    -5     2
    10    -8    -6     1     3
    -9    -7     0     7     9
    -3    -1     6     8   -10
    -2     5    12   -11    -4
```

See Also

`repmat`, `arrayfun`

Purpose

Solve boundary value problems for ordinary differential equations

Syntax

```
sol = bvp4c(odefun,bcfun,solinit)
sol = bvp4c(odefun,bcfun,solinit,options)
solinit = bvpinit(x, yinit, params)
```

Arguments

`odefun`	A function handle that evaluates the differential equations $f(x, y)$. It can have the form
	
	`dydx = odefun(x,y)`
	`dydx = odefun(x,y,parameters)`
	
	where `x` is a scalar corresponding to x, and `y` is a column vector corresponding to y. `parameters` is a vector of unknown parameters. The output `dydx` is a column vector.

`bcfun`	A function handle that computes the residual in the boundary conditions. For two-point boundary value conditions of the form $bc(y(a), y(b))$, `bcfun` can have the form
	
	`res = bcfun(ya,yb)`
	`res = bcfun(ya,yb,parameters)`
	
	where `ya` and `yb` are column vectors corresponding to $y(a)$ and $y(b)$. `parameters` is a vector of unknown parameters. The output `res` is a column vector.
	
	See "Multipoint Boundary Value Problems" on page 2-416 for a description of `bcfun` for multipoint boundary value problems.

`solinit`	A structure containing the initial guess for a solution. You create `solinit` using the function `bvpinit`. `solinit` has the following fields.

	x	Ordered nodes of the initial mesh. Boundary conditions are imposed at a = solinit.x(1) and b = solinit.x(end).
	y	Initial guess for the solution such that solinit.y(:,i) is a guess for the solution at the node solinit.x(i).
	parameters	Optional. A vector that provides an initial guess for unknown parameters.
	The structure can have any name, but the fields must be named x, y, and parameters. You can form solinit with the helper function bvpinit. See bvpinit for details.	
options	Optional integration argument. A structure you create using the bvpset function. See bvpset for details.	

Description

sol = bvp4c(odefun,bcfun,solinit) integrates a system of ordinary differential equations of the form

$$y' = f(x, y)$$

on the interval [a,b] subject to two-point boundary value conditions

$$bc(y(a), y(b)) = 0$$

odefun and bcfun are function handles. See "Function Handles" in the MATLAB Programming documentation for more information.

"Parameterizing Functions Called by Function Functions" in the MATLAB mathematics documentation, explains how to provide additional parameters to the function odefun, as well as the boundary condition function bcfun, if necessary.

bvp4c can also solve multipoint boundary value problems. See "Multipoint Boundary Value Problems" on page 2-416. You can use the function bvpinit to specify the boundary points, which are stored in the input argument solinit. See the reference page for bvpinit for more information.

The bvp4c solver can also find unknown parameters p for problems of the form

$$y' = f(x, y, p)$$
$$0 = bc(y(a), y(b), p)$$

where p corresponds to parameters. You provide bvp4c an initial guess for any unknown parameters in solinit.parameters. The bvp4c solver returns the final values of these unknown parameters in sol.parameters.

bvp4c produces a solution that is continuous on [a,b] and has a continuous first derivative there. Use the function deval and the output sol of bvp4c to evaluate the solution at specific points xint in the interval [a,b].

```
sxint = deval(sol,xint)
```

The structure sol returned by bvp4c has the following fields:

sol.x	Mesh selected by bvp4c
sol.y	Approximation to $y(x)$ at the mesh points of sol.x
sol.yp	Approximation to $y'(x)$ at the mesh points of sol.x
sol.parameters	Values returned by bvp4c for the unknown parameters, if any
sol.solver	'bvp4c'

The structure sol can have any name, and bvp4c creates the fields x, y, yp, parameters, and solver.

sol = bvp4c(odefun,bcfun,solinit,options) solves as above with default integration properties replaced by the values in options, a structure created with the bvpset function. See bvpset for details.

`solinit = bvpinit(x, yinit, params)` forms the initial guess `solinit` with the vector `params` of guesses for the unknown parameters.

Singular Boundary Value Problems

`bvp4c` solves a class of singular boundary value problems, including problems with unknown parameters `p`, of the form

$$y' = S \cdot y/x + f(x, y, p)$$
$$0 = bc(y(0), y(b), p)$$

The interval is required to be [0, *b*] with b > 0. Often such problems arise when computing a smooth solution of ODEs that result from partial differential equations (PDEs) due to cylindrical or spherical symmetry. For singular problems, you specify the (constant) matrix `S` as the value of the `'SingularTerm'` option of `bvpset`, and `odefun` evaluates only *f*(*x*, *y*, *p*). The boundary conditions must be consistent with the necessary condition $S \cdot y(0) = 0$ and the initial guess should satisfy this condition.

Multipoint Boundary Value Problems

`bvp4c` can solve multipoint boundary value problems where $a = a_0 < a_1 < a_2 < \ldots < a_n = b$ are boundary points in the interval $[a, b]$. The points $a_1, a_2, \ldots, a_{n-1}$ represent interfaces that divide $[a, b]$ into regions. `bvp4c` enumerates the regions from left to right (from *a* to *b*), with indices starting from 1. In region *k*, $[a_{k-1}, a_k]$, `bvp4c` evaluates the derivative as

```
yp = odefun(x, y, k)
```

In the boundary conditions function

```
bcfun(yleft, yright)
```

yleft(:, k) is the solution at the left boundary of $[a_{k-1}, a_k]$. Similarly, `yright(:, k)` is the solution at the right boundary of region *k*. In particular,

```
yleft(:, 1) = y(a)
```

and

```
yright(:, end) = y(b)
```

When you create an initial guess with

```
solinit = bvpinit(xinit, yinit),
```

use double entries in `xinit` for each interface point. See the reference page for `bvpinit` for more information.

If `yinit` is a function, `bvpinit` calls `y = yinit(x, k)` to get an initial guess for the solution at `x` in region `k`. In the solution structure `sol` returned by `bpv4c`, `sol.x` has double entries for each interface point. The corresponding columns of `sol.y` contain the left and right solution at the interface, respectively.

For an example of solving a three-point boundary value problem, type `threebvp` at the MATLAB command prompt to run a demonstration.

Note The `bvp5c` function is used exactly like `bvp4c`, with the exception of the meaning of error tolerances between the two solvers. If *S(x)* approximates the solution *y(x)*, `bvp4c` controls the residual $|S'(x) - f(x,S(x))|$. This controls indirectly the true error $|y(x) - S(x)|$. `bvp5c` controls the true error directly. `bvp5c` is more efficient than `bvp4c` for small error tolerances.

Examples

Example 1

Boundary value problems can have multiple solutions and one purpose of the initial guess is to indicate which solution you want. The second-order differential equation

$$y'' + |y| = 0$$

has exactly two solutions that satisfy the boundary conditions

$$y(0) = 0$$
$$y(4) = -2$$

Prior to solving this problem with `bvp4c`, you must write the differential equation as a system of two first-order ODEs

$$y_1' = y_2$$
$$y_2' = -|y_1|$$

Here $y_1 = y$ and $y_2 = y'$. This system has the required form

$$y' = f(x, y)$$
$$bc(y(a), y(b)) = 0$$

The function f and the boundary conditions bc are coded in MATLAB as functions `twoode` and `twobc`.

```
function dydx = twoode(x,y)
  dydx = [ y(2)
           -abs(y(1))];

function res = twobc(ya,yb)
  res = [ ya(1)
          yb(1) + 2];
```

Form a guess structure consisting of an initial mesh of five equally spaced points in [0,4] and a guess of constant values $y_1(x) \equiv 1$ and $y_2(x) \equiv 0$ with the command

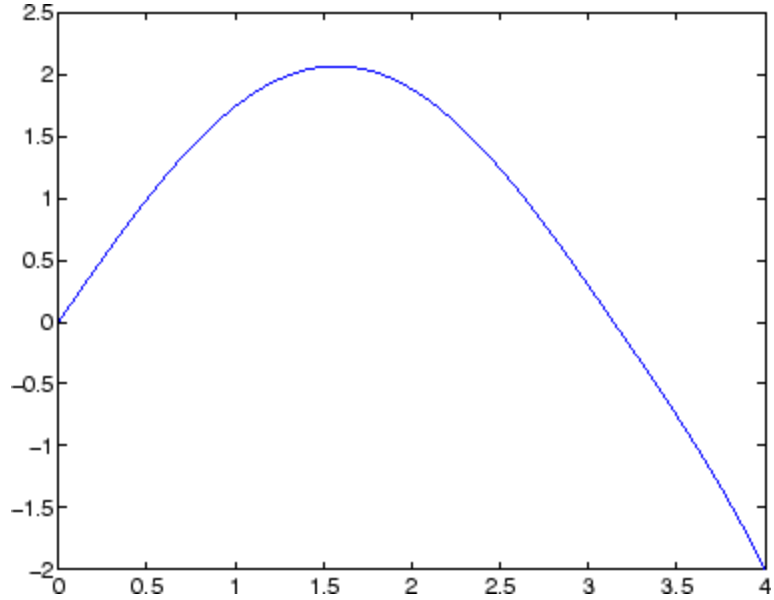
```
solinit = bvpinit(linspace(0,4,5),[1 0]);
```

Now solve the problem with

```
sol = bvp4c(@twoode,@twobc,solinit);
```

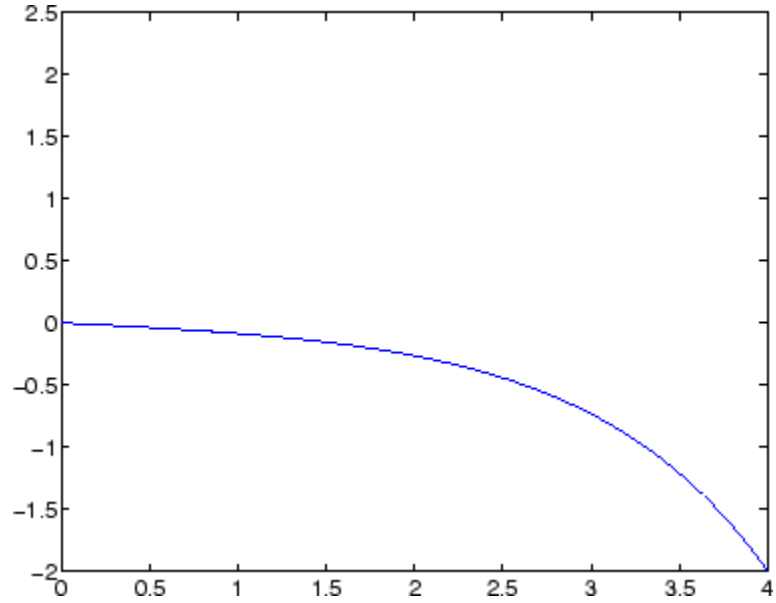
Evaluate the numerical solution at 100 equally spaced points and plot $y(x)$ with

```
x = linspace(0,4);
y = deval(sol,x);
plot(x,y(1,:));
```



You can obtain the other solution of this problem with the initial guess

```
solinit = bvpinit(linspace(0,4,5),[-1 0]);
```



Example 2

This boundary value problem involves an unknown parameter. The task is to compute the fourth ($q = 5$) eigenvalue λ of Mathieu's equation

$$y'' + (\lambda - 2\,q\cos 2x)\,y = 0$$

Because the unknown parameter λ is present, this second-order differential equation is subject to *three* boundary conditions

$$y'(0) = 0$$
$$y'(\pi) = 0$$
$$y(0) = 1$$

It is convenient to use subfunctions to place all the functions required by `bvp4c` in a single M-file.

```
function mat4bvp
```

```
lambda = 15;
solinit = bvpinit(linspace(0,pi,10),@mat4init,lambda);
sol = bvp4c(@mat4ode,@mat4bc,solinit);

fprintf('The fourth eigenvalue is approximately %7.3f.\n',...
        sol.parameters)

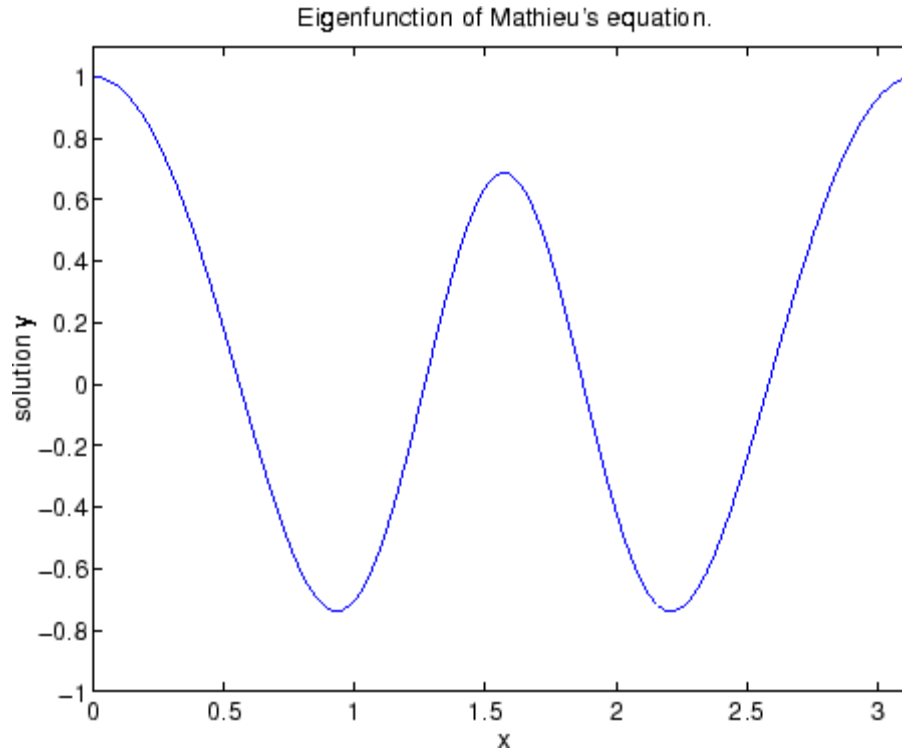
xint = linspace(0,pi);
Sxint = deval(sol,xint);
plot(xint,Sxint(1,:))
axis([0 pi -1 1.1])
title('Eigenfunction of Mathieu''s equation.')
xlabel('x')
ylabel('solution y')
% --------------------------------------------------------------
function dydx = mat4ode(x,y,lambda)
q = 5;
dydx = [  y(2)
         -(lambda - 2*q*cos(2*x))*y(1) ];
% --------------------------------------------------------------
function res = mat4bc(ya,yb,lambda)
res = [  ya(2)
         yb(2)
        ya(1)-1 ];
% --------------------------------------------------------------
function yinit = mat4init(x)
yinit = [  cos(4*x)
          -4*sin(4*x) ];
```

The differential equation (converted to a first-order system) and the boundary conditions are coded as subfunctions `mat4ode` and `mat4bc`, respectively. Because unknown parameters are present, these functions must accept three input arguments, even though some of the arguments are not used.

The guess structure `solinit` is formed with `bvpinit`. An initial guess for the solution is supplied in the form of a function `mat4init`. We chose

$y = \cos 4x$ because it satisfies the boundary conditions and has the correct qualitative behavior (the correct number of sign changes). In the call to `bvpinit`, the third argument (`lambda = 15`) provides an initial guess for the unknown parameter λ.

After the problem is solved with `bvp4c`, the field `sol.parameters` returns the value $\lambda = 17.097$, and the plot shows the eigenfunction associated with this eigenvalue.



Algorithms

`bvp4c` is a finite difference code that implements the three-stage Lobatto IIIa formula. This is a collocation formula and the collocation polynomial provides a C^1-continuous solution that is fourth-order

accurate uniformly in `[a,b]`. Mesh selection and error control are based on the residual of the continuous solution.

Purpose

Solve boundary value problems for ordinary differential equations

Syntax

```
sol = bvp5c(odefun,bcfun,solinit)
sol = bvp5c(odefun,bcfun,solinit,options)
solinit = bvpinit(x, yinit, params)
```

Arguments

`odefun`	A function handle that evaluates the differential equations $f(x, y)$. It can have the form
	`dydx = odefun(x,y)`
	`dydx = odefun(x,y,parameters)`
	where `x` is a scalar corresponding to x, and `y` is a column vector corresponding to y. `parameters` is a vector of unknown parameters. The output `dydx` is a column vector.	

`bcfun`	A function handle that computes the residual in the boundary conditions. For two-point boundary value conditions of the form $bc(y(a), y(b))$, `bcfun` can have the form
	`res = bcfun(ya,yb)`
	`res = bcfun(ya,yb,parameters)`
	where `ya` and `yb` are column vectors corresponding to $y(a)$ and $y(b)$. `parameters` is a vector of unknown parameters. The output `res` is a column vector.	

`solinit`	A structure containing the initial guess for a solution. You create `solinit` using the function `bvpinit`. `solinit` has the following fields.	
	`x`	Ordered nodes of the initial mesh. Boundary conditions are imposed at a = `solinit.x(1)` and b = `solinit.x(end)`.

	`y`	Initial guess for the solution such that `solinit.y(:,i)` is a guess for the solution at the node `solinit.x(i)`.
	`parameters`	Optional. A vector that provides an initial guess for unknown parameters.
	The structure can have any name, but the fields must be named `x`, `y`, and `parameters`. You can form `solinit` with the helper function `bvpinit`. See `bvpinit` for details.	
`options`	Optional integration argument. A structure you create using the `bvpset` function. See `bvpset` for details.	

Description

`sol = bvp5c(odefun,bcfun,solinit)` integrates a system of ordinary differential equations of the form

$$y' = f(x, y)$$

on the interval [a,b] subject to two-point boundary value conditions

$$bc(y(a), y(b)) = 0$$

`odefun` and `bcfun` are function handles. See “Function Handles” in the MATLAB Programming documentation for more information.

“Parameterizing Functions Called by Function Functions” in the MATLAB mathematics documentation, explains how to provide additional parameters to the function `odefun`, as well as the boundary condition function `bcfun`, if necessary. You can use the function `bvpinit` to specify the boundary points, which are stored in the input argument `solinit`. See the reference page for `bvpinit` for more information.

The `bvp5c` solver can also find unknown parameters p for problems of the form

$$y' = f(x, y, p)$$
$$0 = bc(y(a), y(b), p)$$

where p corresponds to `parameters`. You provide `bvp5c` an initial guess for any unknown parameters in `solinit.parameters`. The `bvp5c` solver returns the final values of these unknown parameters in `sol.parameters`.

`bvp5c` produces a solution that is continuous on `[a,b]` and has a continuous first derivative there. Use the function `deval` and the output `sol` of `bvp5c` to evaluate the solution at specific points `xint` in the interval `[a,b]`.

```
sxint = deval(sol,xint)
```

The structure `sol` returned by `bvp5c` has the following fields:

`sol.x`	Mesh selected by `bvp5c`
`sol.y`	Approximation to $y(x)$ at the mesh points of `sol.x`
`sol.parameters`	Values returned by `bvp5c` for the unknown parameters, if any
`sol.solver`	'bvp5c'

The structure `sol` can have any name, and `bvp5c` creates the fields `x`, `y`, `parameters`, and `solver`.

`sol = bvp5c(odefun,bcfun,solinit,options)` solves as above with default integration properties replaced by the values in `options`, a structure created with the `bvpset` function. See `bvpset` for details.

`solinit = bvpinit(x, yinit, params)` forms the initial guess `solinit` with the vector `params` of guesses for the unknown parameters.

Note The `bvp5c` function is used exactly like `bvp4c`, with the exception of the meaning of error tolerances between the two solvers. If *S(x)* approximates the solution *y(x)*, `bvp4c` controls the residual $|S'(x) - f(x,S(x))|$. This controls indirectly the true error $|y(x) - S(x)|$. `bvp5c` controls the true error directly. `bvp5c` is more efficient than `bvp4c` for small error tolerances.

Singular Boundary Value Problems

`bvp5c` solves a class of singular boundary value problems, including problems with unknown parameters `p`, of the form

$$y' = S \cdot y/x + f(x, y, p)$$
$$0 = bc(y(0), y(b), p)$$

The interval is required to be [0, *b*] with b > 0. Often such problems arise when computing a smooth solution of ODEs that result from partial differential equations (PDEs) due to cylindrical or spherical symmetry. For singular problems, you specify the (constant) matrix `S` as the value of the `'SingularTerm'` option of `bvpset`, and `odefun` evaluates only *f*(*x*, *y*, *p*). The boundary conditions must be consistent with the necessary condition $S \cdot y(0) = 0$ and the initial guess should satisfy this condition.

Algorithms

`bvp5c` is a finite difference code that implements the four-stage Lobatto IIIa formula. This is a collocation formula and the collocation polynomial provides a C^1-continuous solution that is fifth-order accurate uniformly in `[a,b]`. The formula is implemented as an implicit Runge-Kutta formula. `bvp5c` solves the algebraic equations directly; `bvp4c` uses analytical condensation. `bvp4c` handles unknown parameters directly; while `bvp5c` augments the system with trivial differential equations for unknown parameters.

`function_handle` (`@`), `bvp4c`, `bvpget`, `bvpinit`, `bvpset`, `bvpxtend`, `deval`

Purpose

Extract properties from options structure created with `bvpset`

Syntax

```
val = bvpget(options,'name')
val = bvpget(options,'name',default)
```

Description

`val = bvpget(options,'name')` extracts the value of the named property from the structure `options`, returning an empty matrix if the property value is not specified in `options`. It is sufficient to type only the leading characters that uniquely identify the property. Case is ignored for property names. `[]` is a valid `options` argument.

`val = bvpget(options,'name',default)` extracts the named property as above, but returns `val = default` if the named property is not specified in `options`. For example,

```
val = bvpget(opts,'RelTol',1e-4);
```

returns `val = 1e-4` if the `RelTol` is not specified in `opts`.

See Also

`bvp4c`, `bvp5c`, `bvpinit`, `bvpset`, `deval`

bvpinit

Purpose

Form initial guess for `bvp4c`

Syntax

```
solinit = bvpinit(x,yinit)
solinit = bvpinit(x,yinit,parameters)
solinit = bvpinit(sol,[anew bnew])
solinit = bvpinit(sol,[anew bnew],parameters)
```

Description

`solinit = bvpinit(x,yinit)` forms the initial guess for the boundary value problem solver `bvp4c`.

`x` is a vector that specifies an initial mesh. If you want to solve the boundary value problem (BVP) on $[a, b]$, then specify `x(1)` as a and `x(end)` as b. The function `bvp4c` adapts this mesh to the solution, so a guess like `xb=nlinspace(a,b,10)` often suffices. However, in difficult cases, you should place mesh points where the solution changes rapidly. The entries of `x` must be in

- Increasing order if $a < b$
- Decreasing order if $a > b$

For two-point boundary value problems, the entries of `x` must be distinct. That is, if $a < b$, the entries must satisfy `x(1) < x(2) < ... < x(end)`. If $a > b$, the entries must satisfy `x(1) > x(2) > ... > x(end)`

For multipoint boundary value problem, you can specify the points in $[a, b]$ at which the boundary conditions apply, other than the endpoints *a* and *b*, by repeating their entries in `x`. For example, if you set

```
x = [0, 0.5, 1, 1,  1.5, 2];
```

the boundary conditions apply at three points: the endpoints `0` and `2`, and the repeated entry 1. In general, repeated entries represent boundary points between regions in $[a, b]$. In the preceding example, the repeated entry 1 divides the interval `[0,2]` into two regions: `[0,1]` and `[1,2]`.

`yinit` is a guess for the solution. It can be either a vector, or a function:

- Vector – For each component of the solution, `bvpinit` replicates the corresponding element of the vector as a constant guess across all mesh points. That is, `yinit(i)` is a constant guess for the `i`th component `yinit(i,:)` of the solution at all the mesh points in `x`.
- Function – For a given mesh point, the guess function must return a vector whose elements are guesses for the corresponding components of the solution. The function must be of the form

  ```
  y = guess(x)
  ```

  where `x` is a mesh point and `y` is a vector whose length is the same as the number of components in the solution. For example, if the guess function is an M-file function, `bvpinit` calls

  ```
  y(:,j) = guess(x(j))
  ```

  at each mesh point.

  For multipoint boundary value problems, the guess function must be of the form

  ```
  y = guess(x, k)
  ```

  where `y` an initial guess for the solution at `x` in region `k`. The function must accept the input argument `k`, which is provided for flexibility in writing the guess function. However, the function is not required to use `k`.

`solinit = bvpinit(x,yinit,parameters)` indicates that the boundary value problem involves unknown parameters. Use the vector `parameters` to provide a guess for all unknown parameters.

`solinit` is a structure with the following fields. The structure can have any name, but the fields must be named `x`, `y`, and `parameters`.

`x`	Ordered nodes of the initial mesh.
`y`	Initial guess for the solution with `solinit.y(:,i)` a guess for the solution at the node `solinit.x(i)`.
`parameters`	Optional. A vector that provides an initial guess for unknown parameters.

`solinit = bvpinit(sol,[anew bnew])` forms an initial guess on the interval `[anew bnew]` from a solution `sol` on an interval $[a, b]$. The new interval must be larger than the previous one, so either `anew <=`a `<`b `<= bnew` or `anew >=`a `>`b `>= bnew`. The solution `sol` is extrapolated to the new interval. If `sol` contains `parameters`, they are copied to `solinit`.

`solinit = bvpinit(sol,[anew bnew],parameters)` forms `solinit` as described above, but uses `parameters` as a guess for unknown parameters in `solinit`.

Purpose

Create or alter options structure of boundary value problem

Syntax

```
options = bvpset('name1',value1,'name2',value2,...)
options = bvpset(oldopts,'name1',value1,...)
options = bvpset(oldopts,newopts)
bvpset
```

Description

`options = bvpset('name1',value1,'name2',value2,...)` creates a structure `options` that you can supply to the boundary value problem solver `bvp4c`, in which the named properties have the specified values. Any unspecified properties retain their default values. For all properties, it is sufficient to type only the leading characters that uniquely identify the property. `bvpset` ignores case for property names.

`options = bvpset(oldopts,'name1',value1,...)` alters an existing options structure `oldopts`. This overwrites any values in `oldopts` that are specified using name/value pairs and returns the modified structure as the output argument.

`options = bvpset(oldopts,newopts)` combines an existing options structure `oldopts` with a new options structure `newopts`. Any values set in `newopts` overwrite the corresponding values in `oldopts`.

`bvpset` with no input arguments displays all property names and their possible values, indicating defaults with braces `{}`.

You can use the function `bvpget` to query the `options` structure for the value of a specific property.

BVP Properties

`bvpset` enables you to specify properties for the boundary value problem solver `bvp4c`. There are several categories of properties that you can set:

- "Error Tolerance Properties" on page 2-434
- "Vectorization" on page 2-435
- "Analytical Partial Derivatives" on page 2-436
- "Singular BVPs" on page 2-439

Error Tolerance Properties

Because `bvp4c` uses a collocation formula, the numerical solution is based on a mesh of points at which the collocation equations are satisfied. Mesh selection and error control are based on the residual of this solution, such that the computed solution $S(x)$ is the exact solution of a perturbed problem $S'(x) = f(x, S(x)) + res(x)$. On each subinterval of the mesh, a norm of the residual in the `i`th component of the solution, `res(i)`, is estimated and is required to be less than or equal to a tolerance. This tolerance is a function of the relative and absolute tolerances, `RelTol` and `AbsTol`, defined by the user.

$$\| (\text{res(i)}/\max(\text{abs(f(i))}, \text{AbsTol(i)}/\text{RelTol})) \| \leq \text{RelTol}$$

The following table describes the error tolerance properties.

BVP Error Tolerance Properties

Property	Value	Description
`RelTol`	Positive scalar {`1e-3`}	A relative error tolerance that applies to all components of the residual vector. It is a measure of the residual relative to the size of $f(x, y)$. The default, `1e-3`, corresponds to 0.1% accuracy. The computed solution $S(x)$ is the exact solution of $S'(x) = F(x, S(x)) + \mathtt{res}(x)$. On each subinterval of the mesh, the residual $\mathtt{res}(x)$ satisfies $\|(\mathrm{res(i)/max(abs(F(i)),AbsTol(i)/RelTol))}\| \le \mathrm{RelTol}$
`AbsTol`	Positive scalar or vector {`1e-6`}	Absolute error tolerances that apply to the corresponding components of the residual vector. `AbsTol(i)` is a threshold below which the values of the corresponding components are unimportant. If a scalar value is specified, it applies to all components.

Vectorization

The following table describes the BVP vectorization property. Vectorization of the ODE function used by `bvp4c` differs from the vectorization used by the ODE solvers:

- For `bvp4c`, the ODE function must be vectorized with respect to the first argument as well as the second one, so that `F([x1 x2 ...],[y1 y2 ...])` returns `[F(x1,y1) F(x2,y2)...]`.
- `bvp4c` benefits from vectorization even when analytical Jacobians are provided. For stiff ODE solvers, vectorization is ignored when analytical Jacobians are used.

Vectorization Properties

Property	Value	Description

`Vectorized`	`on` | {`off`}	Set on to inform `bvp4c` that you have coded the ODE function F so that `F([x1 x2 ...],[y1 y2 ...])` returns `[F(x1,y1) F(x2,y2) ...]`. That is, your ODE function can pass to the solver a whole array of column vectors at once. This enables the solver to reduce the number of function evaluations and may significantly reduce solution time.
		
		With the MATLAB array notation, it is typically an easy matter to vectorize an ODE function. In the `shockbvp` example shown previously, the shockODE function has been vectorized using colon notation into the subscripts and by using the array multiplication (.*) operator.
		
		`function dydx = shockODE(x,y,e)`
		`pix = pi*x;`
		`dydx = [ y(2,:)...`
		`-x/e.*y(2,:)-pi^2*cos(pix)-`
		`pix/e.*sin(pix)];`

Analytical Partial Derivatives

By default, the `bvp4c` solver approximates all partial derivatives with finite differences. `bvp4c` can be more efficient if you provide analytical partial derivatives $\partial f / \partial y$ of the differential equations,

and analytical partial derivatives, $\partial bc/\partial ya$ and $\partial bc/\partial yb$, of the boundary conditions. If the problem involves unknown parameters, you must also provide partial derivatives, $\partial f/\partial p$ and $\partial bc/\partial p$, with respect to the parameters.

The following table describes the analytical partial derivatives properties.

BVP Analytical Partial Derivative Properties

Property	Value	Description
`FJacobian`	Function handle	Handle to a function that computes the analytical partial derivatives of $f(x, y)$. When solving $y' = f(x, y)$, set this property to `@fjac` if `dfdy = fjac(x,y)` evaluates the Jacobian $\partial f / \partial y$. If the problem involves unknown parameters p, `[dfdy,dfdp] = fjac(x,y,p)` must also return the partial derivative $\partial f / \partial p$. For problems with constant partial derivatives, set this property to the value of `dfdy` or to a cell array `{dfdy,dfdp}`. See "Function Handles" in the MATLAB Programming documentation for more information.
`BCJacobian`	Function handle	Handle to a function that computes the analytical partial derivatives of $bc(ya, yb)$. For boundary conditions $bc(ya, yb)$, set this property to `@bcjac` if `[dbcdya,dbcdyb] = bcjac(ya,yb)` evaluates the partial derivatives $\partial bc / \partial ya$, and $\partial bc / \partial yb$. If the problem involves unknown parameters p, `[dbcdya,dbcdyb,dbcdp] = bcjac(ya,yb,p)` must also return the partial derivative $\partial bc / \partial p$. For problems with constant partial derivatives, set this property to a cell array `{dbcdya,dbcdyb}` or `{dbcdya,dbcdyb,dbcdp}`.

Singular BVPs

bvp4c can solve singular problems of the form

$$y' = S\frac{y}{x} + f(x, y, p)$$

posed on the interval $[0, b]$ where $b > 0$. For such problems, specify the constant matrix S as the value of SingularTerm. For equations of this form, odefun evaluates only the $f(x, y, p)$ term, where p represents unknown parameters, if any.

Singular BVP Property

Property	Value	Description
SingularTerm	Constant matrix	Singular term of singular BVPs. Set to the constant matrix S for equations of the form $y' = S\frac{y}{x} + f(x, y, p)$ posed on the interval $[0, b]$ where $b > 0$.

Mesh Size Property

bvp4c solves a system of algebraic equations to determine the numerical solution to a BVP at each of the mesh points. The size of the algebraic system depends on the number of differential equations (n) and the number of mesh points in the current mesh (N). When the allowed number of mesh points is exhausted, the computation stops, bvp4c displays a warning message and returns the solution it found so far. This solution does not satisfy the error tolerance, but it may provide an

excellent initial guess for computations restarted with relaxed error tolerances or an increased value of NMax.

The following table describes the mesh size property.

BVP Mesh Size Property

Property	Value	Description
NMax	positive integer {floor(1000/n)}	Maximum number of mesh points allowed when solving the BVP, where n is the number of differential equations in the problem. The default value of NMax limits the size of the algebraic system to about 1000 equations. For systems of a few differential equations, the default value of NMax should be sufficient to obtain an accurate solution.

Solution Statistic Property

The Stats property lets you view solution statistics.

The following table describes the solution statistics property.

BVP Solution Statistic Property

Property	Value	Description
`Stats`	`on` | {`off`}	Specifies whether statistics about the computations are displayed. If the `stats` property is `on`, after solving the problem, `bvp4c` displays: • The number of points in the mesh • The maximum residual of the solution • The number of times it called the differential equation function `odefun` to evaluate $f(x, y)$ • The number of times it called the boundary condition function `bcfun` to evaluate $bc(y(a), y(b))$

Example

To create an options structure that changes the relative error tolerance of `bvp4c` from the default value of `1e-3` to `1e-4`, enter

```
options = bvpset('RelTol', 1e-4);
```

To recover the value of `'RelTol'` from `options`, enter

```
bvpget(options, 'RelTol')

ans =

   1.0000e-004
```

bvpxtend

Purpose

Form guess structure for extending boundary value solutions

Syntax

```
solinit = bvpxtend(sol,xnew,ynew)
solinit = bvpxtend(sol,xnew,extrap)
solinit = bvpxtend(sol,xnew)
solinit = bvpxtend(sol,xnew,ynew,pnew)
solinit = bvpxtend(sol,xnew,extrap,pnew)
```

Description

`solinit = bvpxtend(sol,xnew,ynew)` uses solution `sol` computed on `[a,b]` to form a solution guess for the interval extended to `xnew`. The extension point `xnew` must be outside the interval `[a,b]`, but on either side. The vector `ynew` provides an initial guess for the solution at `xnew`.

`solinit = bvpxtend(sol,xnew,extrap)` forms the guess at `xnew` by extrapolating the solution `sol`. `extrap` is a string that determines the extrapolation method. `extrap` has three possible values:

- `'constant'` — `ynew` is a value nearer to end point of solution in `sol`.
- `'linear'` — `ynew` is a value at `xnew` of linear interpolant to the value and slope at the nearer end point of solution in `sol`.
- `'solution'` — `ynew` is the value of (cubic) solution in `sol` at `xnew`.

The value of `extrap` is case-insensitive and only the leading, unique portion needs to be specified.

`solinit = bvpxtend(sol,xnew)` uses the extrapolating solution where `extrap` is `'constant'`. If there are unknown parameters, values present in `sol` are used as the initial guess for parameters in `solinit`.

`solinit = bvpxtend(sol,xnew,ynew,pnew)` specifies a different guess `pnew`. `pnew` can be used with extrapolation, using the syntax `solinit = bvpxtend(sol,xnew,extrap,pnew)`. To modify parameters without changing the interval, use `[]` as place holder for `xnew` and `ynew`.

See Also

`bvp4c`, `bvp5c`, `bvpinit`

Purpose

Calendar for specified month

Syntax

```
c = calendar
c = calendar(d)
c = calendar(y, m)
```

Description

`c = calendar` returns a 6-by-7 matrix containing a calendar for the current month. The calendar runs Sunday (first column) to Saturday.

`c = calendar(d)`, where `d` is a serial date number or a date string, returns a calendar for the specified month.

`c = calendar(y, m)`, where `y` and `m` are integers, returns a calendar for the specified month of the specified year.

Examples

The command

```
calendar(1957,10)
```

reveals that the Space Age began on a Friday (on October 4, 1957, when Sputnik 1 was launched).

```
                Oct 1957
   S     M     Tu     W     Th     F     S
   0     0      1     2      3     4     5
   6     7      8     9     10    11    12
  13    14     15    16     17    18    19
  20    21     22    23     24    25    26
  27    28     29    30     31     0     0
   0     0      0     0      0     0     0
```

See Also

`datenum`

Purpose

Call function in external library

Syntax

```
[x1, ..., xN] = calllib('libname', 'funcname', arg1, ...,
   argN)
```

Description

`[x1, ..., xN] = calllib('libname', 'funcname', arg1, ..., argN)` calls the function `funcname` in library `libname`, passing input arguments `arg1` through `argN`. `calllib` returns output values obtained from function `funcname` in `x1` through `XN`.

If you used an alias when initially loading the library, then you must use that alias for the `libname` argument.

Ways to Call calllib

The following examples show ways calls to `calllib`. By using `libfunctionsview`, you determined that the `addStructByRef` function in the shared library `shrlibsample` requires a pointer to a `c_struct` data type as its argument.

Load the library:

```
addpath([matlabroot '\extern\examples\shrlib'])
loadlibrary shrlibsample shrlibsample.h
```

Create a MATLAB structure and use `libstruct` to create a C structure of the proper type (`c_struct` here):

```
struct.p1 = 4; struct.p2 = 7.3; struct.p3 = -290;
[res,st] = calllib('shrlibsample','addStructByRef',...
 libstruct('c_struct',struct));
```

Let MATLAB convert `struct` to the proper type of C structure:

```
[res,st] = calllib('shrlibsample','addStructByRef',struct);
```

Pass an empty array to `libstruct` and assign the values from your C function:

```
[res,st] = calllib('shrlibsample','addStructByRef',...
```

```
libstruct('c_struct',[]);
```

Let MATLAB create the proper type of structure and assign values from your C function:

```
[res,st] = calllib('shrlibsample','addStructByRef',[]);
```

Examples

This example calls functions from the `libmx` library to test the value stored in `y`:

```
hfile = [matlabroot '\extern\include\matrix.h'];
loadlibrary('libmx', hfile)

y = rand(4, 7, 2);

calllib('libmx', 'mxGetNumberOfElements', y)
ans =
    56

calllib('libmx', 'mxGetClassID', y)
ans =
   mxDOUBLE_CLASS

unloadlibrary libmx
```

See Passing Arguments for information on defining the correct data types for library function arguments.

callSoapService

Purpose

Send SOAP message off to endpoint

Syntax

```
callSoapService(endpoint, soapAction, message)
```

Description

`callSoapService(endpoint, soapAction, message)` sends `message`, a Java document object model (DOM), to the `soapAction` service at the `endpoint`.

Example

```
message = createSoapMessage(...
'urn:xmethods-delayed-quotes','getQuote',{'GOOG'},{'symbol'},...
{'{http://www.w3.org/2001/XMLSchema}string'},'rpc')
response = callSoapService('http://64.124.140.30:9090/soap',...
'urn:xmethods-delayed-quotes#getQuote',message)
price = parseSoapResponse(response)
```

See Also

`createClassFromWsdl`, `CreateSoapMessage`, `parseSoapResponse`

Purpose

Move camera position and target

Syntax

```
camdolly(dx,dy,dz)
camdolly(dx,dy,dz,'targetmode')
camdolly(dx,dy,dz,'targetmode','coordsys')
camdolly(axes_handle,...)
```

Description

`camdolly` moves the camera position and the camera target by the specified amounts.

`camdolly(dx,dy,dz)` moves the camera position and the camera target by the specified amounts (see Coordinate Systems).

`camdolly(dx,dy,dz,'targetmode')` The *`targetmode`* argument can take on two values that determine how MATLAB moves the camera:

- `movetarget` (default) — Move both the camera and the target.
- `fixtarget` — Move only the camera.

`camdolly(dx,dy,dz,'targetmode','coordsys')` The *`coordsys`* argument can take on three values that determine how MATLAB interprets `dx`, `dy`, and `dz`:

Coordinate Systems

- `camera` (default) — Move in the camera's coordinate system. `dx` moves left/right, `dy` moves down/up, and `dz` moves along the viewing axis. The units are normalized to the scene.

  For example, setting `dx` to 1 moves the camera to the right, which pushes the scene to the left edge of the box formed by the axes position rectangle. A negative value moves the scene in the other direction. Setting `dz` to 0.5 moves the camera to a position halfway between the camera position and the camera target.

- `pixels` — Interpret `dx` and `dy` as pixel offsets. `dz` is ignored.
- `data` — Interpret `dx`, `dy`, and `dz` as offsets in axes data coordinates.

`camdolly(axes_handle,...)` operates on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `camdolly` operates on the current axes.

Remarks

`camdolly` sets the axes `CameraPosition` and`CameraTarget` properties, which in turn causes the `CameraPositionMode` and `CameraTargetMode` properties to be set to `manual`.

Examples

This example moves the camera along the *x*- and *y*-axes in a series of steps.

```
surf(peaks)
axis vis3d
t = 0:pi/20:2*pi;
dx = sin(t)./40;
dy = cos(t)./40;
for i = 1:length(t);
    camdolly(dx(i),dy(i),0)
    drawnow
end
```

The axes properties `CameraPosition`, `CameraTarget`, `CameraUpVector`, `CameraViewAngle`, `Projection`

"Controlling the Camera Viewpoint" on page 1-99 for related functions

See "Defining Scenes with Camera Graphics" for more information on camera properties.

Purpose

Control camera toolbar programmatically

Syntax

```
cameratoolbar
cameratoolbar('NoReset')
cameratoolbar('SetMode',mode)
cameratoolbar('SetCoordSys',coordsys)
cameratoolbar('Show')
cameratoolbar('Hide')
cameratoolbar('Toggle')
cameratoolbar('ResetCameraAndSceneLight')
cameratoolbar('ResetCamera')
cameratoolbar('ResetSceneLight')
cameratoolbar('ResetTarget')
mode = cameratoolbar('GetMode')
paxis = cameratoolbar('GetCoordsys')
vis = cameratoolbar('GetVisible')
cameratoolbar(fig,...)
h = cameratoolbar
cameratoolbar('Close')
```

Description

`cameratoolbar` creates a new toolbar that enables interactive manipulation of the axes camera and light when users drag the mouse on the figure window. Several axes camera properties are set when the toolbar is initialized.

`cameratoolbar('NoReset')` creates the toolbar without setting any camera properties.

`cameratoolbar('SetMode',mode)` sets the toolbar mode (depressed button). *`mode`* can be `'orbit'`, `'orbitscenelight'`, `'pan'`, `'dollyhv'`, `'dollyfb'`, `'zoom'`, `'roll'`, `'nomode'`.

`cameratoolbar('SetCoordSys',coordsys)` sets the principal axis of the camera motion. *`coordsys`* can be: `'x'`, `'y'`, `'z'`, `'none'`.

`cameratoolbar('Show')` shows the toolbar on the current figure.

`cameratoolbar('Hide')` hides the toolbar on the current figure.

`cameratoolbar('Toggle')` toggles the visibility of the toolbar.

`cameratoolbar('ResetCameraAndSceneLight')` resets the current camera and scenelight.

`cameratoolbar('ResetCamera')` resets the current camera.

`cameratoolbar('ResetSceneLight')` resets the current scenelight.

`cameratoolbar('ResetTarget')` resets the current camera target.

`mode = cameratoolbar('GetMode')` returns the current mode.

`paxis = cameratoolbar('GetCoordsys')` returns the current principal axis.

`vis = cameratoolbar('GetVisible')` returns the visibility of the toolbar (`1` if visible, `0` if not visible).

`cameratoolbar(fig,...)` specifies the figure to operate on by passing the figure handle as the first argument.

`h = cameratoolbar` returns the handle to the toolbar.

`cameratoolbar('Close')` removes the toolbar from the current figure.

Note that, in general, the use of OpenGL hardware improves rendering performance.

`rotate3d`, `zoom`

Purpose

Create or move light object in camera coordinates

Syntax

```
camlight('headlight')
camlight('right')
camlight('left')
camlight
camlight(az,el)
camlight(...,'style')
camlight(light_handle,...)
light_handle = camlight(...)
```

Description

`camlight('headlight')` creates a light at the camera position.

`camlight('right')` creates a light right and up from camera.

`camlight('left')` creates a light left and up from camera.

`camlight` with no arguments is the same as `camlight('right')`.

`camlight(az,el)` creates a light at the specified azimuth (`az`) and elevation (`el`) with respect to the camera position. The camera target is the center of rotation and `az` and `el` are in degrees.

`camlight(...,'style')` The style argument can take on two values:

- `local` (default) — The light is a point source that radiates from the location in all directions.
- `infinite` — The light shines in parallel rays.

`camlight(light_handle,...)` uses the light specified in `light_handle`.

`light_handle = camlight(...)` returns the light's handle.

Remarks

`camlight` sets the light object `Position` and `Style` properties. A light created with `camlight` will not track the camera. In order for the light to stay in a constant position relative to the camera, you must call `camlight` whenever you move the camera.

Examples

This example creates a light positioned to the left of the camera and then repositions the light each time the camera is moved:

```
surf(peaks)
axis vis3d
h = camlight('left');
for i = 1:20;
 camorbit(10,0)
 camlight(h,'left')
 drawnow;
end
```

See Also

`light`, `lightangle`

"Lighting" on page 1-101 for related functions

"Lighting as a Visualization Tool" for more information on using lights

Purpose

Position camera to view object or group of objects

Syntax

```
camlookat(object_handles)
camlookat(axes_handle)
camlookat
```

Description

`camlookat(object_handles)` views the objects identified in the vector `object_handles`. The vector can contain the handles of axes children.

`camlookat(axes_handle)` views the objects that are children of the axes identified by `axes_handle`.

`camlookat` views the objects that are in the current axes.

Remarks

`camlookat` moves the camera position and camera target while preserving the relative view direction and camera view angle. The object (or objects) being viewed roughly fill the axes position rectangle.

`camlookat` sets the axes `CameraPosition` and `CameraTarget` properties.

Examples

This example creates three spheres at different locations and then progressively positions the camera so that each sphere is the object around which the scene is composed:

```
[x y z] = sphere;
s1 = surf(x,y,z);
hold on
s2 = surf(x+3,y,z+3);
s3 = surf(x,y,z+6);
daspect([1 1 1])
view(30,10)
camproj perspective
camlookat(gca) % Compose the scene around the current axes
pause(2)
camlookat(s1)  % Compose the scene around sphere s1
pause(2)
camlookat(s2)  % Compose the scene around sphere s2
pause(2)
```

```
camlookat(s3)  % Compose the scene around sphere s3
pause(2)
camlookat(gca)
```

`campos`, `camtarget`

"Controlling the Camera Viewpoint" on page 1-99 for related functions

"Defining Scenes with Camera Graphics" for more information

Purpose

Rotate camera position around camera target

Syntax

```
camorbit(dtheta,dphi)
camorbit(dtheta,dphi,'coordsys')
camorbit(dtheta,dphi,'coordsys','direction')
camorbit(axes_handle,...)
```

Description

`camorbit(dtheta,dphi)` rotates the camera position around the camera target by the amounts specified in `dtheta` and `dphi` (both in degrees). `dtheta` is the horizontal rotation and `dphi` is the vertical rotation.

`camorbit(dtheta,dphi,'coordsys')` The *`coordsys`* argument determines the center of rotation. It can take on two values:

- `data` (default) — Rotate the camera around an axis defined by the camera target and the `direction` (default is the positive *z* direction).
- `camera` — Rotate the camera about the point defined by the camera target.

`camorbit(dtheta,dphi,'coordsys','direction')` The `direction` argument, in conjunction with the camera target, defines the axis of rotation for the data coordinate system. Specify `direction` as a three-element vector containing the `x`, `y`, and `z` components of the direction or one of the characters, `x`, `y`, or `z`, to indicate `[1 0 0]`, `[0 1 0]`, or `[0 0 1]` respectively.

`camorbit(axes_handle,...)` operates on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `camorbit` operates on the current axes.

Examples

Compare rotation in the two coordinate systems with these `for` loops. The first rotates the camera horizontally about a line defined by the camera target point and a direction that is parallel to the *y*-axis. Visualize this rotation as a cone formed with the camera target at the apex and the camera position forming the base:

```
surf(peaks)
```

```
axis vis3d
for i=1:36
 camorbit(10,0,'data',[0 1 0])
 drawnow
end
```

Rotation in the `camera` coordinate system orbits the camera around the axes along a circle while keeping the center of a circle at the camera target.

```
surf(peaks)
axis vis3d
for i=1:36
 camorbit(10,0,'camera')
 drawnow
end
```

See Also

`axes`, `axis('vis3d')`, `camdolly`, `campan`, `camzoom`, `camroll`

"Controlling the Camera Viewpoint" on page 1-99 for related functions

Purpose

Rotate camera target around camera position

Syntax

```
campan(dtheta,dphi)
campan(dtheta,dphi,'coordsys')
campan(dtheta,dphi,'coordsys','direction')
campan(axes_handle,...)
```

Description

`campan(dtheta,dphi)` rotates the camera target around the camera position by the amounts specified in `dtheta` and `dphi` (both in degrees). `dtheta` is the horizontal rotation and `dphi` is the vertical rotation.

`campan(dtheta,dphi,'coordsys')` The `coordsys` argument determines the center of rotation. It can take on two values:

- `data` (default) — Rotate the camera target around an axis defined by the camera position and the `direction` (default is the positive *z* direction)
- `camera` — Rotate the camera about the point defined by the camera target.

`campan(dtheta,dphi,'coordsys','direction')` The `direction` argument, in conjunction with the camera position, defines the axis of rotation for the data coordinate system. Specify `direction` as a three-element vector containing the x, y, and z components of the direction or one of the characters, `x`, `y`, or `z`, to indicate `[1 0 0]`, `[0 1 0]`, or `[0 0 1]` respectively.

`campan(axes_handle,...)` operates on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `campan` operates on the current axes.

campos

Purpose

Set or query camera position

Syntax

```
campos
campos([camera_position])
campos('mode')
campos('auto')
campos('manual')
campos(axes_handle,...)
```

Description

`campos` with no arguments returns the camera position in the current axes.

`campos([camera_position])` sets the position of the camera in the current axes to the specified value. Specify the position as a three-element vector containing the *x*-, *y*-, and *z*-coordinates of the desired location in the data units of the axes.

`campos('mode')` returns the value of the camera position mode, which can be either `auto` (the default) or `manual`.

`campos('auto')` sets the camera position mode to `auto`.

`campos('manual')` sets the camera position mode to `manual`.

`campos(axes_handle,...)` performs the set or query on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `campos` operates on the current axes.

Remarks

`campos` sets or queries values of the axes `CameraPosition` and `CameraPositionMode` properties. The camera position is the point in the Cartesian coordinate system of the axes from which you view the scene.

Examples

This example moves the camera along the *x*-axis in a series of steps:

```
surf(peaks)
axis vis3d off
for x = -200:5:200
    campos([x,5,10])
    drawnow
```

```
end
```

The axes properties `CameraPosition`, `CameraTarget`, `CameraUpVector`, `CameraViewAngle`, `Projection`

“Controlling the Camera Viewpoint” on page 1-99 for related functions

“Defining Scenes with Camera Graphics” for more information

camproj

Purpose

Set or query projection type

Syntax

```
camproj
camproj('projection_type')
camproj(axes_handle,...)
```

Description

The projection type determines whether MATLAB uses a perspective or orthographic projection for 3-D views.

`camproj` with no arguments returns the projection type setting in the current axes.

`camproj('projection_type')` sets the projection type in the current axes to the specified value. Possible values for *`projection_type`* are `orthographic` and `perspective`.

`camproj(axes_handle,...)` performs the set or query on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `camproj` operates on the current axes.

Remarks

`camproj` sets or queries values of the axes object `Projection` property.

See Also

`campos`, `camtarget`, `camup`, `camva`

The axes properties `CameraPosition`, `CameraTarget`, `CameraUpVector`, `CameraViewAngle`, `Projection`

“Controlling the Camera Viewpoint” on page 1-99 for related functions

“Defining Scenes with Camera Graphics” for more information

Purpose

Rotate camera about view axis

Syntax

```
camroll(dtheta)
camroll(axes_handle,dtheta)
```

Description

`camroll(dtheta)` rotates the camera around the camera viewing axis by the amounts specified in `dtheta` (in degrees). The viewing axis is defined by the line passing through the camera position and the camera target.

`camroll(axes_handle,dtheta)` operates on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `camroll` operates on the current axes.

Remarks

`camroll` sets the axes `CameraUpVector` property and thereby also sets the `CameraUpVectorMode` property to `manual`.

See Also

`axes`, `axis('vis3d')`, `camdolly`, `camorbit`, `camzoom`, `campan`

“Controlling the Camera Viewpoint” on page 1-99 for related functions

“Defining Scenes with Camera Graphics” for more information

camtarget

Purpose

Set or query location of camera target

Syntax

```
camtarget
camtarget([camera_target])
camtarget('mode')
camtarget('auto')
camtarget('manual')
camtarget(axes_handle,...)
```

Description

The camera target is the location in the axes that the camera points to. The camera remains oriented toward this point regardless of its position.

`camtarget` with no arguments returns the location of the camera target in the current axes.

`camtarget([camera_target])` sets the camera target in the current axes to the specified value. Specify the target as a three-element vector containing the *x*-, *y*-, and *z*-coordinates of the desired location in the data units of the axes.

`camtarget('mode')` returns the value of the camera target mode, which can be either `auto` (the default) or `manual`.

`camtarget('auto')` sets the camera target mode to `auto`.

`camtarget('manual')` sets the camera target mode to `manual`.

`camtarget(axes_handle,...)` performs the set or query on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `camtarget` operates on the current axes.

Remarks

`camtarget` sets or queries values of the axes object `CameraTarget` and `CameraTargetMode` properties.

When the camera target mode is `auto`, MATLAB positions the camera target at the center of the axes plot box.

Examples

This example moves the camera position and the camera target along the *x*-axis in a series of steps:

```
surf(peaks);
axis vis3d
xp = linspace(-150,40,50);
xt = linspace(25,50,50);
for i=1:50
     campos([xp(i),25,5]);
     camtarget([xt(i),30,0])
     drawnow
end
```

See Also

The axes properties `CameraPosition`, `CameraTarget`, `CameraUpVector`, `CameraViewAngle`, `Projection`

"Controlling the Camera Viewpoint" on page 1-99 for related functions

"Defining Scenes with Camera Graphics" for more information

camup

Purpose

Set or query camera up vector

Syntax

```
camup
camup([up_vector])
camup('mode')
camup('auto')
camup('manual')
camup(axes_handle,...)
```

Description

The camera up vector specifies the direction that is oriented up in the scene.

`camup` with no arguments returns the camera up vector setting in the current axes.

`camup([up_vector])` sets the up vector in the current axes to the specified value. Specify the up vector as *x*, *y*, and *z* components. See Remarks.

`camup('mode')` returns the current value of the camera up vector mode, which can be either `auto` (the default) or `manual`.

`camup('auto')` sets the camera up vector mode to `auto`. In `auto` mode, MATLAB uses a value for the up vector of `[0 1 0]` for 2-D views. This means the *z*-axis points up.

`camup('manual')` sets the camera up vector mode to `manual`. In `manual` mode, MATLAB does not change the value of the camera up vector.

`camup(axes_handle,...)` performs the set or query on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `camup` operates on the current axes.

Remarks

`camup` sets or queries values of the axes object `CameraUpVector` and `CameraUpVectorMode` properties.

Specify the camera up vector as the *x*-, *y*-, and *z*-coordinates of a point in the axes coordinate system that forms the directed line segment PQ, where P is the point (0,0,0) and Q is the specified *x*-, *y*-, and *z*-coordinates. This line always points up. The length of the line PQ has

no effect on the orientation of the scene. This means a value of `[0 0 1]` produces the same results as `[0 0 25]`.

See Also

The axes properties `CameraPosition`, `CameraTarget`, `CameraUpVector`, `CameraViewAngle`, `Projection`

"Controlling the Camera Viewpoint" on page 1-99 for related functions

"Defining Scenes with Camera Graphics" for more information

camva

Purpose

Set or query camera view angle

Syntax

```
camva
camva(view_angle)
camva('mode')
camva('auto')
camva('manual')
camva(axes_handle,...)
```

Description

The camera view angle determines the field of view of the camera. Larger angles produce a smaller view of the scene. You can implement zooming by changing the camera view angle.

`camva` with no arguments returns the camera view angle setting in the current axes.

`camva(view_angle)` sets the view angle in the current axes to the specified value. Specify the view angle in degrees.

`camva('mode')` returns the current value of the camera view angle mode, which can be either `auto` (the default) or `manual`. See Remarks.

`camva('auto')` sets the camera view angle mode to `auto`.

`camva('manual')` sets the camera view angle mode to `manual`. See Remarks.

`camva(axes_handle,...)` performs the set or query on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `camva` operates on the current axes.

Remarks

`camva` sets or queries values of the axes object `CameraViewAngle` and `CameraViewAngleMode` properties.

When the camera view angle mode is `auto`, MATLAB adjusts the camera view angle so that the scene fills the available space in the window. If you move the camera to a different position, MATLAB changes the camera view angle to maintain a view of the scene that fills the available area in the window.

Setting a camera view angle or setting the camera view angle to `manual` disables the MATLAB stretch-to-fill feature (stretching of the axes to fit the window). This means setting the camera view angle to its current value,

```
camva(camva)
```

can cause a change in the way the graph looks. See the Remarks section of the `axes` reference page for more information.

Examples

This example creates two pushbuttons, one that zooms in and another that zooms out.

```
uicontrol('Style','pushbutton',...
  'String','Zoom In',...
  'Position',[20 20 60 20],...
  'Callback','if camva <= 1;return;else;camva(camva-1);end');
uicontrol('Style','pushbutton',...
  'String','Zoom Out',...
  'Position',[100 20 60 20],...
  'Callback','if camva >= 179;return;else;camva(camva+1);end');
```

Now create a graph to zoom in and out on:

```
surf(peaks);
```

Note the range checking in the callback statements. This keeps the values for the camera view angle in the range greater than zero and less than 180.

See Also

The axes properties `CameraPosition`, `CameraTarget`, `CameraUpVector`, `CameraViewAngle`, `Projection`

“Controlling the Camera Viewpoint” on page 1-99 for related functions

“Defining Scenes with Camera Graphics” for more information

camzoom

Purpose

Zoom in and out on scene

Syntax

```
camzoom(zoom_factor)
camzoom(axes_handle,...)
```

Description

`camzoom(zoom_factor)` zooms in or out on the scene depending on the value specified by `zoom_factor`. If `zoom_factor` is greater than 1, the scene appears larger; if `zoom_factor` is greater than zero and less than 1, the scene appears smaller.

`camzoom(axes_handle,...)` operates on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `camzoom` operates on the current axes.

Remarks

`camzoom` sets the axes `CameraViewAngle` property, which in turn causes the `CameraViewAngleMode` property to be set to `manual`. Note that setting the `CameraViewAngle` property disables the MATLAB stretch-to-fill feature (stretching of the axes to fit the window). This may result in a change to the aspect ratio of your graph. See the `axes` function for more information on this behavior.

"Controlling the Camera Viewpoint" on page 1-99 for related functions

"Defining Scenes with Camera Graphics" for more information

Purpose

Transform Cartesian coordinates to polar or cylindrical

Syntax

```
[THETA,RHO,Z] = cart2pol(X,Y,Z)
[THETA,RHO] = cart2pol(X,Y)
```

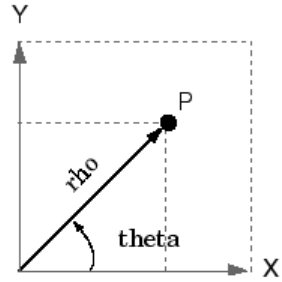
Description

`[THETA,RHO,Z] = cart2pol(X,Y,Z)` transforms three-dimensional Cartesian coordinates stored in corresponding elements of arrays `X`, `Y`, and `Z`, into cylindrical coordinates. `THETA` is a counterclockwise angular displacement in radians from the positive *x*-axis, `RHO` is the distance from the origin to a point in the *x-y* plane, and `Z` is the height above the *x-y* plane. Arrays `X`, `Y`, and `Z` must be the same size (or any can be scalar).

`[THETA,RHO] = cart2pol(X,Y)` transforms two-dimensional Cartesian coordinates stored in corresponding elements of arrays `X` and `Y` into polar coordinates.

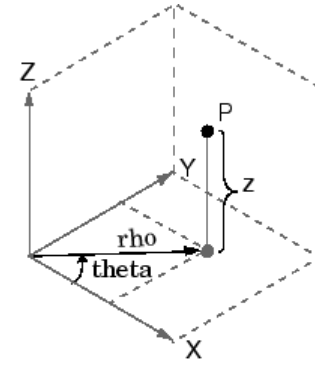
Algorithm

The mapping from two-dimensional Cartesian coordinates to polar coordinates, and from three-dimensional Cartesian coordinates to cylindrical coordinates is



Two-Dimensional Mapping

```
theta = atan2(y,x)
rho = sqrt(x.^2 + y.^2)
```



Three-Dimensional Mapping

```
theta = atan2(y,x)
rho = sqrt(x.^2 + y.^2)
z = z
```

See Also

`cart2sph`, `pol2cart`, `sph2cart`

cart2sph

Purpose

Transform Cartesian coordinates to spherical

Syntax

```
[THETA,PHI,R] = cart2sph(X,Y,Z)
```

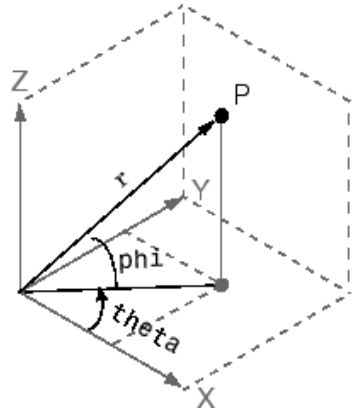
Description

`[THETA,PHI,R] = cart2sph(X,Y,Z)` transforms Cartesian coordinates stored in corresponding elements of arrays `X`, `Y`, and `Z` into spherical coordinates. Azimuth `THETA` and elevation `PHI` are angular displacements in radians measured from the positive *x*-axis, and the *x-y* plane, respectively; and `R` is the distance from the origin to a point.

Arrays `X`, `Y`, and `Z` must be the same size.

Algorithm

The mapping from three-dimensional Cartesian coordinates to spherical coordinates is



```
theta = atan2(y,x)
  phi = atan2(z, sqrt(x.^2 + y.^2))
    r = sqrt(x.^2+y.^2+z.^2)
```

The notation for spherical coordinates is not standard. For the `cart2sph` function, the angle PHI is measured from the *x-y* plane. Notice that if PHI = 0 then the point is in the *x-y* plane and if PHI = pi/2 then the point is on the positive *z*-axis.

`cart2pol`, `pol2cart`, `sph2cart`

Purpose

Execute block of code if condition is `true`

Syntax

```
switch switch_expr
 case case_expr
    statement, ..., statement
  case {case_expr1, case_expr2, case_expr3, ...}
    statement, ..., statement
  otherwise
    statement, ..., statement
end
```

Description

`case` is part of the `switch` statement syntax which allows for conditional execution. A particular case consists of the `case` statement itself followed by a case expression and one or more statements.

`case case_expr` compares the value of the expression `switch_expr` declared in the preceding `switch` statement with one or more values in `case_expr`, and executes the block of code that follows if any of the comparisons yield a `true` result.

You typically use multiple `case` statements in the evaluation of a single `switch` statement. The block of code associated with a particular `case` statement is executed only if its associated `case` expression (`case_expr`) is the first to match the switch expression (`switch_expr`).

To enter more than one `case` expression in a `switch` statement, put the expressions in a cell array, as shown above.

Examples

To execute a certain block of code based on what the string, `method`, is set to,

```
method = 'Bilinear';

switch lower(method)
   case {'linear','bilinear'}
      disp('Method is linear')
   case 'cubic'
```

```
      disp('Method is cubic')
   case 'nearest'
      disp('Method is nearest')
   otherwise
      disp('Unknown method.')
end

Method is linear
```

See Also

switch, otherwise, end, if, else, elseif, while

Purpose

Cast variable to different data type

Syntax

```
B = cast(A, newclass)
```

Description

`B = cast(A, newclass)` casts `A` to class `newclass`. `A` must be convertible to class `newclass`. `newclass` must be the name of one of the built in data types.

Examples

```
a = int8(5);
b = cast(a,'uint8');
class(b)

ans =

uint8
```

See Also

`class`

Purpose

Concatenate arrays along specified dimension

Syntax

```
C = cat(dim, A, B)
C = cat(dim, A1, A2, A3, A4, ...)
```

Description

`C = cat(dim, A, B)` concatenates the arrays `A` and `B` along `dim`.

`C = cat(dim, A1, A2, A3, A4, ...)` concatenates all the input arrays (`A1`, `A2`, `A3`, `A4`, and so on) along `dim`.

`cat(2, A, B)` is the same as `[A, B]`, and `cat(1, A, B)` is the same as `[A; B]`.

Remarks

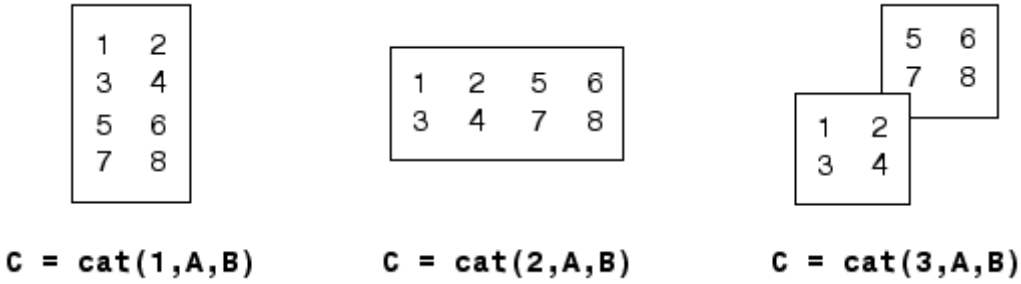
When used with comma-separated list syntax, `cat(dim, C{:})` or `cat(dim, C.field)` is a convenient way to concatenate a cell or structure array containing numeric matrices into a single matrix.

Examples

Given

```
A =                 B =
     1     2               5     6
     3     4               7     8
```

concatenating along different dimensions produces



The commands

```
A = magic(3); B = pascal(3);
C = cat(4, A, B);
```

produce a 3-by-3-by-1-by-2 array.

See Also

`num2cell`

The `special character []`

catch

Purpose

Specify how to respond to error in `try` statement

Syntax

```
catch ME
catch
```

Description

`catch ME` marks the start of a *catch block* in a `try-catch` statement. It returns object `ME`, which is an instance of the MATLAB class `MException`. This object contains information about an error caught in the preceding *try block* and can be useful in helping your program respond to the error appropriately.

A `try-catch` statement is a programming device that enables you to define how certain errors are to be handled in your program. This bypasses the default MATLAB error-handling mechanism when these errors are detected. The `try-catch` statement consists of two blocks of MATLAB code, a *try block* and a *catch block*, delimited by the keywords `try`, `catch`, and `end`:

```
try
   MATLAB commands     % Try block
catch ME
   MATLAB commands     % Catch block
end
```

Each of these blocks consists of one or more MATLAB commands. The `try` block is just another piece of your program code; the commands in this block execute just like any other part of your program. Any errors MATLAB encounters in the `try` block are dealt with by the respective `catch` block. This is where you write your error-handling code. If the `try` block executes without error, MATLAB skips the `catch` block entirely. If an error occurs while executing the `catch` block, the program terminates unless this error is caught by another `try-catch` block.

`catch` marks the start of a catch block but does not return an `MException` object. You can obtain the error string that was generated by calling the `lasterror` function.

Specifying the `try`, `catch`, and `end` commands, as well as the commands that make up the `try` and `catch` blocks, on separate lines is recommended. If you combine any of these components on the same line, separate them with commas:

```
try, surf, catch ME, ME.stack, end
ans =
    file: 'matlabroot\toolbox\matlab\graph3d\surf.m'
    name: 'surf'
    line: 54
```

Examples

The `catch` block in this example checks to see if the specified file could not be found. If this is the case, the program allows for the possibility that a common variation of the filename extension (e.g., `jpeg` instead of `jpg`) was used by retrying the operation with a modified extension. This is done using a `try-catch` statement that is nested within the original `try-catch`.

```
function d_in = read_image(filename)
file_format = regexp(filename, '(?<=\.)\w+$', 'match');

try
  fid = fopen(filename, 'r');
  d_in = fread(fid);
catch ME1
  % Get last segment of the error message identifier.
  idSegLast = regexp(ME1.identifier, '(?<=:)\w+$', 'match');

  % Did the read fail because the file could not be found?
  if strcmp(idSegLast, 'InvalidFid') && ~exist(filename, 'file')

    % Yes. Try modifying the filename extension.
    switch file_format
    case 'jpg'    % Change jpg to jpeg
      filename = regexprep(filename, '(?<=\.)\w+$', 'jpeg');
    case 'jpeg'   % Change jpeg to jpg
      filename = regexprep(filename, '(?<=\.)\w+$', 'jpg');
```

```
        case 'tif'    % Change tif to tiff
          filename = regexprep(filename, '(?<=\.)\w+$', 'tiff');
        case 'tiff'   % Change tiff to tif
          filename = regexprep(filename, '(?<=\.)\w+$', 'tif');
        otherwise
          disp(sprintf('File %s not found', filename));
           rethrow(ME1);
        end

        % Try again, with modifed filenames.
        try
          fid = fopen(filename, 'r');
          d_in = fread(fid);
        catch ME2
          disp(sprintf('Unable to access file %s', filename));
          ME2 = addCause(ME2, ME1);
          rethrow(ME2)
        end
      end
    end
```

See Also

try, rethrow, end, lasterror, eval, evalin

Purpose

Color axis scaling

Syntax

```
caxis([cmin cmax])
caxis auto
caxis manual
caxis(caxis) freeze
v = caxis
caxis(axes_handle,...)
```

Description

`caxis` controls the mapping of data values to the colormap. It affects any surfaces, patches, and images with indexed `CData` and `CDataMapping` set to scaled. It does not affect surfaces, patches, or images with true color `CData` or with `CDataMapping` set to `direct`.

`caxis([cmin cmax])` sets the color limits to specified minimum and maximum values. Data values less than `cmin` or greater than `cmax` map to `cmin` and `cmax`, respectively. Values between `cmin` and `cmax` linearly map to the current colormap.

`caxis auto` lets MATLAB compute the color limits automatically using the minimum and maximum data values. This is the default behavior. Color values set to `Inf` map to the maximum color, and values set to `-Inf` map to the minimum color. Faces or edges with color values set to `NaN` are not drawn.

`caxis manual` and `caxis(caxis) freeze` the color axis scaling at the current limits. This enables subsequent plots to use the same limits when `hold` is `on`.

`v = caxis` returns a two-element row vector containing the `[cmin cmax]` currently in use.

`caxis(axes_handle,...)` uses the axes specified by `axes_handle` instead of the current axes.

Remarks

`caxis` changes the `CLim` and `CLimMode` properties of axes graphics objects.

How Color Axis Scaling Works

Surface, patch, and image graphics objects having indexed `CData` and `CDataMapping` set to `scaled` map `CData` values to colors in the figure colormap each time they render. `CData` values equal to or less than `cmin` map to the first color value in the colormap, and `CData` values equal to or greater than `cmax` map to the last color value in the colormap. MATLAB performs the following linear transformation on the intermediate values (referred to as `C` below) to map them to an entry in the colormap (whose length is `m`, and whose row index is referred to as `index` below).

```
index = fix((C-cmin)/(cmax-cmin)*m)+1
```

Examples

Create `(X,Y,Z)` data for a sphere and view the data as a surface.

```
[X,Y,Z] = sphere;
C = Z;
surf(X,Y,Z,C)
```

Values of `C` have the range [-1 1]. Values of `C` near -1 are assigned the lowest values in the colormap; values of `C` near 1 are assigned the highest values in the colormap.

To map the top half of the surface to the highest value in the color table, use

```
caxis([-1 0])
```

To use only the bottom half of the color table, enter

```
caxis([-1 3])
```

which maps the lowest `CData` values to the bottom of the colormap, and the highest values to the middle of the colormap (by specifying a `cmax` whose value is equal to `cmin` plus twice the range of the `CData`).

The command

```
caxis auto
```

resets axis scaling back to autoranging and you see all the colors in the surface. In this case, entering

```
caxis
```

returns

```
[-1 1]
```

Adjusting the color axis can be useful when using images with scaled color data. For example, load the image data and colormap for Cape Cod, Massachusetts.

```
load cape
```

This command loads the image's data `X` and the image's colormap `map` into the workspace. Now display the image with `CDataMapping` set to `scaled` and install the image's colormap.

```
image(X,'CDataMapping','scaled')colormap(map)
```

MATLAB sets the color limits to span the range of the image data, which is 1 to 192:

```
caxis
ans =
     1   192
```

The blue color of the ocean is the first color in the colormap and is mapped to the lowest data value (1). You can effectively move sea level by changing the lower color limit value. For example,

Purpose

Change working directory

Graphical Interface

As an alternative to the `cd` function, use the current directory field

in the MATLAB desktop toolbar.

Syntax

```
cd
w = cd
cd('directory')
cd('..')
cd directory
```

Description

`cd` displays the current working directory.

`w = cd` assigns the current working directory to `w`.

`cd('directory')` sets the current working directory to `directory`. Use the full pathname for `directory`. On UNIX platforms, the character ~ is interpreted as the user's root directory.

`cd('..')` changes the current working directory to the directory above it.

`cd directory` or cd .. is the unquoted form of the syntax.

Examples

On UNIX

```
cd('/usr/local/matlab/toolbox/control/ctrldemos')
```

changes the current working directory to `ctrldemos` for the Control System Toolbox.

On Windows

```
cd('c:/matlab/toolbox/control/ctrldemos')
```

changes the current working directory to `ctrldemos` for the Control System Toolbox. Then typing

```
cd ..
```

changes the current working directory to `control`, and typing

```
cd ..
```

again, changes the current working directory to `toolbox`.

On any platform, use `cd` with the `matlabroot` function to change to a directory relative to the directory in which MATLAB is installed. For example

```
cd([matlabroot '/toolbox/control/ctrldemos'])
```

changes the current working directory to `ctrldemos` for the Control System Toolbox.

See Also

`dir`, `fileparts`, `mfilename`, `path`, `pwd`, `what`

cd (ftp)

Purpose

Change current directory on FTP server

Syntax

```
cd(f)
cd(f,'dirname')
cd(f,'..')
```

Description

`cd(f)` Displays the current directory on the FTP server `f`, where `f` was created using `ftp`.

`cd(f,'dirname')` Changes the current directory on the FTP server `f` to `dirname`, where `f` was created using `ftp`. After running cd, the object `f` remembers the current directory on the FTP server. You can then perform file operations functions relative to `f` using the methods `delete`, `dir`, `mget`, `mkdir`, `mput`, `rename`, and `rmdir`.

`cd(f,'..')` changes the current directory on the FTP server `f` to the directory above the current one.

Examples

Connect to the MathWorks FTP server.

```
tmw=ftp('ftp.mathworks.com');
```

View the contents.

```
dir(tmw)
```

Change the current directory to `pub`.

```
cd(tmw,'pub');
```

View the contents of `pub`.

```
dir(tmw)
```

See Also

`dir (ftp)`, `ftp`

Purpose

Convert complex diagonal form to real block diagonal form

Syntax

```
[V,D] = cdf2rdf(V,D)
[V,D] = cdf2rdf(V,D)
```

Description

If the eigensystem `[V,D] = eig(X)` has complex eigenvalues appearing in complex-conjugate pairs, `cdf2rdf` transforms the system so `D` is in real diagonal form, with 2-by-2 real blocks along the diagonal replacing the complex pairs originally there. The eigenvectors are transformed so that

```
X = V*D/V
```

continues to hold. The individual columns of `V` are no longer eigenvectors, but each pair of vectors associated with a 2-by-2 block in `D` spans the corresponding invariant vectors.

Examples

The matrix

```
X =
     1     2     3
     0     4     5
     0    -5     4
```

has a pair of complex eigenvalues.

```
[V,D] = eig(X)

V =

    1.0000      -0.0191 - 0.4002i      -0.0191 + 0.4002i
         0            0 - 0.6479i            0 + 0.6479i
         0       0.6479                 0.6479

D =

    1.0000            0                      0
```

```
         0       4.0000 + 5.0000i            0
         0            0                 4.0000 - 5.0000i
```

Converting this to real block diagonal form produces

```
[V,D] = cdf2rdf(V,D)

V =

    1.0000    -0.0191     -0.4002
         0          0     -0.6479
         0     0.6479           0

D =

    1.0000          0           0
         0     4.0000      5.0000
         0    -5.0000      4.0000
```

Algorithm

The real diagonal form for the eigenvalues is obtained from the complex form using a specially constructed similarity transformation.

`eig`, `rsf2csf`

Purpose

Construct cdfepoch object for Common Data Format (CDF) export

Syntax

```
E = cdfepoch(date)
```

Description

`E = cdfepoch(date)` constructs a `cdfepoch` object, where `date` is a valid string (`datestr`), a number (`datenum`) representing a date, or a `cdfepoch` object.

When writing data to a CDF using `cdfwrite`, use `cdfepoch` to convert MATLAB formatted dates to CDF formatted dates. The MATLAB `cdfepoch` object simulates the `CDFEPOCH` data type in CDF files.

Use the `todatenum` function to convert a `cdfepoch` object into a MATLAB serial date number.

Note A CDF epoch is the number of milliseconds since 1-Jan-0000. MATLAB `datenums` are the number of days since 0-Jan-0000.

See Also

`cdfinfo`, `cdfread`, `cdfwrite`, `datenum`

Purpose

Information about Common Data Format (CDF) file

Syntax

```
info = cdfinfo(filename)
```

Description

`info = cdfinfo(filename)` returns information about the Common Data Format (CDF) file specified in the string `filename`.

Note Because `cdfinfo` creates temporary files, the current working directory must be writeable.

The return value, `info`, is a structure that contains the fields listed alphabetically in the following table.

Field	Description
`FileModDate`	Text string indicating the date the file was last modified
`Filename`	Text string specifying the name of the file
`FileSettings`	Structure array containing library settings used to create the file
`FileSize`	Double scalar specifying the size of the file, in bytes
`Format`	Text string specifying the file format
`FormatVersion`	Text string specifying the version of the CDF library used to create the file
`GlobalAttributes`	Structure array that contains one field for each global attribute. The name of each field corresponds to the name of an attribute. The data in each field, contained in a cell array, represents the entry values for that attribute.

Field	Description
`Subfiles`	Filenames containing the CDF file's data, if it is a multifile CDF
`VariableAttributes`	Structure array that contains one field for each variable attribute. The name of each field corresponds to the name of an attribute. The data in each field is contained in a *n*-by-2 cell array, where *n* is the number of variables. The first column of this cell array contains the variable names associated with the entries. The second column contains the entry values.

Field	Description	
`Variables`	N-by-6 cell array, where N is the number of variables, containing information about the variables in the file. The columns present the following information:	
	Column 1	Text string specifying name of variable
	Column 2	Double array specifying the dimensions of the variable, as returned by the `size` function
	Column 3	Double scalar specifying the number of records assigned for the variable
	Column 4	Text string specifying the data type of the variable, as stored in the CDF file

	Column 5	Text string specifying the record and dimension variance settings for the variable. The single `T` or `F` to the left of the slash designates whether values vary by record. The zero or more `T` or `F` letters to the right of the slash designate whether values vary at each dimension. Here are some examples.
		`T/ (scalar variable`
		`F/T (one-dimensional variable)`
		T/TFF (three-dimensional variable)

	Column 6	Text string specifying the sparsity of the variable's records, with these possible values: `'Full' 'Sparse (padded)' 'Sparse (nearest)'`

Note Attribute names returned by `cdfinfo` might not match the names of the attributes in the CDF file exactly. Attribute names can contain characters that are illegal in MATLAB field names. `cdfinfo` removes illegal characters that appear at the beginning of attributes and replaces other illegal characters with underscores ('_'). When `cdfinfo` modifies an attribute name, it appends the attribute's internal number to the end of the field name. For example, the attribute name `Variable%Attribute` becomes `Variable_Attribute_013`.

Examples

```
info = cdfinfo('example.cdf')
info =
               Filename: 'example.cdf'
            FileModDate: '09-Mar-2001 15:45:22'
               FileSize: 1240
                 Format: 'CDF'
          FormatVersion: '2.7.0'
           FileSettings: [1x1 struct]
               Subfiles: {}
              Variables: {5x6 cell}
       GlobalAttributes: [1x1 struct]
    VariableAttributes: [1x1 struct]

info.Variables
ans =
  'Time'         [1x2 double] [24] 'epoch'  'T/'     'Full'
  'Longitude'    [1x2 double] [ 1] 'int8'   'F/FT'   'Full'
  'Latitude'     [1x2 double] [ 1] 'int8'   'F/TF'   'Full'
  'Data'         [1x3 double] [ 1] 'double' 'T/TTT'  'Full'
  'multidim'     [1x4 double] [ 1] 'uint8'  'T/TTTT' 'Full'
```

`cdfread`

Purpose

Read data from Common Data Format (CDF) file

Syntax

```
data = cdfread(filename)
data = cdfread(filename, param1, val1, param2, val2, ...)
[data, info] = cdfread(filename, ...)
```

Description

`data = cdfread(filename)` reads all the data from the Common Data Format (CDF) file specified in the string `filename`. CDF data sets typically contain a set of variables, of a specific data type, each with an associated set of records. The variable might represent time values with each record representing a specific time that an observation was recorded. `cdfread` returns all the data in a cell array where each column represents a variable and each row represents a record associated with a variable. If the variables have varying numbers of associated records, `cdfread` pads the rows to create a rectangular cell array, using pad values defined in the CDF file.

Note Because `cdfread` creates temporary files, the current working directory must be writeable.

`data = cdfread(filename, param1, val1, param2, val2, ...)` reads data from the file, where *param1*, *param2*, and so on, can be any of the following parameters.

Parameter	Value
`'Records'`	A vector specifying which records to read. Record numbers are zero-based. `cdfread` returns a cell array with the same number of rows as the number of records read and as many columns as there are variables.

Parameter	Value
`'Variables'`	A 1-by-*n* or *n*-by-1 cell array specifying the names of the variables to read from the file. *n* must be less than or equal to the total number of variables in the file. `cdfread` returns a cell array with the same number of columns as the number of variables read, and a row for each record read.
`'Slices'`	An *m*-by-3 array, where each row specifies where to start reading along a particular dimension of a variable, the skip interval to use on that dimension (every item, every other item, etc.), and the total number of values to read on that dimension. *m* must be less than or equal to the number of dimensions of the variable. If *m* is less than the total number of dimensions, `cdfread` reads every value from the unspecified dimensions (`[0 1 n]`, where *n* is the total number of elements in the dimension. Note: Because the `'Slices'` parameter describes how to process a single variable, it must be used in conjunction with the `'Variables'` parameter.

Parameter	Value
'ConvertEpochToDatenum'	A Boolean value that determines whether cdfread automatically converts CDF epoch data types to MATLAB serial date numbers. If set to false (the default), cdfread wraps epoch values in MATLABcdfepoch objects. Note: For better performance when reading large data sets, set this parameter to true.
'CombineRecords'	A Boolean value that determines how cdfread returns the CDF data sets read from the file. If set to false (the default), cdfread stores the data in an *m*-by-*n* cell array, where *m* is the number of records and *n* is the number of variables requested. If set to true, cdfread combines all records for a particular variable into one cell in the output cell array. In this cell, cdfread stores scalar data as a column array. cdfread extends the dimensionality of nonscalar and string data. For example, instead of creating 1000 elements containing 20-by-30 arrays for each record, cdfread stores all the records in one cell as a 1000-by-20-by-30 array Note: If you use the 'Records' parameter to specify which records to read, you cannot use the 'CombineRecords' parameter. Note: When using the 'Variable' parameter to read one variable, if the 'CombineRecords' parameter is true, cdfread returns the data as an M-by-N numeric or character array; it does not put the data into a cell array.

`[data, info] = cdfread(`*`filename`*`, ...)` returns details about the CDF file in the `info` structure.

Note To maximize performance, specify both the `'ConvertEpochToDatenum'` and `'CombineRecords'` parameters, setting their values to `'true'`.

Examples

Read all the data from a CDF file.

```
data = cdfread('example.cdf');
```

Read the data from the variable `'Time'`.

```
data = cdfread('example.cdf', 'Variable', {'Time'});
```

Read the first value in the first dimension, the second value in the second dimension, the first and third values in the third dimension, and all values in the remaining dimension of the variable `'multidimensional'`.

```
data = cdfread('example.cdf', ...
               'Variable', {'multidimensional'}, ...
               'Slices', [0 1 1; 1 1 1; 0 2 2]);
```

This is similar to reading the whole variable into `data` and then using matrix indexing, as in the following.

```
data{1}(1, 2, [1 3], :)
```

Collapse the records from a data set and convert CDF epoch data types to MATLAB serial date numbers.

```
data = cdfread('example.cdf', ...
               'CombineRecords', true, ...
               'ConvertEpochToDatenum', true);
```

See Also

`cdfepoch`, `cdfinfo`, `cdfwrite`

For more information about using this function, see “Common Data Format (CDF) Files”.

Purpose

Write data to Common Data Format (CDF) file

Syntax

```
cdfwrite(filename,variablelist)
cdfwrite(...,'PadValues',padvals)
cdfwrite(...,'GlobalAttributes',gattrib)
cdfwrite(..., 'VariableAttributes', vattrib)
cdfwrite(...,'WriteMode',mode)
cdfwrite(...,'Format',format)
```

Description

`cdfwrite(filename,variablelist)` writes out a Common Data Format (CDF) file, specified in `filename`. The `filename` input is a string enclosed in single quotes. The `variablelist` argument is a cell array of ordered pairs, each of which comprises a CDF variable name (a string) and the corresponding CDF variable value. To write out multiple records for a variable, put the values in a cell array where each element in the cell array represents a record.

Note Because `cdfwrite` creates temporary files, both the destination directory for the file and the current working directory must be writeable.

`cdfwrite(...,'PadValues',padvals)` writes out pad values for given variable names. `padvals` is a cell array of ordered pairs, each of which comprises a variable name (a string) and a corresponding pad value. Pad values are the default values associated with the variable when an out-of-bounds record is accessed. Variable names that appear in `padvals` must appear in `variablelist`.

`cdfwrite(...,'GlobalAttributes',gattrib)` writes the structure `gattrib` as global metadata for the CDF file. Each field of the structure is the name of a global attribute. The value of each field contains the value of the attribute. To write out multiple values for an attribute, put the values in a cell array where each element in the cell array represents a record.

Note To specify a global attribute name that is illegal in MATLAB, create a field called `'CDFAttributeRename'` in the attribute structure. The value of this field must have a value that is a cell array of ordered pairs. The ordered pair consists of the name of the original attribute, as listed in the `GlobalAttributes` structure, and the corresponding name of the attribute to be written to the CDF file.

`cdfwrite(..., 'VariableAttributes', vattrib)` writes the structure `vattrib` as variable metadata for the CDF. Each field of the struct is the name of a variable attribute. The value of each field should be an M-by-2 cell array where M is the number of variables with attributes. The first element in the cell array should be the name of the variable and the second element should be the value of the attribute for that variable.

Note To specify a variable attribute name that is illegal in MATLAB, create a field called `'CDFAttributeRename'` in the attribute structure. The value of this field must have a value that is a cell array of ordered pairs. The ordered pair consists of the name of the original attribute, as listed in the `VariableAttributes` struct, and the corresponding name of the attribute to be written to the CDF file. If you are specifying a variable attribute of a CDF variable that you are renaming, the name of the variable in the `VariableAttributes` structure must be the same as the renamed variable.

`cdfwrite(...,'WriteMode',`*`mode`*`)`, where *`mode`* is either `'overwrite'` or `'append'`, indicates whether or not the specified variables should be appended to the CDF file if the file already exists. By default, `cdfwrite` overwrites existing variables and attributes.

`cdfwrite(...,'Format',`*`format`*`)`, where *`format`* is either `'multifile'` or `'singlefile'`, indicates whether or not the data is written out as a multifile CDF. In a multifile CDF, each variable is stored in a separate

file with the name `*.vN`, where `N` is the number of the variable that is written out to the CDF. By default, `cdfwrite` writes out a single file CDF. When `'WriteMode'` is set to `'Append'`, the `'Format'` option is ignored, and the format of the preexisting CDF is used.

Examples

Write out a file `'example.cdf'` containing a variable `'Longitude'` with the value `[0:360]`.

```
cdfwrite('example', {'Longitude', 0:360});
```

Write out a file `'example.cdf'` containing variables `'Longitude'` and `'Latitude'` with the variable `'Latitude'` having a pad value of 10 for all out-of-bounds records that are accessed.

```
cdfwrite('example', {'Longitude', 0:360, 'Latitude', 10:20}, ...
         'PadValues', {'Latitude', 10});
```

Write out a file `'example.cdf'`, containing a variable `'Longitude'` with the value `[0:360]`, and with a variable attribute of `'validmin'` with the value 10.

```
varAttribStruct.validmin = {'longitude' [10]};
cdfwrite('example', {'Longitude' 0:360}, 'VarAttribStruct', ...
         varAttribStruct);
```

`cdfread`, `cdfinfo`, `cdfepoch`

Purpose

Round toward infinity

Syntax

```
B = ceil(A)
```

Description

`B = ceil(A)` rounds the elements of `A` to the nearest integers greater than or equal to `A`. For complex `A`, the imaginary and real parts are rounded independently.

Examples

```
a = [-1.9, -0.2, 3.4, 5.6, 7, 2.4+3.6i]

a =
  Columns 1 through 4
  -1.9000        -0.2000        3.4000        5.6000

  Columns 5 through 6
   7.0000        2.4000 + 3.6000i

ceil(a)

ans =
  Columns 1 through 4
  -1.0000        0              4.0000        6.0000

  Columns 5 through 6
   7.0000        3.0000 + 4.0000i
```

See Also

`fix`, `floor`, `round`

Purpose

Construct cell array

Syntax

```
c = cell(n)
c = cell(m, n)
c = cell([m, n])
c = cell(m, n, p,...)
c = cell([m n p ...])
c = cell(size(A))
c = cell(javaobj)
```

Description

`c = cell(n)` creates an `n`-by-`n` cell array of empty matrices. An error message appears if `n` is not a scalar.

`c = cell(m, n)` or `c = cell([m, n])` creates an `m`-by-`n` cell array of empty matrices. Arguments `m` and `n` must be scalars.

`c = cell(m, n, p,...)` or `c = cell([m n p ...])` creates an `m`-by-`n`-by-`p`-... cell array of empty matrices. Arguments `m`, `n`, `p`,`...` must be scalars.

`c = cell(size(A))` creates a cell array the same size as `A` containing all empty matrices.

`c = cell(javaobj)` converts a Java array or Java object `javaobj` into a MATLAB cell array. Elements of the resulting cell array will be of the MATLAB type (if any) closest to the Java array elements or Java object.

Remarks

This type of cell is not related to “cell mode,” a MATLAB feature used in debugging and publishing.

Examples

This example creates a cell array that is the same size as another array, `A`.

```
A = ones(2,2)

A =
     1     1
     1     1
```

```
c = cell(size(A))

c =
     []     []
     []     []
```

The next example converts an array of `java.lang.String` objects into a MATLAB cell array.

```
strArray = java_array('java.lang.String', 3);
strArray(1) = java.lang.String('one');
strArray(2) = java.lang.String('two');
strArray(3) = java.lang.String('three');

cellArray = cell(strArray)
cellArray =
    'one'
    'two'
    'three'
```

See Also

`num2cell`, `ones`, `rand`, `randn`, `zeros`

Purpose

Convert cell array of matrices to single matrix

Syntax

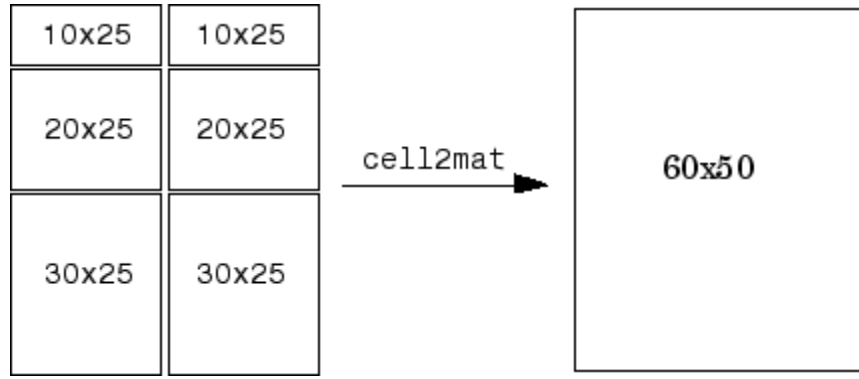
```
m = cell2mat(c)
```

Description

`m = cell2mat(c)` converts a multidimensional cell array `c` with contents of the same data type into a single matrix, `m`. The contents of `c` must be able to concatenate into a hyperrectangle. Moreover, for each pair of neighboring cells, the dimensions of the cells' contents must match, excluding the dimension in which the cells are neighbors.

The example shown below combines matrices in a 3-by-2 cell array into a single 60-by-50 matrix:

```
cell2mat(c)
```



Remarks

The dimensionality (or number of dimensions) of `m` will match the highest dimensionality contained in the cell array.

`cell2mat` is not supported for cell arrays containing cell arrays or objects.

Examples

Combine the matrices in four cells of cell array `C` into the single matrix, `M`:

```
C = {[1] [2 3 4]; [5; 9] [6 7 8; 10 11 12]}
```

```
C =
    [         1]    [1x3 double]
    [2x1 double]    [2x3 double]

C{1,1}                      C{1,2}
ans =                       ans =
     1                           2     3     4

C{2,1}                      C{2,2}
ans =                       ans =
     5                          6     7     8
     9                         10    11    12

M = cell2mat(C)
M =
     1     2     3     4
     5     6     7     8
     9    10    11    12
```

See Also

mat2cell, num2cell

Purpose

Convert cell array to structure array

Syntax

```
s = cell2struct(c, fields, dim)
```

Description

`s = cell2struct(c, fields, dim)` creates a structure array `s` from the information contained within cell array `c`.

The `fields` argument specifies field names for the structure array. `fields` can be a character array or a cell array of strings.

The `dim` argument controls which axis of the cell array is to be used in creating the structure array. The length of `c` along the specified dimension must match the number of fields named in `fields`. In other words, the following must be true.

```
size(c,dim) == length(fields)   % If fields is a cell array
size(c,dim) == size(fields,1)   % If fields is a char array
```

Examples

The cell array `c` in this example contains information on trees. The three columns of the array indicate the common name, genus, and average height of a tree.

```
c = {'birch', 'betula', 65;  'maple', 'acer', 50}
c =
    'birch'    'betula'    [65]
    'maple'    'acer'      [50]
```

To put this information into a structure with the fields `name`, `genus`, and `height`, use `cell2struct` along the second dimension of the 2-by-3 cell array.

```
fields = {'name', 'genus', 'height'};
s = cell2struct(c, fields, 2);
```

This yields the following 2-by-1 structure array.

```
s(1)                        s(2)
ans =                       ans =
      name: 'birch'               name: 'maple'
```

```
      genus: 'betula'             genus: 'acer'
     height: 65                  height: 50
```

`struct2cell`, `cell`, `iscell`, `struct`, `isstruct`, `fieldnames`, dynamic field names

celldisp

Purpose

Cell array contents

Syntax

```
celldisp(C)
celldisp(C, name)
```

Description

`celldisp(C)` recursively displays the contents of a cell array.

`celldisp(C, name)` uses the string *name* for the display instead of the name of the first input (or `ans`).

Examples

Use `celldisp` to display the contents of a 2-by-3 cell array:

```
C = {[1 2] 'Tony' 3+4i; [1 2;3 4] -5 'abc'};
celldisp(C)

C{1,1} =
     1     2

C{2,1} =
     1     2
     3     4

C{1,2} =
Tony

C{2,2} =
    -5

C{1,3} =
   3.0000+ 4.0000i

C{2,3} =
abc
```

See Also

`cellplot`

Purpose

Apply function to each cell in cell array

Syntax

```
A = cellfun(fun, C)
A = cellfun(fun, C, D, ...)
[A, B, ...] = cellfun(fun, C, ...)
[A, ...] = cellfun(fun, C, ..., 'param1', value1, ...)
A = cellfun('fname', C)
A = cellfun('size', C, k)
A = cellfun('isclass', C, 'classname')
```

Description

`A = cellfun(fun, C)` applies the function specified by `fun` to the contents of each cell of cell array `C`, and returns the results in array `A`. The value `A` returned by `cellfun` is the same size as `C`, and the `(I,J,...)`th element of `A` is equal to `fun(C{I,J,...})`. The first input argument `fun` is a function handle to a function that takes one input argument and returns a scalar value. `fun` must return values of the same class each time it is called. The order in which `cellfun` computes elements of `A` is not specified and should not be relied upon.

If `fun` is bound to more than one built-in or M-file (that is, if it represents a set of overloaded functions), then the class of the values that `cellfun` actually provides as input arguments to `fun` determines which functions are executed.

`A = cellfun(fun, C, D, ...)` evaluates `fun` using the contents of the cells of cell arrays `C`, `D`, `...` as input arguments. The `(I,J,...)`th element of `A` is equal to `fun(C{I,J,...}, D{I,J,...}, ...)`. All input arguments must be of the same size and shape.

`[A, B, ...] = cellfun(fun, C, ...)` evaluates `fun`, which is a function handle to a function that returns multiple outputs, and returns arrays `A`, `B`, `...`, each corresponding to one of the output arguments of `fun`. `cellfun` calls `fun` each time with as many outputs as there are in the call to `cellfun`. `fun` can return output arguments having different classes, but the class of each output must be the same each time `fun` is called.

`[A, ...] = cellfun(fun, C, ..., 'param1', value1, ...)` enables you to specify optional parameter name and value pairs.

Parameters recognized by `cellfun` are shown below. Enclose each parameter name with single quotes.

Parameter Name	Parameter Value
`UniformOutput`	Logical 1 (`true`) or 0 (`false`), indicating whether or not the outputs of `fun` can be returned without encapsulation in a cell array. See "UniformOutput Parameter" on page 2-510 below.
`ErrorHandler`	Function handle, specifying the function that `cellfun` is to call if the call to `fun` fails. See "ErrorHandler Parameter" on page 2-510 below.

UniformOutput Parameter

If you set the `UniformOutput` parameter to `true` (the default), `fun` must return scalar values that can be concatenated into an array. These values can also be a cell array.

If `UniformOutput` is `false`, `cellfun` returns a cell array (or multiple cell arrays), where the `(I,J,...)`th cell contains the value

```
fun(C{I,J,...}, ...)
```

ErrorHandler Parameter

MATLAB calls the function represented by the `ErrorHandler` parameter with two input arguments:

- A structure having three fields, named `identifier`, `message`, and `index`, respectively containing the identifier of the error that occurred, the text of the error message, and a linear index into the input array or arrays for which the error occurred
- The set of input arguments for which the call to the function failed

The error handling function must either rethrow the error that was caught, or it must return the output values from the call to `fun`. Error

handling functions that do not rethrow the error must have the same number of outputs as `fun`. MATLAB places these output values in the output variables used in the call to `arrayfun`.

Shown here is an example of a simple error handling function, `errorfun`:

```
function [A, B] = errorfun(S, varargin)
warning(S.identifier, S.message);
A = NaN;  B = NaN;
```

If `'UniformOutput'` is set to logical 1 (`true`), the outputs of the error handler must be scalars and of the same data type as the outputs of function `fun`.

If you do not specify an error handler, `cellfun` rethrows the error.

Backward Compatibility

The following syntaxes are also accepted for backward compatibility:

`A = cellfun('fname', C)` applies the function `fname` to the elements of cell array `C` and returns the results in the double array `A`. Each element of `A` contains the value returned by `fname` for the corresponding element in `C`. The output array `A` is the same size as the cell array `C`.

These functions are supported:

Function	Return Value
`isempty`	`true` for an empty cell element
`islogical`	`true` for a logical cell element
`isreal`	`true` for a real cell element
`length`	Length of the cell element
`ndims`	Number of dimensions of the cell element
`prodofsize`	Number of elements in the cell element

`A = cellfun('size', C, k)` returns the size along the `k`th dimension of each element of `C`.

`A = cellfun('isclass', C, 'classname')` returns logical `1` (`true`) for each element of `C` that matches `classname`. This function syntax returns logical 0 (`false`) for objects that are a subclass of `classname`.

Note For the previous three syntaxes, if `C` contains objects, `cellfun` does not call any overloaded versions of MATLAB functions corresponding to the above strings.

Examples

Compute the mean of several data sets:

```
C = {1:10, [2; 4; 6], []};

Cmeans = cellfun(@mean, C)
Cmeans =
    5.5000    4.0000       NaN
```

Compute the size of these data sets:

```
[Cnrows, Cncols] = cellfun(@size, C)
Cnrows =
     1     3     0
Cncols =
    10     1     0
```

Again compute the size, but with `UniformOutput` set to `false`:

```
Csize = cellfun(@size, C, 'UniformOutput', false)
Csize =
    [1x2 double]    [1x2 double]    [1x2 double]

Csize{:}
ans =
     1    10
ans =
     3     1
ans =
```

```
     0     0
```

Find the positive values in several data sets.

```
C = {randn(10,1), randn(20,1), randn(30,1)};

Cpositives = cellfun(@(x) x(x>0), C, 'UniformOutput',false)
Cpositives =
    [6x1 double]    [11x1 double]    [15x1 double]

Cpositives{:}
ans =
    0.1253
    0.2877
    1.1909
     etc.
ans =
    0.7258
    2.1832
    0.1139
     etc.
ans =
    0.6900
    0.8156
    0.7119
     etc.
```

Compute the covariance between several pairs of data sets:

```
C = {randn(10,1), randn(20,1), randn(30,1)};
D = {randn(10,1), randn(20,1), randn(30,1)};

CDcovs = cellfun(@cov, C, D, 'UniformOutput', false)
CDcovs =
    [2x2 double]    [2x2 double]    [2x2 double]

CDcovs{:}
ans =
```

```
    0.7353   -0.2148
   -0.2148    0.6080
ans =
    0.5743   -0.2912
   -0.2912    0.8505
ans =
    0.7130    0.1750
    0.1750    0.6910
```

See Also

arrayfun, spfun, function_handle, cell2mat

Purpose

Graphically display structure of cell array

Syntax

```
cellplot(c)
cellplot(c, 'legend')
handles = cellplot(c)
```

Description

`cellplot(c)` displays a figure window that graphically represents the contents of `c`. Filled rectangles represent elements of vectors and arrays, while scalars and short text strings are displayed as text.

`cellplot(c, 'legend')` places a colorbar next to the plot labelled to identify the data types in `c`.

`handles = cellplot(c)` displays a figure window and returns a vector of surface handles.

Limitations

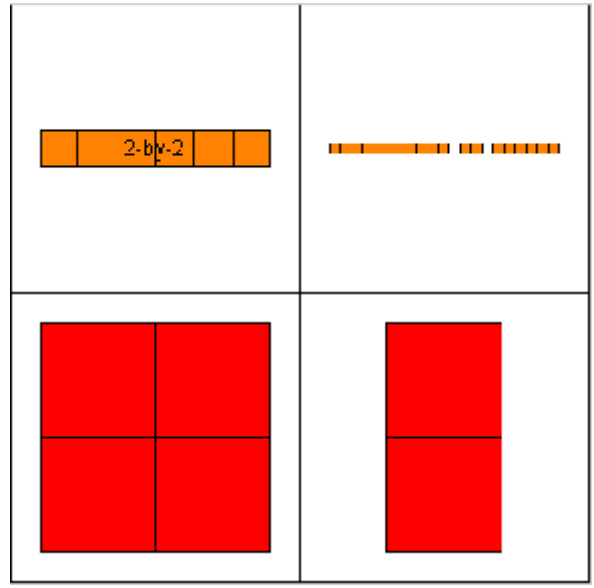
The `cellplot` function can display only two-dimensional cell arrays.

Examples

Consider a 2-by-2 cell array containing a matrix, a vector, and two text strings:

```
c{1,1} = '2-by-2';
c{1,2} = 'eigenvalues of eye(2)';
c{2,1} = eye(2);
c{2,2} = eig(eye(2));
```

The command `cellplot(c)` produces



Purpose

Create cell array of strings from character array

Syntax

```
c = cellstr(S)
```

Description

`c = cellstr(S)` places each row of the character array `S` into separate cells of `c`. Any trailing spaces in the rows of `S` are removed.

Use the `char` function to convert back to a string matrix.

Examples

Given the string matrix

```
S = ['abc '; 'defg'; 'hi  ']

S =
    abc
    defg
    hi

whos S
  Name      Size          Bytes  Class
  S         3x4              24  char array
```

The following command returns a 3-by-1 cell array.

```
c = cellstr(S)

c =
    'abc'
    'defg'
    'hi'

whos c
  Name      Size          Bytes  Class
  c         3x1              294  cell array
```

`iscellstr`, `strings`, `char`, `isstrprop`

Purpose

Conjugate gradients squared method

Syntax

```
x = cgs(A,b)
cgs(A,b,tol)
cgs(A,b,tol,maxit)
cgs(A,b,tol,maxit,M)
cgs(A,b,tol,maxit,M1,M2)
cgs(A,b,tol,maxit,M1,M2,x0)
[x,flag] = cgs(A,b,...)
[x,flag,relres] = cgs(A,b,...)
[x,flag,relres,iter] = cgs(A,b,...)
[x,flag,relres,iter,resvec] = cgs(A,b,...)
```

Description

`x = cgs(A,b)` attempts to solve the system of linear equations `A*x = b` for `x`. The `n`-by-`n` coefficient matrix `A` must be square and should be large and sparse. The column vector `b` must have length `n`. `A` can be a function handle `afun` such that `afun(x)` returns `A*x`. See "Function Handles" in the MATLAB Programming documentation for more information.

"Parameterizing Functions Called by Function Functions", in the MATLAB Mathematics documentation, explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `cgs` converges, a message to that effect is displayed. If `cgs` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual `norm(b-A*x)/norm(b)` and the iteration number at which the method stopped or failed.

`cgs(A,b,tol)` specifies the tolerance of the method, `tol`. If `tol` is `[]`, then `cgs` uses the default, `1e-6`.

`cgs(A,b,tol,maxit)` specifies the maximum number of iterations, `maxit`. If `maxit` is `[]` then `cgs` uses the default, `min(n,20)`.

`cgs(A,b,tol,maxit,M)` and `cgs(A,b,tol,maxit,M1,M2)` use the preconditioner `M` or `M = M1*M2` and effectively solve the system `inv(M)*A*x = inv(M)*b` for `x`. If `M` is `[]` then `cgs` applies no

preconditioner. `M` can be a function handle `mfun` such that `mfun(x)` returns `M\x`.

`cgs(A,b,tol,maxit,M1,M2,x0)` specifies the initial guess `x0`. If `x0` is `[]`, then `cgs` uses the default, an all-zero vector.

`[x,flag] = cgs(A,b,...)` returns a solution `x` and a flag that describes the convergence of `cgs`.

Flag	Convergence
0	`cgs` converged to the desired tolerance `tol` within `maxit` iterations.
1	`cgs` iterated `maxit` times but did not converge.
2	Preconditioner `M` was ill-conditioned.
3	`cgs` stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during `cgs` became too small or too large to continue computing.

Whenever `flag` is not `0`, the solution `x` returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = cgs(A,b,...)` also returns the relative residual `norm(b-A*x)/norm(b)`. If `flag` is `0`, then `relres <= tol`.

`[x,flag,relres,iter] = cgs(A,b,...)` also returns the iteration number at which `x` was computed, where `0 <= iter <= maxit`.

`[x,flag,relres,iter,resvec] = cgs(A,b,...)` also returns a vector of the residual norms at each iteration, including `norm(b-A*x0)`.

Examples

Example

```
A = gallery('wilk',21);
b = sum(A,2);
```

```
tol = 1e-12;  maxit = 15;
M1 = diag([10:-1:1 1 1:10]);
x = cgs(A,b,tol,maxit,M1);
```

displays the message

```
cgs converged at iteration 13 to a solution with relative residual
1.3e-016
```

Example 2

This example replaces the matrix `A` in Example 1 with a handle to a matrix-vector product function `afun`, and the preconditioner `M1` with a handle to a backsolve function `mfun`. The example is contained in an M-file `run_cgs` that

- Calls `cgs` with the function handle `@afun` as its first argument.
- Contains `afun` as a nested function, so that all variables in `run_cgs` are available to `afun` and `myfun`.

The following shows the code for `run_cgs`:

```
function x1 = run_cgs
n = 21;
A = gallery('wilk',n);
b = sum(A,2);
tol = 1e-12;  maxit = 15;
x1 = cgs(@afun,b,tol,maxit,@mfun);

    function y = afun(x)
        y = [0; x(1:n-1)] + ...
              [((n-1)/2:-1:0)'; (1:(n-1)/2)'].*x + ...
              [x(2:n); 0];
    end

    function y = mfun(r)
        y = r ./ [((n-1)/2:-1:1)'; 1; (1:(n-1)/2)'];
    end
```

```
end
```

When you enter

```
x1 = run_cgs
```

MATLAB returns

```
cgs converged at iteration 13 to a solution with relative residual
1.3e-016
```

Example 3

```
load west0479
A = west0479
b = sum(A,2)
[x,flag] = cgs(A,b)
```

`flag` is `1` because `cgs` does not converge to the default tolerance `1e-6` within the default 20 iterations.

```
[L1,U1] = luinc(A,1e-5)
[x1,flag1] = cgs(A,b,1e-6,20,L1,U1)
```

`flag1` is `2` because the upper triangular `U1` has a zero on its diagonal, and `cgs` fails in the first iteration when it tries to solve a system such as `U1*y = r` for `y` with backslash.

```
[L2,U2] = luinc(A,1e-6)
[x2,flag2,relres2,iter2,resvec2] = cgs(A,b,1e-15,10,L2,U2)
```

`flag2` is `0` because `cgs` converges to the tolerance of `6.344e-16` (the value of `relres2`) at the fifth iteration (the value of `iter2`) when preconditioned by the incomplete LU factorization with a drop tolerance of `1e-6`. `resvec2(1) = norm(b)` and `resvec2(6) = norm(b-A*x2)`. You can follow the progress of `cgs` by plotting the relative residuals at each iteration starting from the initial estimate (iterate number 0) with

```
semilogy(0:iter2,resvec2/norm(b),'-o')
xlabel('iteration number')
```

```
ylabel('relative residual')
```

Purpose

Convert to character array (string)

Syntax

```
S = char(X)
S = char(C)
S = char(t1, t2, t3, ...)
```

Description

`S = char(X)` converts the array `X` that contains nonnegative integers representing character codes into a MATLAB character array. The actual characters displayed depend on the character encoding scheme for a given font. The result for any elements of `X` outside the range from 0 to 65535 is not defined (and can vary from platform to platform). Use `double` to convert a character array into its numeric codes.

`S = char(C)`, when `C` is a cell array of strings, places each element of `C` into the rows of the character array `s`. Use `cellstr` to convert back.

`S = char(t1, t2, t3, ...)` forms the character array `S` containing the text strings `T1`, `T2`, `T3`, `...` as rows, automatically padding each string with blanks to form a valid matrix. Each text parameter, `T`*`i`*, can itself be a character array. This allows the creation of arbitrarily large character arrays. Empty strings are significant.

Examples

To print a 3-by-32 display of the printable ASCII characters,

```
ascii = char(reshape(32:127, 32, 3)')
ascii =
   !"#$%&'()*+,-./0123456789:;<=>?
  @ABCDEFGHIJKLMNOPQRSTUVWXYZ[\]^_
  'abcdefghijklmnopqrstuvwxyz{|}~
```

checkin

Purpose

Check files into source control system (UNIX)

GUI Alternatives

As an alternative to the `checkin` function, use **File > Source Control > Check In** in the Editor/Debugger, Simulink, or Stateflow, or in the context menu of the Current Directory browser. For more information, see "Checking Files Into the Source Control System on UNIX".

Syntax

```
checkin('filename','comments','comment_text')
checkin({'filename1','filename2'},'comments','comment_text')
checkin('filename','comments', 'comment_text','option',
   'value')
```

Description

`checkin('filename','comments','comment_text')` checks in the file named `filename` to the source control system. Use the full path for `filename` and include the file extension. You must save the file before checking it in, but the file can be open or closed. The comment_text argument is a MATLAB string containing checkin comments for the source control system. You must supply **`comments`** and comment_text.

`checkin({'filename1','filename2'},'comments','comment_text')` checks in the files `filename1` through `filenamen` to the source control system. Use the full paths for the files and include file extensions. Comments apply to all files checked in.

`checkin('filename','comments', 'comment_text','option','value')` provides additional `checkin` options. For multiple filenames, use an array of strings instead of `filename`, that is, `{'filename1','filename2',...}`. Options apply to all filenames. The *`option`* and *`value`* arguments are shown in the following table.

option Argument	value Argument	Purpose
`'force'`	`'on'`	`filename` is checked in even if the file has not changed since it was checked out.
`'force'`	`'off'` (default)	`filename` is not checked in if there were no changes since checkout.
`'lock'`	`'on'`	`filename` is checked in with comments, and is automatically checked out.
`'lock'`	`'off'` (default)	`filename` is checked in with comments but does not remain checked out.

Examples

Check In a File

Typing

```
checkin('/myserver/mymfiles/clock.m','comments',...
'Adjustment for leapyear')
```

checks the file `/myserver/mymfiles/clock.m` into the source control system, with the comment `Adjustment for leapyear`.

Check In Multiple Files

Typing

```
checkin({'/myserver/mymfiles/clock.m', ...
'/myserver/mymfiles/calendar.m'},'comments',...
'Adjustment for leapyear')
```

checks the two files into the source control system, using the same comment for each.

Check In a File and Keep It Checked Out

Typing

```
checkin('/myserver/mymfiles/clock.m','comments',...
'Adjustment for leapyear','lock','on')
```

checks the file `/myserver/mymfiles/clock.m` into the source control system and keeps the file checked out.

See Also

`checkout`, `cmopts`, `undocheckout`

For Windows platforms, use `verctrl`.

Purpose

Check files out of source control system (UNIX)

GUI Alternatives

As an alternative to the `checkout` function, select **Source Control > Check Out** from the **File** menu in the Editor/Debugger, Simulink, or Stateflow, or in the context menu of the Current Directory browser. For details, see "Checking Files Out of the Source Control System on UNIX".

Syntax

```
checkout('filename')
checkout({'filename1','filename2', ...})
checkout('filename','option','value',...)
```

Description

`checkout('filename')` checks out the file named `filename` from the source control system. Use the full path for `filename` and include the file extension. The file can be open or closed when you use `checkout`.

`checkout({'filename1','filename2', ...})` checks out the files named `filename1` through `filenamen` from the source control system. Use the full paths for the files and include the file extensions.

`checkout('filename','option','value',...)` provides additional `checkout` options. For multiple filenames, use an array of strings instead of `filename`, that is, `{'filename1','filename2', ...}`. Options apply to all filenames. The *`option`* and *`value`* arguments are shown in the following table.

option Argument	value Argument	Purpose
`'force'`	`'on'`	The checkout is forced, even if you already have the file checked out. This is effectively an `undocheckout` followed by a `checkout`.

option Argument	value Argument	Purpose
`'force'`	`'off'` (default)	Prevents you from checking out the file if you already have it checked out.
`'lock'`	`'on'` (default)	The checkout gets the file, allows you to write to it, and locks the file so that access to the file for others is read only.
`'lock'`	`'off'`	The checkout gets a read-only version of the file, allowing another user to check out the file for updating. You do not have to check the file in after checking it out with this option.
`'revision'`	`'version_num'`	Checks out the specified revision of the file.

If you end the MATLAB session, the file remains checked out. You can check in the file from within MATLAB during a later session, or directly from your source control system.

Examples

Check Out a File

Typing

```
checkout('/myserver/mymfiles/clock.m')
```

checks out the file `/myserver/mymfiles/clock.m` from the source control system.

Check Out Multiple Files

Typing

```
checkout({'/myserver/mymfiles/clock.m',...
'/myserver/mymfiles/calendar.m'})
```

checks out `/matlab/mymfiles/clock.m` and `/matlab/mymfiles/calendar.m` from the source control system.

Force a Checkout, Even If File Is Already Checked Out

Typing

```
checkout('/myserver/mymfiles/clock.m','force','on')
```

checks out `/matlab/mymfiles/clock.m` even if `clock.m` is already checked out to you.

Check Out Specified Revision of File

Typing

```
checkout('/matlab/mymfiles/clock.m','revision','1.1')
```

checks out revision `1.1` of `clock.m`.

See Also

`checkin`, `cmopts`, `undocheckout`, `customverctrl`

For Windows platforms, use `verctrl`.

Purpose

Cholesky factorization

Syntax

```
R = chol(A)
L = chol(A,'lower')
[R,p] = chol(A)
[L,p] = chol(A,'lower')
[R,p,S] = chol(A)
[R,p,s] = chol(A,'vector')
[L,p,s] = chol(A,'lower','vector')
```

Description

`R = chol(A)` produces an upper triangular matrix `R` from the diagonal and upper triangle of matrix `A`, satisfying the equation `R'*R=A`. The lower triangle is assumed to be the (complex conjugate) transpose of the upper triangle. Matrix `A` must be positive definite; otherwise, MATLAB displays an error message.

`L = chol(A,'lower')` produces a lower triangular matrix `L` from the diagonal and lower triangle of matrix `A`, satisfying the equation `L*L'=A`. When `A` is sparse, this syntax of `chol` is typically faster. Matrix `A` must be positive definite; otherwise MATLAB displays an error message.

`[R,p] = chol(A)` for positive definite `A`, produces an upper triangular matrix `R` from the diagonal and upper triangle of matrix `A`, satisfying the equation `R'*R=A` and `p` is zero. If `A` is not positive definite, then `p` is a positive integer and MATLAB does not generate an error. When `A` is full, `R` is an upper triangular matrix of order `q=p-1` such that `R'*R=A(1:q,1:q)`. When `A` is sparse, `R` is an upper triangular matrix of size `q`-by-`n` so that the `L`-shaped region of the first `q` rows and first `q` columns of `R'*R` agree with those of `A`.

`[L,p] = chol(A,'lower')` for positive definite `A`, produces a lower triangular matrix `L` from the diagonal and lower triangle of matrix `A`, satisfying the equation `L'*L=A` and `p` is zero. If `A` is not positive definite, then `p` is a positive integer and MATLAB does not generate an error. When `A` is full, `L` is a lower triangular matrix of order `q=p-1` such that `L'*L=A(1:q,1:q)`. When `A` is sparse, `L` is a lower triangular matrix of size `q`-by-`n` so that the `L`-shaped region of the first `q` rows and first `q` columns of `L'*L` agree with those of `A`.

`[R,p,S] = chol(A)`, when `A` is sparse, returns a permutation matrix `S`. Note that the preordering `S` may differ from that obtained from `amd` since `chol` will slightly change the ordering for increased performance. When `p=0`, `R` is an upper triangular matrix such that `R'*R=S'*A*S`. When `p` is not zero, `R` is an upper triangular matrix of size `q`-by-`n` so that the `L`-shaped region of the first `q` rows and first `q` columns of `R'*R` agree with those of `S'*A*S`. The factor of `S'*A*S` tends to be sparser than the factor of `A`.

`[R,p,s] = chol(A,'vector')` returns the permutation information as a vector `s` such that `A(s,s)=R'*R`, when `p=0`. You can use the `'matrix'` option in place of `'vector'` to obtain the default behavior.

`[L,p,s] = chol(A,'lower','vector')` uses only the diagonal and the lower triangle of `A` and returns a lower triangular matrix `L` and a permutation vector `s` such that `A(s,s)=L*L'`, when `p=0`. As above, you can use the `'matrix'` option in place of `'vector'` to obtain a permutation matrix.

For sparse `A`, CHOLMOD is used to compute the Cholesky factor.

Note Using `chol` is preferable to using `eig` for determining positive definiteness.

Examples

The binomial coefficients arranged in a symmetric array create an interesting positive definite matrix.

```
n = 5;
X = pascal(n)
X =
     1     1     1     1     1
     1     2     3     4     5
     1     3     6    10    15
     1     4    10    20    35
     1     5    15    35    70
```

It is interesting because its Cholesky factor consists of the same coefficients, arranged in an upper triangular matrix.

```
R = chol(X)
R =
     1     1     1     1     1
     0     1     2     3     4
     0     0     1     3     6
     0     0     0     1     4
     0     0     0     0     1
```

Destroy the positive definiteness (and actually make the matrix singular) by subtracting 1 from the last element.

```
X(n,n) = X(n,n)-1

X =
     1     1     1     1     1
     1     2     3     4     5
     1     3     6    10    15
     1     4    10    20    35
     1     5    15    35    69
```

Now an attempt to find the Cholesky factorization fails.

Algorithm

For full matrices `X`, `chol` uses the LAPACK routines listed in the following table.

	Real	Complex
`X double`	DPOTRF	ZPOTRF
`X single`	SPOTRF	CPOTRF

For sparse matrices, MATLAB uses CHOLMOD to compute the Cholesky factor.

`cholinc`, `cholupdate`

cholinc

Purpose

Sparse incomplete Cholesky and Cholesky-Infinity factorizations

Syntax

```
R = cholinc(X,droptol)
R = cholinc(X,options)
R = cholinc(X,'0')
[R,p] = cholinc(X,'0')
R = cholinc(X,'inf')
```

Description

`cholinc` produces two different kinds of incomplete Cholesky factorizations: the drop tolerance and the 0 level of fill-in factorizations. These factors may be useful as preconditioners for a symmetric positive definite system of linear equations being solved by an iterative method such as `pcg` (Preconditioned Conjugate Gradients). `cholinc` works only for sparse matrices.

`R = cholinc(X,droptol)` performs the incomplete Cholesky factorization of `X`, with drop tolerance `droptol`.

`R = cholinc(X,options)` allows additional options to the incomplete Cholesky factorization. `options` is a structure with up to three fields:

`droptol`	Drop tolerance of the incomplete factorization
`michol`	Modified incomplete Cholesky
`rdiag`	Replace zeros on the diagonal of `R`

Only the fields of interest need to be set.

`droptol` is a non-negative scalar used as the drop tolerance for the incomplete Cholesky factorization. This factorization is computed by performing the incomplete LU factorization with the pivot threshold option set to `0` (which forces diagonal pivoting) and then scaling the rows of the incomplete upper triangular factor, `U`, by the square root of the diagonal entries in that column. Since the nonzero entries `U(i,j)` are bounded below by `droptol*norm(X(:,j))` (see `luinc`), the nonzero entries `R(i,j)` are bounded below by the local drop tolerance `droptol*norm(X(:,j))/R(i,i)`.

Setting `droptol = 0` produces the complete Cholesky factorization, which is the default.

`michol` stands for modified incomplete Cholesky factorization. Its value is either `0` (unmodified, the default) or `1` (modified). This performs the modified incomplete LU factorization of `X` and scales the returned upper triangular factor as described above.

`rdiag` is either `0` or `1`. If it is `1`, any zero diagonal entries of the upper triangular factor R are replaced by the square root of the local drop tolerance in an attempt to avoid a singular factor. The default is `0`.

`R = cholinc(X,'0')` produces the incomplete Cholesky factor of a real sparse matrix that is symmetric and positive definite using no fill-in. The upper triangular `R` has the same sparsity pattern as `triu(X)`, although `R` may be zero in some positions where `X` is nonzero due to cancellation. The lower triangle of `X` is assumed to be the transpose of the upper. Note that the positive definiteness of `X` does not guarantee the existence of a factor with the required sparsity. An error message results if the factorization is not possible. If the factorization is successful, `R'*R` agrees with `X` over its sparsity pattern.

`[R,p] = cholinc(X,'0')` with two output arguments, never produces an error message. If `R` exists, `p` is `0`. If `R` does not exist, then `p` is a positive integer and `R` is an upper triangular matrix of size `q`-by-`n` where `q = p-1`. In this latter case, the sparsity pattern of `R` is that of the `q`-by-`n` upper triangle of `X`. `R'*R` agrees with `X` over the sparsity pattern of its first `q` rows and first `q` columns.

`R = cholinc(X,'inf')` produces the Cholesky-Infinity factorization. This factorization is based on the Cholesky factorization, and additionally handles real positive semi-definite matrices. It may be useful for finding a solution to systems which arise in interior-point methods. When a zero pivot is encountered in the ordinary Cholesky factorization, the diagonal of the Cholesky-Infinity factor is set to `Inf` and the rest of that row is set to `0`. This forces a `0` in the corresponding entry of the solution vector in the associated system of linear equations. In practice, `X` is assumed to be positive semi-definite so even negative pivots are replaced with a value of `Inf`.

Remarks

The incomplete factorizations may be useful as preconditioners for solving large sparse systems of linear equations. A single `0` on the diagonal of the upper triangular factor makes it singular. The incomplete factorization with a drop tolerance prints a warning message if the upper triangular factor has zeros on the diagonal. Similarly, using the `rdiag` option to replace a zero diagonal only gets rid of the symptoms of the problem, but it does not solve it. The preconditioner may not be singular, but it probably is not useful, and a warning message is printed.

The Cholesky-Infinity factorization is meant to be used within interior-point methods. Otherwise, its use is not recommended.

Examples

Example 1

Start with a symmetric positive definite matrix, `S`.

```
S = delsq(numgrid('C',15));
```

S is the two-dimensional, five-point discrete negative Lapacian on the grid generated by numgrid('C',15).

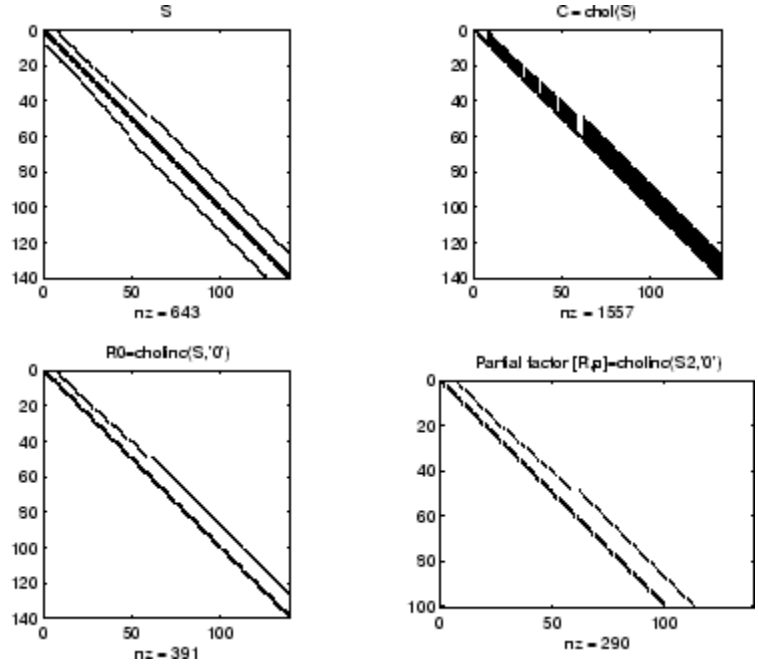
Compute the Cholesky factorization and the incomplete Cholesky factorization of level 0 to compare the fill-in. Make `S` singular by zeroing out a diagonal entry and compute the (partial) incomplete Cholesky factorization of level `0`.

```
C = chol(S);
R0 = cholinc(S,'0');
S2 = S; S2(101,101) = 0;
[R,p] = cholinc(S2,'0');
```

Fill-in occurs within the bands of `S` in the complete Cholesky factor, but none in the incomplete Cholesky factor. The incomplete factorization of the singular `S2` stopped at row `p = 101` resulting in a 100-by-139 partial factor.

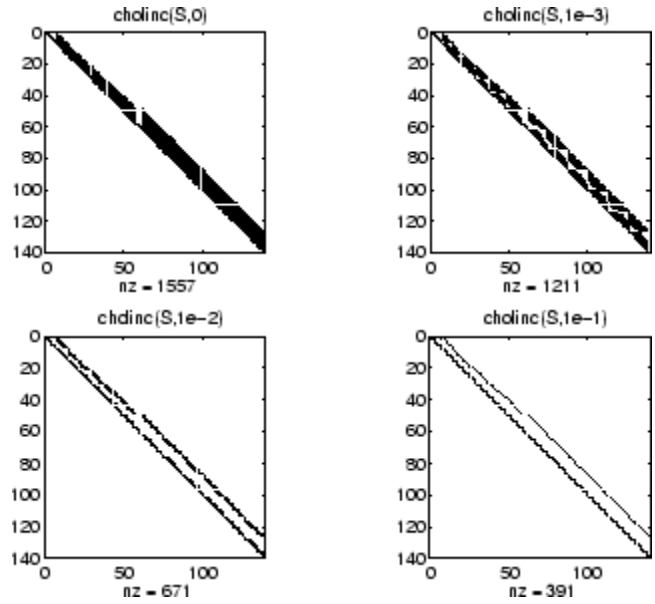
```
D1 = (R0'*R0).*spones(S)-S;
D2 = (R'*R).*spones(S2)-S2;
```

`D1` has elements of the order of `eps`, showing that `R0'*R0` agrees with `S` over its sparsity pattern. `D2` has elements of the order of `eps` over its first 100 rows and first 100 columns, `D2(1:100,:)` and `D2(:,1:100)`.

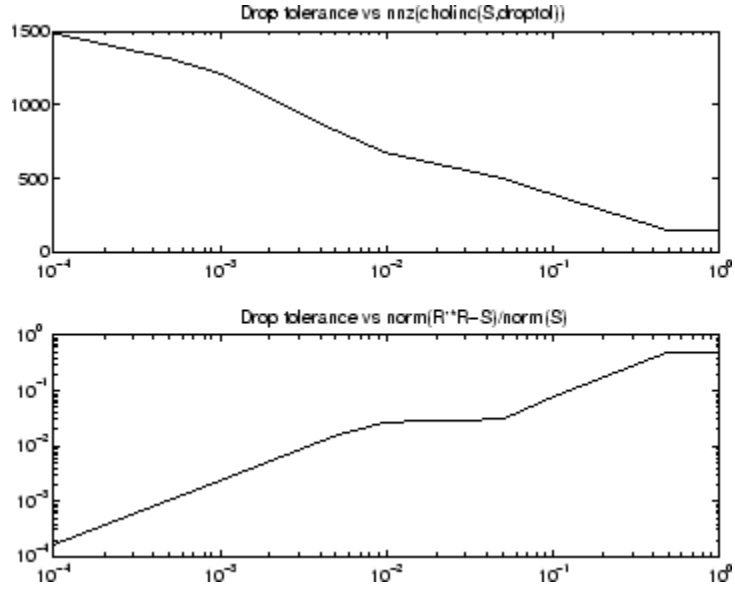


Example 2

The first subplot below shows that `cholinc(S,0)`, the incomplete Cholesky factor with a drop tolerance of `0`, is the same as the Cholesky factor of `S`. Increasing the drop tolerance increases the sparsity of the incomplete factors, as seen below.



Unfortunately, the sparser factors are poor approximations, as is seen by the plot of drop tolerance versus `norm(R'*R-S,1)/norm(S,1)` in the next figure.



Example 3

The Hilbert matrices have (i,j) entries 1/(i+j-1) and are theoretically positive definite:

```
H3 = hilb(3)
H3 =
    1.0000    0.5000    0.3333
    0.5000    0.3333    0.2500
    0.3333    0.2500    0.2000
R3 = chol(H3)
R3 =
    1.0000    0.5000    0.3333
         0    0.2887    0.2887
         0         0    0.0745
```

In practice, the Cholesky factorization breaks down for larger matrices:

```
H20 = sparse(hilb(20));
```

```
[R,p] = chol(H20);
p =
    14
```

For `hilb(20)`, the Cholesky factorization failed in the computation of row 14 because of a numerically zero pivot. You can use the Cholesky-Infinity factorization to avoid this error. When a zero pivot is encountered, `cholinc` places an `Inf` on the main diagonal, zeros out the rest of the row, and continues with the computation:

```
Rinf = cholinc(H20,'inf');
```

In this case, all subsequent pivots are also too small, so the remainder of the upper triangular factor is:

```
full(Rinf(14:end,14:end))
ans =
   Inf     0     0     0     0     0     0
     0   Inf     0     0     0     0     0
     0     0   Inf     0     0     0     0
     0     0     0   Inf     0     0     0
     0     0     0     0   Inf     0     0
     0     0     0     0     0   Inf     0
     0     0     0     0     0     0   Inf
```

Limitations

`cholinc` works on square sparse matrices only. For `cholinc(X,'0')` and `cholinc(X,'inf')`, `X` must be real.

Algorithm

`R = cholinc(X,droptol)` is obtained from `[L,U] = luinc(X,options)`, where `options.droptol = droptol` and `options.thresh = 0`. The rows of the uppertriangular `U` are scaled by the square root of the diagonal in that row, and this scaled factor becomes `R`.

`R = cholinc(X,options)` is produced in a similar manner, except the `rdiag` option translates into the `udiag` option and the `milu` option takes the value of the `michol` option.

`R = cholinc(X,'0')` is based on the "KJI" variant of the Cholesky factorization. Updates are made only to positions which are nonzero in the upper triangle of `X`.

`R = cholinc(X,'inf')` is based on the algorithm in Zhang [2].

Purpose

Rank 1 update to Cholesky factorization

Syntax

```
R1 = cholupdate(R,x)
R1 = cholupdate(R,x,'+')
R1 = cholupdate(R,x,'-')
[R1,p] = cholupdate(R,x,'-')
```

Description

`R1 = cholupdate(R,x)` where `R = chol(A)` is the original Cholesky factorization of `A`, returns the upper triangular Cholesky factor of `A + x*x'`, where `x` is a column vector of appropriate length. `cholupdate` uses only the diagonal and upper triangle of `R`. The lower triangle of `R` is ignored.

`R1 = cholupdate(R,x,'+')` is the same as `R1 = cholupdate(R,x)`.

`R1 = cholupdate(R,x,'-')` returns the Cholesky factor of `A - x*x'`. An error message reports when R is not a valid Cholesky factor or when the downdated matrix is not positive definite and so does not have a Cholesky factorization.

`[R1,p] = cholupdate(R,x,'-')` will not return an error message. If `p` is `0`, `R1` is the Cholesky factor of `A - x*x'`. If `p` is greater than `0`, `R1` is the Cholesky factor of the original `A`. If `p` is `1`, `cholupdate` failed because the downdated matrix is not positive definite. If `p` is `2`, `cholupdate` failed because the upper triangle of `R` was not a valid Cholesky factor.

Remarks

`cholupdate` works only for full matrices.

Example

```
A = pascal(4)
A =

     1     1     1     1
     1     2     3     4
     1     3     6    10
     1     4    10    20

R = chol(A)
R =
```

```
     1     1     1     1
     0     1     2     3
     0     0     1     3
     0     0     0     1
x = [0 0 0 1]';
```

This is called a rank one update to `A` since `rank(x*x')` is `1`:

```
A + x*x'
ans =

     1     1     1     1
     1     2     3     4
     1     3     6    10
     1     4    10    21
```

Instead of computing the Cholesky factor with `R1 = chol(A + x*x')`, we can use `cholupdate`:

```
R1 = cholupdate(R,x)
R1 =

    1.0000    1.0000    1.0000    1.0000
         0    1.0000    2.0000    3.0000
         0         0    1.0000    3.0000
         0         0         0    1.4142
```

Next destroy the positive definiteness (and actually make the matrix singular) by subtracting `1` from the last element of `A`. The downdated matrix is:

```
A - x*x'
ans =

     1     1     1     1
     1     2     3     4
```

```
     1     3     6    10
     1     4    10    19
```

Compare `chol` with `cholupdate`:

```
R1 = chol(A-x*x')
??? Error using ==> chol
Matrix must be positive definite.
R1 = cholupdate(R,x,'-')
??? Error using ==> cholupdate
Downdated matrix must be positive definite.
```

However, subtracting `0.5` from the last element of `A` produces a positive definite matrix, and we can use `cholupdate` to compute its Cholesky factor:

```
x = [0 0 0 1/sqrt(2)]';
R1 = cholupdate(R,x,'-')
R1 =
    1.0000    1.0000    1.0000    1.0000
         0    1.0000    2.0000    3.0000
         0         0    1.0000    3.0000
         0         0         0    0.7071
```

Algorithm

`cholupdate` uses the algorithms from the LINPACK subroutines `ZCHUD` and `ZCHDD`. `cholupdate` is useful since computing the new Cholesky factor from scratch is an $O(N^3)$ algorithm, while simply updating the existing factor in this way is an $O(N^2)$ algorithm.

`chol`, `qrupdate`

References

[1] Dongarra, J.J., J.R. Bunch, C.B. Moler, and G.W. Stewart, *LINPACK Users' Guide*, SIAM, Philadelphia, 1979.

Purpose

Shift array circularly

Syntax

```
B = circshift(A,shiftsize)
```

Description

`B = circshift(A,shiftsize)` circularly shifts the values in the array, `A`, by `shiftsize` elements. `shiftsize` is a vector of integer scalars where the `n`-th element specifies the shift amount for the `n`-th dimension of array `A`. If an element in `shiftsize` is positive, the values of `A` are shifted down (or to the right). If it is negative, the values of `A` are shifted up (or to the left). If it is `0`, the values in that dimension are not shifted.

Example

Circularly shift first dimension values down by 1.

```
A = [ 1 2 3;4 5 6; 7 8 9]
A =
     1     2     3
     4     5     6
     7     8     9

B = circshift(A,1)
B =
     7     8     9
     1     2     3
     4     5     6
```

Circularly shift first dimension values down by 1 and second dimension values to the left by 1.

```
B = circshift(A,[1 -1]);
B =
    8     9     7
    2     3     1
    5     6     4
```

See Also

`fftshift`, `shiftdim`

cla

Purpose

Clear current axes

GUI Alternatives

Remove axes and clear objects from them in *plot edit* mode. For details, see "Working in Plot Edit Mode" in the MATLAB Graphics documentation.

Syntax

```
cla
cla reset
cla(ax)
cla(ax,'reset')
```

Description

`cla` deletes from the current axes all graphics objects whose handles are not hidden (i.e., their `HandleVisibility` property is set to `on`).

`cla reset` deletes from the current axes all graphics objects regardless of the setting of their `HandleVisibility` property and resets all axes properties, except `Position` and `Units`, to their default values.

`cla(ax)` or `cla(ax,'reset')` clears the single axes with handle `ax`.

Remarks

The `cla` command behaves the same way when issued on the command line as it does in callback routines — it does not recognize the `HandleVisibility` setting of `callback`. This means that when issued from within a callback routine, `cla` deletes only those objects whose `HandleVisibility` property is set to `on`.

See Also

`clf`, `hold`, `newplot`, `reset`

"Axes Operations" on page 1-96 for related functions

Purpose

Contour plot elevation labels

Syntax

```
clabel(C,h)
clabel(C,h,v)
clabel(C,h,'manual')
clabel(C)
clabel(C,v)
clabel(C,'manual')
text_handles = clabel(...)
clabel(...,'PropertyName',propertyvalue,...)
clabel(...'LabelSpacing',points)
```

Description

The `clabel` function adds height labels to a 2-D contour plot.

`clabel(C,h)` rotates the labels and inserts them in the contour lines. The function inserts only those labels that fit within the contour, depending on the size of the contour.

`clabel(C,h,v)` creates labels only for those contour levels given in vector `v`, then rotates the labels and inserts them in the contour lines.

`clabel(C,h,'manual')` places contour labels at locations you select with a mouse. Press the left mouse button (the mouse button on a single-button mouse) or the space bar to label a contour at the closest location beneath the center of the cursor. Press the **Return** key while the cursor is within the figure window to terminate labeling. The labels are rotated and inserted in the contour lines.

`clabel(C)` adds labels to the current contour plot using the contour array `C` output from `contour`. The function labels all contours displayed and randomly selects label positions.

`clabel(C,v)` labels only those contour levels given in vector `v`.

`clabel(C,'manual')` places contour labels at locations you select with a mouse.

`text_handles = clabel(...)` returns the handles of text objects created by clabel. The `UserData` properties of the text objects contain the contour values displayed. If you call `clabel` without the `h` argument,

`text_handles` also contains the handles of line objects used to create the `'+'` symbols.

`clabel(...,'`*`PropertyName`*`',propertyvalue,...)` enables you to specify text object property/value pairs for the label strings. (See `Text Properties`.)

`clabel(...'LabelSpacing',`*`points`*`)` specifies the spacing between labels on the same contour line, in units of points (72 points equal one inch).

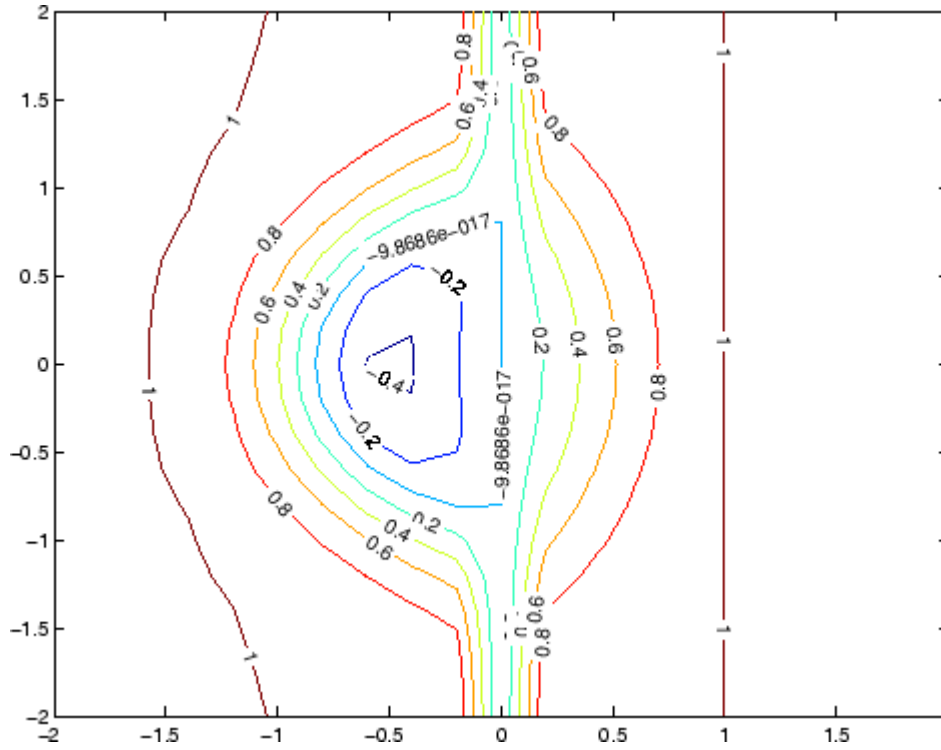
Remarks

When the syntax includes the argument `h`, this function rotates the labels and inserts them in the contour lines (see Examples). Otherwise, the labels are displayed upright and a `'+'` indicates which contour line the label is annotating.

Examples

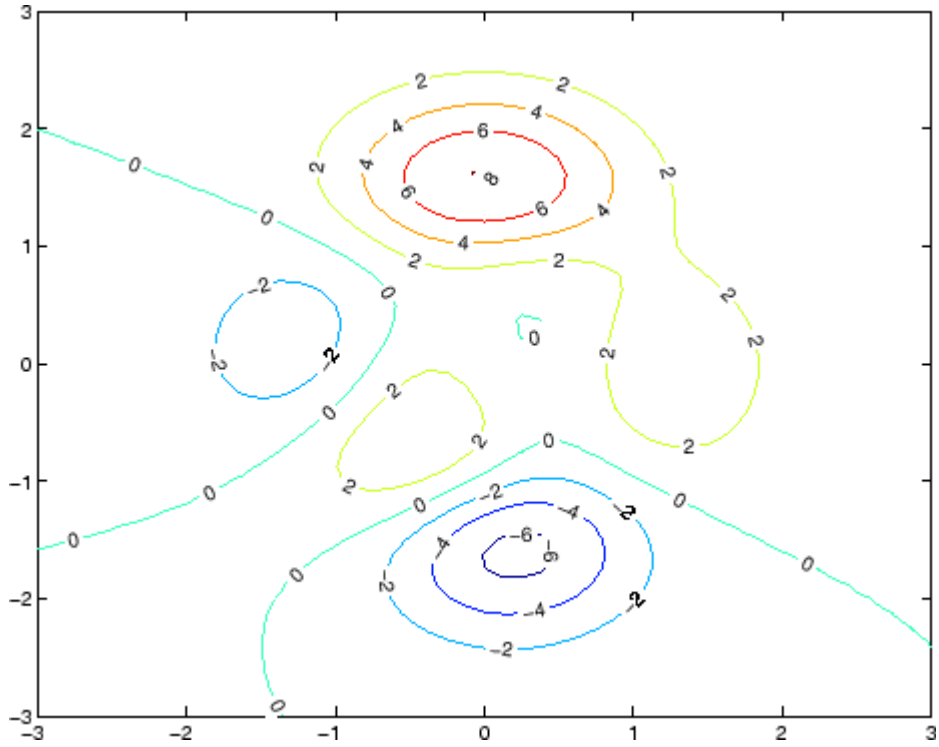
Generate, draw, and label a simple contour plot.

```
[x,y] = meshgrid(-2:.2:2);
z = x.^exp(-x.^2-y.^2);
[C,h] = contour(x,y,z);
clabel(C,h);
```



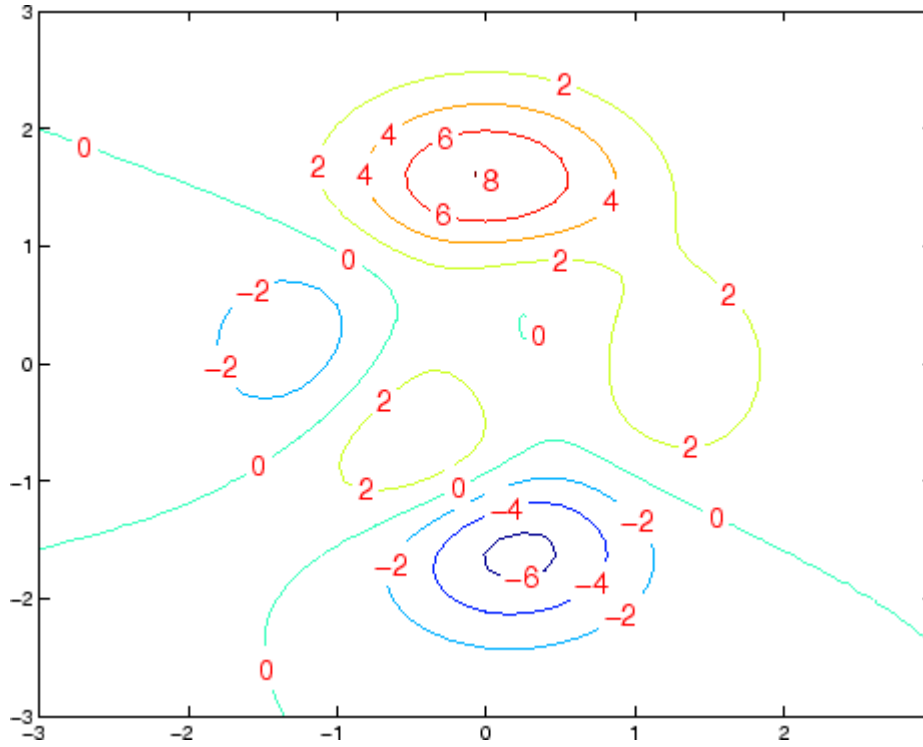
Label a contour plot with label spacing set to 72 points (one inch).

```
[x,y,z] = peaks;
[C,h] = contour(x,y,z);
clabel(C,h,'LabelSpacing',72)
```



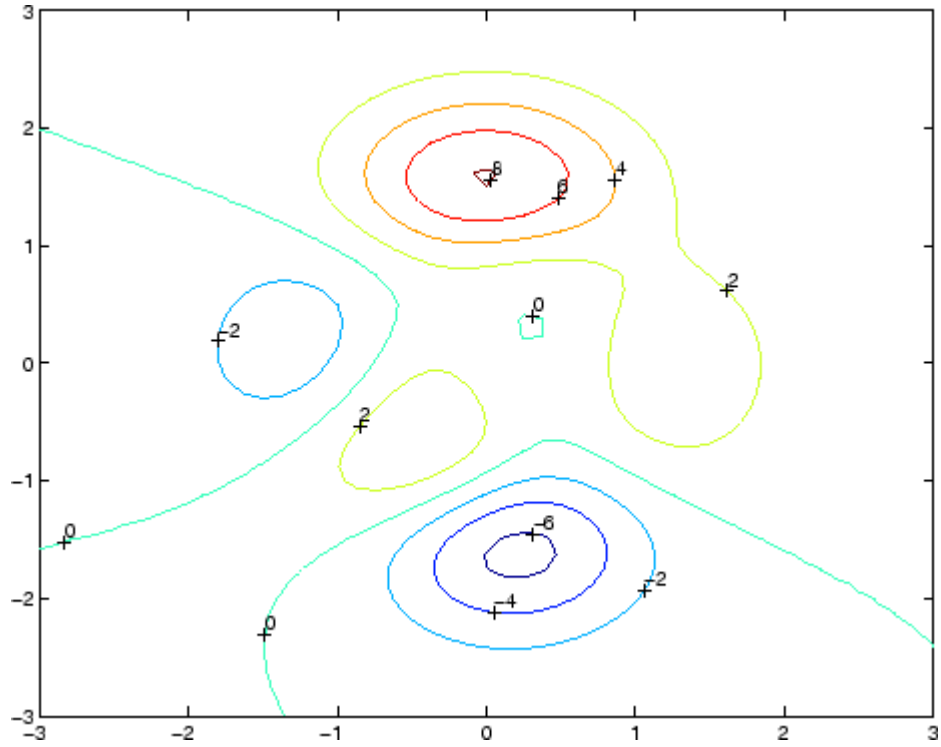
Label a contour plot with 15 point red text.

```
[x,y,z] = peaks;
[C,h] = contour(x,y,z);
clabel(C,h,'FontSize',15,'Color','r','Rotation',0)
```



Label a contour plot with upright text and `'+'` symbols indicating which contour line each label annotates.

```
[x,y,z] = peaks;
C = contour(x,y,z);
clabel(C)
```



See Also

`contour`, `contourc`, `contourf`

“Annotating Plots” on page 1-87 for related functions

“Drawing Text in a Box” for an example that illustrates the use of contour labels

Purpose

Create object or return class of object

Syntax

```
str = class(object)
obj = class(s, 'class_name')
obj = class(s, 'class_name', parent1, parent2, ...)
obj = class(struct([]), 'class_name', parent1, parent2, ...)
```

Description

`str = class(object)` returns a string specifying the class of `object`.

The following table lists the object class names that can be returned. All except the last one are MATLAB classes.

`logical`	Logical array of `true` and `false` values
`char`	Character array
`int8`	8-bit signed integer array
`uint8`	8-bit unsigned integer array
`int16`	16-bit signed integer array
`uint16`	16-bit unsigned integer array
`int32`	32-bit signed integer array
`uint32`	32-bit unsigned integer array
`int64`	64-bit signed integer array
`uint64`	64-bit unsigned integer array
`single`	Single-precision floating-point number array
`double`	Double-precision floating-point number array
`cell`	Cell array
`struct`	Structure array
`function handle`	Array of values for calling functions indirectly
'*`class_name`*'	Custom MATLAB object class or Java class

`obj = class(s, 'class_name')` creates an object of MATLAB class `'class_name'` using structure `s` as a template. This syntax is valid only in a function named `class_name.m` in a directory named `@class_name` (where `'class_name'` is the same as the string passed in to `class`).

`obj = class(s, 'class_name', parent1, parent2, ...)` creates an object of MATLAB class `'class_name'` that inherits the methods and fields of the parent objects `parent1`, `parent2`, and so on. Structure `s` is used as a template for the object.

`obj = class(struct([]), 'class_name', parent1, parent2, ...)` creates an object of MATLAB class `'class_name'` that inherits the methods and fields of the parent objects `parent1`, `parent2`, and so on. Specifying the empty structure `struct([])` as the first argument ensures that the object created contains no fields other than those that are inherited from the parent objects.

Examples

To return in `nameStr` the name of the class of Java object `j`,

```
nameStr = class(j)
```

To create a user-defined MATLAB object of class `polynom`,

```
p = class(p, 'polynom')
```

`inferiorto`, `isa`, `superiorto`

The “Classes and Objects” and the “Calling Java from MATLAB” chapters in MATLAB Programming and Data Types documentation.

Purpose

Clear Command Window

GUI Alternatives

As an alternative to the `clc` function, select **Edit > Clear Command Window** in the MATLAB desktop.

Syntax

```
clc
```

Description

`clc` clears all input and output from the Command Window display, giving you a "clean screen."

After using `clc`, you cannot use the scroll bar to see the history of functions, but you still can use the up arrow to recall statements from the command history.

Examples

Use `clc` in an M-file to always display output in the same starting position on the screen.

See Also

`clear`, `clf`, `close`, `home`

Purpose

Remove items from workspace, freeing up system memory

Graphical Interface

As an alternative to the `clear` function, use **Edit > Clear Workspace** in the MATLAB desktop.

Syntax

```
clear
clear name
clear name1 name2 name3 ...
clear global name
clear -regexp expr1 expr2 ...
clear global -regexp expr1 expr2 ...
clear keyword
clear('name1','name2','name3',...)
```

Description

`clear` removes all variables from the workspace. This frees up system memory.

`clear name` removes just the M-file or MEX-file function or variable `name` from the workspace. You can use wildcards (`*`) to remove items selectively. For example, `clear my*` removes any variables whose names begin with the string `my`. It removes debugging breakpoints in M-files and reinitializes persistent variables, since the breakpoints for a function and persistent variables are cleared whenever the M-file is changed or cleared. If `name` is global, it is removed from the current workspace, but left accessible to any functions declaring it global. If `name` has been locked by `mlock`, it remains in memory.

Use a `partial path` to distinguish between different overloaded versions of a function. For example, `clear polynom/display` clears only the `display` method for `polynom` objects, leaving any other implementations in memory.

`clear name1 name2 name3 ...` removes `name1`, `name2`, and `name3` from the workspace.

`clear global name` removes the global variable `name`. If `name` is global, `clear name` removes `name` from the current workspace, but leaves it

accessible to any functions declaring it global. Use `clear global name` to completely remove a global variable.

`clear -regexp expr1 expr2 ...` clears all variables that match any of the regular expressions `expr1`, `expr2`, etc. This option only clears variables.

`clear global -regexp expr1 expr2 ...` clears all global variables that match any of the regular expressions `expr1`, `expr2`, etc.

`clear keyword` clears the items indicated by *`keyword`*.

Keyword	Items Cleared
`all`	Removes all variables, functions, and MEX-files from memory, leaving the workspace empty. Using `clear all` removes debugging breakpoints in M-files and reinitializes persistent variables, since the breakpoints for a function and persistent variables are cleared whenever the M-file is changed or cleared. When issued from the Command Window prompt, also removes the Java packages import list.
`classes`	The same as `clear all`, but also clears MATLAB class definitions. If any objects exist outside the workspace (for example, in user data or persistent variables in a locked M-file), a warning is issued and the class definition is not cleared. Issue a `clear classes` function if the number or names of fields in a class are changed.
`functions`	Clears all the currently compiled M-functions and MEX-functions from memory. Using `clear function` removes debugging breakpoints in the function M-file and reinitializes persistent variables, since the breakpoints for a function and persistent variables are cleared whenever the M-file is changed or cleared.

Keyword	Items Cleared
`global`	Clears all global variables from the workspace.
`import`	Removes the Java packages import list. It can only be issued from the Command Window prompt. It cannot be used in a function.
`java`	The same as `clear all`, but also clears the definitions of all Java classes defined by files on the Java dynamic class path (see "The Java Class Path" in the External Interfaces documentation). If any java objects exist outside the workspace (for example, in user data or persistent variables in a locked M-file), a warning is issued and the Java class definition is not cleared. Issue a `clear java` command after modifying any files on the Java dynamic class path.
`variables`	Clears all variables from the workspace.

`clear('name1','name2','name3',...)` is the function form of the syntax. Use this form when the variable name or function name is stored in a string.

Remarks

When you use `clear` in a function, it has the following effect on items in your function and base workspaces:

- `clear name` — If `name` is the name of a function, the function is cleared in both the function workspace and in your base workspace.
- `clear` **`functions`** — All functions are cleared in both the function workspace and in your base workspace.
- `clear` **`global`** — All global variables are cleared in both the function workspace and in your base workspace.
- `clear` **`all`** — All functions, global variables, and classes are cleared in both the function workspace and in your base workspace.

Limitations

`clear` does not affect the amount of memory allocated to the MATLAB process under UNIX.

The `clear` function does not clear Simulink models. Use `close` instead.

Examples

Given a workspace containing the following variables

```
  Name        Size          Bytes  Class

  c           3x4            1200  cell array
  frame       1x1                  java.awt.Frame
  gbl1        1x1               8  double array (global)
  gbl2        1x1               8  double array (global)
  xint        1x1               1  int8 array
```

you can clear a single variable, `xint`, by typing

```
clear xint
```

To clear all global variables, type

```
clear global
whos
  Name       Size          Bytes  Class

  c          3x4            1200  cell array
  frame      1x1                  java.awt.Frame
```

Using regular expressions, clear those variables with names that begin with `Mon`, `Tue`, or `Wed`:

```
clear('-regexp', '^Mon|^Tue|^Wed');
```

To clear all compiled M- and MEX-functions from memory, type `clear functions`. In the case shown below, `clear functions` was unable to clear one M-file function from memory, `testfun`, because the function is locked.

```
clear functions    % Attempt to clear all functions.
```

```
inmem

ans =
   'testfun'       % One M-file function remains in memory.

mislocked testfun
ans =
    1              % This function is locked in memory.
```

Once you unlock the function from memory, you can clear it.

```
munlock testfun
clear functions

inmem
ans =
   Empty cell array: 0-by-1
```

See Also

clc, close, import, inmem, load, mlock, munlock, pack, persistent, save, who, whos, workspace

Purpose

Remove serial port object from MATLAB workspace

Syntax

```
clear obj
```

Arguments

`obj`	A serial port object or an array of serial port objects.

Description

`clear obj` removes `obj` from the MATLAB workspace.

Remarks

If `obj` is connected to the device and it is cleared from the workspace, then `obj` remains connected to the device. You can restore `obj` to the workspace with the `instrfind` function. A serial port object connected to the device has a `Status` property value of `open`.

To disconnect `obj` from the device, use the `fclose` function. To remove `obj` from memory, use the `delete` function. You should remove invalid serial port objects from the workspace with `clear`.

Example

This example creates the serial port object `s`, copies `s` to a new variable `scopy`, and clears `s` from the MATLAB workspace. `s` is then restored to the workspace with `instrfind` and is shown to be identical to `scopy`.

```
s = serial('COM1');
scopy = s;
clear s
s = instrfind;
isequal(scopy,s)
ans =
     1
```

See Also

Functions

`delete`, `fclose`, `instrfind`, `isvalid`

Properties

`Status`

Purpose

Clear current figure window

GUI Alternatives

Use **Clear Figure** from the figure window's **File** menu to clear the contents of a figure. You can also create a *desktop shortcut* to clear the current figure with one mouse click. See "Shortcuts for MATLAB — Easily Run a Group of Statements" in the MATLAB Desktop Environment documentation.

Syntax

```
clf('reset')
clf(fig)
clf(fig,'reset')
figure_handle = clf(...)
```

Description

`clf` deletes from the current figure all graphics objects whose handles are not hidden (i.e., their `HandleVisibility` property is set to `on`).

`clf('reset')` deletes from the current figure all graphics objects regardless of the setting of their `HandleVisibility` property and resets all figure properties except `Position`, `Units`, `PaperPosition`, and `PaperUnits` to their default values.

`clf(fig)` or `clf(fig,'reset')` clears the single figure with handle `fig`.

`figure_handle = clf(...)` returns the handle of the figure. This is useful when the figure `IntegerHandle` property is `off` because the noninteger handle becomes invalid when the reset option is used (i.e., `IntegerHandle` is reset to `on`, which is the default).

Remarks

The `clf` command behaves the same way when issued on the command line as it does in callback routines — it does not recognize the `HandleVisibility` setting of `callback`. This means that when issued from within a callback routine, `clf` deletes only those objects whose `HandleVisibility` property is set to `on`.

`cla`, `clc`, `hold`, `reset`

"Figure Windows" on page 1-95 for related functions

Purpose

Copy and paste strings to and from system clipboard

Graphical Interface

As an alternative to `clipboard`, use the Import Wizard. To use the Import Wizard to copy data from the clipboard, select **Paste to Workspace** from the **Edit** menu.

Syntax

```
clipboard('copy', data)
str = clipboard('paste')
data = clipboard('pastespecial')
```

Description

`clipboard('copy', data)` sets the clipboard contents to `data`. If `data` is not a character array, the clipboard uses `mat2str` to convert it to a string.

`str = clipboard('paste')` returns the current contents of the clipboard as a string or as an empty string (`' '`), if the current clipboard contents cannot be converted to a string.

`data = clipboard('pastespecial')` returns the current contents of the clipboard as an array using `uiimport`.

Note Requires an active X display on UNIX, and Java elsewhere.

See Also

`load`, `uiimport`

clock

Purpose

Current time as date vector

Syntax

```
c = clock
```

Description

`c = clock` returns a 6-element date vector containing the current date and time in decimal form:

```
c = [year month day hour minute seconds]
```

The first five elements are integers. The `seconds` element is accurate to several digits beyond the decimal point. The statement `fix(clock)` rounds to integer display format.

Remarks

When timing the duration of an event, use the `tic` and `toc` functions instead of `clock` or `etime`. These latter two functions are based on the system time which can be adjusted periodically by the operating system and thus might not be reliable in time comparison operations.

See Also

`cputime`, `datenum`, `datevec`, `etime`, `tic`, `toc`

Purpose

Remove specified figure

Syntax

```
close
close(h)
close name
close all
close all hidden
status = close(...)
```

Description

`close` deletes the current figure or the specified figure(s). It optionally returns the status of the close operation.

`close` deletes the current figure (equivalent to `close(gcf)`).

`close(h)` deletes the figure identified by h. If h is a vector or matrix, `clse` deletes all figures identified by h.

`close name` deletes the figure with the specified name.

`close all` deletes all figures whose handles are not hidden.

`close all hidden` deletes all figures including those with hidden handles.

`status = close(...)` returns `1` if the specified windows have been deleted and `0` otherwise.

Remarks

The `close` function works by evaluating the specified figure's `CloseRequestFcn` property with the statement

```
eval(get(h,'CloseRequestFcn'))
```

The default `CloseRequestFcn`, `closereq`, deletes the current figure using `delete(get(0,'CurrentFigure'))`. If you specify multiple figure handles, `close` executes each figure's `CloseRequestFcn` in turn. If MATLAB encounters an error that terminates the execution of a `CloseRequestFcn`, the figure is not deleted. Note that using your computer's window manager (i.e., the **Close** menu item) also calls the figure's `CloseRequestFcn`.

If a figure's handle is hidden (i.e., the figure's `HandleVisibility` property is set to `callback` or `off` and the root `ShowHiddenHandles` property is set to `on`), you must specify the `hidden` option when trying to access a figure using the `all` option.

To delete all figures unconditionally, use the statements

```
set(0,'ShowHiddenHandles','on')
delete(get(0,'Children'))
```

The `delete` function does not execute the figure's `CloseRequestFcn`; it simply deletes the specified figure.

The figure `CloseRequestFcn` allows you to either delay or abort the closing of a figure once the `close` function has been issued. For example, you can display a dialog box to see if the user really wants to delete the figure or save and clean up before closing.

The figure `HandleVisibility` property

The root `ShowHiddenHandles` property

"Figure Windows" on page 1-95 for related functions

Purpose

Close Audio/Video Interleaved (AVI) file

Syntax

```
aviobj = close(aviobj)
```

Description

`aviobj = close(aviobj)` finishes writing and closes the AVI file associated with `aviobj`, which is an AVI file object created using the `avifile` function.

See Also

`avifile`, `addframe`, `movie2avi`

close (ftp)

Purpose

Close connection to FTP server

Syntax

```
close(f)
```

Description

`close(f)` closes the connection to the FTP server, represented by object `f`, which was created using `ftp`. Be sure to use `close` after completing work on the server. If you do not run `close`, the connection will be terminated automatically either because of the server's time-out feature or by exiting MATLAB.

Examples

Connect to the MathWorks FTP server and then disconnect.

```
tmw=ftp('ftp.mathworks.com');
close(tmw)
```

See Also

`ftp`

Purpose

Default figure close request function

Syntax

```
closereq
```

Description

`closereq` deletes the current figure.

See Also

The figure `CloseRequestFcn` property

"Figure Windows" on page 1-95 for related functions

Purpose

Name of source control system

GUI Alternatives

As an alternative to `cmopts`, select **File > Preferences > General > Source Control** to view the currently selected source control system.

Syntax

```
cmopts
```

Description

`cmopts` displays the name of the source control system you selected using preferences, which is one of the following:

- `clearcase` (UNIX only)
- `customverctrl` (UNIX only)
- `cvs` (UNIX only)
- `pvcs` (UNIX only, used for PVCS and ChangeMan)
- `rcs` (UNIX only)
- `sourcesafe` (Windows only)

If you have not selected a source control system, `cmopts` displays

```
none
```

For more information, see "Specify Source Control System in MATLAB" for PC platforms, and "Specifying the Source Control System on UNIX" for UNIX platforms in the MATLAB Desktop Tools and Development Environment documentation.

Examples

Type

```
cmopts
```

and MATLAB returns

```
ans =
Microsoft Visual SourceSafe
```

which is the source control system specified in preferences.

See Also

`checkin`, `checkout`, `customverctrl`, `verctrl`

Purpose

Column approximate minimum degree permutation

Syntax

```
p = colamd(S)
```

Description

`p = colamd(S)` returns the column approximate minimum degree permutation vector for the sparse matrix `S`. For a non-symmetric matrix `S`, `S(:,p)` tends to have sparser LU factors than `S`. The Cholesky factorization of `S(:,p)' * S(:,p)` also tends to be sparser than that of `S'*S`.

`knobs` is a two-element vector. If S is `m`-by-`n`, then rows with more than `(knobs(1))*n` entries are ignored. Columns with more than `(knobs(2))*m` entries are removed prior to ordering, and ordered last in the output permutation `p`. If the `knobs` parameter is not present, then `knobs(1) = knobs(2) = spparms('wh_frac')`.

`stats` is an optional vector that provides data about the ordering and the validity of the matrix `S`.

`stats(1)`	Number of dense or empty rows ignored by `colamd`
`stats(2)`	Number of dense or empty columns ignored by `colamd`
`stats(3)`	Number of garbage collections performed on the internal data structure used by `colamd` (roughly of size `2.2*nnz(S) + 4*m + 7*n` integers)
`stats(4)`	`0` if the matrix is valid, or `1` if invalid
`stats(5)`	Rightmost column index that is unsorted or contains duplicate entries, or `0` if no such column exists

`stats(6)`	Last seen duplicate or out-of-order row index in the column index given by `stats(5)`, or `0` if no such row index exists
`stats(7)`	Number of duplicate and out-of-order row indices

Although, MATLAB built-in functions generate valid sparse matrices, a user may construct an invalid sparse matrix using the MATLAB C or Fortran APIs and pass it to `colamd`. For this reason, `colamd` verifies that `S` is valid:

- If a row index appears two or more times in the same column, `colamd` ignores the duplicate entries, continues processing, and provides information about the duplicate entries in `stats(4:7)`.
- If row indices in a column are out of order, `colamd` sorts each column of its internal copy of the matrix `S` (but does not repair the input matrix `S`), continues processing, and provides information about the out-of-order entries in `stats(4:7)`.
- If `S` is invalid in any other way, `colamd` cannot continue. It prints an error message, and returns no output arguments (`p` or `stats`) .

The ordering is followed by a column elimination tree post-ordering.

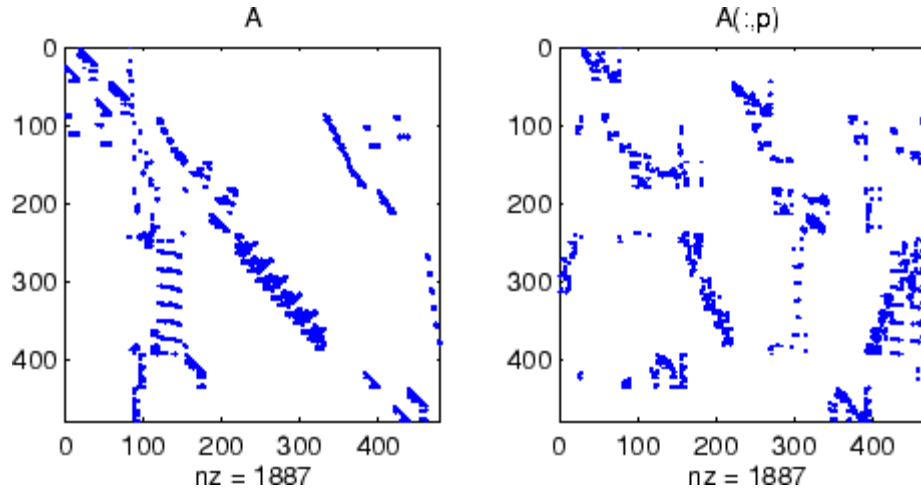
Note `colamd` tends to be faster than `colmmd` and tends to return a better ordering.

Examples

The Harwell-Boeing collection of sparse matrices and the MATLAB demos directory include a test matrix `west0479`. It is a matrix of order 479 resulting from a model due to Westerberg of an eight-stage chemical distillation column. The spy plot shows evidence of the eight stages. The `colamd` ordering scrambles this structure.

```
load west0479
```

```
A = west0479;
p = colamd(A);
subplot(1,2,1), spy(A,4), title('A')
subplot(1,2,2), spy(A(:,p),4), title('A(:,p)')
```



Comparing the spy plot of the LU factorization of the original matrix with that of the reordered matrix shows that minimum degree reduces the time and storage requirements by better than a factor of 2.8. The nonzero counts are 16777 and 5904, respectively.

```
spy(lu(A),4)
spy(lu(A(:,p)),4)
```

References

[1] The authors of the code for "colamd" are Stefan I. Larimore and Timothy A. Davis (davis@cise.ufl.edu), University of Florida. The algorithm was developed in collaboration with John Gilbert, Xerox PARC, and Esmond Ng, Oak Ridge National Laboratory. Sparse Matrix Algorithms Research at the University of Florida: `http://www.cise.ufl.edu/research/sparse/`

colmmd

Purpose

Sparse column minimum degree permutation

Syntax

```
p = colmmd(S)
```

Note `colmmd` is obsolete and will be removed from a future version of MATLAB. Use `colamd` instead.

Description

`p = colmmd(S)` returns the column minimum degree permutation vector for the sparse matrix `S`. For a nonsymmetric matrix `S`, this is a column permutation `p` such that `S(:,p)` tends to have sparser LU factors than `S`.

The `colmmd` permutation is automatically used by `\` and `/` for the solution of nonsymmetric and symmetric indefinite sparse linear systems.

Use `spparms` to change some options and parameters associated with heuristics in the algorithm.

Algorithm

The minimum degree algorithm for symmetric matrices is described in the review paper by George and Liu [1]. For nonsymmetric matrices, the MATLAB minimum degree algorithm is new and is described in the paper by Gilbert, Moler, and Schreiber [2]. It is roughly like symmetric minimum degree for `A'*A`, but does not actually form `A'*A`.

Each stage of the algorithm chooses a vertex in the graph of `A'*A` of lowest degree (that is, a column of `A` having nonzero elements in common with the fewest other columns), eliminates that vertex, and updates the remainder of the graph by adding fill (that is, merging rows). If the input matrix `S` is of size `m`-by-`n`, the columns are all eliminated and the permutation is complete after `n` stages. To speed up the process, several heuristics are used to carry out multiple stages simultaneously.

colorbar

Purpose

Colorbar showing color scale

GUI Alternatives

Add a colorbar to a plot with the colorbar tool  on the figure toolbar, or use **Insert —> Colorbar** from the figure menu. Use the Property Editor to modify the position, font and other properties of a legend. . For details, see “Working in Plot Edit Mode” in the MATLAB Graphics documentation.

Syntax

```
colorbar
colorbar(...,'peer',axes_handle)
colorbar(...,'location')
colorbar(...,'PropertyName',propertyvalue)
cbar_axes = colorbar(...)
colorbar(axes_handle)
```

Description

The `colorbar` function displays the current colormap in the current figure and resizes the current axes to accommodate the colorbar.

`colorbar` adds a new vertical colorbar on the right side of the current axes. If a colorbar exists in that location, `colorbar` replaces it with a new one. If a colorbar exists at a nondefault location, it is retained along with the new colorbar

`colorbar(...,'peer',axes_handle)` creates a colorbar associated with the axes `axes_handle` instead of the current axes.

`colorbar(...,'location')` adds a colorbar in the specified orientation with respect to the axes. If a colorbar exists at the location specified, it is replaced. Any colorbars not occupying the specified location are retained. Possible values for *`location`* are

`North`	Inside plot box near top
`South`	Inside bottom
`East`	Inside right
`West`	Inside left

`NorthOutside`	Outside plot box near top
`SouthOutside`	Outside bottom
`EastOutside`	Outside right
`WestOutside`	Outside left

Using one of the `...Outside` values for *`location`* ensures that the colorbar does not overlap the plot, whereas overlaps can occur when you specify any of the other four values.

`colorbar(...,'`*`PropertyName`*`',propertyvalue)` specifies property names and values for the axes object used to create the colorbar. See axes properties for a description of the properties you can set. The *`location`* property applies only to colorbars and legends, not to axes.

`cbar_axes = colorbar(...)` returns a handle to the colorbar, which is an axes graphics object that contains one additional property, `Location`.

Backward-Compatible Version

`h = colorbar('v6',...)` creates a colorbar compatible with MATLAB 6.5 and earlier. It returns the handles of patch objects instead of a colorbar object.

`colorbar(axes_handle)` adds the colorbar to the axes `axes_handle` in the default (`right`) orientation. As in Version 6 and earlier releases, no new axes is created.

Note The `v6` option enables users of Version 7.x of MATLAB to create FIG-files that previous versions can open. It is obsolete and will be removed in a future version of MATLAB.

See Plot Objects and Backward Compatibility for more information.

Remarks

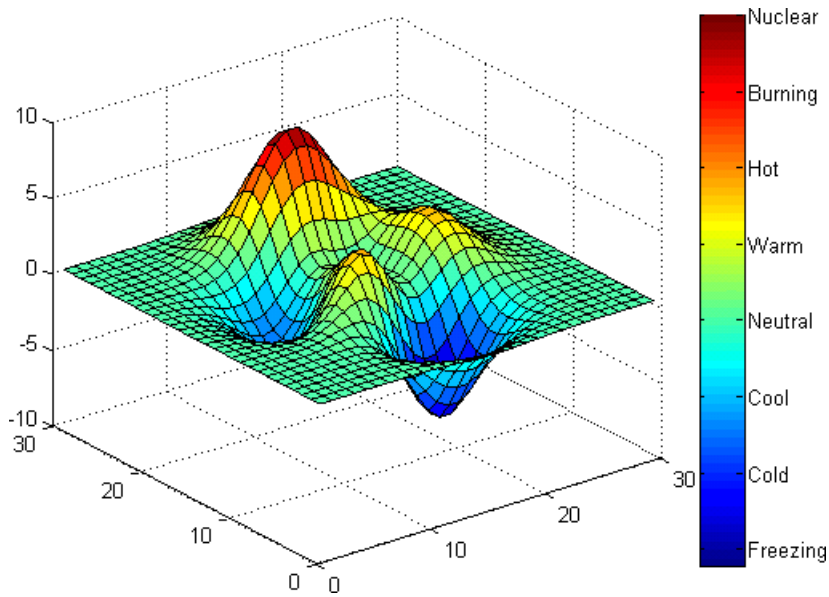
You can use `colorbar` with 2-D and 3-D plots.

Examples

Example 1

Display a colorbar beside the axes and use descriptive text strings as *y*-tick labels. Note that labels will repeat cyclically when the number of *y*-ticks is greater than the number of labels, and not all labels will appear if there are fewer *y*-ticks than labels you have specified. Also note that when colorbars are horizontal, their ticks and labels are governed by the `XTick` property rather than the `YTick` property. For more information, see "Labeling Colorbar Ticks".

```
surf(peaks(30))
colorbar('YTickLabel',...
    {'Freezing','Cold','Cool','Neutral',...
     'Warm','Hot','Burning','Nuclear'})
```

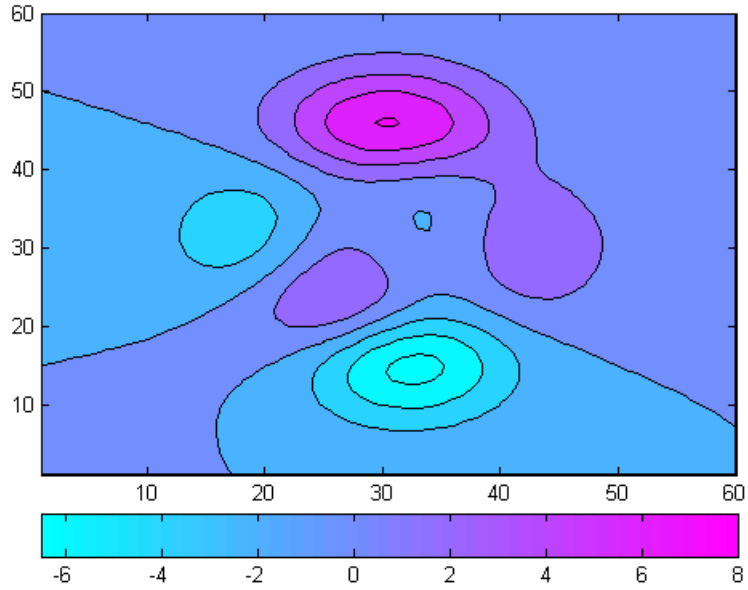


Example 2

Display a horizontal colorbar beneath the axes of a filled contour plot:

```
contourf(peaks(60))
```

```
colormap cool
colorbar('location','southoutside')
```



See Also

`colormap`

"Color Operations" on page 1-98 for related functions

colordef

Purpose

Set default property values to display different color schemes

Syntax

```
colordef white
colordef black
colordef none
colordef(fig,color_option)
h = colordef('new',color_option)
```

Description

`colordef` enables you to select either a white or black background for graphics display. It sets axis lines and labels so that they contrast with the background color.

`colordef white` sets the axis background color to white, the axis lines and labels to black, and the figure background color to light gray.

`colordef black` sets the axis background color to black, the axis lines and labels to white, and the figure background color to dark gray.

`colordef none` sets the figure coloring to that used by MATLAB Version 4. The most noticeable difference is that the axis background is set to `'none'`, making the axis background and figure background colors the same. The figure background color is set to black.

`colordef(fig,color_option)` sets the color scheme of the figure identified by the handle `fig` to one of the color options `'white'`, `'black'`, or `'none'`. When you use this syntax to apply `colordef` to an existing figure, the figure must have no graphic content. If it does, you should first clear it (via `clf`) before using this form of the command.

`h = colordef('new',color_option)` returns the handle to a new figure created with the specified color options (i.e., `'white'`, `'black'`, or `'none'`). This form of the command is useful for creating GUIs when you may want to control the default environment. The figure is created with `'visible','off'` to prevent flashing.

Remarks

`colordef` affects only subsequently drawn figures, not those currently on the display. This is because `colordef` works by setting default property values (on the root or figure level). You can list the currently set default values on the root level with the statement

```
get(0,'defaults')
```

You can remove all default values using the `reset` command:

```
reset(0)
```

See the `get` and `reset` references pages for more information.

See Also

`whitebg`, `clf`

"Color Operations" on page 1-98 for related functions

colormap

Purpose

Set and get current colormap

GUI Alternatives

Select a built-in colormap with the Property Editor. To modify the current colormap, use the Colormap Editor, accessible from **Edit —> Colormap** on the figure menu.

Syntax

```
colormap(map)
colormap('default')
cmap = colormap
```

Description

A colormap is an *m*-by-3 matrix of real numbers between 0.0 and 1.0. Each row is an RGB vector that defines one color. The *k*th row of the colormap defines the *k*th color, where `map(k,:) = [r(k) g(k) b(k)]` specifies the intensity of red, green, and blue.

`colormap(map)` sets the colormap to the matrix `map`. If any values in `map` are outside the interval [0 1], MATLAB returns the error `Colormap must have values in [0,1]`.

`colormap('default')` sets the current colormap to the default colormap.

`cmap = colormap` retrieves the current colormap. The values returned are in the interval [0 1].

Specifying Colormaps

M-files in the `color` directory generate a number of colormaps. Each M-file accepts the colormap size as an argument. For example,

```
colormap(hsv(128))
```

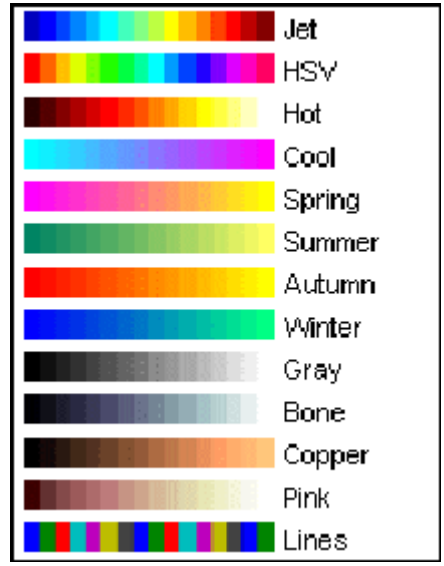
creates an `hsv` colormap with 128 colors. If you do not specify a size, MATLAB creates a colormap the same size as the current colormap.

Supported Colormaps

MATLAB supports a number of built-in colormaps, illustrated and described below. In addition to specifying built-in colormaps

programmatically, you can use the **Colormap** menu in the **Figure Properties** pane of the **Plot Tools** GUI to select one interactively.

The named built-in colormaps are the following:



- `autumn` varies smoothly from red, through orange, to yellow.
- `bone` is a grayscale colormap with a higher value for the blue component. This colormap is useful for adding an “electronic” look to grayscale images.
- `colorcube` contains as many regularly spaced colors in RGB colorspace as possible, while attempting to provide more steps of gray, pure red, pure green, and pure blue.
- `cool` consists of colors that are shades of cyan and magenta. It varies smoothly from cyan to magenta.
- `copper` varies smoothly from black to bright copper.

- `flag` consists of the colors red, white, blue, and black. This colormap completely changes color with each index increment.
- `gray` returns a linear grayscale colormap.
- `hot` varies smoothly from black through shades of red, orange, and yellow, to white.
- `hsv` varies the hue component of the hue-saturation-value color model. The colors begin with red, pass through yellow, green, cyan, blue, magenta, and return to red. The colormap is particularly appropriate for displaying periodic functions. `hsv(m)` is the same as `hsv2rgb([h ones(m,2)])` where `h` is the linear ramp, `h = (0:m 1)'/m`.
- `jet` ranges from blue to red, and passes through the colors cyan, yellow, and orange. It is a variation of the `hsv` colormap. The `jet` colormap is associated with an astrophysical fluid jet simulation from the National Center for Supercomputer Applications. See the "Examples" on page 2-586 section.
- `lines` produces a colormap of colors specified by the axes `ColorOrder` property and a shade of gray.
- `pink` contains pastel shades of pink. The pink colormap provides sepia tone colorization of grayscale photographs.
- `prism` repeats the six colors red, orange, yellow, green, blue, and violet.
- `spring` consists of colors that are shades of magenta and yellow.
- `summer` consists of colors that are shades of green and yellow.
- `white` is an all white monochrome colormap.
- `winter` consists of colors that are shades of blue and green.

Examples

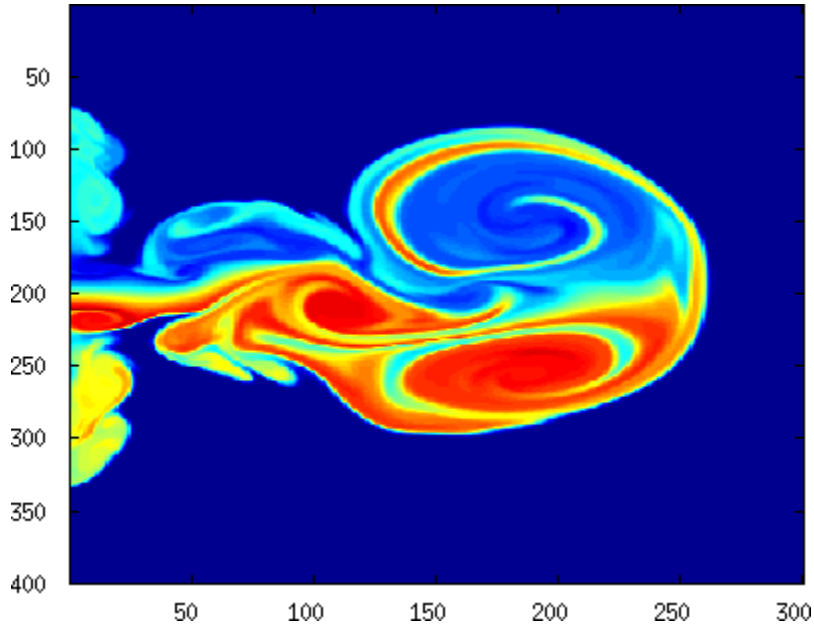
The images and colormaps demo, `imagedemo`, provides an introduction to colormaps. Select **Color Spiral** from the menu. This uses the `pcolor` function to display a 16-by-16 matrix whose elements vary from 0 to 255 in a rectilinear spiral. The `hsv` colormap starts with red in the center,

then passes through yellow, green, cyan, blue, and magenta before returning to red at the outside end of the spiral. Selecting **Colormap Menu** gives access to a number of other colormaps.

The `rgbplot` function plots colormap values. Try `rgbplot(hsv)`, `rgbplot(gray)`, and `rgbplot(hot)`.

The following commands display the `flujet` data using the `jet` colormap.

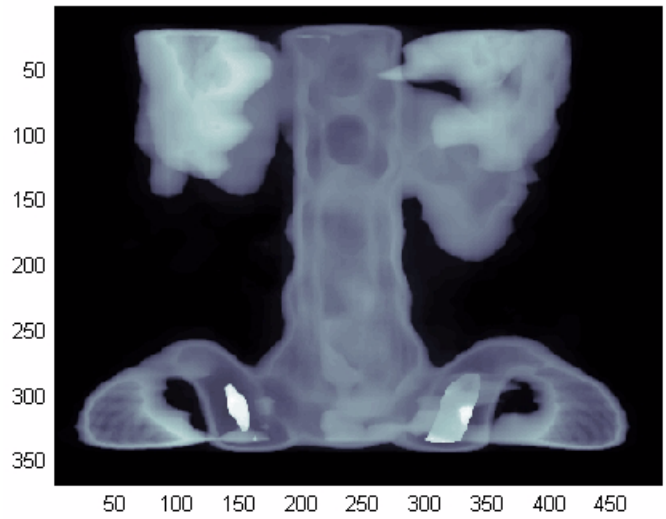
```
load flujet
image(X)
colormap(jet)
```



The `demos` directory contains a CAT scan image of a human spine. To view the image, type the following commands:

```
load spine
image(X)
```

```
colormap bone
```



Algorithm

Each figure has its own `Colormap` property. `colormap` is an M-file that sets and gets this property.

The `Colormap` property of figure graphics objects

“Color Operations” on page 1-98 for related functions

“Coloring Mesh and Surface Plots” for more information about colormaps and other coloring methods

Purpose

Start colormap editor

Syntax

```
colormapeditor
```

Description

`colormapeditor` displays the current figure's colormap as a strip of rectangular cells in the colormap editor. Node pointers are colored cells below the colormap strip that indicate points in the colormap where the rate of the variation of R, G, and B values changes. You can also work in the HSV colorspace by setting the **Interpolating Colorspace** selector to HSV.

You can also start the colormap editor by selecting **Colormap** from the **Edit** menu.

Node Pointer Operations

You can select and move node pointers to change a range of colors in the colormap. The color of a node pointer remains constant as you move it, but the colormap changes by linearly interpolating the RGB values between nodes.

Change the color at a node by double-clicking the node pointer. MATLAB displays a color picker from which you can select a new color. After you select a new color at a node, MATLAB reinterpolates the colors in between nodes.

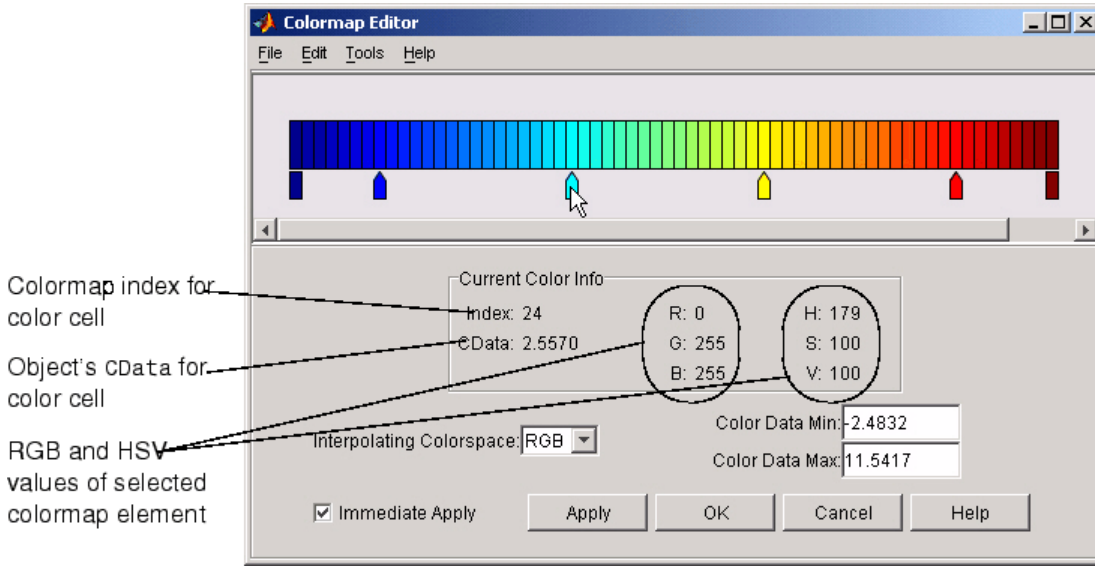
Operation	How to Perform
Add a node	Click below the corresponding cell in the colormap strip.
Select a node	Left-click the node.
Select multiple nodes	Adjacent: left-click first node, **Shift+click** the last node. Nonadjacent: left-click first node, **Ctrl+click** subsequent nodes.

Operation	How to Perform
Move a node	Select and drag with the mouse or select and use the left and right arrow keys.
Move multiple nodes	Select multiple nodes and use the left and right arrow keys to move nodes as a group. Movement stops when one of the selected nodes hits an unselected node or an end node.
Delete a node	Select the node and then press the **Delete** key, or select **Delete** from the **Edit** menu, or type **Ctrl+x**.
Delete multiple nodes	Select the nodes and then press the **Delete** key, or select **Delete** from the **Edit** menu, or type **Ctrl+x**.
Display color picker for a node	Double-click the node pointer.

Current Color Info

When you put the mouse over a color cell or node pointer, the colormap editor displays the following information about that colormap element:

- The element's index in the colormap
- The value from the graphics object color data that is mapped to the node's color (i.e., data from the `CData` property of any image, patch, or surface objects in the figure)
- The color's RGB and HSV color value



Interpolating Colorspace

The colorspace determines what values are used to calculate the colors of cells between nodes. For example, in the RGB colorspace, internode colors are calculated by linearly interpolating the red, green, and blue intensity values from one node to the next. Switching to the HSV colorspace causes the colormap editor to recalculate the colors between nodes using the hue, saturation, and value components of the color definition.

Note that when you switch from one colorspace to another, the color editor preserves the number, color, and location of the node pointers, which can cause the colormap to change.

Interpolating in HSV. Since hue is conceptually mapped about a color circle, the interpolation between hue values can be ambiguous. To minimize this ambiguity, the interpolation uses the shortest distance around the circle. For example, interpolating between two nodes, one with hue of 2 (slightly orange red) and another with a hue of 356 (slightly magenta red), does not result in hues 3,4,5...353,354,355 (orange/red-yellow-green-cyan-blue-magenta/red). Taking the shortest distance around the circle gives 357,358,1,2 (orange/red-red-magenta/red).

Color Data Min and Max

The **Color Data Min** and **Color Data Max** text fields enable you to specify values for the axes `CLim` property. These values change the mapping of object color data (the `CData` property of images, patches, and surfaces) to the colormap. See "Axes Color Limits — the CLim Property" for discussion and examples of how to use this property.

Examples

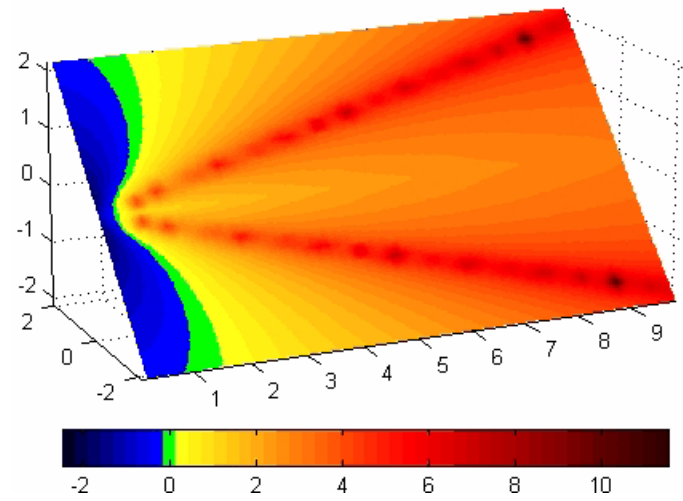
This example modifies a default MATLAB colormap so that ranges of data values are displayed in specific ranges of color. The graph is a slice plane illustrating a cross section of fluid flow through a jet nozzle. See the `slice` reference page for more information on this type of graph.

Example Objectives

The objectives are as follows:

- Regions of flow from left to right (positive data) are mapped to colors from yellow through orange to dark red. Yellow is slowest and dark red is the fastest moving fluid.
- Regions that have a speed close to zero are colored green.
- Regions where the fluid is actually moving right to left (negative data) are shades of blue (darker blue is faster).

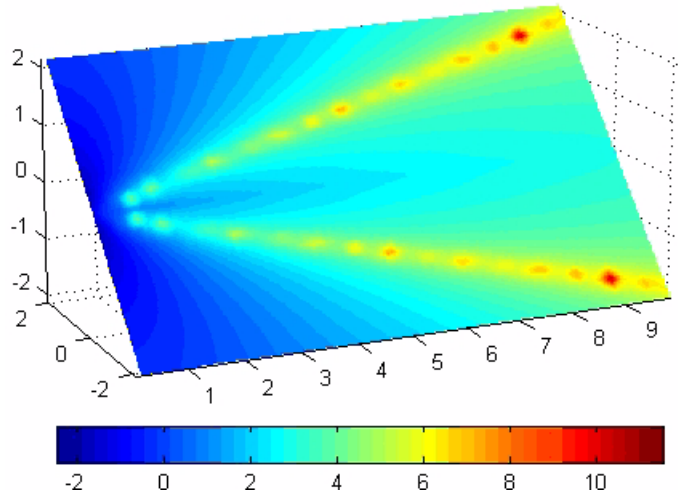
The following picture shows the desired coloring of the slice plane. The colorbar shows the data to color mapping.



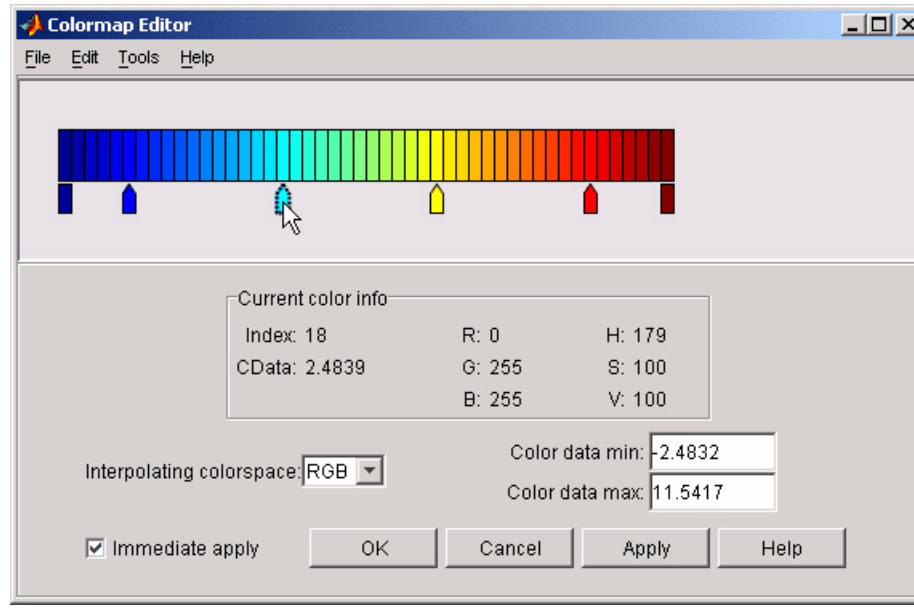
Running the Example

Note If you are viewing this documentation in the MATLAB help browser, you can display the graph used in this example by running this M-file from the MATLAB editor (select **Run** from the **Debug** menu).

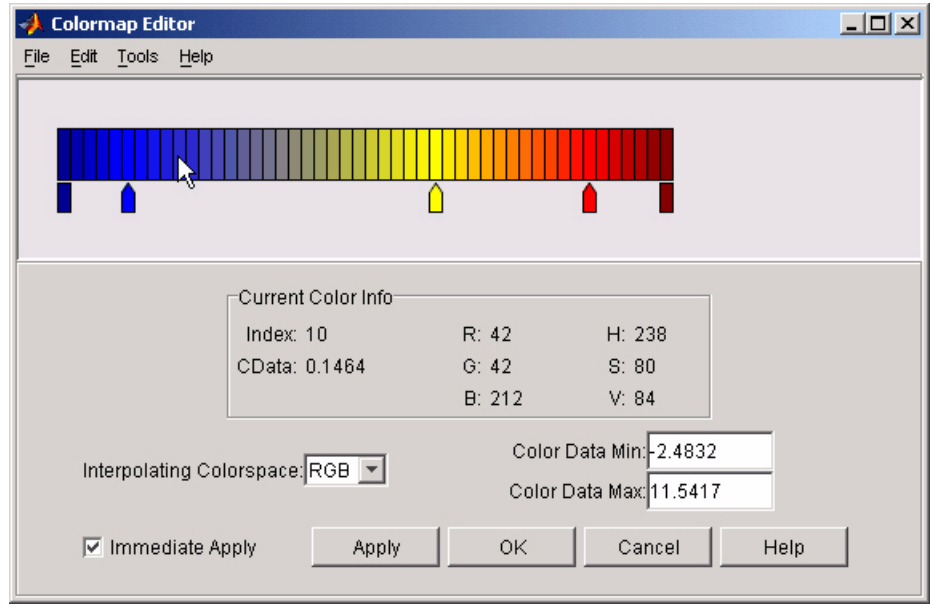
Initially, the default colormap (`jet`) colored the slice plane, as illustrated in the following picture. Note that this example uses a colormap that is 48 elements to display wider bands of color (the default is 64 elements).



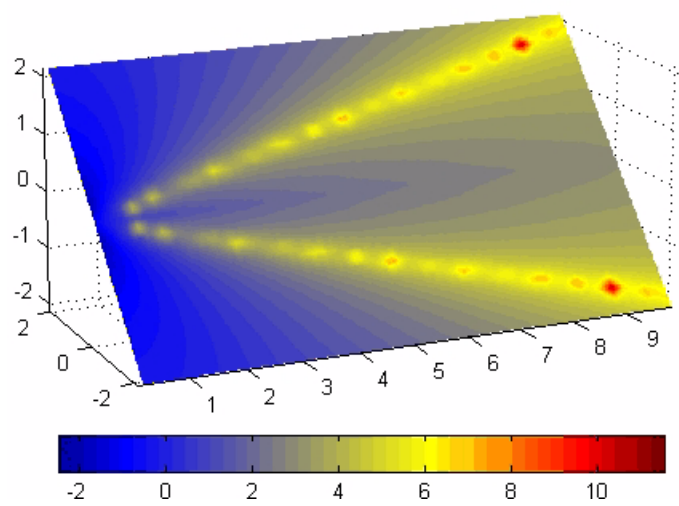
1 Start the colormap editor using the `colormapeditor` command. The color map editor displays the current figure' s colormap, as shown in the following picture.



2 Since we want the regions of left-to-right flow (positive speed) to range from yellow to dark red, we can delete the cyan node pointer. To do this, first select it by clicking with the left mouse button and press **Delete**. The colormap now looks like this.

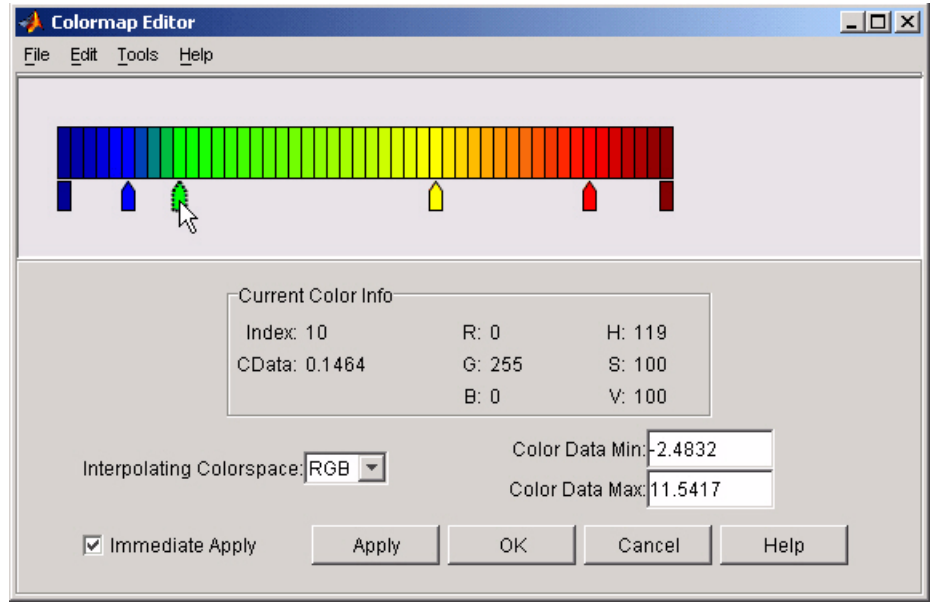


The **Immediate Apply** box is checked, so the graph displays the results of the changes made to the colormap.

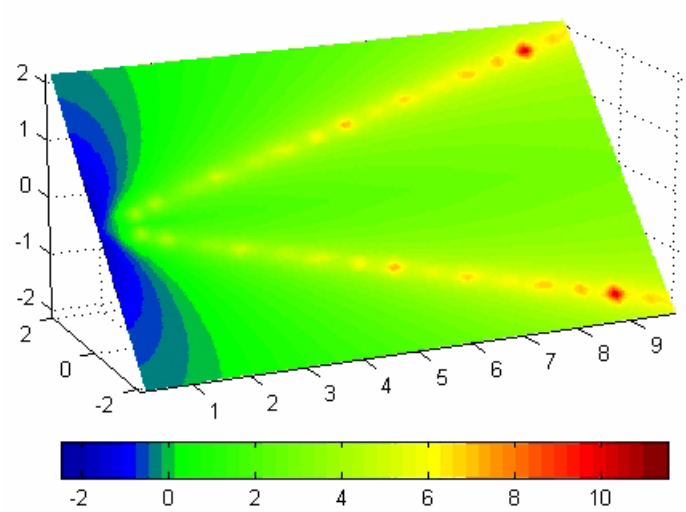


3 We want the fluid speed values around zero to stand out, so we need to find the color cell where the negative-to-positive transition occurs. Dragging the cursor over the color strip enables you to read the data values in the **Current Color Info** panel.

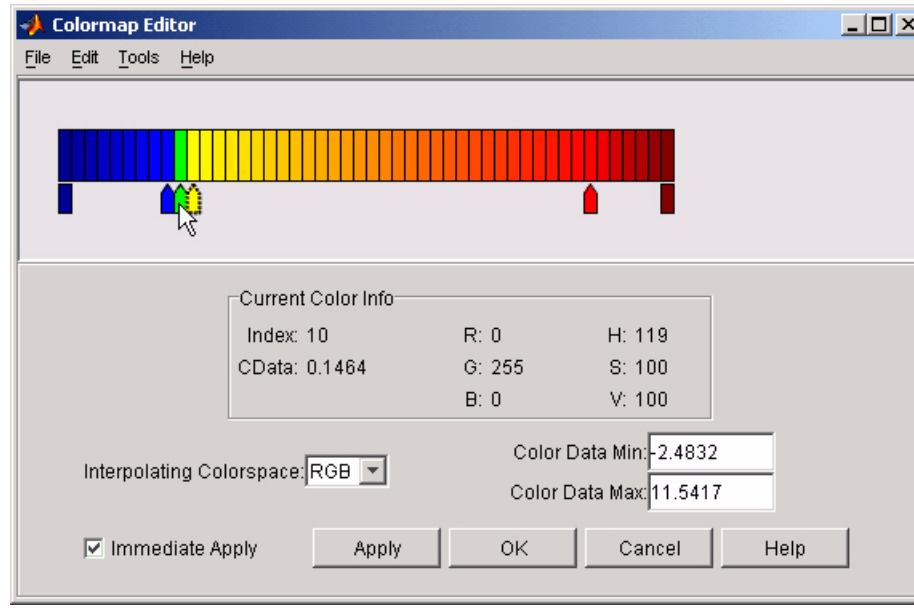
In this case, cell 10 is the first positive value, so we click below that cell and create a node pointer. Double-clicking the node pointer displays the color picker. Set the color of this node to green.



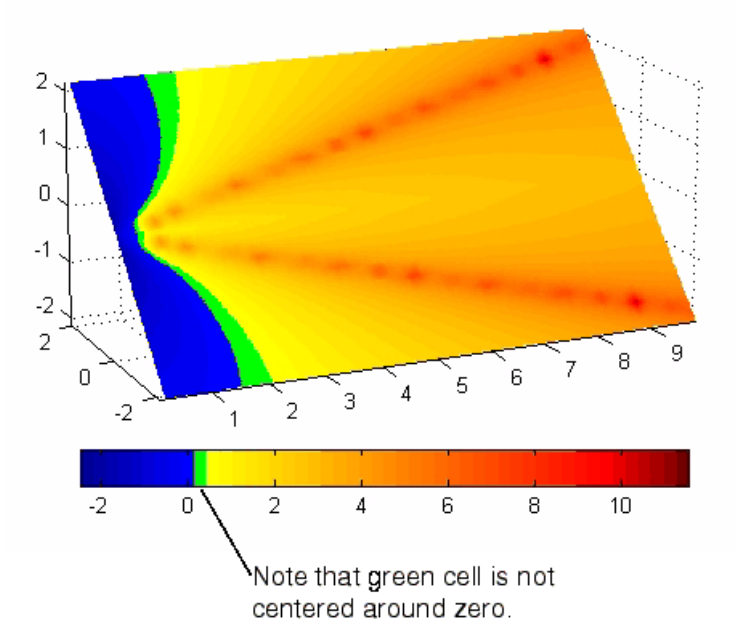
The graph continues to update to the modified colormap.



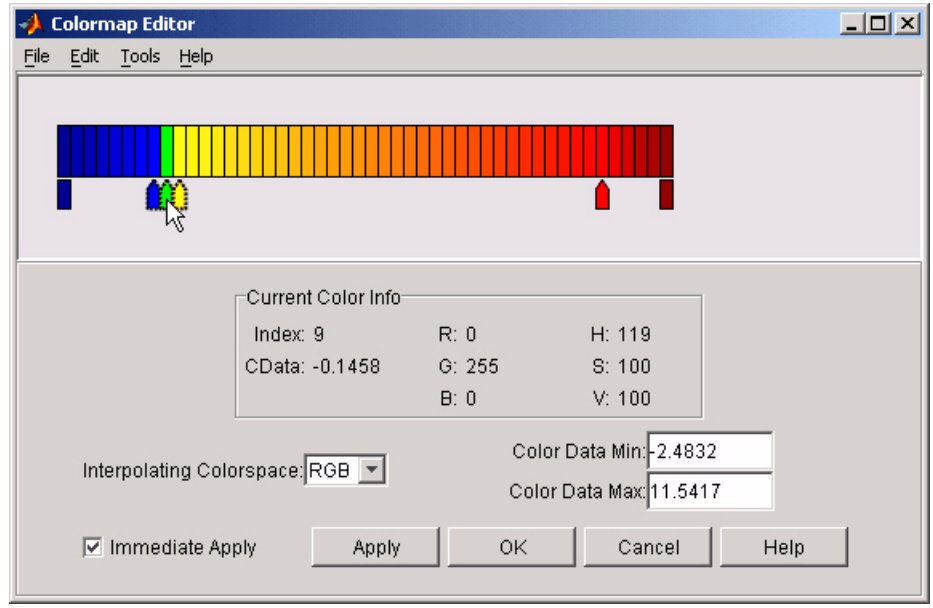
4 In the current state, the colormap colors are interpolated from the green node to the yellowish node about 20 cells away. We actually want only the single cell that is centered around zero to be colored green. To limit the color green to one cell, move the blue and yellow node pointers next to the green pointer.



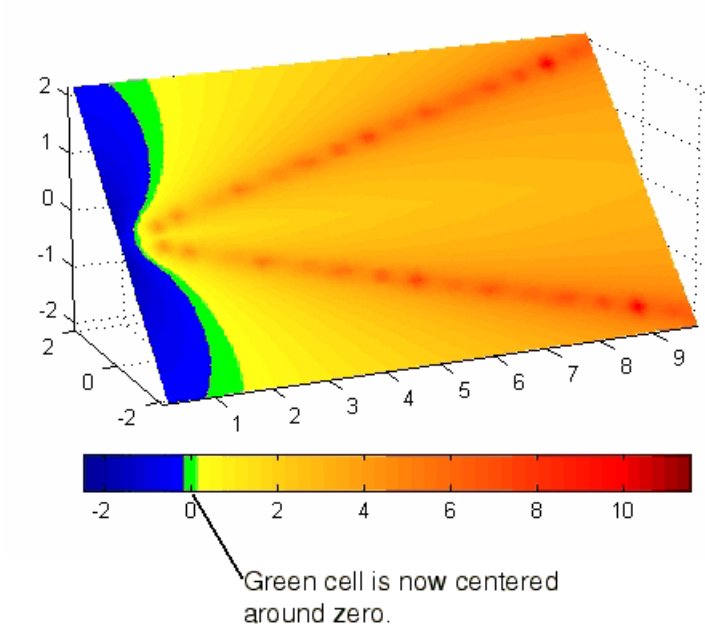
5 Before making further adjustments to the colormap, we need to move the green cell so that it is centered around zero. Use the colorbar to locate the green cell.



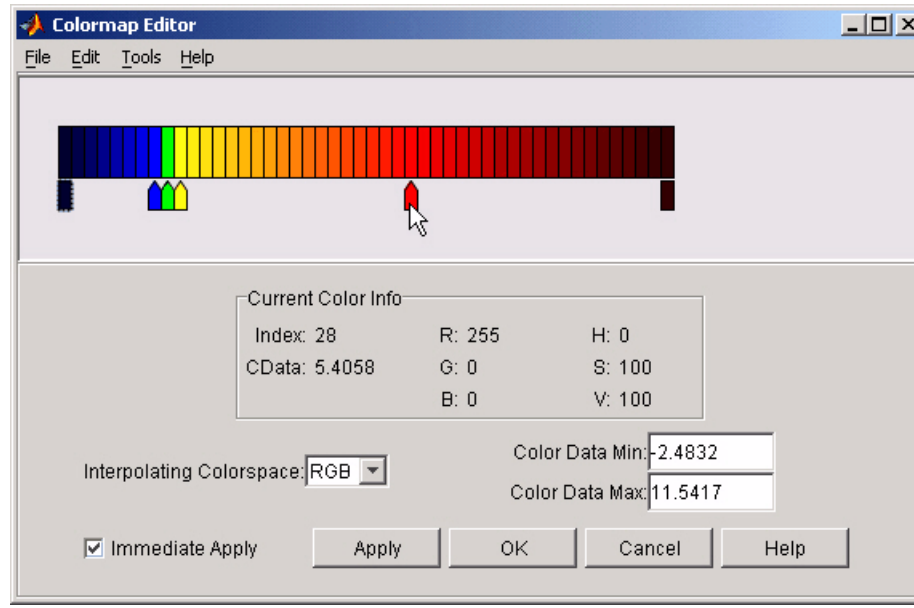
To recenter the green cell around zero, select the blue, green, and yellow node pointers (left-click blue, **Shift+click** yellow) and move them as a group using the left arrow key. Watch the colorbar in the figure window to see when the green color is centered around zero.



The slice plane now has the desired range of colors for negative, zero, and positive data.

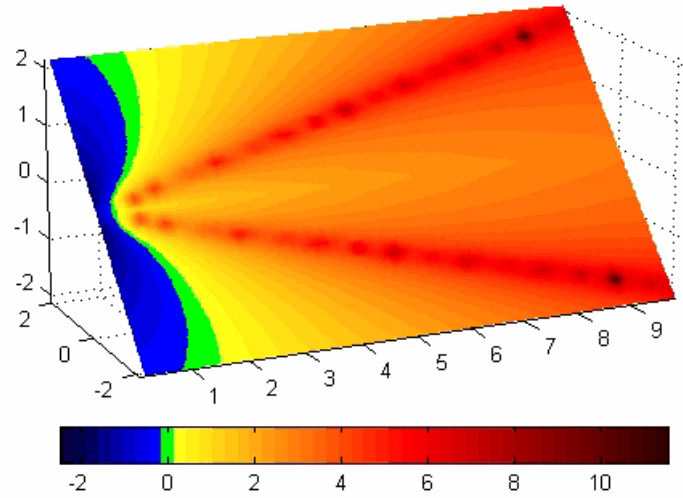


6 Increase the orange-red coloring in the slice by moving the red node pointer toward the yellow node.



7 Darken the endpoints to bring out more detail in the extremes of the data. Double-click the end nodes to display the color picker. Set the red endpoint to the RGB value [50 0 0] and set the blue endpoint to the RGB value [0 0 50].

The slice plane coloring now matches the example objectives.



Saving the Modified Colormap

You can save the modified colormap using the `colormap` function or the figure `Colormap` property.

After you have applied your changes, save the current figure colormap in a variable:

```
mycmap = get(fig,'Colormap'); % fig is figure
handle or use gcf
```

To use this colormap in another figure, set that figure's `Colormap` property:

```
set(new_fig,'Colormap',mycmap)
```

To save your modified colormap in a MAT-file, use the `save` command to save the `mycmap` workspace variable:

```
save('MyColormaps','mycmap')
```

To use your saved colormap in another MATLAB session, `load` the variable into the workspace and assign the colormap to the figure:

```
load('MyColormaps','mycmap')
set(fig,'Colormap',mycmap)
```

See Also

`colormap`, `get`, `load`, `save`, `set`

Color Operations for related functions

See “Colormaps” for more information on using MATLAB colormaps.

Purpose

Color specification

Description

`ColorSpec` is not a function; it refers to the three ways in which you specify color in MATLAB:

- RGB triple
- Short name
- Long name

The short names and long names are MATLAB strings that specify one of eight predefined colors. The RGB triple is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color; the intensities must be in the range [0 1]. The following table lists the predefined colors and their RGB equivalents.

RGB Value	Short Name	Long Name
`[1 1 0]`	`y`	`yellow`
`[1 0 1]`	`m`	`magenta`
`[0 1 1]`	`c`	`cyan`
`[1 0 0]`	`r`	`red`
`[0 1 0]`	`g`	`green`
`[0 0 1]`	`b`	`blue`
`[1 1 1]`	`w`	`white`
`[0 0 0]`	`k`	`black`

Remarks

The eight predefined colors and any colors you specify as RGB values are not part of a figure's colormap, nor are they affected by changes to the figure's colormap. They are referred to as *fixed* colors, as opposed to *colormap* colors.

Some high-level functions (for example, `scatter`) accept a colorspec as an input argument and use it to set the `CData` of graphic objects they

create. When using such functions, take care not to specify a colorspec in a property/value pair that sets `CData`; values for `CData` are always n-length vectors or n-by-3 matrices, where n is the length of `XData` and `YData`, never strings.

Examples

To change the background color of a figure to green, specify the color with a short name, a long name, or an RGB triple. These statements generate equivalent results:

```
whitebg('g')
whitebg('green')
whitebg([0 1 0]);
```

You can use `ColorSpec` anywhere you need to define a color. For example, this statement changes the figure background color to pink:

```
set(gcf,'Color',[1,0.4,0.6])
```

See Also

`bar`, `bar3`, `colordef`, `colormap`, `fill`, `fill3`, `whitebg`

"Color Operations" on page 1-98 for related functions

Purpose

Sparse column permutation based on nonzero count

Syntax

```
j = colperm(S)
```

Description

`j = colperm(S)` generates a permutation vector `j` such that the columns of `S(:,j)` are ordered according to increasing count of nonzero entries. This is sometimes useful as a preordering for LU factorization; in this case use `lu(S(:,j))`.

If `S` is symmetric, then `j = colperm(S)` generates a permutation `j` so that both the rows and columns of `S(j,j)` are ordered according to increasing count of nonzero entries. If `S` is positive definite, this is sometimes useful as a preordering for Cholesky factorization; in this case use `chol(S(j,j))`.

Algorithm

The algorithm involves a sort on the counts of nonzeros in each column.

Examples

The `n`-by-`n` *arrowhead* matrix

```
A = [ones(1,n); ones(n-1,1) speye(n-1,n-1)]
```

has a full first row and column. Its LU factorization, `lu(A)`, is almost completely full. The statement

```
j = colperm(A)
```

returns `j = [2:n 1]`. So `A(j,j)` sends the full row and column to the bottom and the rear, and `lu(A(j,j))` has the same nonzero structure as `A` itself.

On the other hand, the Bucky ball example,

```
B = bucky
```

has exactly three nonzero elements in each row and column, so `j = colperm(B)` is the identity permutation and is no help at all for reducing fill-in with subsequent factorizations.

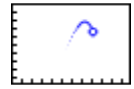
Purpose

2-D comet plot



GUI Alternatives

To graph selected variables, use the Plot Selector  in the Workspace Browser, or use the Figure Palette Plot Catalog. Manipulate graphs in *plot edit* mode with the Property Editor. For details, see Plotting Tools — Interactive Plotting in the MATLAB Graphics documentation and Creating Graphics from the Workspace Browser in the MATLAB Desktop Tools documentation.

Syntax

```
comet(y)
comet(x,y)
comet(x,y,p)
comet(axes_handle,...)
```

Description

A comet graph is an animated graph in which a circle (the comet *head*) traces the data points on the screen. The comet *body* is a trailing segment that follows the head. The *tail* is a solid line that traces the entire function.

`comet(y)` displays a comet graph of the vector `y`.

`comet(x,y)` displays a comet graph of vector `y` versus vector `x`.

`comet(x,y,p)` specifies a comet body of length `p*length(y)`. `p` defaults to `0.1`.

`comet(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

Remarks

The trace left by `comet` is created by using an `EraseMode` of `none`, which means you cannot print the graph (you get only the comet head), and it disappears if you cause a redraw (e.g., by resizing the window).

Examples

Create a simple comet graph:

```
t = 0:.01:2*pi;
x = cos(2*t).*(cos(t).^2);
y = sin(2*t).*(sin(t).^2);
comet(x,y);
```

See Also

`comet3`

"Direction and Velocity Plots" on page 1-89 for related functions

Purpose

3-D comet plot

GUI Alternatives

To graph selected variables, use the Plot Selector  in the Workspace Browser, or use the Figure Palette Plot Catalog. Manipulate graphs in *plot edit* mode with the Property Editor. For details, see Plotting Tools — Interactive Plotting in the MATLAB Graphics documentation and Creating Graphics from the Workspace Browser in the MATLAB Desktop Tools documentation.

Syntax

```
comet3(z)
comet3(x,y,z)
comet3(x,y,z,p)
comet3(axes_handle,...)
```

Description

A comet plot is an animated graph in which a circle (the comet *head*) traces the data points on the screen. The comet *body* is a trailing segment that follows the head. The *tail* is a solid line that traces the entire function.

`comet3(z)` displays a 3-D comet graph of the vector `z`.

`comet3(x,y,z)` displays a comet graph of the curve through the points `[x(i),y(i),z(i)]`.

`comet3(x,y,z,p)` specifies a comet body of length `p*length(y)`.

`comet3(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

Remarks

The trace left by `comet3` is created by using an `EraseMode` of `none`, which means you cannot print the graph (you get only the comet head), and it disappears if you cause a redraw (e.g., by resizing the window).

Examples

Create a 3-D comet graph.

```
t = -10*pi:pi/250:10*pi;
comet3((cos(2*t).^2).*sin(t),(sin(2*t).^2).*cos(t),t);
```

`comet`

"Direction and Velocity Plots" on page 1-89 for related functions

Purpose

Open Command History window, or select it if already open

GUI Alternatives

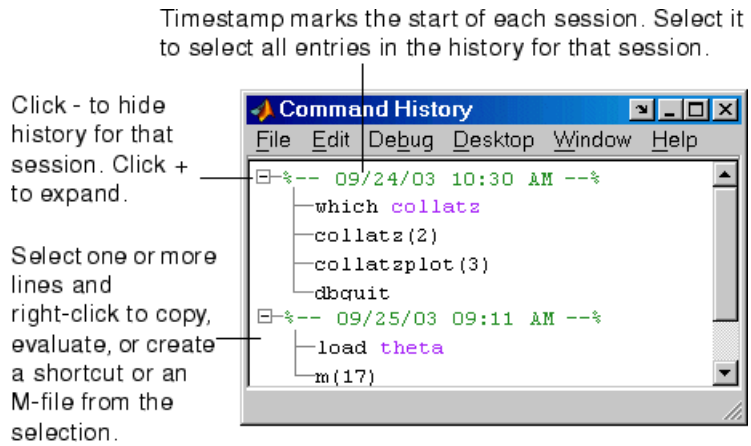
As an alternative to `commandhistory`, select **Desktop > Command History** to open it, or **Window > Command History** to select it.

Syntax

```
commandhistory
```

Description

`commandhistory` opens the MATLAB Command History window when it is closed, and selects the Command History window when it is open. The Command History window presents a log of the statements most recently run in the Command Window.



See Also

`diary`, `prefdir`, `startup`

MATLAB Desktop Tools and Development Environment Documentation

- “Recalling Previous Lines”
- “Command History Window”

commandwindow

Purpose

Open Command Window, or select it if already open

GUI Alternatives

As an alternative to `commandwindow`, select **Desktop > Command Window** to open it, or **Window > Command Window** to select it.

Syntax

```
commandwindow
```

Description

`commandwindow` opens the MATLAB Command Window when it is closed, and selects the Command Window when it is open.

Remarks

To determine the number of columns and rows that display in the Command Window, given its current size, use

```
get(0,'CommandWindowSize')
```

The number of columns is based on the width of the Command Window. With the matrix display width preference set to 80 columns, the number of columns is always 80.

See Also

`commandhistory`, `input`, `inputdlg`

- “Opening and Arranging Tools”
- “Running Functions and Programs, and Entering Variables”
- “Preferences for the Command Window”

Purpose

Companion matrix

Syntax

```
A = compan(u)
```

Description

`A = compan(u)` returns the corresponding companion matrix whose first row is `-u(2:n)/u(1)`, where `u` is a vector of polynomial coefficients. The eigenvalues of `compan(u)` are the roots of the polynomial.

Examples

The polynomial $(x-1)(x-2)(x+3) = x^3 - 7x + 6$ has a companion matrix given by

```
u = [1  0  -7  6]
A = compan(u)
A =
     0     7    -6
     1     0     0
     0     1     0
```

The eigenvalues are the polynomial roots:

```
eig(compan(u))

ans =
    -3.0000
     2.0000
     1.0000
```

This is also `roots(u)`.

See Also

`eig`, `poly`, `polyval`, `roots`

Purpose

Plot arrows emanating from origin

GUI Alternatives

To graph selected variables, use the Plot Selector  in the Workspace Browser, or use the Figure Palette Plot Catalog. Manipulate graphs in *plot edit* mode with the Property Editor. For details, see Plotting Tools — Interactive Plotting in the MATLAB Graphics documentation and Creating Graphics from the Workspace Browser in the MATLAB Desktop Tools documentation.

Syntax

```
compass(U,V)
compass(Z)
compass(...,LineSpec)
compass(axes_handle,...)
h = compass(...)
```

Description

A compass graph displays the vectors with components `(U,V)` as arrows emanating from the origin. `U`, `V`, and `Z` are in Cartesian coordinates and plotted on a circular grid.

`compass(U,V)` displays a compass graph having *n* arrows, where *n* is the number of elements in `U` or `V`. The location of the base of each arrow is the origin. The location of the tip of each arrow is a point relative to the base and determined by `[U(i),V(i)]`.

`compass(Z)` displays a compass graph having *n* arrows, where *n* is the number of elements in `Z`. The location of the base of each arrow is the origin. The location of the tip of each arrow is relative to the base as determined by the real and imaginary components of `Z`. This syntax is equivalent to `compass(real(Z),imag(Z))`.

`compass(...,LineSpec)` draws a compass graph using the line type, marker symbol, and color specified by `LineSpec`.

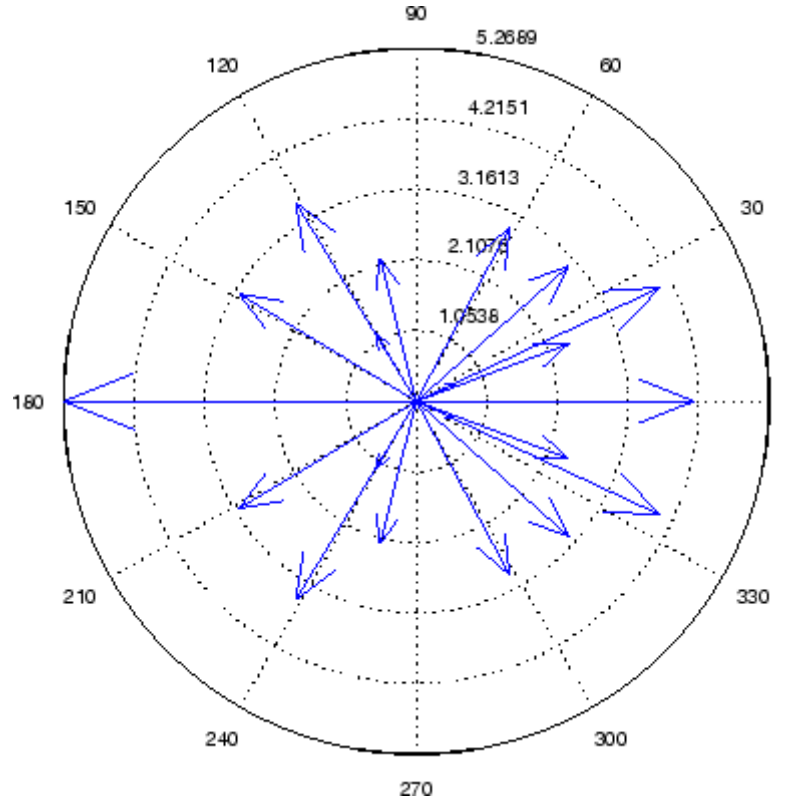
`compass(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = compass(...)` returns handles to line objects.

Examples

Draw a compass graph of the eigenvalues of a matrix.

```
Z = eig(randn(20,20));
compass(Z)
```



See Also

`feather`, `LineSpec`, `quiver`, `rose`

"Direction and Velocity Plots" on page 1-89 for related functions

"Compass Plots" for another example

complex

Purpose

Construct complex data from real and imaginary components

Syntax

```
c = complex(a,b)
```

Description

`c = complex(a,b)` creates a complex output, `c`, from the two real inputs.

```
c = a + bi
```

The output is the same size as the inputs, which must be scalars or equally sized vectors, matrices, or multi-dimensional arrays.

Note If `b` is all zeros, `c` is complex and the value of all its imaginary components is `0`. In contrast, the result of the addition `a+0i` returns a strictly real result.

The following describes when `a` and `b` can have different data types, and the resulting data type of the output `c`:

- If either of `a` or `b` has type `single`, `c` has type `single`.
- If either of `a` or `b` has an integer data type, the other must have the same integer data type or type scalar `double`, and `c` has the same integer data type.

`c = complex(a)` for real `a` returns the complex result `c` with real part `a` and `0` as the value of all imaginary components. Even though the value of all imaginary components is `0`, `c` is complex and `isreal(c)` returns false.

The `complex` function provides a useful substitute for expressions such as

```
a + i*b   or   a + j*b
```

in cases when the names "i" and "j" may be used for other variables (and do not equal $\sqrt{-1}$), when a and b are not single or double, or when b is all zero.

Example

Create complex uint8 vector from two real uint8 vectors.

```
a = uint8([1;2;3;4])
b = uint8([2;2;7;7])
c = complex(a,b)
c =
   1.0000 + 2.0000i
   2.0000 + 2.0000i
   3.0000 + 7.0000i
   4.0000 + 7.0000i
```

See Also

abs, angle, conj, i, imag, isreal, j, real

Purpose

Information about computer on which MATLAB is running

Syntax

```
str = computer
[str,maxsize] = computer
[str,maxsize,endian] = computer
```

Description

`str = computer` returns the string `str` with the computer type on which MATLAB is running.

`[str,maxsize] = computer` returns the integer `maxsize`, which contains the maximum number of elements allowed in an array with this version of MATLAB.

`[str,maxsize,endian] = computer` also returns either 'L' for little endian byte ordering or 'B' for big endian byte ordering.

The list of supported computers changes as new computers are added and others become obsolete. A typical list follows.

32–bit Platforms

str	Computer	ispc	isunix	ismac
GLNX86	GNU Linux on x86	0	1	0
MAC	Apple Macintosh OS X on PPC	0	1	1
MACI	Apple Macintosh OS X on x86	0	1	1
PCWIN	Microsoft Windows on x86	1	0	0

64–bit Platforms

str	Computer	ispc	isunix	ismac
GLNXA64	GNU Linux on x86_64	0	1	0

64-bit Platforms (Continued)

str	Computer	ispc	isunix	ismac
PCWIN64	Microsoft Windows on x64	1	0	0
SOL64	Sun Solaris on SPARC	0	1	0

See Also

getenv, setenv, ispc, isunix, ismac

Purpose

Condition number with respect to inversion

Syntax

```
c = cond(X)
c = cond(X,p)
```

Description

The *condition number* of a matrix measures the sensitivity of the solution of a system of linear equations to errors in the data. It gives an indication of the accuracy of the results from matrix inversion and the linear equation solution. Values of `cond(X)` and `cond(X,p)` near 1 indicate a well-conditioned matrix.

`c = cond(X)` returns the 2-norm condition number, the ratio of the largest singular value of `X` to the smallest.

`c = cond(X,p)` returns the matrix condition number in `p`-norm:

```
norm(X,p) * norm(inv(X),p
```

If p is...	Then cond(X,p) returns the...
1	1-norm condition number
2	2-norm condition number
'fro'	Frobenius norm condition number
inf	Infinity norm condition number

Algorithm

The algorithm for `cond` (when `p = 2`) uses the singular value decomposition, `svd`.

`condeig`, `condest`, `norm`, `normest`, `rank`, `rcond`, `svd`

References

[1] Anderson, E., Z. Bai, C. Bischof, S. Blackford, J. Demmel, J. Dongarra, J. Du Croz, A. Greenbaum, S. Hammarling, A. McKenney, and D. Sorensen, *LAPACK User's Guide* (`http://www.netlib.org/lapack/lug/lapack_lug.html`), Third Edition, SIAM, Philadelphia, 1999.

Purpose

Condition number with respect to eigenvalues

Syntax

```
c = condeig(A)
[V,D,s] = condeig(A)
```

Description

`c = condeig(A)` returns a vector of condition numbers for the eigenvalues of `A`. These condition numbers are the reciprocals of the cosines of the angles between the left and right eigenvectors.

`[V,D,s] = condeig(A)` is equivalent to

```
[V,D] = eig(A);
s = condeig(A);
```

Large condition numbers imply that `A` is near a matrix with multiple eigenvalues.

See Also

`balance`, `cond`, `eig`

condest

Purpose

1-norm condition number estimate

Syntax

```
c = condest(A)
c = condest(A,t)
[c,v] = condest(A)
```

Description

`c = condest(A)` computes a lower bound C for the 1-norm condition number of a square matrix A.

`c = condest(A,t)` changes `t`, a positive integer parameter equal to the number of columns in an underlying iteration matrix. Increasing the number of columns usually gives a better condition estimate but increases the cost. The default is `t = 2`, which almost always gives an estimate correct to within a factor 2.

`[c,v] = condest(A)` also computes a vector `v` which is an approximate null vector if `c` is large. `v` satisfies `norm(A*v,1) = norm(A,1)*norm(v,1)/c`.

Note `condest` invokes `rand`. If repeatable results are required then invoke `rand('state',j)`, for some `j`, before calling this function.

This function is particularly useful for sparse matrices.

Algorithm

`condest` is based on the 1-norm condition estimator of Hager [1] and a block oriented generalization of Hager's estimator given by Higham and Tisseur [2]. The heart of the algorithm involves an iterative search to estimate $\|A^{-1}\|_1$ without computing A^{-1}. This is posed as the convex, but nondifferentiable, optimization problem

$$\max \|A^{-1} x\|_1 \text{ subject to } \|x\|_1 = 1$$

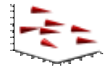
coneplot

Purpose

Plot velocity vectors as cones in 3-D vector field



GUI Alternatives

To graph selected variables, use the Plot Selector  in the Workspace Browser, or use the Figure Palette Plot Catalog. Manipulate graphs in *plot edit* mode with the Property Editor. For details, see Plotting Tools — Interactive Plotting in the MATLAB Graphics documentation and Creating Graphics from the Workspace Browser in the MATLAB Desktop Tools documentation.

Syntax

```
coneplot(X,Y,Z,U,V,W,Cx,Cy,Cz)
coneplot(U,V,W,Cx,Cy,Cz)
coneplot(...,s)
coneplot(...,color)
coneplot(...,'quiver')
coneplot(...,'method')
coneplot(X,Y,Z,U,V,W,'nointerp')
coneplot(axes_handle,...)
h = coneplot(...)
```

Description

`coneplot(X,Y,Z,U,V,W,Cx,Cy,Cz)` plots velocity vectors as cones pointing in the direction of the velocity vector and having a length proportional to the magnitude of the velocity vector.

- `X`, `Y`, `Z` define the coordinates for the vector field.
- `U`, `V`, `W` define the vector field. These arrays must be the same size, monotonic, and 3-D plaid (such as the data produced by `meshgrid`).
- `Cx`, `Cy`, `Cz` define the location of the cones in the vector field. The section “Specifying Starting Points for Stream Plots” in Visualization Techniques provides more information on defining starting points.

`coneplot(U,V,W,Cx,Cy,Cz)` (omitting the `X`, `Y`, and `Z` arguments) assumes `[X,Y,Z] = meshgrid(1:n,1:m,1:p)`, where `[m,n,p]= size(U)`.

`coneplot(...,s)` MATLAB automatically scales the cones to fit the graph and then stretches them by the scale factor `s`. If you do not specify a value for `s`, MATLAB uses a value of 1. Use `s = 0` to plot the cones without automatic scaling.

`coneplot(...,color)` interpolates the array `color` onto the vector field and then colors the cones according to the interpolated values. The size of the `color` array must be the same size as the `U`, `V`, `W` arrays. This option works only with cones (i.e., not with the `quiver` option).

`coneplot(...,'quiver')` draws arrows instead of cones (see `quiver3` for an illustration of a quiver plot).

`coneplot(...,'`*`method`*`')` specifies the interpolation method to use. *`method`* can be `linear`, `cubic`, or `nearest`. `linear` is the default. (See `interp3` for a discussion of these interpolation methods.)

`coneplot(X,Y,Z,U,V,W,'nointerp')` does not interpolate the positions of the cones into the volume. The cones are drawn at positions defined by `X`, `Y`, `Z` and are oriented according to `U`, `V`, `W`. Arrays `X`, `Y`, `Z`, `U`, `V`, `W` must all be the same size.

`coneplot(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = coneplot(...)` returns the handle to the `patch` object used to draw the cones. You can use the `set` command to change the properties of the cones.

Remarks

`coneplot` automatically scales the cones to fit the graph, while keeping them in proportion to the respective velocity vectors.

It is usually best to set the data aspect ratio of the axes before calling `coneplot`. You can set the ratio using the `daspect` command.

```
daspect([1,1,1])
```

Examples

This example plots the velocity vector cones for vector volume data representing the motion of air through a rectangular region of space. The final graph employs a number of enhancements to visualize the data more effectively:

- Cone plots indicate the magnitude and direction of the wind velocity.
- Slice planes placed at the limits of the data range provide a visual context for the cone plots within the volume.
- Directional lighting provides visual cues to the orientation of the cones.
- View adjustments compose the scene to best reveal the information content of the data by selecting the view point, projection type, and magnification.

1. Load and Inspect Data

The `winds` data set contains six 3-D arrays: `u`, `v`, and `w` specify the vector components at each of the coordinates specified in `x`, `y`, and `z`. The coordinates define a lattice grid structure where the data is sampled within the volume.

It is useful to establish the range of the data to place the slice planes and to specify where you want the cone plots (`min`, `max`).

```
load wind
xmin = min(x(:));
xmax = max(x(:));
ymin = min(y(:));
ymax = max(y(:));
zmin = min(z(:));
```

2. Create the Cone Plot

- Decide where in data space you want to plot cones. This example selects the full range of `x` and `y` in eight steps and the range 3 to 15 in four steps in `z` (`linspace`, `meshgrid`).

- Use `daspect` to set the data aspect ratio of the axes before calling `coneplot` so MATLAB can determine the proper size of the cones.
- Draw the cones, setting the scale factor to 5 to make the cones larger than the default size.
- Set the coloring of each cone (`FaceColor`, `EdgeColor`).

```
daspect([2,2,1])
xrange = linspace(xmin,xmax,8);
yrange = linspace(ymin,ymax,8);
zrange = 3:4:15;
[cx cy cz] = meshgrid(xrange,yrange,zrange);
hcones = coneplot(x,y,z,u,v,w,cx,cy,cz,5);
set(hcones,'FaceColor','red','EdgeColor','none')
```

3. Add the Slice Planes

- Calculate the magnitude of the vector field (which represents wind speed) to generate scalar data for the `slice` command.
- Create slice planes along the *x*-axis at `xmin` and `xmax`, along the *y*-axis at `ymax`, and along the *z*-axis at `zmin`.
- Specify interpolated face color so the slice coloring indicates wind speed, and do not draw edges (`hold`, `slice`, `FaceColor`, `EdgeColor`).

```
hold on
wind_speed = sqrt(u.^2 + v.^2 + w.^2);
hsurfaces = slice(x,y,z,wind_speed,[xmin,xmax],ymax,zmin);
set(hsurfaces,'FaceColor','interp','EdgeColor','none')
hold off
```

4. Define the View

- Use the `axis` command to set the axis limits equal to the range of the data.
- Orient the `view` to azimuth = 30 and elevation = 40. (`rotate3d` is a useful command for selecting the best view.)

- Select perspective projection to provide a more realistic looking volume (`camproj`).
- Zoom in on the scene a little to make the plot as large as possible (`camzoom`).

```
axis tight; view(30,40); axis off
camproj perspective; camzoom(1.5)
```

5. Add Lighting to the Scene

The light source affects both the slice planes (surfaces) and the cone plots (patches). However, you can set the lighting characteristics of each independently:

- Add a light source to the right of the camera and use Phong lighting to give the cones and slice planes a smooth, three-dimensional appearance (`camlight`, `lighting`).
- Increase the value of the `AmbientStrength` property for each slice plane to improve the visibility of the dark blue colors. (Note that you can also specify a different `colormap` to change the coloring of the slice planes.)
- Increase the value of the `DiffuseStrength` property of the cones to brighten particularly those cones not showing specular reflections.

```
camlight right; lighting phong
set(hsurfaces,'AmbientStrength',.6)
set(hcones,'DiffuseStrength',.8)
```

"Volume Visualization" on page 1-102 for related functions

Purpose

Complex conjugate

Syntax

```
ZC = conj(Z)
```

Description

`ZC = conj(Z)` returns the complex conjugate of the elements of `Z`.

Algorithm

If `Z` is a complex array:

```
conj(Z) = real(Z) - i*imag(Z)
```

See Also

`i`, `j`, `imag`, `real`

Purpose

Pass control to next iteration of `for` or `while` loop

Syntax

```
continue
```

Description

`continue` passes control to the next iteration of the `for` or `while` loop in which it appears, skipping any remaining statements in the body of the loop. The same holds true for `continue` statements in nested loops. That is, execution continues at the beginning of the loop in which the `continue` statement was encountered.

Examples

The example below shows a `continue` loop that counts the lines of code in the file `magic.m`, skipping all blank lines and comments. A `continue` statement is used to advance to the next line in `magic.m` without incrementing the count whenever a blank line or comment line is encountered.

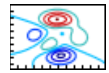
```
fid = fopen('magic.m','r');
count = 0;
while ~feof(fid)
    line = fgetl(fid);
    if isempty(line) | strncmp(line,'%',1)
        continue
    end
    count = count + 1;
end
disp(sprintf('%d lines',count));
```

See Also

`for`, `while`, `end`, `break`, `return`

Purpose

Contour plot of matrix



GUI Alternatives

To graph selected variables, use the Plot Selector  in the Workspace Browser, or use the Figure Palette Plot Catalog. Manipulate graphs in *plot edit* mode with the Property Editor. For details, see "Plotting Tools — Interactive Plotting" in the MATLAB Graphics documentation and "Creating Graphics from the Workspace Browser" in the MATLAB Desktop Tools documentation.

Syntax

```
contour(Z)
contour(Z,n)
contour(Z,v)
contour(X,Y,Z)
contour(X,Y,Z,n)
contour(X,Y,Z,v)
contour(...,LineSpec)
contour(ax,...)
[C,h] = contour(...)
[C,h] = contour('v6',...)
```

Description

A contour plot displays isolines of matrix `Z`. Label the contour lines using `clabel`.

`contour(Z)` draws a contour plot of matrix `Z`, where `Z` is interpreted as heights with respect to the *x*-*y* plane. `Z` must be at least a 2-by-2 matrix that contains at least two different values. The number of contour levels and the values of the contour levels are chosen automatically based on the minimum and maximum values of `Z`. The ranges of the *x*- and *y*-axis are `[1:n]` and `[1:m]`, where `[m,n] = size(Z)`.

`contour(Z,n)` draws a contour plot of matrix `Z` with `n` contour levels.

`contour(Z,v)` draws a contour plot of matrix `Z` with contour lines at the data values specified in vector `v`. The number of contour levels is equal

to `length(v)`. To draw a single contour of level `i`, use `contour(Z,[i i])`.

`contour(X,Y,Z)`, `contour(X,Y,Z,n)`, and `contour(X,Y,Z,v)` draw contour plots of `Z`. `X` and `Y` specify the *x*- and *y*-axis limits. When `X` and `Y` are matrices, they must be the same size as `Z`, in which case they specify a surface, as defined by the `surf` function. `X` and `Y` must be monotonically increasing.

If `X` or `Y` is irregularly spaced, `contour` calculates contours using a regularly spaced contour grid, and then transforms the data to `X` or `Y`.

`contour(...,LineSpec)` draws the contours using the line type and color specified by `LineSpec`. `contour` ignores marker symbols.

`contour(ax,...)` plots into axes `ax` instead of `gca`.

`[C,h] = contour(...)` returns a contour matrix, `C`, derived from the matrix returned by the low-level `contourc` function, and a handle, `h`, to a contourgroup object. `clabel` uses the contour matrix `C` to create the labels. (See descriptions of `contourgroup properties`.)

Backward Compatible Version

`[C,h] = contour('v6',...)` returns the contour matrix `C` (see `contourc`) and a vector of handles, `h`, to graphics objects. `clabel` uses the contour matrix `C` to create the labels. When called with the `'v6'` flag, `contour` creates patch graphics objects, unless you specify a `LineSpec`, in which case `contour` creates line graphics objects. In this case, contour lines are not mapped to colors in the figure colormap, but are colored using the colors defined in the axes `ColorOrder` property. If you do not specify a `LineSpec` argument, the figure colormap (`colormap`) and the color limits (`caxis`) control the color of the contour lines (patch objects).

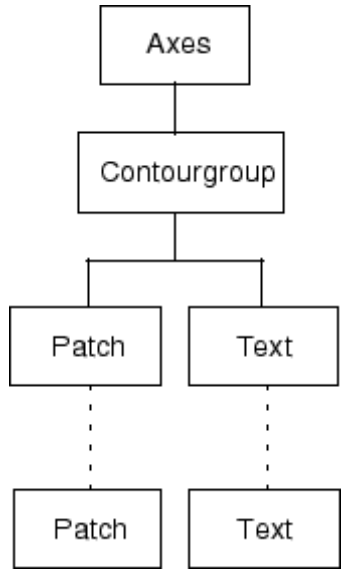
Note The `v6` option enables users of Version 7.x of MATLAB to create FIG-files that previous versions can open. It is obsolete and will be removed in a future version of MATLAB.

See Plot Objects and Backward Compatibility for more information.

Remarks

Use contourgroup object properties to control the contour plot appearance.

The following diagram illustrates the parent-child relationship in contour plots.



Examples

Contour Plot of a Function

To view a contour plot of the function

$$z = xe^{(-x^2 - y^2)}$$

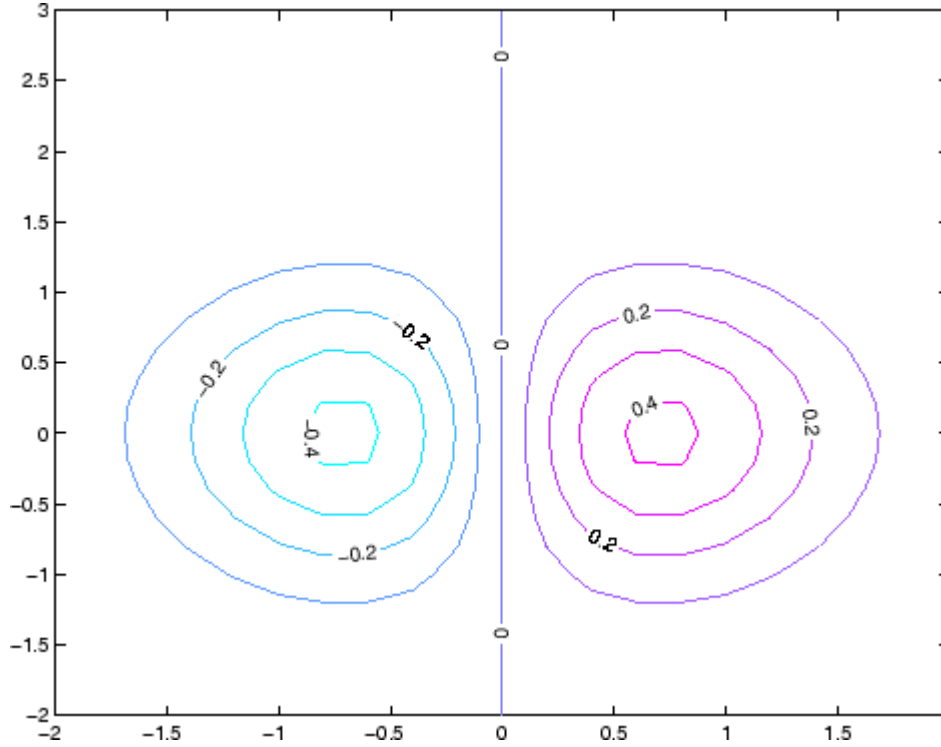
over the range $-2 \le x \le 2$, $-2 \le y \le 3$, create matrix `Z` using the statements

```
[X,Y] = meshgrid(-2:.2:2,-2:.2:3);
Z = X.*exp(-X.^2-Y.^2);
```

Then, generate a contour plot of `Z`.

- Display contour labels by setting the `ShowText` property to `on`.
- Label every other contour line by setting the `TextStep` property to twice the contour interval (i.e., two times the `LevelStep` property).
- Use a smoothly varying colormap.

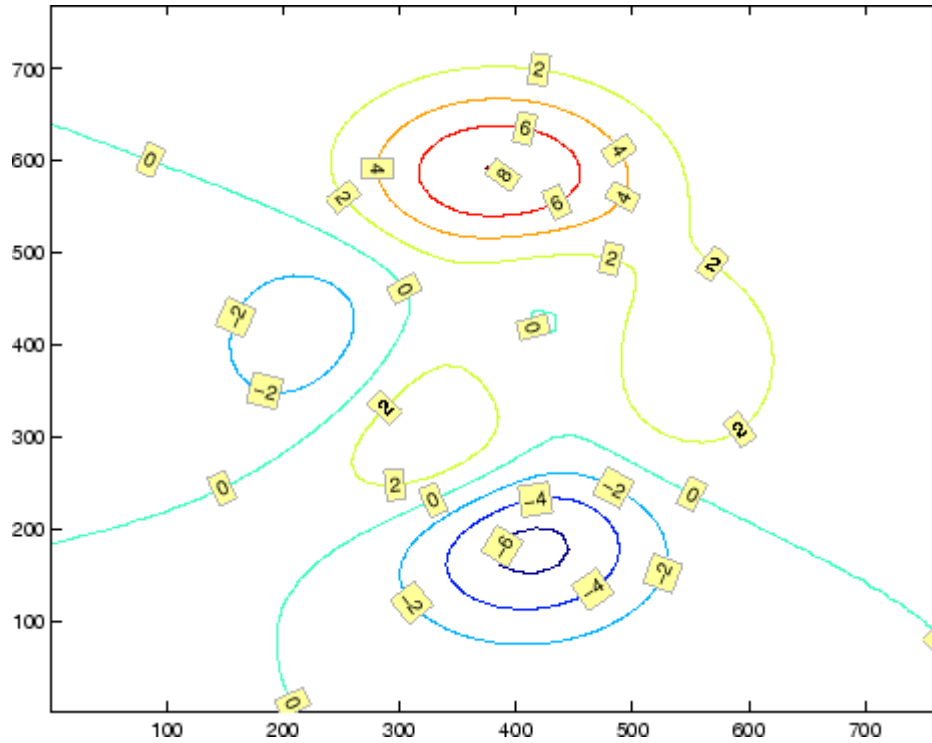
```
[C,h] = contour(X,Y,Z);
set(h,'ShowText','on','TextStep',get(h,'LevelStep')*2)
colormap cool
```



Smoothing Contour Data

Use `interp2` to create smoother contours. Also set the contour label text `BackgroundColor` to a light yellow and the `EdgeColor` to light gray.

```
Z = peaks;
[C,h] = contour(interp2(Z,4));
text_handle = clabel(C,h);
set(text_handle,'BackgroundColor',[1 1 .6],...
    'Edgecolor',[.7 .7 .7])
```



Setting the Axis Limits on Contour Plots

Suppose, for example, your data represents a region that is 1000 meters in the *x* dimension and 3000 meters in the *y* dimension. Use the following statements to set the axis limits correctly:

```
Z = rand(24,36); % assume data is a 24-by-36 matrix
X = linspace(0,1000,size(Z,2));
```

```
Y = linspace(0,3000,size(Z,1));
[c,h] = contour(X,Y,Z);
axis equal tight % set the axes aspect ratio
```

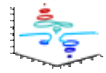
contour3, contourc, contourf, contourslice

See Contourgroup Properties for property descriptions.

Purpose

3-D contour plot



GUI Alternatives

To graph selected variables, use the Plot Selector  in the Workspace Browser, or use the Figure Palette Plot Catalog. Manipulate graphs in *plot edit* mode with the Property Editor. For details, see "Plotting Tools — Interactive Plotting" in the MATLAB Graphics documentation and "Creating Graphics from the Workspace Browser" in the MATLAB Desktop Tools documentation.

Syntax

```
contour3(Z)
contour3(Z,n)
contour3(Z,v)
contour3(X,Y,Z)
contour3(X,Y,Z,n)
contour3(X,Y,Z,v)
contour3(...,LineSpec)
contour3(axes_handle,...)
[C,h] = contour3(...)
```

Description

`contour3` creates a 3-D contour plot of a surface defined on a rectangular grid.

`contour3(Z)` draws a contour plot of matrix `Z` in a 3-D view. `Z` is interpreted as heights with respect to the *x*-*y* plane. `Z` must be at least a 2-by-2 matrix that contains at least two different values. The number of contour levels and the values of contour levels are chosen automatically. The ranges of the *x*- and *y*-axis are `[1:n]` and `[1:m]`, where `[m,n] = size(Z)`.

`contour3(Z,n)` draws a contour plot of matrix `Z` with `n` contour levels in a 3-D view.

`contour3(Z,v)` draws a contour plot of matrix `Z` with contour lines at the values specified in vector `v`. The number of contour levels is equal to `length(v)`. To draw a single contour of level `i`, use `contour(Z,[i i])`.

`contour3(X,Y,Z)`, `contour3(X,Y,Z,n)`, and `contour3(X,Y,Z,v)` use `X` and `Y` to define the *x*- and *y*-axis limits. If `X` is a matrix, `X(1,:)` defines the *x*-axis. If `Y` is a matrix, `Y(:,1)` defines the *y*-axis. When `X` and `Y` are matrices, they must be the same size as `Z`, in which case they specify a surface as `surf` does.

`contour3(...,LineSpec)` draws the contours using the line type and color specified by `LineSpec`.

`contour3(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`[C,h] = contour3(...)` returns the contour matrix `C`, as described in the function `contourc` and a column vector `h`, containing handles to graphics objects. `contour3` creates `patch` graphics objects unless you specify `LineSpec`, in which case `contour3` creates `line` graphics objects.

Remarks

If `X` or `Y` is irregularly spaced, `contour3` calculates contours using a regularly spaced contour grid, and then transforms the data to `X` or `Y`.

If you do not specify `LineSpec`, `colormap` and `caxis` control the color.

`contour3(...)` works the same as `contour(...)` with these exceptions:

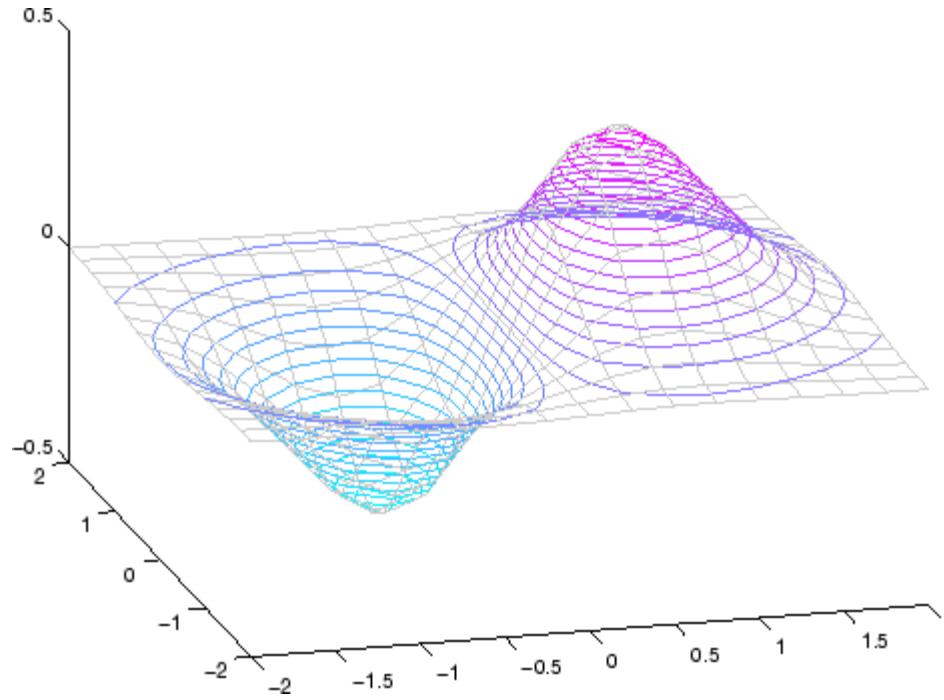
- The contours are drawn at their corresponding Z level.
- Multiple `patch` objects are created instead of a `contourgroup`.
- Calling `contour3` with trailing property-value pairs is not allowed.

Examples

Plot the three-dimensional contour of a function and superimpose a surface plot to enhance visualization of the function.

```
[X,Y] = meshgrid([-2:.25:2]);
Z = X.*exp(-X.^2-Y.^2);
contour3(X,Y,Z,30)
surface(X,Y,Z,'EdgeColor',[.8 .8 .8],'FaceColor','none')
grid off
view(-15,25)
```

```
colormap cool
```



See Also

`contour`, `contourc`, `meshc`, `meshgrid`, `surfc`

"Contour Plots" on page 1-89 category for related functions

"Contour Plots" section for more examples

Purpose

Low-level contour plot computation

Syntax

```
C = contourc(Z)
C = contourc(Z,n)
C = contourc(Z,v)
C = contourc(x,y,Z)
C = contourc(x,y,Z,n)
C = contourc(x,y,Z,v)
```

Description

`contourc` calculates the contour matrix `C` used by `contour`, `contour3`, and `contourf`. The values in `Z` determine the heights of the contour lines with respect to a plane. The contour calculations use a regularly spaced grid determined by the dimensions of `Z`.

`C = contourc(Z)` computes the contour matrix from data in matrix `Z`, where `Z` must be at least a 2-by-2 matrix. The contours are isolines in the units of `Z`. The number of contour lines and the corresponding values of the contour lines are chosen automatically.

`C = contourc(Z,n)` computes contours of matrix `Z` with `n` contour levels.

`C = contourc(Z,v)` computes contours of matrix `Z` with contour lines at the values specified in vector `v`. The length of `v` determines the number of contour levels. To compute a single contour of level `i`, use `contourc(Z,[i i])`.

`C = contourc(x,y,Z)`, `C = contourc(x,y,Z,n)`, and `C = contourc(x,y,Z,v)` compute contours of `Z` using vectors `x` and `y` to determine the *x*- and *y*-axis limits. `x` and `y` must be monotonically increasing.

Remarks

`C` is a two-row matrix specifying all the contour lines. Each contour line defined in matrix `C` begins with a column that contains the value of the contour (specified by `v` and used by `clabel`), and the number of `(x,y)` vertices in the contour line. The remaining columns contain the data for the `(x,y)` pairs.

```
C = [value1xdata(1)xdata(2)..value2xdata(1)xdata(2)...;
```

```
dim1ydata(1)ydata(2)...dim2 ydata(1)ydata(2)...]
```

Specifying irregularly spaced `x` and `y` vectors is not the same as contouring irregularly spaced data. If `x` or `y` is irregularly spaced, `contourc` calculates contours using a regularly spaced contour grid, then transforms the data to `x` or `y`.

See Also

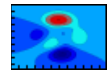
`clabel`, `contour`, `contour3`, `contourf`

"Contour Plots" on page 1-89 for related functions

"The Contouring Algorithm" for more information

Purpose

Filled 2-D contour plot



GUI Alternatives

To graph selected variables, use the Plot Selector in the Workspace Browser, or use the Figure Palette Plot Catalog. Manipulate graphs in *plot edit* mode with the Property Editor. For details, see "Plotting Tools — Interactive Plotting" in the MATLAB Graphics documentation and "Creating Graphics from the Workspace Browser" in the MATLAB Desktop Tools documentation.

Syntax

```
contourf(Z)
contourf(Z,n)
contourf(Z,v)
contourf(X,Y,Z)
contourf(X,Y,Z,n)
contourf(X,Y,Z,v)
contourf(axes_handle,...)
C = contourf(...)
[C,h] = contourf(...)
[C,h,CF] = contourf(...)
```

Description

A filled contour plot displays isolines calculated from matrix `Z` and fills the areas between the isolines using constant colors. The color of the filled areas depends on the current figure's colormap. `NaN`s in the Z-data leave white holes with black borders in the contour plot. The function creates and optionally returns a handle to a `Contourgroup Properties` object containing the filled contours.

`contourf(Z)` draws a contour plot of matrix `Z`, where `Z` is interpreted as heights with respect to a plane. `Z` must be at least a 2-by-2 matrix that contains at least two different values. The number of contour lines and the values of the contour lines are chosen automatically.

`contourf(Z,n)` draws a contour plot of matrix `Z` with `n` contour levels.

`contourf(Z,v)` draws a contour plot of matrix `Z` with contour levels at the values specified in vector `v`. When you use the `contourf(Z,v)` syntax to specify a vector of contour levels (`v` must increase monotonically), contour regions with `Z`-values less than `v(1)` are not filled (they are rendered in white). To fill such regions with a color, make `v(1)` less than or equal to the minimum `Z`-data value.

`contourf(X,Y,Z)`, `contourf(X,Y,Z,n)`, and `contourf(X,Y,Z,v)` produce contour plots of `Z` using `X` and `Y` to determine the *x*- and *y*-axis limits. When `X` and `Y` are matrices, they must be the same size as `Z`, in which case they specify a surface as `surf` does. `X` and `Y` must be monotonically increasing.

`contourf(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`C = contourf(...)` returns the contour matrix `C` as calculated by the function `contourc` and used by `clabel`.

`[C,h] = contourf(...)` also returns a handle `h` for the contourgroup object.

Backward-Compatible Version

`[C,h,CF] = contourf(...)` returns the contour matrix `C` as calculated by the function `contourc` and used by `clabel`, a vector of handles `h` to patch graphics objects (instead of a contourgroup object, for compatibility with MATLAB 6.5 and earlier) and a contour matrix `CF` for the filled areas.

Note The `v6` option enables users of Version 7.x of MATLAB to create FIG-files that previous versions can open. It is obsolete and will be removed in a future version of MATLAB.

See Plot Objects and Backward Compatibility for more information.

Remarks

If `X` or `Y` is irregularly spaced, `contourf` calculates contours using a regularly spaced contour grid, and then transforms the data to `X` or `Y`.

Examples

Create a filled contour plot of the peaks function.

```
[C,h] = contourf(peaks(20),10);
colormap autumn
```

"Contour Plots" on page 1-89 for related functions

Contourgroup Properties

Purpose

Define contourgroup properties

Modifying Properties

You can set and query graphics object properties using the `set` and `get` commands or the Property Editor (`propertyeditor`).

Note that you cannot define default properties for contourgroup objects.

See “Plot Objects” for more information on contourgroup objects.

Contourgroup Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

`Annotation`

`hg.Annotation` object Read Only

Control the display of contourgroup objects in legends. The `Annotation` property enables you to specify whether this contourgroup object is represented in a figure legend.

Querying the `Annotation` property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the contourgroup object is displayed in a figure legend:

IconDisplayStyle Value	Purpose
`on`	Include the contourgroup object in a legend as one entry, but not its children objects
`off`	Do not include the contourgroup or its children in a legend (default)
`children`	Include only the children of the contourgroup as separate entries in the legend

Setting the `IconDisplayStyle` property

These commands set the `IconDisplayStyle` of a graphics object with handle `hobj` to `children`, which causes each child object to have an entry in the legend:

```
hAnnotation = get(hobj,'Annotation');
hLegendEntry = get(hAnnotation','LegendInformation');
set(hLegendEntry,'IconDisplayStyle','children')
```

Using the `IconDisplayStyle` property

See "Controlling Legends" for more information and examples.

`BeingDeleted`
`on | {off}` Read Only

This object is being deleted. The `BeingDeleted` property provides a mechanism that you can use to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object's delete function might call other functions that act on a number of different objects. These functions might not need to perform actions on objects if the objects are going to be deleted, and therefore, can check the object's `BeingDeleted` property before acting.

`BusyAction`
`cancel | {queue}`

Callback routine interruption. The `BusyAction` property enables you to control how MATLAB handles events that potentially interrupt executing callbacks. If there is a callback function executing, callbacks invoked subsequently always attempt to interrupt it.

If the `Interruptible` property of the object whose callback is executing is set to `on` (the default), then interruption occurs at the next point where the event queue is processed. If the `Interruptible` property is `off`, the `BusyAction` property (of the object owning the executing callback) determines how MATLAB handles the event. The choices are

- `cancel` — Discard the event that attempted to execute a second callback routine.
- `queue` — Queue the event that attempted to execute a second callback routine until the current callback finishes.

`ButtonDownFcn`
string or function handle

Button press callback function. A callback that executes whenever you press a mouse button while the pointer is over this object, but not over another graphics object. See the `HitTestArea` property for information about selecting objects of this type.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

This property can be

- A string that is a valid MATLAB expression
- The name of an M-file
- A function handle

Set this property to a function handle that references the callback. The expressions execute in the MATLAB workspace.

See "Function Handle Callbacks" for information on how to use function handles to define the callbacks.

`Children`
array of graphics object handles

Children of this object. The handle of a patch object that is the child of this object (whether visible or not).

Note that if a child object's `HandleVisibility` property is set to `callback` or `off`, its handle does not show up in this object's `Children` property unless you set the root `ShowHiddenHandles` property to `on`:

```
set(0,'ShowHiddenHandles','on')
```

`Clipping`
`{on} | off`

Clipping mode. MATLAB clips graphs to the axes plot box by default. If you set `Clipping` to `off`, portions of graphs can be displayed outside the axes plot box. This can occur if you create a plot object, set `hold` to `on`, freeze axis scaling (`axis manual`), and then create a larger plot object.

`ContourMatrix`
2-by-n matrix Read Only

A two-row matrix specifying all the contour lines. Each contour line defined in the `ContourMatrix` begins with a column that contains the value of the contour (specified by the `LevelList` property and is used by `clabel`), and the number of `(x,y)` vertices in the contour line. The remaining columns contain the data for the `(x,y)` pairs:

```
C = [value1 xdata(1) xdata(2)...value2 xdata(1) xdata(2)...;
       dim1 ydata(1) ydata(2)...  dim2 ydata(1) ydata(2)...]
```

That is,

```
C = [C(1) C(2)...C(I)...C(N)]
```

where `N` is the number of contour levels, and

```
C(i) = [ level(i) x(1) x(2)...x(  numel(i));
```

```
numel(i) y(1) y(2)...y(  numel(i))];
```

For further information, see The Contouring Algorithm.

`CreateFcn`
string or function handle

Callback routine executed during object creation. This property defines a callback that executes when MATLAB creates an object. You must specify the callback during the creation of the object. For example,

```
area(y,'CreateFcn',@CallbackFcn)
```

where `@CallbackFcn` is a function handle that references the callback function.

MATLAB executes this routine after setting all other object properties. Setting this property on an existing object has no effect.

The handle of the object whose `CreateFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See "Function Handle Callbacks" for information on how to use function handles to define the callback function.

`DeleteFcn`
string or function handle

Callback executed during object deletion. A callback that executes when this object is deleted (e.g., this might happen when you issue a `delete` command on the object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object's properties so the callback routine can query these values.

The handle of the object whose DeleteFcn is being executed is accessible only through the root CallbackObject property, which can be queried using gcbo.

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

See the BeingDeleted property for related information.

DisplayName

string (default is empty string)

String used by legend for this contourgroup object. The legend function uses the string defined by the DisplayName property to label this contourgroup object in the legend.

- If you specify string arguments with the legend function, DisplayName is set to this contourgroup object’s corresponding string and that string is used for the legend.
- If DisplayName is empty, legend creates a string of the form, ['data' *n*], where *n* is the number assigned to the object based on its location in the list of legend entries. However, legend does not set DisplayName to this string.
- If you edit the string directly in an existing legend, DisplayName is set to the edited string.
- If you specify a string for the DisplayName property and create the legend using the figure toolbar, then MATLAB uses the string defined by DisplayName.
- To add programmatically a legend that uses the DisplayName string, call legend with the toggle or show option.

See “Controlling Legends” for more examples.

EraseMode

{normal} | none | xor | background

Erase mode. This property controls the technique MATLAB uses to draw and erase objects and their children. Alternative erase modes are useful for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to ensure that all objects are rendered correctly. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- `none` — Do not erase objects when they are moved or destroyed. While the objects are still visible on the screen after erasing with `EraseMode none`, you cannot print these objects because MATLAB stores no information about their former locations.
- `xor` — Draw and erase the object by performing an exclusive OR (XOR) with each pixel index of the screen behind it. Erasing the object does not damage the color of the objects behind it. However, the color of the erased object depends on the color of the screen behind it and it is correctly colored only when it is over the axes background color (or the figure background color if the axes `Color` property is set to `none`). That is, it isn't erased correctly if there are objects behind it.
- `background` — Erase the graphics objects by redrawing them in the axes background color, (or the figure background color if the axes `Color` property is set to `none`). This damages other graphics objects that are behind the erased object, but the erased object is always properly colored.

Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB can mathematically combine

layers of colors (e.g., performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

Set the axes background color with the axes `Color` property. Set the figure background color with the figure `Color` property.

You can use the MATLAB `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

`Fill`

`{off} | on`

Color spaces between contour lines. By default, `contour` draws only the contour lines of the surface. If you set `Fill` to `on`, `contour` colors the regions in between the contour lines according to the Z-value of the region and changes the contour lines to black.

`HandleVisibility`

`{on} | callback | off`

Control access to object's handle by command-line users and GUIs. This property determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally accessing objects that you need to protect for some reason.

- `on` — Handles are always visible when `HandleVisibility` is `on`.
- `callback` — Setting `HandleVisibility` to `callback` causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.

- `off` — Setting `HandleVisibility` to `off` makes handles invisible at all times. This might be necessary when a callback invokes a function that might potentially damage the GUI (such as evaluating a user-typed string) and so temporarily hides its own handles during the execution of that function.

Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Properties Affected by Handle Visibility

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

Overriding Handle Visibility

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings (this does not affect the values of the `HandleVisibility` properties). See also `findall`.

Handle Validity

Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

`HitTest`
`{on} | off`

Selectable by mouse click. `HitTest` determines whether this object can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the objects that compose the area graph. If `HitTest` is `off`, clicking this object selects the object below it (which is usually the axes containing it).

`HitTestArea`
`on | {off}`

Select the object by clicking lines or area of extent. This property enables you to select plot objects in two ways:

- Select by clicking lines or markers (default).
- Select by clicking anywhere in the extent of the plot.

When `HitTestArea` is `off`, you must click th eobject's lines or markers (excluding the baseline, if any) to select the object. When `HitTestArea` is `on`, you can select this object by clicking anywhere within the extent of the plot (i.e., anywhere within a rectangle that encloses it).

`Interruptible`
`{on} | off`

Callback routine interruption mode. The `Interruptible` property controls whether an object's callback can be interrupted by callbacks invoked subsequently.

Only callbacks defined for the `ButtonDownFcn` property are affected by the `Interruptible` property. MATLAB checks for events that can interrupt a callback only when it encounters a `drawnow`, `figure`, `getframe`, or `pause` command in the routine. See the `BusyAction` property for related information.

Setting `Interruptible` to `on` allows any graphics object's callback to interrupt callback routines originating from a bar property. Note that MATLAB does not save the state of variables or the display (e.g., the handle returned by the `gca` or `gcf` command) when an interruption occurs.

`LabelSpacing`
distance in points (default = 144)

Spacing between labels on each contour line. When you display contour line labels using either the `ShowText` property or the `clabel` command, the labels are spaced 144 points (2 inches) apart on each line. You can specify the spacing by setting the `LabelSpacing` property to a value in points. If the length of an individual contour line is less than the specified value, MATLAB displays only one contour label on that line.

`LevelList`
vector of `ZData`-values

Values at which contour lines are drawn. When the `LevelListMode` property is `auto`, the `contour` function automatically chooses contour values that span the range of values in `ZData` (the input argument `Z`). You can set this property to the values at which you want contour lines drawn.

To specify the contour interval (space between contour lines) use the `LevelStep` property.

`LevelListMode`
{auto} | manual

User-specified or autogenerated `LevelList` *values*. By default, the `contour` function automatically generates the values at which contours are drawn. If you set this property to `manual`, contour does not change the values in `LevelList` as you change the values of `ZData`.

`LevelStep`
scalar

Spacing of contour lines. The `contour` function draws contour lines at regular intervals determined by the value of `LevelStep`. When the `LevelStepMode` property is set to `auto`, `contour` determines the contour interval automatically based on the `ZData`.

`LevelStepMode`
{auto} | manual

User-specified or autogenerated `LevelStep` *values*. By default, the `contour` function automatically determines a value for the `LevelStep` property. If you set this property to `manual`, contour does not change the value of `LevelStep` as you change the values of `ZData`.

`LineColor`
`{auto} | ColorSpec | none`

Color of the contour lines. This property determines how MATLAB colors the contour lines.

- `auto`— Each contour line is a single color determined by its contour value, the figure colormap, and the color axis (`caxis`).
- `ColorSpec` — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for edges. The default edge color is black. See `ColorSpec` for more information on specifying color.
- `none` — No contour lines are drawn.

`LineStyle`

`{-} | -- | : | -. | none`

Line style. This property specifies the line style of the object. Available line styles are shown in the following table.

Specifier String	Line Style
`-`	Solid line (default)
`--`	Dashed line
`:`	Dotted line
`-.`	Dash-dot line
`none`	No line

You can use `LineStyle none` when you want to place a marker at each point but do not want the points connected with a line (see the `Marker` property).

`LineWidth`

scalar

The width of linear objects and edges of filled areas. Specify this value in points (1 point = $^1/_{72}$ inch). The default `LineWidth` is 0.5 points.

`Parent`

handle of parent axes, hggroup, or hgtransform

Parent of this object. This property contains the handle of the object's parent. The parent is normally the axes, hggroup, or hgtransform object that contains the object.

See "Objects That Can Contain Other Objects" for more information on parenting graphics objects.

`Selected`
`on | {off}`

Is object selected? When you set this property to `on`, MATLAB displays selection "handles" at the corners and midpoints if the `SelectionHighlight` property is also `on` (the default). You can, for example, define the `ButtonDownFcn` callback to set this property to `on`, thereby indicating that this particular object is selected. This property is also set to `on` when an object is manually selected in plot edit mode.

`SelectionHighlight`
`{on} | off`

Objects are highlighted when selected. When the `Selected` property is `on`, MATLAB indicates the selected state by drawing four edge handles and four corner handles. When `SelectionHighlight` is `off`, MATLAB does not draw the handles except when in plot edit mode and objects are selected manually.

`ShowText`
`on | {off}`

Display labels on contour lines. When you set this property to on, MATLAB displays text labels on each contour line indicating the contour value. See also `LevelList`, `clabel`, and the example “Contour Plot of a Function” on page 2-638.

`Tag`
string

User-specified object label. The `Tag` property provides a means to identify graphics objects with a user-specified label. This is particularly useful when you are constructing interactive graphics programs that would otherwise need to define object handles as global variables or pass them as arguments between callbacks. You can define `Tag` as any string.

For example, you might create an areaseries object and set the `Tag` property.

```
t = area(Y,'Tag','area1')
```

When you want to access objects of a given type, you can use `findobj` to find the object's handle. The following statement changes the `FaceColor` property of the object whose `Tag` is `area1`.

```
set(findobj('Tag','area1'),'FaceColor','red')
```

`TextList`

vector of contour values

Contour values to label. This property contains the contour values where text labels are placed. By default, these values are the same as those contained in the `LevelList` property, which define where the contour lines are drawn. Note that there must be an equivalent contour line to display a text label.

For example, the following statements create and label a contour plot:

```
[c,h]=contour(peaks);
clabel(c,h)
```

You can get the `LevelList` property to see the contour line values:

```
get(h,'LevelList')
```

Suppose you want to view the contour value `4.375` instead of the value of `4` that the contour function used. To do this, you need to set both the `LevelList` and `TextList` properties:

```
set(h,'LevelList',[-6 -4 -2 0 2 4.375 6 8],...
 'TextList',[-6 -4 -2 0 2 4.375 6 8])
```

See the example "Contour Plot of a Function" on page 2-638 for additional information.

`TextListMode`
`{auto} | manual`

User-specified or auto `TextList` values. When this property is set to `auto`, MATLAB sets the `TextList` property equal to the values of the `LevelList` property (i.e., a text label for each contour line). When this property is set to `manual`, MATLAB does not set the values of the `TextList` property. Note that specifying values for the `TextList` property causes the `TextListMode` property to be set to `manual`.

`TextStep`
scalar

Determines which contour line have numeric labels. The `contour` function labels contour lines at regular intervals which are determined by the value of the `TextStep` property. When the `TextStepMode` property is set to `auto`, `contour` labels every contour line when the `ShowText` property is `on`. See "Contour Plot of a Function" on page 2-638 for an example that uses the `TextStep` property.

`TextStepMode`
{auto} | manual

User-specified or autogenerated `TextStep` values. By default, the `contour` function automatically determines a value for the `TextStep` property. If you set this property to `manual`, `contour` does not change the value of `TextStep` as you change the values of `ZData`.

`Type`
string (read only)

Type of graphics object. This property contains a string that identifies the class of graphics object. For contourgroup objects, `Type` is '`hggroup`'. This statement finds all the hggroup objects in the current axes.

```
t = findobj(gca,'Type','hggroup');
```

`UIContextMenu`
handle of a uicontextmenu object

Associate a context menu with this object. Assign this property the handle of a uicontextmenu object created in the object's parent figure. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the object.

`UserData`
array

User-specified data. This property can be any data you want to associate with this object (including cell arrays and structures). The object does not set values for this property, but you can access it using the `set` and `get` functions.

`Visible`
`{on} | off`

Visibility of this object and its children. By default, a new object's visibility is `on`. This means all children of the object are visible unless the child object's `Visible` property is set to `off`. Setting an object's `Visible` property to `off` prevents the object from being displayed. However, the object still exists and you can set and query its properties.

`XData`
vector or matrix

The x-axis values for a graph. The *x*-axis values for graphs are specified by the `X` input argument. If `XData` is a vector, `length(XData)` must equal `length(YData)` and must be monotonic. If `XData` is a matrix, `size(XData)` must equal `size(YData)` and each column must be monotonic.

You can use XData to define meaningful coordinates for an underlying surface whose topography is being mapped. See "Setting the Axis Limits on Contour Plots" on page 2-640 for more information.

XDataMode
{auto} | manual

Use automatic or user-specified x-axis values. If you specify XData (by setting the XData property or specifying the x input argument), MATLAB sets this property to manual and uses the specified values to label the *x*-axis.

If you set XDataMode to auto after having specified XData, MATLAB resets the *x*-axis ticks to 1:size(YData,1) or to the column indices of the ZData, overwriting any previous values for XData.

XDataSource
string (MATLAB variable)

Link XData to MATLAB variable. Set this property to a MATLAB variable that is evaluated in the base workspace to generate the XData.

MATLAB reevaluates this property only when you set it. Therefore, a change to workspace variables appearing in an expression does not change XData.

You can use the refreshdata function to force an update of the object's data. refreshdata also enables you to specify that the data source variable be evaluated in the workspace of a function from which you call refreshdata.

See the refreshdata reference page for more information.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

`YData`

scalar, vector, or matrix

Y-axis limits. This property determines the *y*-axis limits used in the contour plot. If you do not specify a `Y` argument, the `contour` function calculates *y*-axis limits based on the size of the input argument `Z`.

`YData` can be either a matrix equal in size to `ZData` or a vector equal in length to the number of columns in `ZData`.

Use `YData` to define meaningful coordinates for the underlying surface whose topography is being mapped. See "Setting the Axis Limits on Contour Plots" on page 2-640 for more information.

`YDataMode`

{auto} | manual

Use automatic or user-specified y-axis values. In `auto` mode (the default) the `contour` function automatically determines the *y*-axis limits. If you set this property to `manual`, specify a value for `YData`, or specify a `Y` argument, then `contour` sets this property to `manual` and does not change the axis limits.

`YDataSource`

string (MATLAB variable)

Link `YData` to MATLAB variable. Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `YData`.

MATLAB reevaluates this property only when you set it. Therefore, a change to workspace variables appearing in an expression does not change `YData`.

You can use the `refreshdata` function to force an update of the object's data. `refreshdata` also enables you to specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

See the `refreshdata` reference page for more information.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

`ZData`

matrix

Contour data. This property contains the data from which the contour lines are generated (specified as the input argument `Z`). `ZData` must be at least a 2-by-2 matrix. The number of contour levels and the values of the contour levels are chosen automatically based on the minimum and maximum values of `ZData`. The limits of the *x*- and *y*-axis are `[1:n]` and `[1:m]`, where `[m,n] = size(ZData)`.

`ZDataSource`

string (MATLAB variable)

Link `ZData` to MATLAB variable. Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `ZData`.

MATLAB reevaluates this property only when you set it. Therefore, a change to workspace variables appearing in an expression does not change `ZData`.

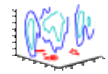
You can use the `refreshdata` function to force an update of the object's data. `refreshdata` also enables you to specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

See the `refreshdata` reference page for more information.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

Purpose

Draw contours in volume slice planes



GUI Alternatives

To graph selected variables, use the Plot Selector in the Workspace Browser, or use the Figure Palette Plot Catalog. Manipulate graphs in *plot edit* mode with the Property Editor. For details, see Plotting Tools — Interactive Plotting in the MATLAB Graphics documentation and Creating Graphics from the Workspace Browser in the MATLAB Desktop Tools documentation.

Syntax

```
contourslice(X,Y,Z,V,Sx,Sy,Sz)
contourslice(X,Y,Z,V,Xi,Yi,Zi)
contourslice(V,Sx,Sy,Sz)
contourslice(V,Xi,Yi,Zi)
contourslice(...,n)
contourslice(...,cvals)
contourslice(...,[cv cv])
contourslice(...,'method')
contourslice(axes_handle,...)
h = contourslice(...)
```

Description

`contourslice(X,Y,Z,V,Sx,Sy,Sz)` draws contours in the *x*-, *y*-, and *z*-axis aligned planes at the points in the vectors `Sx`, `Sy`, `Sz`. The arrays `X`, `Y`, and `Z` define the coordinates for the volume `V` and must be monotonic and 3-D plaid (such as the data produced by `meshgrid`). The color at each contour is determined by the volume `V`, which must be an m-by-n-by-p volume array.

`contourslice(X,Y,Z,V,Xi,Yi,Zi)` draws contours through the volume `V` along the surface defined by the 2-D arrays `Xi,Yi,Zi`. The surface should lie within the bounds of the volume.

`contourslice(V,Sx,Sy,Sz)` and `contourslice(V,Xi,Yi,Zi)` (omitting the `X`, `Y`, and `Z` arguments) assume `[X,Y,Z] = meshgrid(1:n,1:m,1:p)`, where `[m,n,p]= size(v)`.

`contourslice(...,n)` draws `n` contour lines per plane, overriding the automatic value.

`contourslice(...,cvals)` draws `length(cval)` contour lines per plane at the values specified in vector `cvals`.

`contourslice(...,[cv cv])` computes a single contour per plane at the level `cv`.

`contourslice(...,'method')` specifies the interpolation method to use. *`method`* can be `linear`, `cubic`, or `nearest`. `nearest` is the default except when the contours are being drawn along the surface defined by `Xi`, `Yi`, `Zi`, in which case `linear` is the default. (See `interp3` for a discussion of these interpolation methods.)

`contourslice(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = contourslice(...)` returns a vector of handles to `patch` objects that are used to implement the contour lines.

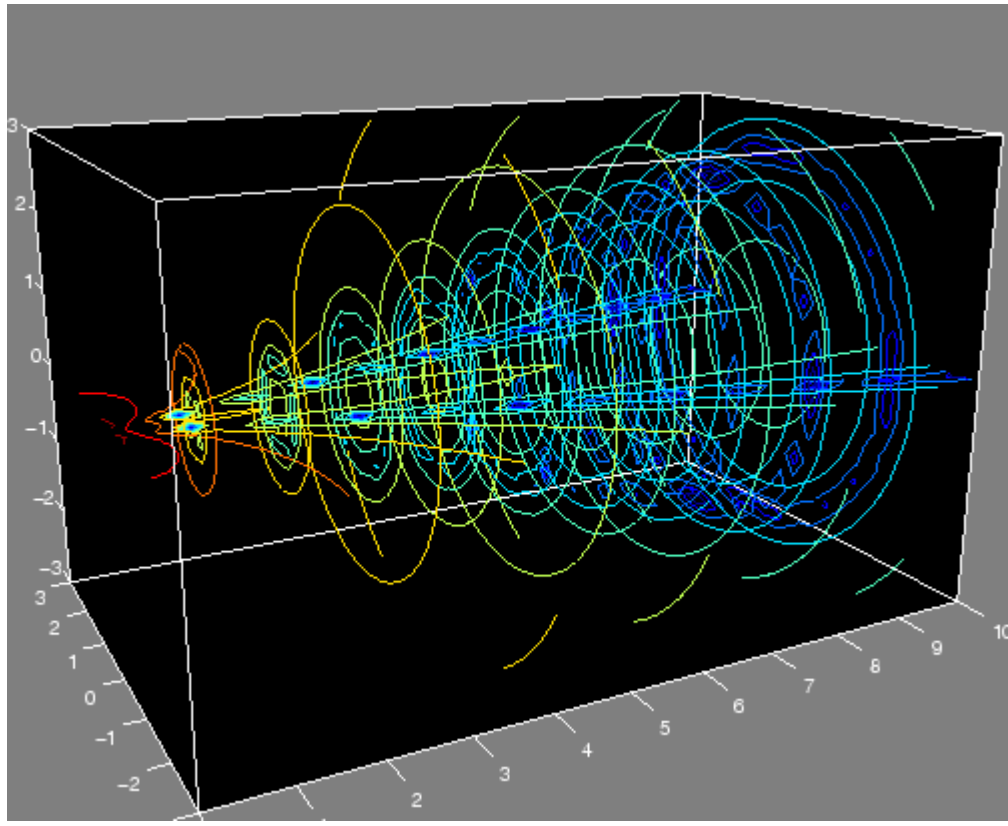
Examples

This example uses the `flow` data set to illustrate the use of contoured slice planes. (Type `doc flow` for more information on this data set.) Notice that this example

- Specifies a vector of `length = 9` for `Sx`, an empty vector for the `Sy`, and a scalar value (0) for `Sz`. This creates nine contour plots along the x direction in the y-z plane, and one in the x-y plane at z = 0.
- Uses `linspace` to define a 10-element vector of linearly spaced values from -8 to 2. This vector specifies that 10 contour lines be drawn, one at each element of the vector.
- Defines the view and projection type (`camva`, `camproj`, `campos`).
- Sets figure (`gcf`) and axes (`gca`) characteristics.

```
[x y z v] = flow;
h = contourslice(x,y,z,v,[1:9],[],[0],linspace(-8,2,10));
axis([0,10,-3,3,-3,3]); daspect([1,1,1])
camva(24); camproj perspective;
```

```
campos([-3,-15,5])
set(gcf,'Color',[.5,.5,.5],'Renderer','zbuffer')
set(gca,'Color','black','XColor','white', ...
 'YColor','white','ZColor','white')
box on
```



This example draws contour slices along a spherical surface within the volume.

```
[x,y,z] = meshgrid(-2:.2:2,-2:.25:2,-2:.16:2);
v = x.*exp(-x.^2-y.^2-z.^2); % Create volume data
```

```
[xi,yi,zi] = sphere; % Plane to contour
contourslice(x,y,z,v,xi,yi,zi)
view(3)
```

"Volume Visualization" on page 1-102 for related functions

Purpose

Grayscale colormap for contrast enhancement

Syntax

```
cmap = contrast(X)
cmap = contrast(X,m)
```

Description

The `contrast` function enhances the contrast of an `image`. It creates a new gray colormap, `cmap`, that has an approximately equal intensity distribution. All three elements in each row are identical.

`cmap = contrast(X)` returns a gray colormap that is the same length as the current colormap.

`cmap = contrast(X,m)` returns an `m`-by-3 gray colormap.

Examples

Add contrast to the clown image defined by `X`.

```
load clown;
cmap = contrast(X);
image(X);
colormap(cmap);
```

See Also

`brighten`, `colormap`, `image`

"Colormaps" on page 1-99 for related functions

Purpose

Convolution and polynomial multiplication

Syntax

```
w = conv(u,v)
```

Description

`w = conv(u,v)` convolves vectors `u` and `v`. Algebraically, convolution is the same operation as multiplying the polynomials whose coefficients are the elements of `u` and `v`.

Definition

Let `m = length(u)` and `n = length(v)` . Then `w` is the vector of length `m+n-1` whose `k`th element is

$$w(k) = \sum_j u(j)v(k+1-j)$$

The sum is over all the values of `j` which lead to legal subscripts for `u(j)` and `v(k+1-j)`, specifically `j = max(1,k+1-n): min(k,m)`. When `m = n`, this gives

```
w(1) = u(1)*v(1)
w(2) = u(1)*v(2)+u(2)*v(1)
w(3) = u(1)*v(3)+u(2)*v(2)+u(3)*v(1)
...
w(n) = u(1)*v(n)+u(2)*v(n-1)+ ... +u(n)*v(1)
...
w(2*n-1) = u(n)*v(n)
```

Algorithm

The convolution theorem says, roughly, that convolving two sequences is the same as multiplying their Fourier transforms. In order to make this precise, it is necessary to pad the two vectors with zeros and ignore roundoff error. Thus, if

```
X = fft([x zeros(1,length(y)-1)])
```

and

```
Y = fft([y zeros(1,length(x)-1)])
```

then `conv(x,y) = ifft(X.*Y)`

See Also

`conv2`, `convn`, `deconv`, `filter`

`convmtx` and `xcorr` in the Signal Processing Toolbox

Purpose

2-D convolution

Syntax

```
C = conv2(A,B)
C = conv2(hcol,hrow,A)
C = conv2(...,'shape')
```

Description

`C = conv2(A,B)` computes the two-dimensional convolution of matrices `A` and `B`. If one of these matrices describes a two-dimensional finite impulse response (FIR) filter, the other matrix is filtered in two dimensions.

The size of `C` in each dimension is equal to the sum of the corresponding dimensions of the input matrices, minus one. That is, if the size of `A` is `[ma,na]` and the size of `B` is `[mb,nb]`, then the size of `C` is `[ma+mb-1,na+nb-1]`.

The indices of the center element of B are defined as `floor(([mb nb]+1)/2)`.

`C = conv2(hcol,hrow,A)` convolves `A` first with the vector `hcol` along the rows and then with the vector `hrow` along the columns. If `hcol` is a column vector and `hrow` is a row vector, this case is the same as `C = conv2(hcol*hrow,A)`.

`C = conv2(...,'shape')` returns a subsection of the two-dimensional convolution, as specified by the `shape` parameter:

`full`	Returns the full two-dimensional convolution (default).
`same`	Returns the central part of the convolution of the same size as `A`.
`valid`	Returns only those parts of the convolution that are computed without the zero-padded edges. Using this option, `C` has size `[ma-mb+1,na-nb+1]` when `all(size(A) >= size(B))`. Otherwise `conv2` returns `[]`.

Note If any of `A`, `B`, `hcol`, and `hrow` are empty, then `C` is an empty matrix `[]`.

Algorithm

`conv2` uses a straightforward formal implementation of the two-dimensional convolution equation in spatial form. If a and b are functions of two discrete variables, n_1 and n_2, then the formula for the two-dimensional convolution of a and b is

$$c(n_1, n_2) = \sum_{k_1 = -\infty}^{\infty} \sum_{k_2 = -\infty}^{\infty} a(k_1, k_2)\, b(n_1 - k_1, n_2 - k_2)$$

In practice however, `conv2` computes the convolution for finite intervals.

Note that matrix indices in MATLAB always start at 1 rather than 0. Therefore, matrix elements `A(1,1)`, `B(1,1)`, and `C(1,1)` correspond to mathematical quantities a (0,0), b (0,0), and c (0,0).

Examples

Example 1

For the `'same'` case, `conv2` returns the central part of the convolution. If there are an odd number of rows or columns, the "center" leaves one more at the beginning than the end.

This example first computes the convolution of A using the default (`'full'`) shape, then computes the convolution using the `'same'` shape. Note that the array returned using `'same'` corresponds to the underlined elements of the array returned using the default shape.

```
A = rand(3);
B = rand(4);
C = conv2(A,B)           % C is 6-by-6

C =
   0.1838   0.2374   0.9727   1.2644   0.7890   0.3750
   0.6929   1.2019   1.5499   2.1733   1.3325   0.3096
   0.5627   1.5150   2.3576   3.1553   2.5373   1.0602
```

```

Cs = conv2(A,B,'same')   % Cs is the same size as A: 3-by-3
Cs =
    2.3576   3.1553   2.5373
    3.4302   3.5128   2.4489
    1.8229   2.1561   1.6364
```

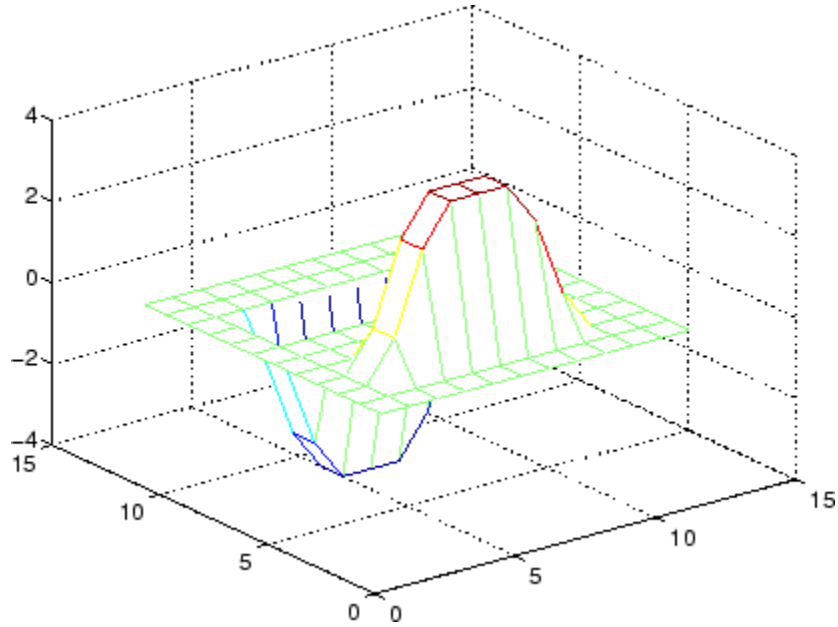
Example 2

In image processing, the Sobel edge finding operation is a two-dimensional convolution of an input array with the special matrix

```
s = [1 2 1; 0 0 0; -1 -2 -1];
```

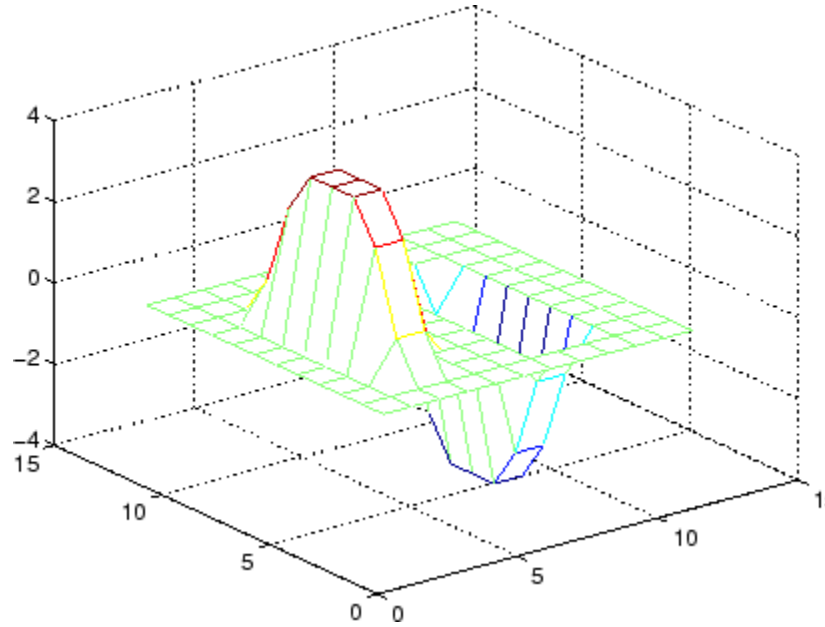
These commands extract the horizontal edges from a raised pedestal.

```
A = zeros(10);
A(3:7,3:7) = ones(5);
H = conv2(A,s);
mesh(H)
```



Transposing the filter `s` extracts the vertical edges of `A`.

```
V = conv2(A,s');
figure, mesh(V)
```



This figure combines both horizontal and vertical edges.

```
figure
mesh(sqrt(H.^2 + V.^2))
```

convhull

Purpose

Convex hull

Syntax

```
K = convhull(x,y)
K = convhull(x,y,options)
[K,a] = convhull(...)
```

Description

`K = convhull(x,y)` returns indices into the `x` and `y` vectors of the points on the convex hull.

`convhull` uses Qhull.

`K = convhull(x,y,options)` specifies a cell array of strings `options` to be used in Qhull via `convhulln`. The default option is `{'Qt'}`.

If `options` is `[]`, the default options are used. If `options` is `{''}`, no options will be used, not even the default. For more information on Qhull and its options, see `http://www.qhull.org`.

`[K,a] = convhull(...)` also returns the area of the convex hull.

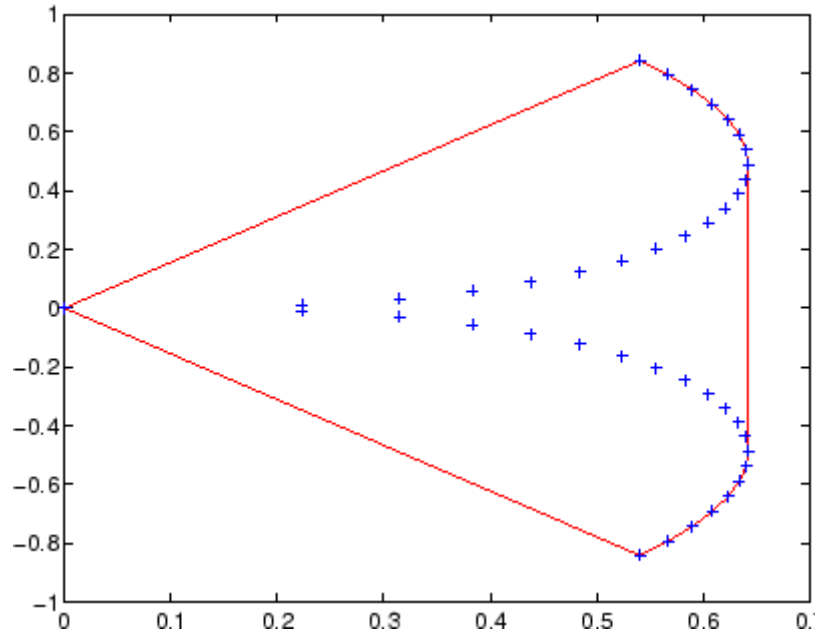
Visualization

Use `plot` to plot the output of `convhull`.

Examples

Example 1

```
xx = -1:.05:1; yy = abs(sqrt(xx));
[x,y] = pol2cart(xx,yy);
k = convhull(x,y);
plot(x(k),y(k),'r-',x,y,'b+')
```



Example 2

The following example illustrates the `options` input for `convhull`. The following commands

```
X = [0 0 0 1];
Y = [0 1e-10 0 1];
K = convhull(X,Y)
```

return a warning.

```
Warning: qhull precision warning:
The initial hull is narrow (cosine of min. angle is
0.9999999999999998).
A coplanar point may lead to a wide facet. Options 'QbB' (scale
to unit box)
or 'Qbb' (scale last coordinate) may remove this warning. Use 'Pp'
to skip
```

```
this warning.
```

To suppress this warning, use the option `'Pp'`. The following command passes the option `'Pp'`, along with the default `'Qt'`, to `convhull`.

```
K = convhull(X,Y,{'Qt','Pp'})

K =

     2
     1
     4
     2
```

Algorithm

`convhull` is based on Qhull [1]. For information about Qhull, see `http://www.qhull.org/`. For copyright information, see `http://www.qhull.org/COPYING.txt`.

See Also

`convhulln`, `delaunay`, `plot`, `polyarea`, `voronoi`

Reference

[1] Barber, C. B., D.P. Dobkin, and H.T. Huhdanpaa, "The Quickhull Algorithm for Convex Hulls," *ACM Transactions on Mathematical Software*, Vol. 22, No. 4, Dec. 1996, p. 469-483. Available in PDF format at `http://www.acm.org/pubs/citations/journals/toms/1996-22-4/p469-barber`.

[2] National Science and Technology Research Center for Computation and Visualization of Geometric Structures (The Geometry Center), *University of Minnesota*, 1993.

Purpose

N-D convex hull

Syntax

```
K = convhulln(X)
K = convulln(X, options)
[K, v] = convhulln(...)
```

Description

`K = convhulln(X)` returns the indices `K` of the points in `X` that comprise the facets of the convex hull of `X`. `X` is an `m`-by-`n` array representing `m` points in N-dimensional space. If the convex hull has `p` facets then `K` is `p`-by-`n`.

`convhulln` uses Qhull.

`K = convulln(X, options)` specifies a cell array of strings `options` to be used as options in Qhull. The default options are:

- `{'Qt'}` for 2-, 3-. and 4-dimensional input
- `{'Qt','Qx'}` for 5-dimensional input and higher.

If `options` is `[]`, the default options are used. If `options` is `{''}`, no options are used, not even the default. For more information on Qhull and its options, see `http://www.qhull.org/`.

`[K, v] = convhulln(...)` also returns the volume `v` of the convex hull.

Visualization

Plotting the output of `convhulln` depends on the value of `n`:

- For `n = 2`, use `plot` as you would for `convhull`.
- For `n = 3`, you can use `trisurf` to plot the output. The calling sequence is

  ```
  K = convhulln(X);
  trisurf(K,X(:,1),X(:,2),X(:,3))
  ```

  For more control over the color of the facets, use `patch` to plot the output. For an example, see “Tessellation and Interpolation

of Scattered Data in Higher Dimensions" in the MATLAB documentation.

- You cannot plot `convhulln` output for `n > 3`.

Example

The following example illustrates the `options` input for `convhulln`. The following commands

```
X = [0 0; 0 1e-10; 0 0; 1 1];
K = convhulln(X)
```

return a warning.

```
Warning: qhull precision warning:
The initial hull is narrow
(cosine of min. angle is 0.9999999999999998).
A coplanar point may lead to a wide facet.
Options 'QbB' (scale to unit box) or 'Qbb'
(scale last coordinate) may remove this warning.
Use 'Pp' to skip this warning.
```

To suppress the warning, use the option `'Pp'`. The following command passes the option `'Pp'`, along with the default `'Qt'`, to `convhulln`.

```
K = convhulln(X,{'Qt','Pp'})

K =

     1     4
     1     2
     4     2
```

Algorithm

`convhulln` is based on Qhull [1]. For information about Qhull, see `http://www.qhull.org/`. For copyright information, see `http://www.qhull.org/COPYING.txt`.

Reference

[1] Barber, C. B., D.P. Dobkin, and H.T. Huhdanpaa, "The Quickhull Algorithm for Convex Hulls," ACM *Transactions on Mathematical Software*, Vol. 22, No. 4, Dec. 1996, p. 469-483.

Purpose

N-D convolution

Syntax

```
C = convn(A,B)
C = convn(A,B,'shape')
```

Description

`C = convn(A,B)` computes the N-dimensional convolution of the arrays `A` and `B`. The size of the result is `size(A)+size(B)-1`.

`C = convn(A,B,'shape')` returns a subsection of the N-dimensional convolution, as specified by the `shape` parameter:

`'full'`	Returns the full N-dimensional convolution (default).
`'same'`	Returns the central part of the result that is the same size as `A`.
`'valid'`	Returns only those parts of the convolution that can be computed without assuming that the array A is zero-padded. The size of the result is `max(size(A)-size(B) + 1, 0)`

`conv`, `conv2`

Purpose

Copy file or directory

Graphical Interface

In the Current Directory browser, select **Edit > Copy**, then **Paste**. See details.

Syntax

```
copyfile('source','destination')
copyfile('source','destination','f')
[status,message,messageid] = copyfile('source','destination',
   'f')
```

Description

`copyfile('source','destination')` copies the file or directory, `source` (and all its contents) to the file or directory, `destination`, where `source` and `destination` are the absolute or relative pathnames for the directory or file. If `source` is a directory, `destination` cannot be a file. If `source` is a directory, `copyfile` copies the contents of `source`, not the directory itself. To rename a file or directory when copying it, make `destination` a different name than `source`. If `destination` already exists, `copyfile` replaces it without warning. Use the wildcard `*` at the end of `source` to copy all matching files. Note that the read-only and archive attributes of `source` are not preserved in `destination`.

`copyfile('source','destination','f')` copies `source` to `destination`, regardless of the read-only attribute of `destination`.

`[status,message,messageid] = copyfile('source','destination','f')` copies `source` to `destination`, returning the status, a message, and the MATLAB error message ID (see `error` and `lasterror`). Here, `status` is `1` for success and `0` for error. Only one output argument is required and the `f` input argument is optional.

Remarks

The `*` wildcard in a path string is supported. Current behavior of `copyfile` differs between UNIX and Windows when using the wildcard `*` or copying directories.

The timestamp given to the `destination` file is identical to that taken from the `source` file.

Examples

Copy File in Current Directory, Assigning a New Name to It

To make a copy of a file `myfun.m` in the current directory, assigning it the name `myfun2.m`, type

```
copyfile('myfun.m','myfun2.m')
```

Copy File to Another Directory

To copy `myfun.m` to the directory `d:/work/myfiles`, keeping the same filename, type

```
copyfile('myfun.m','d:/work/myfiles')
```

Copy All Matching Files by Using a Wildcard

To copy all files in the directory `myfiles` whose names begin with my to the directory `newprojects`, where `newprojects` is at the same level as the current directory, type

```
copyfile('myfiles/my*','../newprojects')
```

Copy Directory and Return Status

In this example, all files and subdirectories in the current directory's `myfiles` directory are copied to the `directory d:/work/myfiles`. Note that before running the `copyfile` function, `d:/work` does not contain the directory `myfiles`. It is created because `myfiles` is appended to `destination` in the `copyfile` function:

```
[s,mess,messid]=copyfile('myfiles','d:/work/myfiles')
s =
     1

mess =
     ''

messid =
     ''
```

The message returned indicates that `copyfile` was successful.

Copy File to Read-Only Directory

Copy `myfile.m` from the current directory to `d:/work/restricted`, where `restricted` is a read-only directory:

```
copyfile('myfile.m','d:/work/restricted','f')
```

After the copy, `myfile.m` exists in `d:/work/restricted`.

copyobj

Purpose

Copy graphics objects and their descendants

Syntax

```
new_handle = copyobj(h,p)
```

Description

`copyobj` creates copies of graphics objects. The copies are identical to the original objects except the copies have different values for their `Parent` property and a new handle. The new parent must be appropriate for the copied object (e.g., you can copy a line object only to another axes object).

`new_handle = copyobj(h,p)` copies one or more graphics objects identified by `h` and returns the handle of the new object or a vector of handles to new objects. The new graphics objects are children of the graphics objects specified by `p`.

Remarks

`h` and `p` can be scalars or vectors. When both are vectors, they must be the same length, and the output argument, `new_handle`, is a vector of the same length. In this case, `new_handle(i)` is a copy of `h(i)` with its `Parent` property set to `p(i)`.

When `h` is a scalar and `p` is a vector, `h` is copied once to each of the parents in `p`. Each `new_handle(i)` is a copy of `h` with its `Parent` property set to `p(i)`, and `length(new_handle)` equals `length(p)`.

When `h` is a vector and `p` is a scalar, each `new_handle(i)` is a copy of `h(i)` with its `Parent` property set to `p`. The length of `new_handle` equals `length(h)`.

Graphics objects are arranged as a hierarchy. See “Handle Graphics Objects” for more information.

Examples

Copy a surface to a new axes within a different figure.

```
h = surf(peaks);
colormap hot
figure    % Create a new figure
axes    % Create an axes object in the figure
new_handle = copyobj(h,gca);
```

```
colormap hot
view(3)
grid on
```

Note that while the surface is copied, the `colormap` (`figure` property), `view`, and `grid` (`axes` properties) are not copies.

`Parent` property for all graphics objects

"Finding and Identifying Graphics Objects" on page 1-93 for related functions

Purpose

Correlation coefficients

Syntax

```
R = corrcoef(X)
R = corrcoef(x,y)
[R,P]=corrcoef(...)
[R,P,RLO,RUP]=corrcoef(...)
[...]=corrcoef(...,'param1',val1,'param2',val2,...)
```

Description

`R = corrcoef(X)` returns a matrix `R` of correlation coefficients calculated from an input matrix `X` whose rows are observations and whose columns are variables. The matrix `R = corrcoef(X)` is related to the covariance matrix `C = cov(X)` by

$$R(i,j) = \frac{C(i,j)}{\sqrt{C(i,i)C(j,j)}}$$

`corrcoef(X)` is the zeroth lag of the normalized covariance function, that is, the zeroth lag of `xcov(x,'coeff')` packed into a square array.

`R = corrcoef(x,y)` where `x` and `y` are column vectors is the same as `corrcoef([x y])`. If `x` and `y` are not column vectors, `corrcoef` converts them to column vectors. For example, in this case `R=corrcoef(x,y)` is equivalent to `R=corrcoef([x(:) y(:)])`.

`[R,P]=corrcoef(...)` also returns `P`, a matrix of p-values for testing the hypothesis of no correlation. Each p-value is the probability of getting a correlation as large as the observed value by random chance, when the true correlation is zero. If `P(i,j)` is small, say less than `0.05`, then the correlation `R(i,j)` is significant.

`[R,P,RLO,RUP]=corrcoef(...)` also returns matrices `RLO` and `RUP`, of the same size as `R`, containing lower and upper bounds for a 95% confidence interval for each coefficient.

`[...]=corrcoef(...,'param1',val1,'param2',val2,...)` specifies additional parameters and their values. Valid parameters are the following.

'alpha'	A number between 0 and 1 to specify a confidence level of 100*(1 - alpha)%. Default is 0.05 for 95% confidence intervals.
'rows'	Either 'all' (default) to use all rows, 'complete' to use rows with no NaN values, or 'pairwise' to compute R(i,j) using rows with no NaN values in either column i or j.

The p-value is computed by transforming the correlation to create a t statistic having n-2 degrees of freedom, where n is the number of rows of X. The confidence bounds are based on an asymptotic normal distribution of 0.5*log((1+R)/(1-R)), with an approximate variance equal to 1/(n-3). These bounds are accurate for large samples when X has a multivariate normal distribution. The 'pairwise' option can produce an R matrix that is not positive definite.

Examples

Generate random data having correlation between column 4 and the other columns.

```
x = randn(30,4);     % Uncorrelated data
x(:,4) = sum(x,2);   % Introduce correlation.
[r,p] = corrcoef(x)  % Compute sample correlation and p-values.
[i,j] = find(p<0.05);  % Find significant correlations.
[i,j]                % Display their (row,col) indices.

r =
    1.0000   -0.3566    0.1929    0.3457
   -0.3566    1.0000   -0.1429    0.4461
    0.1929   -0.1429    1.0000    0.5183
    0.3457    0.4461    0.5183    1.0000

p =
    1.0000    0.0531    0.3072    0.0613
    0.0531    1.0000    0.4511    0.0135
    0.3072    0.4511    1.0000    0.0033
    0.0613    0.0135    0.0033    1.0000
```

```
ans =
     4     2
     4     3
     2     4
     3     4
```

`xcorr`, `xcov` in the Signal Processing Toolbox

Purpose

Cosine of argument in radians

Syntax

```
Y = cos(X)
```

Description

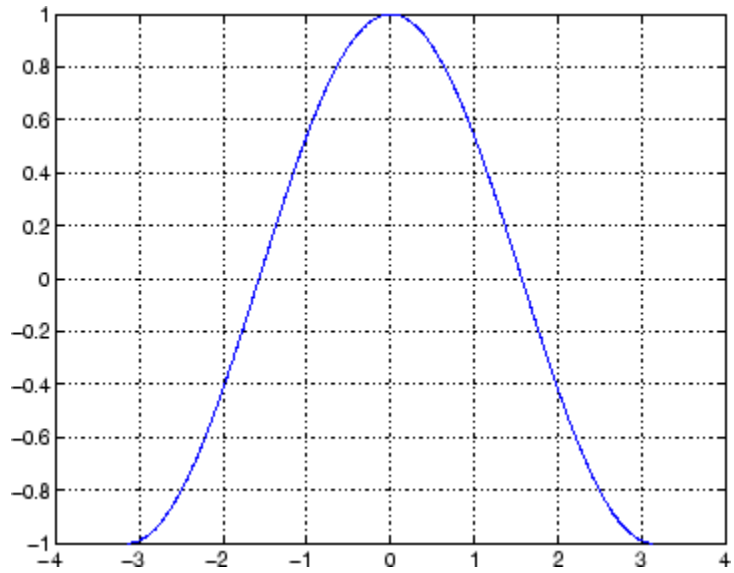
The `cos` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

`Y = cos(X)` returns the circular cosine for each element of `X`.

Examples

Graph the cosine function over the domain $-\pi \le x \le \pi$.

```
x = -pi:0.01:pi;
plot(x,cos(x)), grid on
```



The expression `cos(pi/2)` is not exactly zero but a value the size of the floating-point accuracy, `eps`, because `pi` is only a floating-point approximation to the exact value of π.

Definition

The cosine can be defined as

$$\cos(x+iy) = \cos(x)\cosh(y) - i\sin(x)\sinh(y)$$

$$\cos(z) = \frac{e^{iz}+e^{-iz}}{2}$$

Algorithm

`cos` uses FDLIBM, which was developed at SunSoft, a Sun Microsystems, Inc. business, by Kwok C. Ng, and others. For information about FDLIBM, see `http://www.netlib.org`.

See Also

`cosd`, `cosh`, `acos`, `acosd`, `acosh`

Purpose

Cosine ofo argument in degrees

Syntax

```
Y = cosd(X)
```

Description

`Y = cosd(X)` is the cosine of the elements of `X`, expressed in degrees. For odd integers `n`, `cosd(n*90)` is exactly zero, whereas `cos(n*pi/2)` reflects the accuracy of the floating point value of `pi`.

See Also

`cos`, `cosh`, `acos`, `acosd`, `acosh`

cosh

Purpose

Hyperbolic cosine

Syntax

```
Y = cosh(X)
```

Description

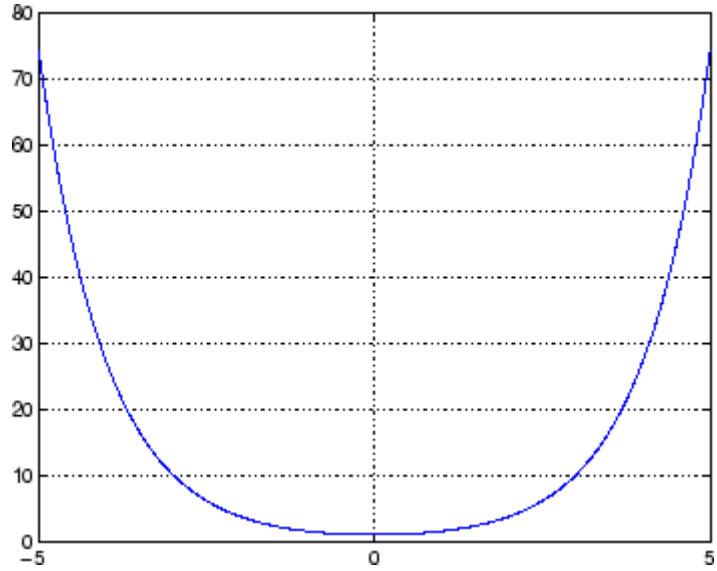
The `cosh` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

`Y = cosh(X)` returns the hyperbolic cosine for each element of `X`.

Examples

Graph the hyperbolic cosine function over the domain $-5 \le x \le 5$.

```
x = -5:0.01:5;
plot(x,cosh(x)), grid on
```



Definition

The hyperbolic cosine can be defined as

$$\cosh(z) = \frac{e^{z} + e^{-z}}{2}$$

Algorithm

`cosh` uses FDLIBM, which was developed at SunSoft, a Sun Microsystems, Inc. business, by Kwok C. Ng, and others. For information about FDLIBM, see `http://www.netlib.org`.

See Also

`acos`, `acosh`, `cos`

Purpose

Cotangent of argument in radians

Syntax

```
Y = cot(X)
```

Description

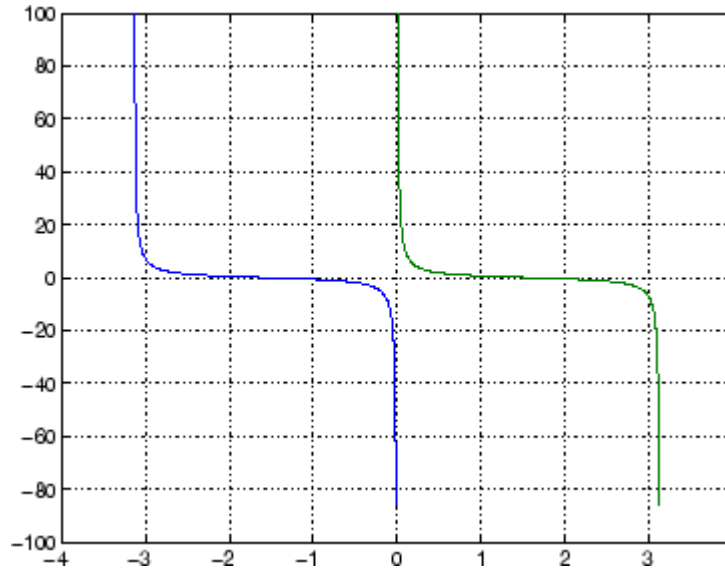
The `cot` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

`Y = cot(X)` returns the cotangent for each element of `X`.

Examples

Graph the cotangent the domains $-\pi < x < 0$ and $0 < x < \pi$.

```
x1 = -pi+0.01:0.01:-0.01;
x2 = 0.01:0.01:pi-0.01;
plot(x1,cot(x1),x2,cot(x2)), grid on
```



Definition

The cotangent can be defined as

$$\cot(z) = \frac{1}{\tan(z)}$$

Algorithm

`cot` uses FDLIBM, which was developed at SunSoft, a Sun Microsystems, Inc. business, by Kwok C. Ng, and others. For information about FDLIBM, see `http://www.netlib.org`.

See Also

`cotd`, `coth`, `acot`, `acotd`, `acoth`

cotd

Purpose

Cotangent of argument in degrees

Syntax

```
Y = cotd(X)
```

Description

`Y = cotd(X)` is the cotangent of the elements of `X`, expressed in degrees. For integers `n`, `cotd(n*180)` is infinite, whereas `cot(n*pi)` is large but finite, reflecting the accuracy of the floating point value of `pi`.

See Also

`cot`, `coth`, `acot`, `acotd`, `acoth`

Purpose

Hyperbolic cotangent

Syntax

```
Y = coth(X)
```

Description

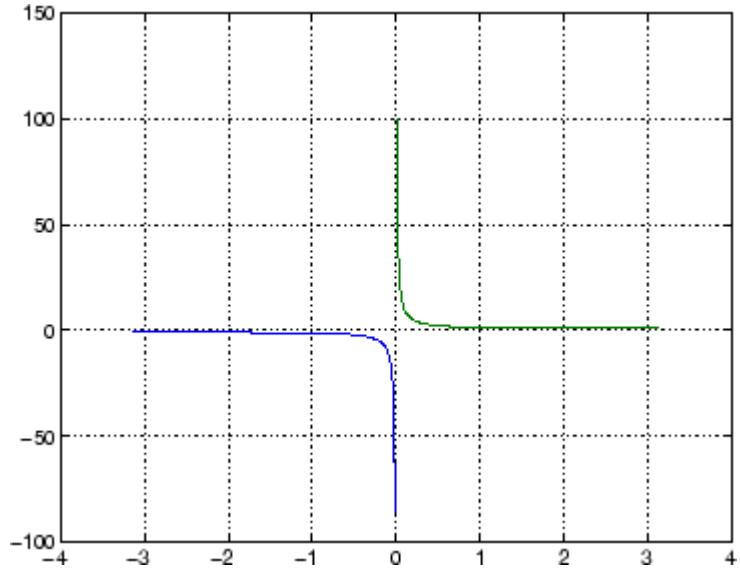
The `coth` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

`Y = coth(X)` returns the hyperbolic cotangent for each element of `X`.

Examples

Graph the hyperbolic cotangent over the domains $-\pi < x < 0$ and $0 < x < \pi$.

```
x1 = -pi+0.01:0.01:-0.01;
x2 = 0.01:0.01:pi-0.01;
plot(x1,coth(x1),x2,coth(x2)), grid on
```



Definition

The hyperbolic cotangent can be defined as

$$\coth(z) = \frac{1}{\tanh(z)}$$

Algorithm

`coth` uses FDLIBM, which was developed at SunSoft, a Sun Microsystems, Inc. business, by Kwok C. Ng, and others. For information about FDLIBM, see `http://www.netlib.org`.

See Also

`acot`, `acoth`, `cot`

Purpose

Covariance matrix

Syntax

```
cov(x)
cov(x) or cov(x,y)
cov(x,1) or cov(x,y,1)
```

Description

`cov(x)`, if `X` is a vector, returns the variance. For matrices, where each row is an observation, and each column is a variable, `cov(X)` is the covariance matrix. `diag(cov(X))` is a vector of variances for each column, and `sqrt(diag(cov(X)))` is a vector of standard deviations. `cov(X,Y)`, where `X` and `Y` are matrices with the same number of elements, is equivalent to `cov([X(:)  Y(:)])`.

`cov(x) or cov(x,y)` normalizes by N-1, if N>1, where N is the number of observations. This makes `cov(X)` the best unbiased estimate of the covariance matrix if the observations are from a normal distribution. For N=1, `cov normalizes by N.`

`cov(x,1) or cov(x,y,1)` normalizes by N and produces the second moment matrix of the observations about their mean. `cov(X,Y,0)` is the same as `cov(X,Y)` and `cov(X,0)` is the same as `cov(X)`.

Remarks

`cov` removes the mean from each column before calculating the result.

The *covariance* function is defined as

$$\mathrm{cov}(x_1,x_2) = E[(x_1-\mu_1)(x_2-\mu_2)]$$

where E is the mathematical expectation and $\mu_i = Ex_i$.

Examples

Consider `A = [-1 1 2 ; -2 3 1 ; 4 0 3]`. To obtain a vector of variances for each column of `A`:

```
v = diag(cov(A))'
v =
   10.3333    2.3333    1.0000
```

Compare vector `v` with covariance matrix `C`:

```
C =
   10.3333   -4.1667    3.0000
   -4.1667    2.3333   -1.5000
    3.0000   -1.5000    1.0000
```

The diagonal elements `C(i,i)` represent the variances for the columns of `A`. The off-diagonal elements `C(i,j)` represent the covariances of columns `i` and `j`.

See Also

`corrcoef`, `mean`, `median`, `std`, `var`

`xcorr`, `xcov` in the Signal Processing Toolbox

Purpose

Sort complex numbers into complex conjugate pairs

Syntax

```
B = cplxpair(A)
B = cplxpair(A,tol)
B = cplxpair(A,[],dim)
B = cplxpair(A,tol,dim)
```

Description

`B = cplxpair(A)` sorts the elements along different dimensions of a complex array, grouping together complex conjugate pairs.

The conjugate pairs are ordered by increasing real part. Within a pair, the element with negative imaginary part comes first. The purely real values are returned following all the complex pairs. The complex conjugate pairs are forced to be exact complex conjugates. A default tolerance of `100*eps` relative to `abs(A(i))` determines which numbers are real and which elements are paired complex conjugates.

If `A` is a vector, `cplxpair(A)` returns `A` with complex conjugate pairs grouped together.

If `A` is a matrix, `cplxpair(A)` returns `A` with its columns sorted and complex conjugates paired.

If `A` is a multidimensional array, `cplxpair(A)` treats the values along the first non-singleton dimension as vectors, returning an array of sorted elements.

`B = cplxpair(A,tol)` overrides the default tolerance.

`B = cplxpair(A,[],dim)` sorts `A` along the dimension specified by scalar dim.

`B = cplxpair(A,tol,dim)` sorts `A` along the specified dimension and overrides the default tolerance.

Diagnostics

If there are an odd number of complex numbers, or if the complex numbers cannot be grouped into complex conjugate pairs within the tolerance, `cplxpair` generates the error message

```
Complex numbers can't be paired.
```

cputime

Purpose

Elapsed CPU time

Syntax

```
cputime
```

Description

`cputime` returns the total CPU time (in seconds) used by MATLAB from the time it was started. This number can overflow the internal representation and wrap around.

Remarks

Although it is possible to measure performance using the `cputime` function, it is recommended that you use the `tic` and `toc` functions for this purpose exclusively. See Using tic and toc Versus the cputime Function in the MATLAB Programming documentation for more information.

Examples

The following code returns the CPU time used to run `surf(peaks(40))`.

```
t = cputime; surf(peaks(40)); e = cputime-t

e =
     0.4667
```

See Also

`clock`, `etime`, `tic`, `toc`

Purpose

Create MATLAB object based on WSDL file

Syntax

```
createClassFromWsdl('source')
```

Description

`createClassFromWsdl('source')` creates a MATLAB object based on a Web Services Description Language (WSDL) application program interface (API). The `source` argument specifies a URL or path to a WSDL API, which defines Web service methods, arguments, and transactions. It returns the name of the new class.

Based on the WSDL API, the `createClassFromWsdl` function creates a new folder in the current directory. The folder contains an M-file for each Web service method. In addition, two default M-files are created: the object's display method (`display.m`) and its constructor (`servicename.m`).

For example, if `myWebService` offers two methods (`method1` and `method2`), the `createClassFromWsdl` function creates

- `@myWebService` folder in the current directory
- `method1.m` — M-file for `method1`
- `method2.m` — M-file for `method2`
- `display.m` — Default M-file for `display` method
- `myWebService.m` — Default M-file for the `myWebService` MATLAB object

Remarks

For more information about WSDL and Web services, see the following resources:

- World Wide Web Consortium (W3C) WSDL specification
- W3C SOAP specification
- XMethods

Example

The following example calls a Web service that returns the stock price for an stock symbol.

```
cd(tempdir)
% Create a class for the Web service
% provided by xmethods.net
url = 'http://services.xmethods.net/soap/
  urn:xmethods-delayed-quotes.wsdl';
createClassFromWsdl(url);
% Instantiate the object
service = StockQuoteService;
% getQuote returns the price of a stock
getQuote(service, 'GOOG');
```

See Also

`callSoapService`, `createSoapMessage`, `parseSoapResponse`

Purpose

Create copy of `inputParser` object

Syntax

```
p.createCopy
createCopy(p)
```

Description

`p.createCopy` creates a copy of `inputParser` object `p`. Because the `inputParser` class uses handle semantics, a normal assignment statement does not create a copy.

`createCopy(p)` is functionally the same as the syntax above.

Note For more information on the `inputParser` class, see Parsing Inputs with inputParser in the MATLAB Programming documentation.

Examples

Write an M-file function called `publish_ip`, based on the MATLAB `publish` function, to illustrate the use of the `inputParser` class. Construct an instance of `inputParser` and assign it to variable `p`:

```
function publish_ip(script, varargin)
p = inputParser;   % Create an instance of the inputParser class.
```

Add arguments to the schema. See the reference pages for the `addRequired`, `addOptional`, and `addParamValue` methods for help with this:

```
p.addRequired('script', @ischar);
p.addOptional('format', 'html', ...
    @(x)any(strcmpi(x,{'html','ppt','xml','latex'})));
p.addParamValue('outputDir', pwd, @ischar);
p.addParamValue('maxHeight', [], @(x)x>0 && mod(x,1)==0);
p.addParamValue('maxWidth', [], @(x)x>0 && mod(x,1)==0);
```

Make a copy of object `p`, assigning it to variable `x`. Use the `Parameters` property of `inputParser` to list the arguments belonging to each object:

```
disp(' ')
```

```
disp 'The input parameters for object p are'
disp(p.Parameters')

x = p.createCopy;

disp(' ')
disp 'The input parameters for the copy of object p are'
disp(x.Parameters')
```

Save the M-file using the **Save** option on the MATLAB **File** menu, and then run it:

```
publish_ip('ipscript.m', 'ppt', 'maxWidth', 500, 'MAXHeight', 300);

The input parameters for object p are
    'format'
    'maxHeight'
    'maxWidth'
    'outputDir'
    'script'

The input parameters for the copy of object p are
    'format'
    'maxHeight'
    'maxWidth'
    'outputDir'
    'script'
```

See Also

`inputParser`, `addRequired(inputParser)`, `addOptional(inputParser)`, `addParamValue(inputParser)`, `parse(inputParser)`

Purpose

Create SOAP message to send to server

Syntax

```
createSoapMessage(namespace, method, values, names, types,
   style)
```

Description

`createSoapMessage(namespace, method, values, names, types, style)` creates a SOAP message. `values`, `names`, and `types` are cell arrays. `names` defaults to dummy names and `types` defaults to unspecified. The optional *`style`* argument specifies '**`document`**' or '**`rpc`**' messages; **`rpc`** is the default.

Example

```
message = createSoapMessage(...
 'urn:xmethods-delay-quotes',...
 'getQuote', ...
 {'GOOG'}, ...
 {'symbol'}, ...
 {'http://www.w3.org/2001/XMLSchema}string'}, ...
 'rpc');
response = callSoapService( ...
 'http://64.124.140.30:9090/soap', ...
 'urn:xmethods-delayed-quotes#getQuote' ...
 message);
price = parseSoapResponse(response)
```

See Also

`callSoapService`, `createClassFromWsdl`, `parseSoapResponse`

Purpose

Vector cross product

Syntax

```
C = cross(A,B)
C = cross(A,B,dim)
```

Description

`C = cross(A,B)` returns the cross product of the vectors `A` and `B`. That is, `C = A x B`. `A` and `B` must be 3-element vectors. If `A` and `B` are multidimensional arrays, `cross` returns the cross product of `A` and `B` along the first dimension of length 3.

`C = cross(A,B,dim)` where `A` and `B` are multidimensional arrays, returns the cross product of `A` and `B` in dimension `dim`. `A` and `B` must have the same size, and both `size(A,dim)` and `size(B,dim)` must be 3.

Remarks

To perform a dot (scalar) product of two vectors of the same size, use `c = dot(a,b)`.

Examples

The cross and dot products of two vectors are calculated as shown:

```
a = [1 2 3];
b = [4 5 6];
c = cross(a,b)

c =
      -3     6    -3

d = dot(a,b)

d =
      32
```

See Also

`dot`

Purpose

Cosecant of argument in radians

Syntax

```
Y = csc(x)
```

Description

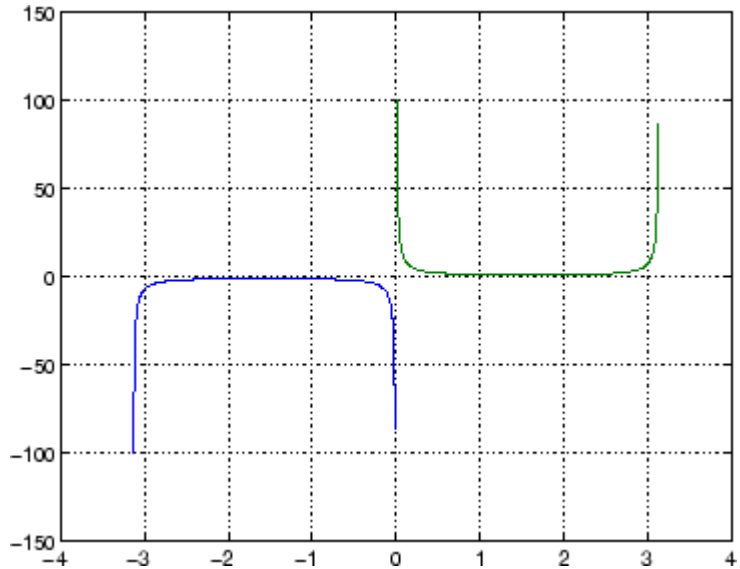
The `csc` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

`Y = csc(x)` returns the cosecant for each element of `x`.

Examples

Graph the cosecant over the domains $-\pi < x < 0$ and $0 < x < \pi$.

```
x1 = -pi+0.01:0.01:-0.01;
x2 = 0.01:0.01:pi-0.01;
plot(x1,csc(x1),x2,csc(x2)), grid on
```



Definition

The cosecant can be defined as

$$\csc(z) = \frac{1}{\sin(z)}$$

Algorithm

`csc` uses FDLIBM, which was developed at SunSoft, a Sun Microsystems, Inc. business, by Kwok C. Ng, and others. For information about FDLIBM, see `http://www.netlib.org`.

See Also

`cscd`, `csch`, `acsc`, `acscd`, `acsch`

Purpose

Cosecant of argument in degrees

Syntax

```
Y = cscd(X)
```

Description

`Y = cscd(X)` is the cosecant of the elements of `X`, expressed in degrees. For integers `n`, `cscd(n*180)` is infinite, whereas `csc(n*pi)` is large but finite, reflecting the accuracy of the floating point value of `pi`.

See Also

`csc`, `csch`, `acsc`, `acscd`, `acsch`

Purpose

Hyperbolic cosecant

Syntax

```
Y = csch(x)
```

Description

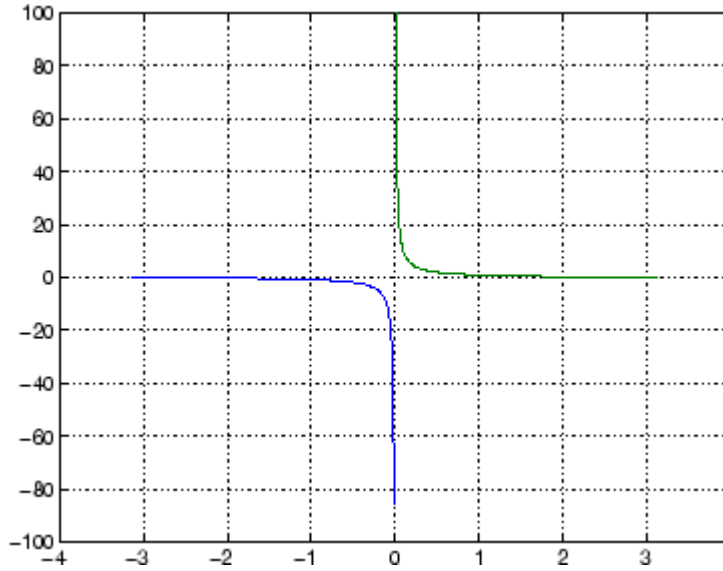
The `csch` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.

`Y = csch(x)` returns the hyperbolic cosecant for each element of `x`.

Examples

Graph the hyperbolic cosecant over the domains $-\pi < x < 0$ and $0 < x < \pi$.

```
x1 = -pi+0.01:0.01:-0.01;
x2 = 0.01:0.01:pi-0.01;
plot(x1,csch(x1),x2,csch(x2)), grid on
```



Definition

The hyperbolic cosecant can be defined as

$$\operatorname{csch}(z) = \frac{1}{\sinh(z)}$$

Algorithm

`csch` uses FDLIBM, which was developed at SunSoft, a Sun Microsystems, Inc. business, by Kwok C. Ng, and others. For information about FDLIBM, see `http://www.netlib.org`.

See Also

`acsc`, `acsch`, `csc`

Purpose

Read comma-separated value file

Syntax

```
M = csvread(filename)
M = csvread(filename, row, col)
M = csvread(filename, row, col, range)
```

Description

`M = csvread(filename)` reads a comma-separated value formatted file, `filename`. The `filename` input is a string enclosed in single quotes. The result is returned in `M`. The file can only contain numeric values.

`M = csvread(filename, row, col)` reads data from the comma-separated value formatted file starting at the specified row and column. The row and column arguments are zero based, so that `row=0` and `col=0` specify the first value in the file.

`M = csvread(filename, row, col, range)` reads only the range specified. Specify `range` using the notation `[R1 C1 R2 C2]` where (`R1`,`C1`) is the upper left corner of the data to be read and (`R2`,`C2`) is the lower right corner. You can also specify the range using spreadsheet notation, as in `range = 'A1..B7'`.

Remarks

`csvread` fills empty delimited fields with zero. Data files having lines that end with a nonspace delimiter, such as a semicolon, produce a result that has an additional last column of zeros.

`csvread` imports any complex number as a whole into a complex numeric field, converting the real and imaginary parts to the specified numeric type. Valid forms for a complex number are

Form	Example
`–<real>–<imag>i|j`	`5.7-3.1i`
`–<imag>i|j`	`-7j`

Embedded white-space in a complex number is invalid and is regarded as a field delimiter.

Examples

Given the file `csvlist.dat` that contains the comma-separated values

```
02, 04, 06, 08, 10, 12
03, 06, 09, 12, 15, 18
05, 10, 15, 20, 25, 30
07, 14, 21, 28, 35, 42
11, 22, 33, 44, 55, 66
```

To read the entire file, use

```
csvread('csvlist.dat')

ans =

     2     4     6     8    10    12
     3     6     9    12    15    18
     5    10    15    20    25    30
     7    14    21    28    35    42
    11    22    33    44    55    66
```

To read the matrix starting with zero-based row 2, column 0, and assign it to the variable `m`,

```
m = csvread('csvlist.dat', 2, 0)

m =

     5    10    15    20    25    30
     7    14    21    28    35    42
    11    22    33    44    55    66
```

To read the matrix bounded by zero-based (2,0) and (3,3) and assign it to `m`,

```
m = csvread('csvlist.dat', 2, 0, [2,0,3,3])

m =
```

```
     5    10    15    20
     7    14    21    28
```

See Also

csvwrite, dlmread, textscan, wk1read, file formats, importdata, uiimport

Purpose

Write comma-separated value file

Syntax

```
csvwrite(filename,M)
csvwrite(filename,M,row,col)
```

Description

`csvwrite(filename,M)` writes matrix `M` into `filename` as comma-separated values. The `filename` input is a string enclosed in single quotes.

`csvwrite(filename,M,row,col)` writes matrix `M` into `filename` starting at the specified row and column offset. The row and column arguments are zero based, so that `row=0` and `C=0` specify the first value in the file.

Remarks

`csvwrite` terminates each line with a line feed character and no carriage return.

Examples

The following example creates a comma-separated value file from the matrix `m`.

```
m = [3 6 9 12 15; 5 10 15 20 25; ...
     7 14 21 28 35; 11 22 33 44 55];

csvwrite('csvlist.dat',m)
type csvlist.dat

3,6,9,12,15
5,10,15,20,25
7,14,21,28,35
11,22,33,44,55
```

The next example writes the matrix to the file, starting at a column offset of `2`.

```
csvwrite('csvlist.dat',m,0,2)
type csvlist.dat
```

```
,,3,6,9,12,15
,,5,10,15,20,25
,,7,14,21,28,35
,,11,22,33,44,55
```

See Also

csvread, dlmwrite, wk1write, file formats, importdata, uiimport

Purpose

Transpose `timeseries` object

Syntax

```
ts1 = ctranspose(ts)
```

Description

`ts1 = ctranspose(ts)` returns a new `timeseries` object `ts1` with `IsTimeFirst` value set to the opposite of what it is for `ts`. For example, if `ts` has the first data dimension aligned with the time vector, `ts1` has the last data dimension aligned with the time vector as a result of this operation.

Remarks

The `ctranspose` function that is overloaded for `timeseries` objects does not transpose the data. Instead, this function changes whether the first or the last dimension of the data is aligned with the time vector.

Note To transpose the data, you must transpose the `Data` property of the `timeseries` object. For example, you can use the syntax `ctranspose(ts.Data)` or `(ts.Data)'`. `Data` must be a 2-D array.

Consider a `timeseries` object with 10 samples with the property `IsTimeFirst = True`. When you transpose this object, the data size is changed from 10-by-1 to 1-by-1-by-10. Note that the first dimension of the `Data` property is shown explicitly.

The following table summarizes how MATLAB displays the size for Data property of the `timeseries` object (up to three dimensions) before and after transposing.

Data Size Before and After Transposing

Size of Original Data	Size of Transposed Data
N-by-1	1-by-1-by-N

Data Size Before and After Transposing (Continued)

Size of Original Data	Size of Transposed Data
N-by-M	M-by-1-by-N
N-by-M-by-L	M-by-L-by-N

Examples

Suppose that a `timeseries` object `ts` has `ts.data` size 10-by-3-by-2 and its time vector has a length of 10. The `IsTimeFirst` property of `ts` is set to `true`, which means that the first dimension of the data is aligned with the time vector. `ctranspose(ts)` modifies `ts` such that the last dimension of the data is now aligned with the time vector. This permutes the data such that the size of `ts.Data` becomes 3-by-2-by-10.

See Also

`transpose (timeseries)`, `tsprops`

Purpose

Cumulative product

Syntax

```
B = cumprod(A)
B = cumprod(A,dim)
```

Description

`B = cumprod(A)` returns the cumulative product along different dimensions of an array.

If `A` is a vector, `cumprod(A)` returns a vector containing the cumulative product of the elements of `A`.

If `A` is a matrix, `cumprod(A)` returns a matrix the same size as `A` containing the cumulative products for each column of `A`.

If `A` is a multidimensional array, `cumprod(A)` works on the first nonsingleton dimension.

`B = cumprod(A,dim)` returns the cumulative product of the elements along the dimension of `A` specified by scalar `dim`. For example, `cumprod(A,1)` increments the first (row) index, thus working along the rows of `A`.

Examples

```
cumprod(1:5)
ans =
     1  2  6  24  120

A = [1 2 3; 4 5 6];

cumprod(A)
ans =
     1     2     3
     4    10    18

cumprod(A,2)
ans =
     1     2     6
     4    20   120
```

See Also

cumsum, prod, sum

Purpose

Cumulative sum

Syntax

```
B = cumsum(A)
B = cumsum(A,dim)
```

Description

`B = cumsum(A)` returns the cumulative sum along different dimensions of an array.

If `A` is a vector, `cumsum(A)` returns a vector containing the cumulative sum of the elements of `A`.

If `A` is a matrix, `cumsum(A)` returns a matrix the same size as `A` containing the cumulative sums for each column of `A`.

If `A` is a multidimensional array, `cumsum(A)` works on the first nonsingleton dimension.

`B = cumsum(A,dim)` returns the cumulative sum of the elements along the dimension of `A` specified by scalar `dim`. For example, `cumsum(A,1)` works across the first dimension (the rows).

Examples

```
cumsum(1:5)
ans =
       [1  3  6  10  15]

A = [1 2 3; 4 5 6];

cumsum(A)
ans =
       1     2     3
       5     7     9

cumsum(A,2)
ans =
       1     3     6
       4     9    15
```

See Also

`cumprod`, `prod`, `sum`

Purpose

Cumulative trapezoidal numerical integration

Syntax

```
Z = cumtrapz(Y)
Z = cumtrapz(X,Y)
Z = cumtrapz(X,Y,dim) or cumtrapz(Y,dim)
```

Description

`Z = cumtrapz(Y)` computes an approximation of the cumulative integral of `Y` via the trapezoidal method with unit spacing. To compute the integral with other than unit spacing, multiply `Z` by the spacing increment. Input `Y` can be complex.

For vectors, `cumtrapz(Y)` is a vector containing the cumulative integral of `Y`.

For matrices, `cumtrapz(Y)` is a matrix the same size as `Y` with the cumulative integral over each column.

For multidimensional arrays, `cumtrapz(Y)` works across the first nonsingleton dimension.

`Z = cumtrapz(X,Y)` computes the cumulative integral of `Y` with respect to `X` using trapezoidal integration. `X` and `Y` must be vectors of the same length, or `X` must be a column vector and `Y` an array whose first nonsingleton dimension is `length(X)`. `cumtrapz` operates across this dimension. Inputs `X` and `Y` can be complex.

If `X` is a column vector and `Y` an array whose first nonsingleton dimension is `length(X)`, `cumtrapz(X,Y)` operates across this dimension.

`Z = cumtrapz(X,Y,dim) or cumtrapz(Y,dim)` integrates across the dimension of `Y` specified by scalar `dim`. The length of `X` must be the same as `size(Y,dim)`.

Example

Example 1

```
Y = [0 1 2; 3 4 5];

cumtrapz(Y,1)
ans =
0         0         0
```

```
    1.5000   2.5000    3.5000

cumtrapz(Y,2)
ans =
0    0.5000    2.0000
        0    3.5000    8.0000
```

Example 2

This example uses two complex inputs:

```
z = exp(1i*pi*(0:100)/100);

ct = cumtrapz(z,1./z);
ct(end)
ans =
   0.0000 + 3.1411i
```

See Also

cumsum, trapz

curl

Purpose

Compute curl and angular velocity of vector field

Syntax

```
[curlx,curly,curlz,cav] = curl(X,Y,Z,U,V,W)
[curlx,curly,curlz,cav] = curl(U,V,W)
[curlz,cav]= curl(X,Y,U,V)
[curlz,cav]= curl(U,V)
[curlx,curly,curlz] = curl(...), curlx,curly] = curl(...)
cav = curl(...)
```

Description

`[curlx,curly,curlz,cav] = curl(X,Y,Z,U,V,W)` computes the curl and angular velocity perpendicular to the flow (in radians per time unit) of a 3-D vector field `U`, `V`, `W`. The arrays `X`, `Y`, `Z` define the coordinates for `U`, `V`, `W` and must be monotonic and 3-D plaid (as if produced by `meshgrid`).

`[curlx,curly,curlz,cav] = curl(U,V,W)` assumes `X`, `Y`, and `Z` are determined by the expression

```
[X Y Z] = meshgrid(1:n,1:m,1:p)
```

where `[m,n,p] = size(U)`.

`[curlz,cav]= curl(X,Y,U,V)` computes the curl z-component and the angular velocity perpendicular to `z` (in radians per time unit) of a 2-D vector field `U`, `V`. The arrays `X`, `Y` define the coordinates for `U`, `V` and must be monotonic and 2-D plaid (as if produced by `meshgrid`).

`[curlz,cav]= curl(U,V)` assumes `X` and `Y` are determined by the expression

```
[X Y] = meshgrid(1:n,1:m)
```

where `[m,n] = size(U)`.

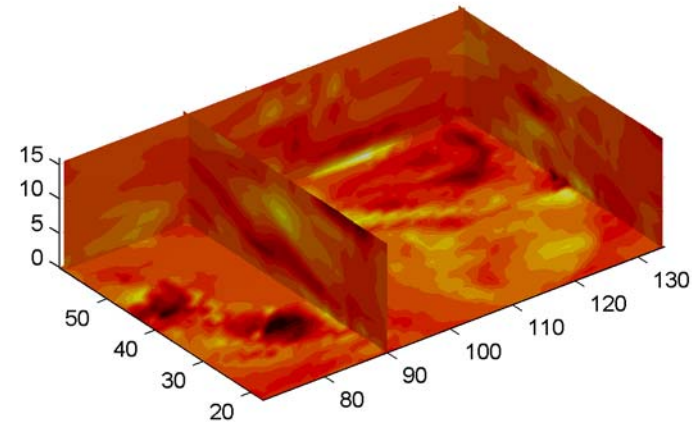
`[curlx,curly,curlz] = curl(...), curlx,curly] = curl(...)` returns only the curl.

`cav = curl(...)` returns only the curl angular velocity.

Examples

This example uses colored slice planes to display the curl angular velocity at specified locations in the vector field.

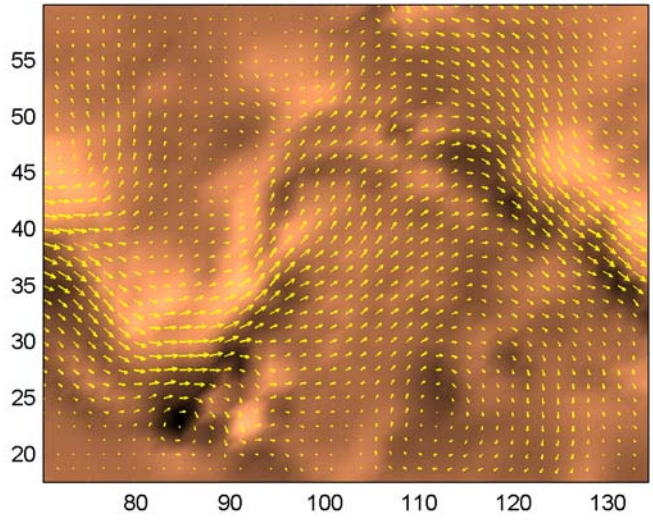
```
load wind
cav = curl(x,y,z,u,v,w);
slice(x,y,z,cav,[90 134],[59],[0]);
shading interp
daspect([1 1 1]); axis tight
colormap hot(16)
camlight
```



This example views the curl angular velocity in one plane of the volume and plots the velocity vectors (`quiver`) in the same plane.

```
load wind
k = 4;
x = x(:,:,k); y = y(:,:,k); u = u(:,:,k); v = v(:,:,k);
cav = curl(x,y,u,v);
pcolor(x,y,cav); shading interp
hold on;
quiver(x,y,u,v,'y')
```

```
hold off
colormap copper
```



See Also

`streamribbon`, `divergence`

"Volume Visualization" on page 1-102 for related functions

"Example — Displaying Curl with Stream Ribbons" for another example

Purpose

Allow custom source control system (UNIX)

Syntax

```
customerverctrl
```

Description

`customerverctrl` function is for customers who want to integrate a source control system that is not supported with MATLAB. When using this function, conform to the structure of one of the supported version control systems, for example, RCS. For examples, see the files `clearcase.m`, `cvs.m`, `pvcs.m`, and `rcs.m` in *`matlabroot`*`\toolbox\matlab\verctrl`.

See Also

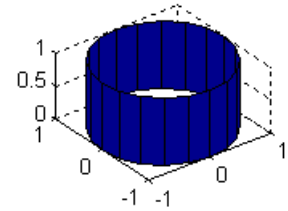
`checkin`, `checkout`, `cmopts`, `undocheckout`

For Windows platforms, use `verctrl`.

cylinder

Purpose

Generate cylinder



Syntax

```
[X,Y,Z] = cylinder
[X,Y,Z] = cylinder(r)
[X,Y,Z] = cylinder(r,n)
cylinder(axes_handle,...)
cylinder(...)
```

Description

`cylinder` generates *x*-, *y*-, and *z*-coordinates of a unit cylinder. You can draw the cylindrical object using `surf` or `mesh`, or draw it immediately by not providing output arguments.

`[X,Y,Z] = cylinder` returns the *x*-, *y*-, and *z*-coordinates of a cylinder with a radius equal to `1`. The cylinder has 20 equally spaced points around its circumference.

`[X,Y,Z] = cylinder(r)` returns the *x*-, *y*-, and *z*-coordinates of a cylinder using `r` to define a profile curve. `cylinder` treats each element in `r` as a radius at equally spaced heights along the unit height of the cylinder. The cylinder has 20 equally spaced points around its circumference.

`[X,Y,Z] = cylinder(r,n)` returns the *x*-, *y*-, and *z*-coordinates of a cylinder based on the profile curve defined by vector `r`. The cylinder has `n` equally spaced points around its circumference.

`cylinder(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`cylinder(...)`, with no output arguments, plots the cylinder using `surf`.

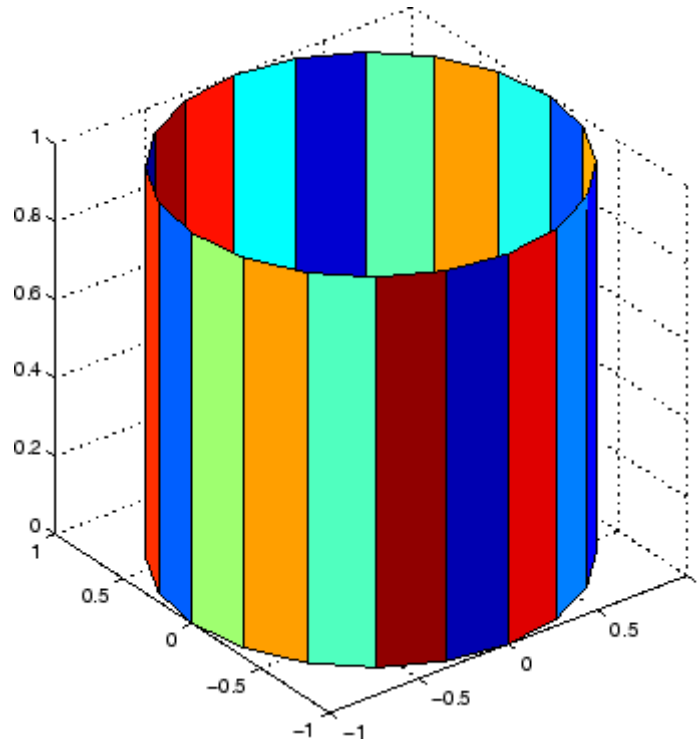
Remarks

`cylinder` treats its first argument as a profile curve. The resulting surface graphics object is generated by rotating the curve about the *x*-axis, and then aligning it with the *z*-axis.

Examples

Create a cylinder with randomly colored faces.

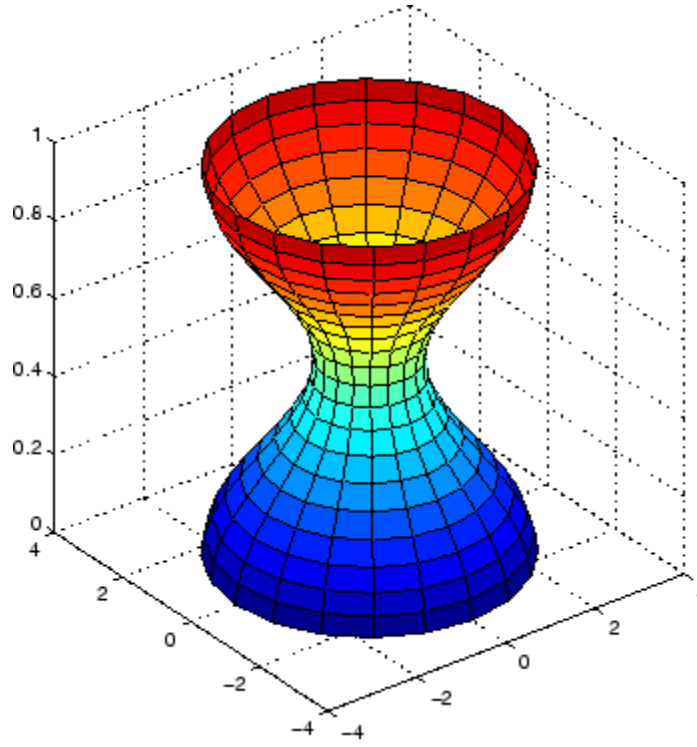
```
cylinder
axis square
h = findobj('Type','surface');
set(h,'CData',rand(size(get(h,'CData'))))
```



Generate a cylinder defined by the profile function `2+sin(t)`.

```
t = 0:pi/10:2*pi;
```

```
[X,Y,Z] = cylinder(2+cos(t));
surf(X,Y,Z)
axis square
```



See Also

`sphere`, `surf`

“Polygons and Surfaces” on page 1-90 for related functions

Purpose

Read Data Acquisition Toolbox (.daq) file

Syntax

```
data = daqread('filename')
[data, time] = daqread(...)
[data, time, abstime] = daqread(...)
[data, time, abstime, events] = daqread(...)
[data, time, abstime, events, daqinfo] = daqread(...)
data = daqread(...,'Param1', Val1,...)
daqinfo = daqread('filename','info')
```

Description

`data = daqread('filename')` reads all the data from the Data Acquisition Toolbox (`.daq`) file specified by `filename`. `daqread` returns `data`, an *m*-by-*n* data matrix, where *m* is the number of samples and *n* is the number of channels. If `data` includes data from multiple triggers, the data from each trigger is separated by a `NaN`. If you set the `OutputFormat` property to `tscollection`, `daqread` returns a time series collection object. See below for more information.

`[data, time] = daqread(...)` returns time/value pairs. `time` is an *m*-by-1 vector, the same length as `data`, that contains the relative time for each sample. Relative time is measured with respect to the first trigger that occurs.

`[data, time, abstime] = daqread(...)` returns the absolute time of the first trigger. `abstime` is returned as a `clock` vector.

`[data, time, abstime, events] = daqread(...)` returns a log of events. `events` is a structure containing event information. If you specify either the`Samples`, `Time`, or `Triggers` parameters (see below), the events structure contains only the specified events.

`[data, time, abstime, events, daqinfo] = daqread(...)` returns a structure, `daqinfo`, that contains two fields: `ObjInfo` and `HwInfo`. `ObjInfo` is a structure containing property name/property value pairs and `HwInfo` is a structure containing hardware information. The entire event log is returned to `daqinfo.ObjInfo.EventLog`.

`data = daqread(...,'Param1', Val1,...)` specifies the amount of data returned and the format of the data, using the following parameters.

Parameter	Description
`Samples`	Specify the sample range.
`Time`	Specify the relative time range.
`Triggers`	Specify the trigger range.
`Channels`	Specify the channel range. Channel names can be specified as a cell array.
`DataFormat`	Specify the data format as `doubles` (default) or `native`.
`TimeFormat`	Specify the time format as `vector` (default) or `matrix`.
`OutputFormat`	Specify the output format as `matrix` (the default) or `tscollection`. When you specify `tscollection`, `daqread` only returns `data`.

The `Samples`, `Time`, and `Triggers` properties are mutually exclusive; that is, either `Samples`, `Triggers` or `Time` can be defined at once.

`daqinfo = daqread('filename','info')` returns metadata from the file in the `daqinfo` structure, without incurring the overhead of reading the data from the file as well. The `daqinfo` structure contains two fields:

`daqinfo.ObjInfo`
: a structure containing parameter/value pairs for the data acquisition object used to create the file, `filename`. Note: The `UserData` property value is not restored.

`daqinfo.HwInfo`
: a structure containing hardware information. The entire event log is returned to `daqinfo.ObjInfo.EventLog`.

Remarks

More About .daq Files

- The format used by `daqread` to return data, relative time, absolute time, and event information is identical to the format used by the `getdata` function that is part of Data Acquisition Toolbox. For more information, see the Data Acquisition Toolbox documentation.
- If data from multiple triggers is read, then the size of the resulting data array is increased by the number of triggers issued because each trigger is separated by a `NaN`.
- `ObjInfo.EventLog` always contains the entire event log regardless of the value specified by `Samples`, `Time`, or `Triggers`.
- The `UserData` property value is not restored when you return device object (`ObjInfo`) information.
- When reading a `.daq` file, the `daqread` function does not return property values that were specified as a cell array.
- Data Acquisition Toolbox (`.daq`) files are created by specifying a value for the `LogFileName` property (or accepting the default value), and configuring the `LoggingMode` property to `Disk` or `Disk&Memory`.

More About Time Series Collection Object Returned

When `OutputFormat` is set to `tscollection`, `daqread` returns a time series collection object. This times series collection object contains an absolute time series object for each channel in the file. The following describes how `daqread` sets some of the properties of the times series collection object and the time series objects.

- The `time` property of the time series collection object is set to the value of the `InitialTriggerTime` property specified in the file.
- The `name` property of each time series object is set to the value of the `Name` property of a channel in the file. If this name cannot be used as a time series object name, `daqread` sets the name to `'Channel'` with the `HwChannel` property of the channel appended.

- The value of the Units property of the time series object depends on the value of the DataFormat parameter. If the DataFormat parameter is set to 'double', daqread sets the DataInfo property of each time series object in the collection to the value of the Units property of the corresponding channel in the file. If the DataFormat parameter is set to 'native', daqread sets the Units property to 'native'. See the Data Acquisition Toolbox documentation for more information on these properties.
- Each time series object will have tsdata.event objects attached corresponding to the log of events associated with the channel.

If daqread returns data from multiple triggers, the data from each trigger is separated by a NaN in the time series data. This increases the length of data and time vectors in the time series object by the number of triggers.

Examples

Use Data Acquisition Toolbox to acquire data. The analog input object, ai, acquires one second of data for four channels, and saves the data to the output file data.daq.

```
ai = analoginput('nidaq','Dev1');
chans = addchannel(ai,0:3);
set(ai,'SampleRate',1000)
ActualRate = get(ai,'SampleRate');
set(ai,'SamplesPerTrigger, ActualRate)
set(ai,'LoggingMode','Disk&Memory')
set(ai,'LogFileName','data.daq')
start(ai)
```

After the data has been collected and saved to a disk file, you can retrieve the data and other acquisition-related information using daqread. To read all the sample-time pairs from data.daq:

```
[data,time] = daqread('data.daq');
```

To read samples 500 to 1000 for all channels from data.daq:

```
data = daqread('data.daq','Samples',[500 1000]);
```

To read only samples 1000 to 2000 of channel indices 2, 4 and 7 in native format from the file, `data.daq`:

```
data = daqread('data.daq', 'Samples', [1000 2000],...
               'Channels', [2 4 7], 'DataFormat', 'native');
```

To read only the data which represents the first and second triggers on all channels from the file, `data.daq`:

```
[data, time] = daqread('data.daq', 'Triggers', [1 2]);
```

To obtain the channel property information from `data.daq`:

```
daqinfo = daqread('data.daq','info');
chaninfo = daqinfo.ObjInfo.Channel;
```

To obtain a list of event types and event data contained by `data.daq`:

```
daqinfo = daqread('data.daq','info');
events = daqinfo.ObjInfo.EventLog;
event_type = {events.Type};
event_data = {events.Data};
```

To read all the data from the file `data.daq` and return it as a time series collection object:

```
data = daqread('data.daq','OutputFormat','tscollection');
```

Functions

`timeseries`, `tscollection`

For more information about using this function, see the Data Acquisition Toolbox documentation.

daspect

Purpose

Set or query axes data aspect ratio

Syntax

```
daspect
daspect([aspect_ratio])
daspect('mode')
daspect('auto')
daspect('manual')
daspect(axes_handle,...)
```

Description

The data aspect ratio determines the relative scaling of the data units along the *x*-, *y*-, and *z*-axes.

`daspect` with no arguments returns the data aspect ratio of the current axes.

`daspect([aspect_ratio])` sets the data aspect ratio in the current axes to the specified value. Specify the aspect ratio as three relative values representing the ratio of the *x*-, *y*-, and *z*-axis scaling (e.g., `[1 1 3]` means one unit in *x* is equal in length to one unit in *y* and three units in *z*).

`daspect('mode')` returns the current value of the data aspect ratio mode, which can be either `auto` (the default) or `manual`. See Remarks.

`daspect('auto')` sets the data aspect ratio mode to `auto`.

`daspect('manual')` sets the data aspect ratio mode to `manual`.

`daspect(axes_handle,...)` performs the set or query on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, `daspect` operates on the current axes.

Remarks

`daspect` sets or queries values of the axes object `DataAspectRatio` and `DataAspectRatioMode` properties.

When the data aspect ratio mode is `auto`, MATLAB adjusts the data aspect ratio so that each axis spans the space available in the figure window. If you are displaying a representation of a real-life object, you should set the data aspect ratio to `[1 1 1]` to produce the correct proportions.

Setting a value for data aspect ratio or setting the data aspect ratio mode to `manual` disables the MATLAB stretch-to-fill feature (stretching of the axes to fit the window). This means setting the data aspect ratio to a value, including its current value,

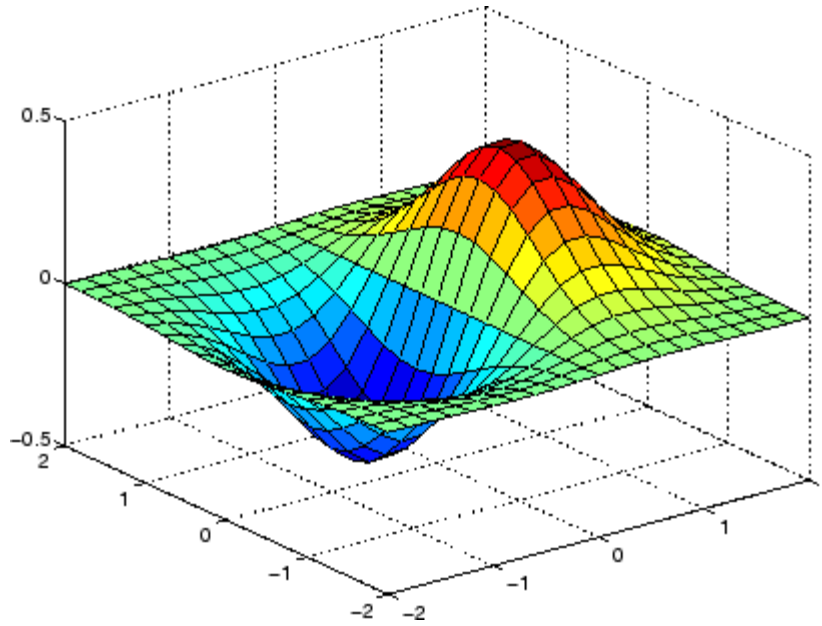
```
daspect(daspect)
```

can cause a change in the way the graphs look. See the Remarks section of the `axes` description for more information.

Examples

The following surface plot of the function $z = xe^{(-x^2 - y^2)}$ is useful to illustrate the data aspect ratio. First plot the function over the range $-2 \le x \le 2$, $-2 \le y \le 2$,

```
[x,y] = meshgrid([-2:.2:2]);
z = x.*exp(-x.^2 - y.^2);
surf(x,y,z)
```



Querying the data aspect ratio shows how MATLAB has drawn the surface.

```
daspect
ans =
     4   4   1
```

Setting the data aspect ratio to `[1 1 1]` produces a surface plot with equal scaling along each axis.

```
daspect([1 1 1])
```

Purpose

Enable or disable interactive data cursor mode

GUI Alternatives

Use the Data Cursor tool  to label x, y, and z values on graphs and surfaces. For details, see Data Cursor — Displaying Data Values Interactively in the MATLAB Graphics documentation.

Syntax

```
datacursormode on
datacursormode off
datacursormode
datacursormode(figure_handle,...)
dcm_obj = datacursormode(figure_handle)
```

Description

`datacursormode on` enables data cursor mode on the current figure.

`datacursormode off` disables data cursor mode on the current figure.

`datacursormode` toggles data cursor mode on the current figure.

`datacursormode(figure_handle,...)` enables or disables data cursor mode on the specified figure.

`dcm_obj = datacursormode(figure_handle)` returns the figure's data cursor mode object, which enables you to customize the data cursor. See "Data Cursor Mode Object" on page 2-751.

Data Cursor Mode Object

The data cursor mode object has properties that enable you to controls certain aspects of the data cursor. You can use the `set` and `get` commands and the returned object (`dcm_obj` in the above syntax) to set and query property values.

Data Cursor Mode Properties

`Enable`
on | off

Specifies whether this mode is currently enabled on the figure.

`SnapToDataVertex`
on | off

Specifies whether the data cursor snaps to the nearest data value or is located at the actual pointer position.

`DisplayStyle`
datatip | window

Determines how the data is displayed.

- `datatip` displays cursor information in a yellow text box next to a marker indicating the actual data point being displayed.
- `window` displays cursor information in a floating window within the figure.

`Updatefcn`
function handle

This property references a function that customizes the text appearing in the data cursor. The function handle must reference a function that has two implicit arguments (these arguments are automatically passed to the function by MATLAB when the function executes). For example, the following function definition line uses the required arguments:

```
function output_txt = myfunction(obj,event_obj)
% obj    Currently not used (empty)
% event_obj    Handle to event object
% output_txt    Data cursor text string (string or cell array of
%     strings).
```

`event_obj` is an object having the following read-only properties.

- `Target` — Handle of the object the data cursor is referencing (the object on which the user clicked).
- `Position` — An array specifying the x, y, (and z for 3-D graphs) coordinates of the cursor.

You can query these properties within your function. For example,

```
pos = get(event_obj,'Position');
```

returns the coordinates of the cursor.

See `Function Handles` for more information on creating a function handle.

See “Change Data Cursor Text” on page 2-755 for an example.

Data Cursor Method

You can use the `getCursorInfo` function with the data cursor mode object (`dcm_obj` in the above syntax) to obtain information about the data cursor. For example,

```
info_struct = getCursorInfo(dcm_obj);
```

returns a vector of structures, one for each data cursor on the graph. Each structure has the following fields:

- `Target` — The handle of the graphics object containing the data point.
- `Position` — An array specifying the x, y, (and z) coordinates of the cursor.

Line and lineseries objects have an additional field:

- `DataIndex` — A scalar index into the data arrays that correspond to the nearest data point. The value is the same for each array.

Examples

This example creates a plot and enables data cursor mode from the command line.

```
surf(peaks)
datacursormode on
% Click mouse on surface to display data cursor
```

Setting Data Cursor Mode Options

This example enables data cursor mode on the current figure and sets data cursor mode options. The following statements

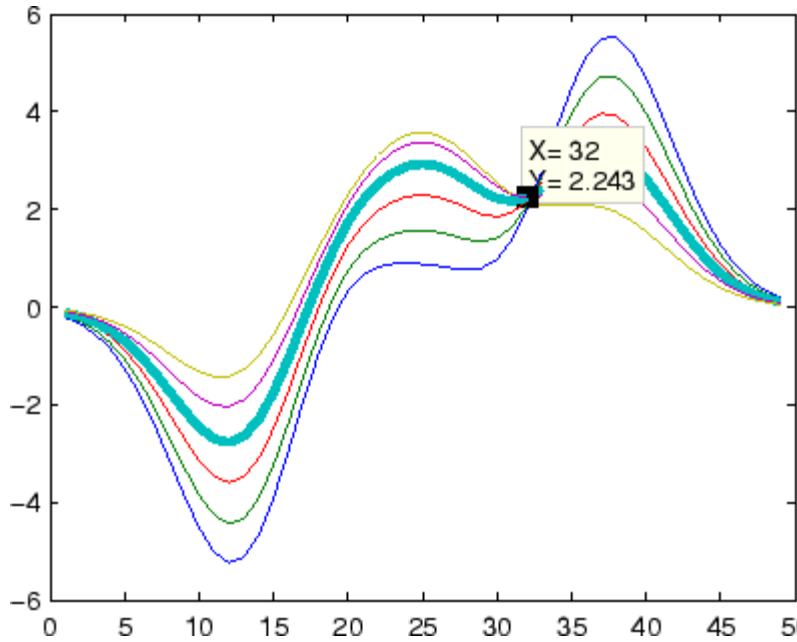
- Create a graph

- Toggle data cursor mode to on
- Save the data cursor mode object to specify options and get the handle of the line to which the datatip is attached

```
fig = figure;
z = peaks;
plot(z(:,30:35))
dcm_obj = datacursormode(fig);
set(dcm_obj,'DisplayStyle','datatip',...
'SnapToDataVertex','off','Enable','on')

% Click on line to place datatip

c_info = getCursorInfo(dcm_obj);
set(c_info.Target,'LineWidth',2) % Make
selected line wider
```



Change Data Cursor Text

This example shows you how to customize the text that is displayed by the data cursor. Suppose you want to replace the text displayed in the datatip and data window with “Time:” and “Amplitude:”

```
function doc_datacursormode
fig = figure;
a = -16; t = 0:60;
plot(t,sin(a*t))
dcm_obj = datacursormode(fig);
set(dcm_obj,'UpdateFcn',@myupdatefcn)

% Click on line to select data point

function txt = myupdatefcn(empt,event_obj)
pos = get(event_obj,'Position');
txt = {['Time: ',num2str(pos(1))],...
 ['Amplitude: ',num2str(pos(2))]};
```

datatipinfo

Purpose

Produce short description of input variable

Syntax

```
datatipinfo(var)
```

Description

`datatipinfo(var)` displays a short description of a variable, similar to what is displayed in a datatip in the MATLAB debugger.

Examples

Get datatip information for a 5-by-5 matrix:

```
A = rand(5);

datatipinfo(A)
A: 5x5 double =
    0.4445    0.3567    0.7458    0.0767    0.4400
    0.7962    0.6575    0.3918    0.8289    0.9746
    0.5641    0.9808    0.0265    0.4838    0.6722
    0.9099    0.9653    0.2508    0.4859    0.4054
    0.2857    0.5198    0.7383    0.9301    0.9604
```

Get datatip information for a 50-by-50 matrix. For this larger matrix, `datatipinfo` displays just the size and data type:

```
A = rand(50);

datatipinfo(A)
A: 50x50 double
```

Also for multidimensional matrices, `datatipinfo` displays just the size and data type:

```
A = rand(5);
A(:,:,2) = A(:,:,1);

datatipinfo(A)
A: 5x5x2 double
```

`debug`

Purpose

Current date string

Syntax

```
str = date
```

Description

`str = date` returns a string containing the date in `dd-mmm-yyyy` format.

See Also

`clock`, `datenum`, `now`

datenum

Purpose

Convert date and time to serial date number

Syntax

```
N = datenum(V)
N = datenum(S, F)
N = datenum(S, F, P)
N = datenum([S, P, F])
N = datenum(Y, M, D)
N = datenum(Y, M, D, H, MN, S)
N = datenum(S)
N = datenum(S, P)
```

Description

`datenum` is one of three conversion functions that enable you to express dates and times in any of three formats in MATLAB: a string (or *date string*), a vector of date and time components (or *date vector*), or as a numeric offset from a known date in time (or *serial date number*). Here is an example of a date and time expressed in the three MATLAB formats:

```
Date String:           '24-Oct-2003 12:45:07'
Date Vector:           [2003  10  24  12  45  07]
Serial Date Number:    7.3188e+005
```

A serial date number represents the whole and fractional number of days from a specific date and time, where `datenum('Jan-1-0000 00:00:00')` returns the number 1. (The year 0000 is merely a reference point and is not intended to be interpreted as a real year in time.)

`N = datenum(V)` converts one or more date vectors `V` to serial date numbers `N`. Input `V` can be an `m`-by-6 or `m`-by-3 matrix containing `m` full or partial date vectors respectively. A full date vector has six elements, specifying year, month, day, hour, minute, and second, in that order. A partial date vector has three elements, specifying year, month, and day, in that order. Each element of `V` must be a positive double-precision number. `datenum` returns a column vector of `m` date numbers, where `m` is the total number of date vectors in `V`.

`N = datenum(S, F)` converts one or more date strings `S` to serial date numbers `N` using format string `F` to interpret each date string. Input `S`

can be a one-dimensional character array or cell array of date strings. All date strings in S must have the same format, and that format must match one of the date string formats shown in the help for the datestr function. datenum returns a column vector of m date numbers, where m is the total number of date strings in S. MATLAB considers date string years that are specified with only two characters (e.g., '79') to fall within 100 years of the current year.

See the datestr reference page to find valid string values for F. These values are listed in Table 1 in the column labeled "Dateform String." You can use any string from that column except for those that include the letter Q in the string (for example, 'QQ-YYYY'). Certain formats may not contain enough information to compute a date number. In these cases, hours, minutes, seconds, and milliseconds default to 0, the month defaults to January, the day to 1, and the year to the current year.

N = datenum(S, F, P) converts one or more date strings S to date numbers N using format F and pivot year P. The pivot year is used in interpreting date strings that have the year specified as two characters. It is the starting year of the 100-year range in which a two-character date string year resides. The default pivot year is the current year minus 50 years.

N = datenum([S, P, F]) is the same as the syntax shown above, except the order of the last two arguments are switched.

N = datenum(Y, M, D) returns the serial date numbers for corresponding elements of the Y, M, and D (year, month, day) arrays. Y, M, and D must be arrays of the same size (or any can be a scalar) of type double. You can also specify the input arguments as a date vector, [Y M D].

For this and the following syntax, values outside the normal range of each array are automatically carried to the next unit. Values outside the normal range of each array are automatically carried to the next unit. For example, month values greater than 12 are carried to years. Month values less than 1 are set to be 1. All other units can wrap and have valid negative values.

`N = datenum(Y, M, D, H, MN, S)` returns the serial date numbers for corresponding elements of the `Y`, `M`, `D`, `H`, `MN`, and `S` (year, month, day, hour, minute, and second) array values. `datenum` does not accept milliseconds in a separate input, but as a fractional part of the seconds (`S`) input. Inputs `Y`, `M`, `D`, `H`, `MN`, and `S` must be arrays of the same size (or any can be a scalar) of type `double`. You can also specify the input arguments as a date vector, `[Y M D H MN S]`.

`N = datenum(S)` converts date string `S` into a serial date number. String `S` must be in one of the date formats 0, 1, 2, 6, 13, 14, 15, 16, or 23, as defined in the reference page for the `datestr` function. MATLAB considers date string years that are specified with only two characters (e.g., `'79'`) to fall within 100 years of the current year. If the format of date string `S` is known, use the syntax `N = datenum(S, F)`.

`N = datenum(S, P)` converts date string `S`, using pivot year `P`. If the format of date string `S` is known, use the syntax `N = datenum(S, F, P)`.

Note The last two calling syntaxes are provided for backward compatibility and are significantly slower than the syntaxes that include a format argument `F`.

Examples

Convert a date string to a serial date number:

```
n = datenum('19-May-2001', 'dd-mmm-yyyy')

n =
      730990
```

Specifying year, month, and day, convert a date to a serial date number:

```
n = datenum(2001, 12, 19)

n =
      731204
```

Convert a date vector to a serial date number:

```
format bank
datenum('March 28, 2005  3:37:07.033 PM')
ans =
     732399.65
```

Convert a date string to a serial date number using the default pivot year:

```
n = datenum('12-jun-17', 'dd-mmm-yy')

n =
       736858
```

Convert the same date string to a serial date number using 1400 as the pivot year:

```
n = datenum('12-jun-17', 'dd-mmm-yy', 1400)

n =
       517712
```

Specify format `'dd.mm.yyyy'` to be used in interpreting a nonstandard date string:

```
n = datenum('19.05.2000', 'dd.mm.yyyy')

n =
       730625
```

See Also

`datestr`, `datevec`, `date`, `clock`, `now`, `datetick`

datestr

Purpose

Convert date and time to string format

Syntax

```
S = datestr(V)
S = datestr(N)
S = datestr(D, F)
S = datestr(S1, F, P)
S = datestr(..., 'local')
```

Description

`datestr` is one of three conversion functions that enable you to express dates and times in any of three formats in MATLAB: a string (or *date string*), a vector of date and time components (or *date vector*), or as a numeric offset from a known date in time (or *serial date number*). Here is an example of a date and time expressed in the three MATLAB formats:

```
Date String:           '24-Oct-2003 12:45:07'
Date Vector:           [2003  10  24  12  45  07]
Serial Date Number:    7.3188e+005
```

A serial date number represents the whole and fractional number of days from 1-Jan-0000 to a specific date. The year 0000 is merely a reference point and is not intended to be interpreted as a real year in time.

`S = datestr(V)` converts one or more date vectors `V` to date strings `S`. Input `V` must be an `m`-by-6 matrix containing `m` full (six-element) date vectors. Each element of `V` must be a positive double-precision number. `datestr` returns a column vector of `m` date strings, where `m` is the total number of date vectors in `V`.

`S = datestr(N)` converts one or more serial date numbers `N` to date strings `S`. Input argument `N` can be a scalar, vector, or multidimensional array of positive double-precision numbers. `datestr` returns a column vector of `m` date strings, where `m` is the total number of date numbers in `N`.

`S = datestr(D, F)` converts one or more date vectors, serial date numbers, or date strings `D` into the same number of date strings `S`.

Input argument F is a format number or string that determines the format of the date string output. Valid values for F are given in the table Standard MATLAB Date Format Definitions on page 2-763, below. Input F may also contain a free-form date format string consisting of format tokens shown in the table Free-Form Date Format Specifiers on page 2-766, below.

Date strings with 2-character years are interpreted to be within the 100 years centered around the current year.

`S = datestr(S1, F, P)` converts date string `S1` to date string `S`, applying format `F` to the output string, and using pivot year `P` as the starting year of the 100-year range in which a two-character year resides. The default pivot year is the current year minus 50 years. All date strings in `S1` must have the same format.

`S = datestr(..., 'local')` returns the string in a localized format. The default is US English ('**en_US**'). This argument must come last in the argument sequence.

Note The vectorized calling syntax can offer significant performance improvement for large arrays.

Standard MATLAB Date Format Definitions

dateform (number)	dateform (string)	Example
0	'dd-mmm-yyyy HH:MM:SS'	01-Mar-2000 15:45:17
1	'dd-mmm-yyyy'	01-Mar-2000
2	'mm/dd/yy'	03/01/00
3	'mmm'	Mar
4	'm'	M

Standard MATLAB Date Format Definitions (Continued)

dateform (number)	dateform (string)	Example
5	'mm'	03
6	'mm/dd'	03/01
7	'dd'	01
8	'ddd'	Wed
9	'd'	W
10	'yyyy'	2000
11	'yy'	00
12	'mmmyy'	Mar00
13	'HH:MM:SS'	15:45:17
14	'HH:MM:SS PM'	3:45:17 PM
15	'HH:MM'	15:45
16	'HH:MM PM'	3:45 PM
17	'QQ-YY'	Q1-01
18	'QQ'	Q1
19	'dd/mm'	01/03
20	'dd/mm/yy'	01/03/00
21	'mmm.dd,yyyy HH:MM:SS'	Mar.01,2000 15:45:17
22	'mmm.dd,yyyy'	Mar.01,2000
23	'mm/dd/yyyy'	03/01/2000
24	'dd/mm/yyyy'	01/03/2000
25	'yy/mm/dd'	00/03/01
26	'yyyy/mm/dd'	2000/03/01

Standard MATLAB Date Format Definitions (Continued)

dateform (number)	dateform (string)	Example
27	'QQ-YYYY'	Q1-2001
28	'mmmyyyy'	Mar2000
29 (ISO 8601)	'yyyy-mm-dd'	2000-03-01
30 (ISO 8601)	'yyyymmddTHHMMSS'	20000301T154517
31	'yyyy-mm-dd HH:MM:SS'	2000-03-01 15:45:17

Note `dateform` numbers 0, 1, 2, 6, 13, 14, 15, 16, and 23 produce a string suitable for input to `datenum` or `datevec`. Other date string formats do not work with these functions unless you specify a date form in the function call.

Note For date formats that specify only a time (i.e., `dateform` numbers 13, 14, 15, and 16), MATLAB sets the date to January 1 of the current year.

Time formats like `'h:m:s'`, `'h:m:s.s'`, `'h:m pm'`, ... can also be part of the input array `S`. If you do not specify a format string `F`, or if you specify `F` as `-1`, the date string format defaults to the following:

1	If `S` contains date information only, e.g., 01-Mar-1995
16	If `S` contains time information only, e.g., 03:45 PM
0	If `S` is a date vector, or a string that contains both date and time information, e.g., 01-Mar-1995 03:45

The following table shows the string symbols to use in specifying a free-form format for the output date string. MATLAB interprets these symbols according to your computer's language setting and the current MATLAB language setting.

Note You cannot use more than one format specifier for any date or time field. For example, `datestr(n, 'dddd dd mmmm')` specifies two formats for the day of the week, and thus returns an error.

Free-Form Date Format Specifiers

Symbol	Interpretation	Example
`yyyy`	Show year in full.	`1990`, `2002`
`yy`	Show year in two digits.	`90`, `02`
`mmmm`	Show month using full name.	`March`, `December`
`mmm`	Show month using first three letters.	`Mar`, `Dec`
`mm`	Show month in two digits.	`03`, `12`
`m`	Show month using capitalized first letter.	`M`, `D`
`dddd`	Show day using full name.	`Monday`, `Tuesday`
`ddd`	Show day using first three letters.	`Mon`, `Tue`
`dd`	Show day in two digits.	`05`, `20`
`d`	Show day using capitalized first letter.	`M`, `T`

Free-Form Date Format Specifiers (Continued)

Symbol	Interpretation	Example
`HH`	Show hour in two digits (no leading zeros when free-form specifier `AM` or `PM` is used (see last entry in this table)).	`05`, `5 AM`
`MM`	Show minute in two digits.	`12`, `02`
`SS`	Show second in two digits.	`07`, `59`
`FFF`	Show millisecond in three digits.	`.057`
`AM or PM`	Append `AM` or `PM` to date string (see note below).	`3:45:02 PM`

Note Free-form specifiers `AM` and `PM` from the table above are identical. They do not influence which characters are displayed following the time (`AM` versus `PM`), but only whether or not they are displayed. MATLAB selects `AM` or `PM` based on the time entered.

Remarks

A vector of three or six numbers could represent either a single date vector, or a vector of individual serial date numbers. For example, the vector `[2000 12 15 11 45 03]` could represent either 11:45:03 on December 15, 2000 or a vector of date numbers 2000, 12, 15, etc.. MATLAB uses the following general rule in interpreting vectors associated with dates:

- A 3- or 6-element vector having a first element within an approximate range of 500 greater than or less than the current year is considered by MATLAB to be a date vector. Otherwise, it is considered to be a vector of serial date numbers.

To specify dates outside of this range as a date vector, first convert the vector to a serial date number using the `datenum` function as shown here:

```
datestr(datenum([1400 12 15 11 45 03]), ...
        'mmm.dd,yyyy HH:MM:SS')
ans =
   Dec.15,1400 11:45:03
```

Examples

Return the current date and time in a string using the default format, `0`:

```
datestr(now)

ans =
   28-Mar-2005 15:36:23
```

Reformat the date and time, and also show milliseconds:

```
dt = datestr(now, 'mmmm dd, yyyy HH:MM:SS.FFF AM')
dt =
   March 28, 2005  3:37:07.952 PM
```

Format the same showing only the date and in the `mm/dd/yy` format. Note that you can specify this format either by number or by string.

```
datestr(now, 2)     -or-     datestr(now, 'mm/dd/yy')

ans =
   03/28/05
```

Display the returned date string using your own format made up of symbols shown in the Free-Form Date Format Specifiers on page 2-766 table above.

```
datestr(now, 'dd.mm.yyyy')

ans =
   28.03.2005
```

Convert a nonstandard date form into a standard MATLAB date form by first converting to a date number and then to a string:

```
datestr(datenum('28.03.2005', 'dd.mm.yyyy'), 2)

ans =
   03/28/05
```

See Also

datenum, datevec, date, clock, now, datetick

Purpose

Date formatted tick labels

Syntax

```
datetick(tickaxis)
datetick(tickaxis,dateform)
datetick(...,'keeplimits')
datetick(...,'keepticks')
datetick(axes_handle,...)
```

Description

`datetick(tickaxis)` labels the tick lines of an axis using dates, replacing the default numeric labels. `tickaxis` is the string `'x'`, `'y'`, or `'z'`. The default is `'x'`. `datetick` selects a label format based on the minimum and maximum limits of the specified axis.

`datetick(tickaxis,dateform)` formats the labels according to the integer *`dateform`* (see table). To produce correct results, the data for the specified axis must be serial date numbers (as produced by `datenum`).

dateform (number)	*`dateform`* (string)	Example
0	'dd-mmm-yyyy HH:MM:SS'	01-Mar-2000 15:45:17
1	'dd-mmm-yyyy'	01-Mar-2000
2	'mm/dd/yy'	03/01/00
3	'mmm'	Mar
4	'm'	M
5	'mm'	03
6	'mm/dd'	03/01
7	'dd'	01
8	'ddd'	Wed
9	'd'	W
10	'yyyy'	2000
11	'yy'	00

dateform (number)	*dateform* (string)	Example
12	'mmmyy'	Mar00
13	'HH:MM:SS'	15:45:17
14	'HH:MM:SS PM'	3:45:17 PM
15	'HH:MM'	15:45
16	'HH:MM PM'	3:45 PM
17	'QQ-YY'	Q1 01
18	'QQ'	Q1
19	'dd/mm'	01/03
20	'dd/mm/yy'	01/03/00
21	'mmm.dd.yyyy HH:MM:SS'	Mar.01,2000 15:45:17
22	'mmm.dd.yyyy'	Mar.01.2000
23	'mm/dd/yyyy'	03/01/2000
24	'dd/mm/yyyy'	01/03/2000
25	'yy/mm/dd'	00/03/01
26	'yyyy/mm/dd'	2000/03/01
27	'QQ-YYYY'	Q1-2001
28	'mmmyyyy'	Mar2000

`datetick(...,'keeplimits')` changes the tick labels to date-based labels while preserving the axis limits.

`datetick(...,'keepticks')` changes the tick labels to date-based labels without changing their locations.

You can use both `keeplimits` and `keepticks` in the same call to `datetick`.

`datetick(axes_handle,...)` uses the axes specified by the handle `ax` instead of the current axes.

Remarks

`datetick` calls `datestr` to convert date numbers to date strings.

To change the tick spacing and locations, set the appropriate axes property (i.e., `XTick`, `YTick`, or `ZTick`) before calling `datetick`.

Example

Consider graphing population data based on the 1990 U.S. census:

```
t = (1900:10:1990)';  % Time interval
p = [75.995 91.972 105.711 123.203 131.669 ...
 150.697 179.323 203.212 226.505 249.633]';  % Population
plot(datenum(t,1,1),p) % Convert years to date numbers and plot
grid on
datetick('x',11)   % Replace x-axis ticks with 2-digit year
labels
```

The axes properties `XTick`, `YTick`, and `ZTick`

`datenum`, `datestr`

"Annotating Plots" on page 1-87 for related functions

Purpose

Convert date and time to vector of components

Syntax

```
V = datevec(N)
V = datevec(S, F)
V = datevec(S, F, P)
V = datevec(S, P, F)
[Y, M, D, H, MN, S] = datevec(...)
V = datevec(S)
V = datevec(S, P)
```

Description

`datevec` is one of three conversion functions that enable you to express dates and times in any of three formats in MATLAB: a string (or *date string*), a vector of date and time components (or *date vector*), or as a numeric offset from a known date in time (or *serial date number*). Here is an example of a date and time expressed in the three MATLAB formats:

```
Date String:           '24-Oct-2003 12:45:07'
Date Vector:           [2003  10  24  12  45  07]
Serial Date Number:    7.3188e+005
```

A serial date number represents the whole and fractional number of days from 1-Jan-0000 to a specific date. The year 0000 is merely a reference point and is not intended to be interpreted as a real year in time.

`V = datevec(N)` converts one or more date numbers `N` to date vectors `V`. Input argument `N` can be a scalar, vector, or multidimensional array of positive date numbers. `datevec` returns an `m`-by-6 matrix containing `m` date vectors, where `m` is the total number of date numbers in `N`.

`V = datevec(S, F)` converts one or more date strings `S` to date vectors `V` using format string `F` to interpret the date strings in `S`. Input argument `S` can be a cell array of strings or a character array where each row corresponds to one date string. All of the date strings in `S` must have the same format which must be composed of date format symbols according to the table “Free-Form Date Format Specifiers” in the `datestr` help.

Formats with 'Q' are not accepted by datevec. datevec returns an m-by-6 matrix of date vectors, where m is the number of date strings in S.

Certain formats may not contain enough information to compute a date vector. In those cases, hours, minutes, and seconds default to 0, days default to 1, months default to January, and years default to the current year. Date strings with two character years are interpreted to be within the 100 years centered around the current year.

V = datevec(S, F, P) converts the date string S to a date vector V using date format F and pivot year P. The pivot year is the starting year of the 100-year range in which a two-character year resides. The default pivot year is the current year minus 50 years.

V = datevec(S, P, F) is the same as the syntax shown above, except the order of the last two arguments are switched.

[Y, M, D, H, MN, S] = datevec(...) takes any of the two syntaxes shown above and returns the components of the date vector as individual variables. datevec does not return milliseconds in a separate output, but as a fractional part of the seconds (S) output.

V = datevec(S) converts date string S to date vector V. Input argument S must be in one of the date formats 0, 1, 2, 6, 13, 14, 15, 16, or 23 as defined in the reference page for the datestr function. This calling syntax is provided for backward compatibility, and is significantly slower than the syntax which specifies the format string. If the format is known, the V = datevec(S, F) syntax is recommended.

V = datevec(S, P) converts the date string S using pivot year P. If the format is known, the V = datevec(S, F, P) or V = datevec(S, P, F) syntax should be used.

Note If more than one input argument is used, the first argument must be a date string or array of date strings.

When creating your own date vector, you need not make the components integers. Any components that lie outside their conventional ranges

affect the next higher component (so that, for instance, the anomalous June 31 becomes July 1). A zeroth month, with zero days, is allowed.

Note The vectorized calling syntax can offer significant performance improvement for large arrays.

Examples

Obtain a date vector using a string as input:

```
format short g

datevec('March 28, 2005  3:37:07.952 PM')
ans =
     2005       3       28       15       37       7.952
```

Obtain a date vector using a serial date number as input:

```
t = datenum('March 28, 2005  3:37:07.952 PM')
t =
     7.324e+005

datevec(t)
ans =
     2005       3       28       15       37       7.952
```

Assign elements of the returned date vector:

```
[y, m, d, h, mn, s] = datevec('March 28, 2005  3:37:07.952 PM');
sprintf('Date: %d/%d/%d   Time: %d:%d:%2.3f\n', m, d, y, h, mn, s)

ans =
   Date: 3/28/2005   Time: 15:37:7.952
```

Use free-form date format `'dd.mm.yyyy'` to indicate how you want a nonstandard date string interpreted:

```
datevec('28.03.2005', 'dd.mm.yyyy')

ans = 2005    3    28    0   0   0
```

dbclear

Purpose

Clear breakpoints

GUI Alternatives

In the Editor/Debugger, click  to clear a breakpoint, or  to clear all breakpoints. For details, see “Disabling and Clearing Breakpoints”.

Syntax

```
dbclear all
dbclear in mfile ...
dbclear if error ...
dbclear if warning ...
dbclear if naninf
dbclear if infnan
```

Description

`dbclear all` removes all breakpoints in all M-files, as well as breakpoints set for errors, caught errors, caught error identifiers, warnings, warning identifiers, and `naninf`/`infnan`.

`dbclear in mfile ...` formats are listed here:

Format	Action
`dbclear in mfile`	Removes all breakpoints in `mfile`.
`dbclear in mfile at lineno`	Removes the breakpoint set at line number `lineno` in `mfile`.
`dbclear in mfile at lineno@`	Removes the breakpoint set in the anonymous function at line number `lineno` in `mfile`.
`dbclear in mfile at lineno@n`	Removes the breakpoint set in the `n`the anonymous function at line number `lineno` in `mfile`.
`dbclear in mfile at subfun`	Removes all breakpoints in subfunction `subfun` in `mfile`.

`dbclear if error ...` formats are listed here:

Format	Action
`dbclear if error`	Removes the breakpoints set using the `dbstop if error` and `dbstop if error identifier` statements.
`dbclear if error identifier`	Removes the breakpoint set using `dbstop if error identifier` for the specified `identifier`. Running this produces an error if `dbstop if error` or `dbstop if error all` is set.
`dbclear if caught error`	Removes the breakpoints set using the `dbstop if caught error` and `dbstop if caught error identifier` statements.
`dbclear if caught error identifier`	Removes the breakpoints set using the `dbstop if caught error identifier` statement for the specified identifier. Running this produces an error if `dbstop if caught error` or `dbstop if caught error all` is set.

`dbclear if warning ...` formats are listed here:

`dbclear if warning`	Removes the breakpoints set using the `dbstop if warning` and `dbstop if warning identifier` statements.
`dbclear if warning identifier`	Removes the breakpoint set using `dbstop if warning identifier` for the specified `identifier`. Running this produces an error if `dbstop if warning` or `dbstop if warning all` is set.

`dbclear if naninf` removes the breakpoint set by `dbstop if naninf` or `dbstop if infnan`.

`dbclear if infnan` removes the breakpoint set by `dbstop if infnan` or `dbstop if naninf`.

Remarks

The **at** and **in** keywords are optional.

In the syntax, `mfile` can be an M-file, or the path to a function within a file. For example

```
dbclear in foo>myfun
```

clears the breakpoint at the `myfun` function in the file `foo.m`.

See Also

`dbcont`, `dbdown`, `dbquit`, `dbstack`, `dbstatus`, `dbstep`, `dbstop`, `dbtype`, `dbup`, `partialpath`

Purpose

Resume execution

GUI Alternatives

Select **Debug > Continue** from most desktop tools, or in the Editor/Debugger, click  .

Syntax

```
dbcont
```

Description

`dbcont` resumes execution of an M-file from a breakpoint. Execution continues until another breakpoint is encountered, a pause condition is met, an error occurs, or MATLAB returns to the base workspace prompt.

Note If you want to edit an M-file as a result of debugging, it is best to first quit debug mode and then edit and save changes to the M-file. If you edit an M-file while paused in debug mode, you can get unexpected results when you resume execution of the file and the results might not be reliable.

See Also

`dbclear`, `dbdown`, `dbquit`, `dbstack`, `dbstatus`, `dbstep`, `dbstop`, `dbtype`, `dbup`

dbdown

Purpose

Change local workspace context when in debug mode

GUI Alternatives

Use the **Stack** field 

in the Editor/Debugger or Workspace browser.

Syntax

```
dbdown
```

Description

`dbdown` changes the current workspace context to the workspace of the called M-file when a breakpoint is encountered. You must have issued the `dbup` function at least once before you issue this function. `dbdown` is the opposite of `dbup`.

Multiple `dbdown` functions change the workspace context to each successively executed M-file on the stack until the current workspace context is the current breakpoint. It is not necessary, however, to move back to the current breakpoint to continue execution or to step to the next line.

See Also

`dbclear`, `dbcont`, `dbquit`, `dbstack`, `dbstatus`, `dbstep`, `dbstop`, `dbtype`, `dbup`

Purpose

Numerically evaluate double integral

Syntax

```
q = dblquad(fun,xmin,xmax,ymin,ymax)
q = dblquad(fun,xmin,xmax,ymin,ymax,tol)
q = dblquad(fun,xmin,xmax,ymin,ymax,tol,method)
```

Description

`q = dblquad(fun,xmin,xmax,ymin,ymax)` calls the `quad` function to evaluate the double integral `fun(x,y)` over the rectangle `xmin <= x <= xmax`, `ymin <= y <= ymax`. `fun` is a function handle. See "Function Handles" in the MATLAB Programming documentation for more information. `fun(x,y)` must accept a vector `x` and a scalar `y` and return a vector of values of the integrand.

"Parameterizing Functions Called by Function Functions" in the MATLAB Mathematics documentation, explains how to provide additional parameters to the function `fun`, if necessary.

`q = dblquad(fun,xmin,xmax,ymin,ymax,tol)` uses a tolerance `tol` instead of the default, which is `1.0e-6`.

`q = dblquad(fun,xmin,xmax,ymin,ymax,tol,method)` uses the quadrature function specified as `method`, instead of the default `quad`. Valid values for `method` are `@quadl` or the function handle of a user-defined quadrature method that has the same calling sequence as `quad` and `quadl`.

Example

Pass M-file function handle `@integrnd` to `dblquad`:

```
Q = dblquad(@integrnd,pi,2*pi,0,pi);
```

where the M-file `integrnd.m` is

```
function z = integrnd(x, y)
z = y*sin(x)+x*cos(y);
```

Pass anonymous function handle `F` to `dblquad`:

```
F = @(x,y)y*sin(x)+x*cos(y);
Q = dblquad(F,pi,2*pi,0,pi);
```

The `integrnd` function integrates `y*sin(x)+x*cos(y)` over the square `pi <= x <= 2*pi`, `0 <= y <= pi`. Note that the integrand can be evaluated with a vector `x` and a scalar `y`.

Nonsquare regions can be handled by setting the integrand to zero outside of the region. For example, the volume of a hemisphere is

```
dblquad(@(x,y)sqrt(max(1-(x.^2+y.^2),0)), -1, 1, -1, 1)
```

or

```
dblquad(@(x,y)sqrt(1-(x.^2+y.^2)).*(x.^2+y.^2<=1), -1, 1, -1, 1)
```

See Also

`quad`, `quadgk`, `quadl`, `triplequad`, `function_handle` (`@`), "Anonymous Functions"

Purpose

Enable MEX-file debugging

Syntax

```
dbmex on
dbmex off
dbmex stop
```

Description

`dbmex on` enables MEX-file debugging for UNIX platforms. It is not supported on the Sun Solaris platform. To use this option, first start MATLAB from within a debugger by typing `matlab -Ddebugger`, where `debugger` is the name of the debugger.

`dbmex off` disables MEX-file debugging.

`dbmex stop` returns to the debugger prompt.

Remarks

On Sun Solaris platforms, `dbmex` is not supported.
See the Technical Support solution 1-17Z0R at `http://www.mathworks.com/support/solutions/data/1-17Z0R.html` for an alternative method of debugging.

See Also

`dbclear`, `dbcont`, `dbdown`, `dbquit`, `dbstack`, `dbstatus`, `dbstep`, `dbstop`, `dbtype`, `dbup`

dbquit

Purpose

Quit debug mode

GUI Alternative

From most desktop tools, select **Debug > Exit Debug Mode**, or in the Editor/Debugger, click .

Syntax

```
dbquit
dbquit('all')
dbquit all
```

Description

`dbquit` terminates debug mode. The Command Window then displays the standard prompt (`>>`). The M-file being processed is *not* completed and no results are returned. All breakpoints remain in effect. As an alternative to `dbquit`, press **Shift+F5**.

If you debug `file1` and step into `file2`, running `dbquit` terminates debugging for both files. However, if you debug `file3` and also debug `file4`, running `dbquit` terminates debugging for `file4`, but `file3` remains in debug mode until you run `dbquit` again.

`dbquit('all')` or the command form, `dbquit all`, ends debugging for all files at once.

Examples

This example illustrates the use of `dbquit` relative to `dbquit('all')`. Set breakpoints in and run `file1` and `file2`:

```
>> dbstop in file1
>> dbstop in file2
>> file1
K>> file2
K>> dbstack
```

MATLAB returns

```
K>> dbstack
  In file1 at 11
  In file2 at 22
```

If you use the `dbquit` syntax

```
K>> dbquit
```

MATLAB ends debugging for `file2` but `file1` is still in debug mode as shown here

```
K>> dbstack
    in file1 at 11
```

Run `dbquit` again to exit debug mode for `file1`.

Alternatively, `dbquit('all')` ends debugging for both files at once:

```
K>> dbstack
  In file1 at 11
  In file2 at 22
dbquit('all')
dbstack
```

returns no result.

See Also

`dbclear`, `dbcont`, `dbdown`, `dbstack`, `dbstatus`, `dbstep`, `dbstop`, `dbtype`, `dbup`

dbstack

Purpose

Function call stack

GUI Alternatives

Use the **Stack** field 

in the Editor/Debugger or Workspace browser.

Syntax

```
dbstack
dbstack(n)
dbstack('-completenames')
[ST,I] = dbstack
```

Description

`dbstack` displays the line numbers and M-file names of the function calls that led to the current breakpoint, listed in the order in which they were executed. The line number of the most recently executed function call (at which the current breakpoint occurred) is listed first, followed by its calling function, which is followed by its calling function, and so on, until the topmost M-file function is reached. Each line number is a hyperlink you can click to go directly to that line in the Editor/Debugger. The notation `functionname>subfunctionname` is used to describe the subfunction location.

`dbstack(n)` omits from the display the first `n` frames. This is useful when issuing a `dbstack` from within, say, an error handler.

`dbstack('-completenames')` outputs the "complete name" (the absolute file name and the entire sequence of functions that nests the function in the stack frame) of each function in the stack.

Either none, one, or both `n` and `'-completenames'` can appear. If both appear, the order is irrelevant.

`[ST,I] = dbstack` returns the stack trace information in an `m`-by-`1` structure `ST` with the fields

`file`	The file in which the function appears. This field will be the empty string if there is no file.
`name`	Function name within the file.
`line`	Function line number.

The current workspace index is returned in `I`.

If you step past the end of an M-file, then `dbstack` returns a negative line number value to identify that special case. For example, if the last line to be executed is line `15`, then the `dbstack` line number is `15` before you execute that line and `-15` afterwards.

Examples

```
dbstack

In /usr/local/matlab/toolbox/matlab/cond.m at line 13
In test1.m at line 2
In test.m at line 3
```

MATLAB Desktop Tools and Development Environment Documentation

- “Editing and Debugging M-Files”
- “Examining Values”

dbstatus

Purpose

List all breakpoints

GUI Alternative

Breakpoint line numbers are displayed graphically via the breakpoint icons when the file is open in the Editor/Debugger.

Syntax

```
dbstatus
dbstatus mfile
dbstatus('-completenames')
s = dbstatus(...)
```

Description

`dbstatus` lists all the breakpoints in effect including errors, caught errors, warnings, and `naninfs`.

`dbstatus mfile` displays a list of the line numbers for which breakpoints are set in the specified M-file, where `mfile` is an M-file function name or a MATLAB relative partial pathname. Each line number is a hyperlink you can click to go directly to that line in the Editor/Debugger.

`dbstatus('-completenames')` displays, for each breakpoint, the absolute filename and the sequence of functions that nest the function containing the breakpoint.

`s = dbstatus(...)` returns breakpoint information in an `m`-by-`1` structure with the fields listed in the following table. Use this syntax to save breakpoint status and restore it at a later time using `dbstop(s)`—see `dbstop` for an example.

`name`	Function name.
`file`	Full pathname for file containing breakpoints.
`line`	Vector of breakpoint line numbers.
`anonymous`	Vector of integers representing the anonymous functions in the `line` field. For example, `2` means the second anonymous function in that line. A value of `0` means the breakpoint is at the start of the line, not in an anonymous function.

`expression`	Cell vector of breakpoint conditional expression strings corresponding to lines in the `line` field.
`cond`	Condition string (`'error'`, `'caught error'`, `'warning'`, or `'naninf'`).
`identifier`	When `cond` is `'error'`, `'caught error'`, or `'warning'`, a cell vector of MATLAB message identifier strings for which the particular `cond` state is set.

Use `dbstatus class/function`, `dbstatus private/function`, or `dbstatus class/private/function` to determine the status for methods, private functions, or private methods (for a class named `class`).

In all forms you can further qualify the function name with a subfunction name, as in `dbstatus function>subfunction`.

Remarks

In the syntax, `mfile` can be an M-file, or the path to a function within a file. For example

```
Breakpoint for foo>mfun is on line 9
```

means there is a breakpoint at the `myfun` subfunction, which is line 9 in the file `foo.m`.

`dbclear`, `dbcont`, `dbdown`, `dbquit`, `dbstack`, `dbstep`, `dbstop`, `dbtype`, `dbup`, `error`, `partialpath`, `warning`

dbstep

Purpose

Execute one or more lines from current breakpoint

GUI Alternatives

As an alternative to `dbstep`, you can select **Debug > Step** or **Step In** in most desktop tools, or click the Step or Step In buttons on the Editor/Debugger toolbar.

Syntax

```
dbstep
dbstep nlines
dbstep in
dbstep out
```

Description

This function allows you to debug an M-file by following its execution from the current breakpoint. At a breakpoint, the `dbstep` function steps through execution of the current M-file one line at a time or at the rate specified by `nlines`.

`dbstep` executes the next executable line of the current M-file. `dbstep` steps over the current line, skipping any breakpoints set in functions called by that line.

`dbstep nlines` executes the specified number of executable lines.

`dbstep` **`in`** steps to the next executable line. If that line contains a call to another M-file function, execution will step to the first executable line of the called M-file function. If there is no call to an M-file on that line, `dbstep in` is the same as `dbstep`.

`dbstep` **`out`** runs the rest of the function and stops just after leaving the function.

For all forms, MATLAB also stops execution at any breakpoint it encounters.

Note If you want to edit an M-file as a result of debugging, it is best to first quit debug mode and then edit and save changes to the M-file. If you edit an M-file while paused in debug mode, you can get unexpected results when you resume execution of the file and the results might not be reliable.

`dbclear`, `dbcont`, `dbdown`, `dbquit`, `dbstack`, `dbstatus`, `dbstop`, `dbtype`, `dbup`

dbstop

Purpose

Set breakpoints

GUI Alternative

Use the **Debug** menu in most desktop tools, or the context menu in Editor/Debugger. See details.

Syntax

```
dbstop in mfile ...
dbstop in nonmfile
dbstop if error ...
dbstop if warning ...
dbstop if naninf
dbstop if infnan
dbstop(s)
```

Description

`dbstop in mfile ...` formats are listed here:

Format	Action	Additional Information
`dbstop in mfile`	Temporarily stops execution of running `mfile` at the first executable line, putting MATLAB in debug mode. `mfile` must be in a directory that is on the search path, or in the current directory. `mfile` can be an M-file, or the path to a function (`subfun`) within the file, using the notation `mfile > subfun`. The **`in`** keyword is optional.	If you have graphical debugging enabled, the MATLAB Debugger opens with a breakpoint at the first executable line of `mfile`. You can then use the debugging utilities, review the workspace, or issue any valid MATLAB function. Use `dbcont` or `dbstep` to resume execution of `mfile`. Use `dbquit` to exit from debug mode.

Format	Action	Additional Information
`dbstop in mfile at lineno`	Temporarily stops execution of running `mfile` just prior to execution of the line whose number is `lineno`, putting MATLAB in debug mode. If that line is not executable, execution stops and the breakpoint is set at the next executable line following `lineno`. `mfile` must be in a directory that is on the search path, or in the current directory. The **`at`** keyword is optional.	If you have graphical debugging enabled, MATLAB opens `mfile` with a breakpoint at line `lineno`. When execution stops, you can use the debugging utilities, review the workspace, or issue any valid MATLAB function. Use `dbcont` or `dbstep` to resume execution of `mfile`. Use `dbquit` to exit from debug mode
`dbstop in mfile at lineno@`	Stops just after any call to the first anonymous function in the specified line number in `mfile`.	
`dbstop in mfile at lineno@n`	Stops just after any call to the `n`the anonymous function in the specified line number in `mfile`.	
`dbstop in mfile at subfun`	Temporarily stops execution of running `mfile` just prior to execution of the subfunction `subfun`, putting MATLAB in debug mode. `mfile` must be in a directory that is on the search path, or in the current directory.	If you have graphical debugging enabled, MATLAB opens `mfile` with a breakpoint at the subfunction `subfun`. You can then use the debugging utilities, review the workspace, or issue any valid MATLAB function. Use `dbcont` or `dbstep` to resume execution of `mfile`. Use `dbquit` to exit from debug mode.

Format	Action	Additional Information
`dbstop in mfile at lineno if expression`	Temporarily stops execution of running `mfile`, just prior to execution of the line whose number is `lineno`, putting MATLAB in debug mode. Execution stops only if expression evaluates to `true`. `expression` is evaluated (as if by `eval`), in `mfile`'s workspace when the breakpoint is encountered, and must evaluate to a scalar logical value (`1` or `0` for true or false). If that line is not executable, execution stops and the breakpoint is set at the next executable line following `lineno`. `mfile` must be in a directory that is on the search path, or in the current directory.	If you have graphical debugging enabled, MATLAB opens `mfile` with a breakpoint at line `lineno`. When execution stops, you can use the debugging utilities, review the workspace, or issue any valid MATLAB function. Use `dbcont` or `dbstep` to resume execution of `mfile`. Use `dbquit` to exit from debug mode.
`dbstop in mfile at lineno@ if expression`	Stops just after any call to the first anonymous function in the specified line number in `mfile` if `expression` evaluates to logical `1` (true).	
`dbstop in mfile at lineno@n if expression`	Stops just after any call to the `n`the anonymous function in the specified line number in `mfile` if `expression` evaluates to logical `1` (true).	

Format	Action	Additional Information
`dbstop in mfile if expression`	Temporarily stops execution of running `mfile`, at the first executable line, putting MATLAB in debug mode. Execution stops only if `expression` evaluates to logical `1` (true). `expression` is evaluated (as if by `eval`), in `mfile`'s workspace when the breakpoint is encountered, and must evaluate to a scalar logical value (`0` or `1` for true or false). `mfile` must be in a directory on the search path, or in the current directory	If you have graphical debugging enabled, MATLAB opens `mfile` with a breakpoint at the first executable line of `mfile`. You can then use the debugging utilities, review the workspace, or issue any valid MATLAB function. Use `dbcont` or `dbstep` to resume execution of `mfile`. Use `dbquit` to exit from debug mode.
`dbstop in mfile at subfun if expression`	Temporarily stops execution of running `mfile`, just prior to execution of the subfunction `subfun`, putting MATLAB in debug mode. Execution stops only if `expression` evaluates to logical `1` (true). `expression` is evaluated (as if by `eval`), in `mfile`'s workspace when the breakpoint is encountered, and must evaluate to a scalar logical value (`0` or `1` for true or false). `mfile` must be in a directory on the search path, or in the current directory	If you have graphical debugging enabled, MATLAB opens `mfile` with a breakpoint at the subfunction specified by `subfun`. You can then use the debugging utilities, review the workspace, or issue any valid MATLAB function. Use `dbcont` or `dbstep` to resume execution of `mfile`. Use `dbquit` to exit from debug mode.

`dbstop in nonmfile` temporarily stops execution of the running M-file at the point where `nonmfile` is called. This puts MATLAB in debug mode, where `nonmfile` is, for example, a built-in or MDL-file. MATLAB issues a warning because it cannot actually stop *in* the file;

rather MATLAB stops prior to the file's execution. Once stopped, you can examine values and code around that point in the execution. Use `dbstop in nonmfile` with caution because the debugger stops in M-files it uses for running and debugging if they contain `nonmfile`. As a result, some debugging features do not operate as expected, such as typing `help functionname` at the `K>>` prompt.

`dbstop` **`if error ...`** formats are listed here:

Format	Action
`dbstop` **`if error`**	Stops execution when any M-file you subsequently run produces a run-time error, putting MATLAB in debug mode, paused at the line that generated the error. The errors that stop execution do not include run-time errors that are detected within a `try...catch` block. You cannot resume execution after an uncaught run-time error. Use `dbquit` to exit from debug mode.
`dbstop` **`if error`** `identifier`	Stops execution when any M-file you subsequently run produces a run-time error whose message identifier is `identifier`, putting MATLAB in debug mode, paused at the line that generated the error. The errors that stop execution do not include run-time errors that are detected within a `try...catch` block. You cannot resume execution after an uncaught run-time error. Use `dbquit` to exit from debug mode.
`dbstop` **`if caught error`**	Stops execution when any M-file you subsequently run produces a run-time error, putting MATLAB in debug mode, paused at the line in the `try` portion of the block that generated the error. The errors that stop execution are those detected within a `try...catch` block.
`dbstop` **`if caught error`** `identifier`	Stops execution when any M-file you subsequently run produces a run-time error whose message identifier is `identifier`, putting MATLAB in debug mode, paused at the line in the `try` portion of the block that generated the error. The errors that stop execution are those detected within a `try...catch` block.

`dbstop` **`if warning ...`** formats are listed here:

Format	Action
`dbstop if warning`	Stops execution when any M-file you subsequently run produces a run-time warning, putting MATLAB in debug mode, paused at the line that generated the warning. Use `dbcont` or `dbstep` to resume execution.
`dbstop if warning identifier`	Stops execution when any M-file you subsequently run produces a runtime warning whose message identifier is `identifier`, putting MATLAB in debug mode, paused at the line that generated the warning. Use `dbcont` or `dbstep` to resume execution.

`dbstop if naninf` or `dbstop if infnan` stops execution when any M-file you subsequently run produces an infinite value (`Inf`) or a value that is not a number (`NaN`) as a result of an operator, function call, or scalar assignment, putting MATLAB in debug mode, paused immediately after the line where `Inf` or `NaN` was encountered. For convenience, you can use either **`naninf`** or **`infnan`**—they perform in exactly the same manner. Use `dbcont` or `dbstep` to resume execution. Use `dbquit` to exit from debug mode.

`dbstop(s)` restores breakpoints previously saved to the structure `s` using `s=dbstatus`. The files for which the breakpoints have been saved need to be on the search path or in the current directory. In addition, because the breakpoints are assigned by line number, the lines in the file need to be the same as when the breakpoints were saved, or the results are unpredictable. See the example “Restore Saved Breakpoints” on page 2-802 and `dbstatus` for more information.

Remarks

Note that MATLAB could become nonresponsive if it stops at a breakpoint while displaying a modal dialog box or figure that your M-file creates. In that event, use **Ctrl+C** to go the MATLAB prompt.

To open the M-file in the Editor/Debugger when execution reaches a breakpoint, select **Debug > Open M-Files When Debugging**.

To stop at each pass through a for loop, do not set the breakpoint at the for statement. For example, in

```
for n = 1:10
    m = n+1;
end
```

MATLAB executes the `for` statement only once, which is efficient. Therefore, when you set a breakpoint at the `for` statement and step through the file, you only stop at the `for` statement once. Instead place the breakpoint at the next line, `m=n+1` to stop at each pass through the loop.

Examples

The file `buggy`, used in these examples, consists of three lines.

```
function z = buggy(x)
n = length(x);
z = (1:n)./x;
```

Stop at First Executable Line

The statements

```
dbstop in buggy
buggy(2:5)
```

stop execution at the first executable line in `buggy`:

```
n = length(x);
```

The function

```
dbstep
```

advances to the next line, at which point you can examine the value of `n`.

Stop if Error

Because `buggy` only works on vectors, it produces an error if the input `x` is a full matrix. The statements

```
dbstop if error
buggy(magic(3))
```

produce

```
??? Error using ==> ./
Matrix dimensions must agree.
Error in ==> c:\buggy.m
On line 3 ==> z = (1:n)./x;
K>>
```

and put MATLAB in debug mode.

Stop if InfNaN

In `buggy`, if any of the elements of the input `x` is zero, a division by zero occurs. The statements

```
dbstop if naninf
buggy(0:2)
```

produce

```
Warning: Divide by zero.
> In c:\buggy.m at line 3
K>>
```

and put MATLAB in debug mode.

Stop at Function in File

In this example, MATLAB stops at the `newTemp` function in the M-file `yearlyAvgs`:

```
dbstop in yearlyAvgs>newTemp
```

Stop at Non M-File

In this example, MATLAB stops at the built-in function `clear` when you run `myfile.m`.

```
dbstop in clear; myfile
```

MATLAB issues a warning, but permits the stop:

```
Warning: MATLAB debugger can only stop in M-files, and
"m_interpreter>clear" is not an M-file.
Instead, the debugger will stop at the point right before
"m_interpreter>clear" is called.
```

Execution stops in `myfile` at the point where the `clear` function is called.

Restore Saved Breakpoints

1. Set breakpoints in `myfile` as follows:

   ```
   dbstop at 12 in myfile
   dbstop if error
   ```

2. Running `dbstatus` shows

   ```
   Breakpoint for myfile is on line 12.
   Stop if error.
   ```

3. Save the breakpoints to the structure `s`, and then save `s` to the MAT-file `myfilebrkpnts`.

   ```
   s = dbstatus
   save myfilebrkpnts s
   ```

   Use `s=dbstatus('completenames')` to save absolute pathnames and the breakpoint function nesting sequence.

4. At this point, you can end the debugging session and clear all breakpoints, or even end the MATLAB session.

   When you want to restore the breakpoints, be sure all of the files containing the breakpoints are on the search path or in the current directory. Then load the MAT-file, which adds `s` to the workspace, and restore the breakpoints as follows:

   ```
   load myfilebrkpnts
   dbstop(s)
   ```

5 Verify the breakpoints by running `dbstatus`, which shows

```
dbstop at 12 in myfile
dbstop if error
```

If you made changes to `myfile` after saving the breakpoints, the results from restoring the breakpoints are not predictable. For example, if you added a new line prior to line 12 in `myfile`, the breakpoint will now be set at the new line 12.

See Also

`assignin`, `break`, `dbclear`, `dbcont`, `dbdown`, `dbquit`, `dbstack`, `dbstatus`, `dbstep`, `dbtype`, `dbup`, `evalin`, `keyboard`, `partialpath`, `return`, `whos`

dbtype

Purpose

List M-file with line numbers

GUI Alternatives

As an alternative to the `dbtype` function, you can see an M-file with line numbers by opening it in the Editor/Debugger.

Syntax

```
dbtype mfilename
dbtype mfilename start:end
```

Description

The `dbtype` command is used to list an M-file with line numbers, which is helpful when setting breakpoints with `dbstop`.

`dbtype mfilename` displays the contents of the specified M-file, with the line number preceding each line. mfilename must be the full pathname of an M-file, or a MATLAB relative `partial pathname`.

`dbtype mfilename start:end` displays the portion of the M-file specified by a range of line numbers from `start` to `end`.

You cannot use `dbtype` for built-in functions.

Examples

To see only the input and output arguments for a function, that is, the first line of the M-file, use the syntax

```
dbtype mfilename 1
```

For example,

```
dbtype fileparts 1
```

returns

```
1     function [path, fname, extension,version] = fileparts(name)
```

See Also

`dbclear`, `dbcont`, `dbdown`, `dbquit`, `dbstack`, `dbstatus`, `dbstep`, `dbstop`, `dbup`, `partialpath`

Purpose

Change local workspace context

GUI Alternatives

As an alternative to the `dbup` function, you can select a different workspace from the **Stack** field in the Editor/Debugger toolbar.

Syntax

```
dbup
```

Description

This function allows you to examine the calling M-file to determine what led to the arguments' being passed to the called function.

`dbup` changes the current workspace context, while the user is in the debug mode, to the workspace of the calling M-file.

Multiple `dbup` functions change the workspace context to each previous calling M-file on the stack until the base workspace context is reached. (It is not necessary, however, to move back to the current breakpoint to continue execution or to step to the next line.)

See Also

`dbclear`, `dbcont`, `dbdown`, `dbquit`, `dbstack`, `dbstatus`, `dbstep`, `dbstop`, `dbtype`

dde23

Purpose

Solve delay differential equations (DDEs) with constant delays

Syntax

```
sol = dde23(ddefun,lags,history,tspan)
sol = dde23(ddefun,lags,history,tspan,options)
```

Arguments

`ddefun`

Function handle that evaluates the right side of the differential equations $y'(t) = f(t, y(t), y(t-\tau_1), \ldots, y(t-\tau_k))$. The function must have the form

```
dydt = ddefun(t,y,Z)
```

where `t` corresponds to the current t, `y` is a column vector that approximates $y(t)$, and `Z(:,j)` approximates $y(t-\tau_j)$ for delay τ_j = `lags(j)`. The output is a column vector corresponding to $f(t, y(t), y(t-\tau_1), \ldots, y(t-\tau_k))$.

`lags`

Vector of constant, positive delays $\tau_1, \ldots, \tau_k$.

`history`

Specify `history` in one of three ways:

- A function of t such that `y = history(t)` returns the solution $y(t)$ for $t \le t_0$ as a column vector
- A constant column vector, if $y(t)$ is constant
- The solution `sol` from a previous integration, if this call continues that integration

`tspan`	Interval of integration as a vector `[t0,tf]` with `t0 < tf`.
`options`	Optional integration argument. A structure you create using the `ddeset` function. See `ddeset` for details.

Description

`sol = dde23(ddefun,lags,history,tspan)` integrates the system of DDEs

$$y'(t) = f(t, y(t), y(t-\tau_1), \ldots, y(t-\tau_k))$$

on the interval $[t_0, t_f]$, where $\tau_1, \ldots, \tau_k$ are constant, positive delays and $t_0 < t_f$. `ddefun` is a function handle. See "Function Handles" in the MATLAB Programming documentation for more information.

"Parameterizing Functions Called by Function Functions" in the MATLAB Mathematics documentation, explains how to provide additional parameters to the function `ddefun`, if necessary.

`dde23` returns the solution as a structure `sol`. Use the auxiliary function `deval` and the output `sol` to evaluate the solution at specific points `tint` in the interval `tspan = [t0,tf]`.

```
yint = deval(sol,tint)
```

The structure `sol` returned by `dde23` has the following fields.

`sol.x`	Mesh selected by `dde23`
`sol.y`	Approximation to $y(x)$ at the mesh points in `sol.x`.
`sol.yp`	Approximation to $y'(x)$ at the mesh points in `sol.x`
`sol.solver`	Solver name, `'dde23'`

`sol = dde23(ddefun,lags,history,tspan,options)` solves as above with default integration properties replaced by values in `options`, an argument created with `ddeset`. See `ddeset` and "Initial Value Problems for DDEs" in the MATLAB documentation for details.

Commonly used options are scalar relative error tolerance `'RelTol'` (`1e-3` by default) and vector of absolute error tolerances `'AbsTol'` (all components are `1e-6` by default).

Use the `'Jumps'` option to solve problems with discontinuities in the history or solution. Set this option to a vector that contains the locations of discontinuities in the solution prior to `t0` (the history) or in coefficients of the equations at known values of t after `t0`.

Use the `'Events'` option to specify a function that `dde23` calls to find where functions $g(t, y(t), y(t-\tau_1), \ldots, y(t-\tau_k))$ vanish. This function must be of the form

```
[value,isterminal,direction] = events(t,y,Z)
```

and contain an event function for each event to be tested. For the `k`th event function in `events`:

- `value(k)` is the value of the `k`th event function.
- `isterminal(k) = 1` if you want the integration to terminate at a zero of this event function and `0` otherwise.
- `direction(k) = 0` if you want `dde23` to compute all zeros of this event function, `+1` if only zeros where the event function increases, and `-1` if only zeros where the event function decreases.

If you specify the `'Events'` option and events are detected, the output structure `sol` also includes fields:

`sol.xe`	Row vector of locations of all events, i.e., times when an event function vanished
`sol.ye`	Matrix whose columns are the solution values corresponding to times in `sol.xe`
`sol.ie`	Vector containing indices that specify which event occurred at the corresponding time in `sol.xe`

Examples

This example solves a DDE on the interval [0, 5] with lags 1 and 0.2. The function `ddex1de` computes the delay differential equations, and `ddex1hist` computes the history for `t <= 0`.

Note The demo `ddex1` contains the complete code for this example. To see the code in an editor, click the example name, or type `edit ddex1` at the command line. To run the example type `ddex1` at the command line.

```
sol = dde23(@ddex1de,[1, 0.2],@ddex1hist,[0, 5]);
```

This code evaluates the solution at 100 equally spaced points in the interval `[0,5]`, then plots the result.

```
tint = linspace(0,5);
yint = deval(sol,tint);
plot(tint,yint);
```

`ddex1` shows how you can code this problem using subfunctions. For more examples see `ddex2`.

Algorithm

`dde23` tracks discontinuities and integrates with the explicit Runge-Kutta (2,3) pair and interpolant of `ode23`. It uses iteration to take steps longer than the lags.

Purpose

Set up advisory link

Syntax

```
rc = ddeadv(channel,item,callback,upmtx,format,timeout)
```

Note Use COM, as described in COM Support in MATLAB. The ddeadv function will be removed in a future version of MATLAB.

Description

`rc = ddeadv(channel,item,callback,upmtx,format,timeout)` sets up an advisory link between MATLAB and a server application. When the data identified by the `item` argument changes, the string specified by the `callback` argument is passed to the `eval` function and evaluated. If the advisory link is a hot link, DDE modifies `upmtx`, the update matrix, to reflect the data in `item`.

If you omit optional arguments that are not at the end of the argument list, you must substitute the empty matrix for the missing argument(s).

If successful, `ddeadv` returns 1 in variable, `rc`. Otherwise it returns 0.

Arguments

`channel`	Conversation channel from `ddeinit`.
`item`	String specifying the DDE item name for the advisory link. Changing the data identified by `item` at the server triggers the advisory link.
`callback`	String specifying the callback that is evaluated on update notification. Changing the data identified by `item` at the server causes `callback` to get passed to the `eval` function to be evaluated.

upmtx (*optional*)	String specifying the name of a matrix that holds data sent with an update notification. If `upmtx` is included, changing `item` at the server causes `upmtx` to be updated with the revised data. Specifying `upmtx` creates a hot link. Omitting `upmtx` or specifying it as an empty string creates a warm link. If `upmtx` exists in the workspace, its contents are overwritten. If `upmtx` does not exist, it is created.
format (*optional*)	Two-element array specifying the format of the data to be sent on update. The first element specifies the Windows clipboard format to use for the data. The only currently supported format is `cf_text`, which corresponds to a value of 1. The second element specifies the type of the resultant matrix. Valid types are `numeric` (the default, which corresponds to a value of `0`) and `string` (which corresponds to a value of `1`). The default format array is `[1 0]`.
timeout (*optional*)	Scalar specifying the time-out limit for this operation. `timeout` is specified in milliseconds. (1000 milliseconds = 1 second). If advisory link is not established within `timeout` milliseconds, the function fails. The default value of `timeout` is three seconds.

Examples

Set up a hot link between a range of cells in Excel (Row 1, Column 1 through Row 5, Column 5) and the matrix `x`. If successful, display the matrix:

```
rc = ddeadv(channel, 'r1c1:r5c5', 'disp(x)', 'x');
```

Communication with Excel must have been established previously with a `ddeinit` command.

See Also

ddeexec, ddeinit, ddepoke, ddereq, ddeterm, ddeunadv

ddeexec

Purpose

Send string for execution

Syntax

```
rc = ddeexec(channel,command,item,timeout)
```

Note Use COM, as described in COM Support in MATLAB. The ddeexec function will be removed in a future version of MATLAB.

Description

`rc = ddeexec(channel,command,item,timeout)` sends a string for execution to another application via an established DDE conversation. Specify the string as the `command` argument.

If you omit optional arguments that are not at the end of the argument list, you must substitute the empty matrix for the missing argument(s).

If successful, `ddeexec` returns 1 in variable, `rc`. Otherwise it returns 0.

Arguments

`channel`	Conversation channel from `ddeinit`.
`command`	String specifying the command to be executed.
`item` (*optional*)	String specifying the DDE item name for execution. This argument is not used for many applications. If your application requires this argument, it provides additional information for `command`. Consult your server documentation for more information.
timeout (*optional*)	Scalar specifying the time-out limit for this operation. `timeout` is specified in milliseconds. (1000 milliseconds = 1 second). The default value of `timeout` is three seconds.

Examples

Given the channel assigned to a conversation, send a command to Excel:

```
rc = ddeexec(channel,'[formula.goto("r1c1")]')
```

Communication with Excel must have been established previously with a `ddeinit` command.

See Also

`ddeadv`, `ddeinit`, `ddepoke`, `ddereq`, `ddeterm`, `ddeunadv`

ddeget

Purpose

Extract properties from delay differential equations options structure

Syntax

```
val = ddeget(options,'name')
val = ddeget(options,'name',default)
```

Description

`val = ddeget(options,'name')` extracts the value of the named property from the structure `options`, returning an empty matrix if the property value is not specified in `options`. It is sufficient to type only the leading characters that uniquely identify the property. Case is ignored for property names. `[]` is a valid `options` argument.

`val = ddeget(options,'name',default)` extracts the named property as above, but returns `val = default` if the named property is not specified in `options`. For example,

```
val = ddeget(opts,'RelTol',1e-4);
```

returns `val = 1e-4` if the `RelTol` is not specified in `opts`.

See Also

`dde23`, `ddesd`, `ddeset`

Purpose

Initiate Dynamic Data Exchange (DDE) conversation

Syntax

Note Use COM, as described in COM Support in MATLAB. The ddeinit function will be removed in a future version of MATLAB.

```
channel = ddeinit('service','topic')
```

Description

`channel = ddeinit('service','topic')` returns a channel handle assigned to the conversation, which is used with other MATLAB DDE functions. `'service'` is a string specifying the service or application name for the conversation. `'topic'` is a string specifying the topic for the conversation.

Examples

To initiate a conversation with Excel for the spreadsheet `'stocks.xls'`:

```
channel = ddeinit('excel','stocks.xls')

channel =
0.00
```

ddepoke

Purpose

Send data to application

Syntax

```
rc = ddepoke(channel,item,data,format,timeout)
```

Note Use COM, as described in COM Support in MATLAB. The ddepoke function will be removed in a future version of MATLAB.

Description

`rc = ddepoke(channel,item,data,format,timeout)` sends data to an application via an established DDE conversation. `ddepoke` formats the data matrix as follows before sending it to the server application:

- String matrices are converted, element by element, to characters and the resulting character buffer is sent.
- Numeric matrices are sent as tab-delimited columns and carriage-return, line-feed delimited rows of numbers. Only the real part of nonsparse matrices are sent.

If you omit optional arguments that are not at the end of the argument list, you must substitute the empty matrix for the missing argument(s).

If successful, `ddepoke` returns 1 in variable, `rc`. Otherwise it returns 0.

Arguments

`channel`	Conversation channel from `ddeinit`.
`item`	String specifying the DDE item for the data sent. Item is the server data entity that is to contain the data sent in the `data` argument.
`data`	Matrix containing the data to send.

`format` (*optional*)	Scalar specifying the format of the data requested. The value indicates the Windows clipboard format to use for the data transfer. The only format currently supported is `cf_text`, which corresponds to a value of `1`.
`timeout` (*optional*)	Scalar specifying the time-out limit for this operation. `timeout` is specified in milliseconds. (1000 milliseconds = 1 second). The default value of `timeout` is three seconds.

Examples

Assume that a conversation channel with Excel has previously been established with `ddeinit`. To send a 5-by-5 identity matrix to Excel, placing the data in Row 1, Column 1 through Row 5, Column 5:

```
rc = ddepoke(channel, 'r1c1:r5c5', eye(5));
```

See Also

`ddeadv`, `ddeexec`, `ddeinit`, `ddereq`, `ddeterm`, `ddeunadv`

ddereq

Purpose

Request data from application

Syntax

```
data = ddereq(channel,item,format,timeout)
```

Note Use COM, as described in COM Support in MATLAB. The ddereq function will be removed in a future version of MATLAB.

Description

`data = ddereq(channel,item,format,timeout)` requests data from a server application via an established DDE conversation. `ddereq` returns a matrix containing the requested data or an empty matrix if the function is unsuccessful.

If you omit optional arguments that are not at the end of the argument list, you must substitute the empty matrix for the missing argument(s).

If successful, `ddereq` returns a matrix containing the requested data in variable, `data`. Otherwise, it returns an empty matrix.

Arguments

`channel`	Conversation channel from `ddeinit`.
`item`	String specifying the server application's DDE item name for the data requested.

format (*optional*)	Two-element array specifying the format of the data requested. The first element specifies the Windows clipboard format to use. The only currently supported format is `cf_text`, which corresponds to a value of 1. The second element specifies the type of the resultant matrix. Valid types are `numeric` (the default, which corresponds to `0`) and `string` (which corresponds to a value of `1`). The default format array is `[1 0]`.
timeout (*optional*)	Scalar specifying the time-out limit for this operation. `timeout` is specified in milliseconds. (1000 milliseconds = 1 second). The default value of `timeout` is three seconds.

Examples

Assume that you have an Excel spreadsheet `stocks.xls`. This spreadsheet contains the prices of three stocks in row 3 (columns 1 through 3) and the number of shares of these stocks in rows 6 through 8 (column 2). Initiate conversation with Excel with the command

```
channel = ddeinit('excel','stocks.xls')
```

DDE functions require the `rxcy` reference style for Excel worksheets. In Excel terminology the prices are in `r3c1:r3c3` and the shares in `r6c2:r8c2`.

Request the prices from Excel:

```
prices = ddereq(channel,'r3c1:r3c3')

prices =
42.50
15.00
78.88
```

Next, request the number of shares of each stock:

```
shares = ddereq(channel, 'r6c2:r8c2')

shares =
100.00
500.00
300.00
```

See Also

ddeadv, ddeexec, ddeinit, ddepoke, ddeterm, ddeunadv

Purpose

Solve delay differential equations (DDEs) with general delays

Syntax

```
sol = ddesd(ddefun,delays,history,tspan)
sol = ddesd(ddefun,delays,history,tspan,options)
```

Arguments

`ddefun`

Function handle that evaluates the right side of the differential equations $y'(t) = f(t, y(t), y(d(1)), \ldots, y(d(k)))$. The function must have the form

```
dydt = ddefun(t,y,Z)
```

where `t` corresponds to the current t, `y` is a column vector that approximates $y(t)$, and `Z(:,j)` approximates $y(d(j))$ for delay $d(j)$ given as component j of `delays(t,y)`. The output is a column vector corresponding to $f(t, y(t), y(d(1)), \ldots, y(d(k)))$.

`delays`

Function handle that returns a column vector of delays $d(j)$. The delays can depend on both t and $y(t)$. `ddesd` imposes the requirement that $d(j) \le t$ by using `min(`$d(j)$`,` t`)`.

If all the delay functions have the form $d(j) = t - \tau_j$, you can set the argument `delays` to a constant vector `delays`$(j) = \tau_j$. With delay functions of this form, `ddesd` is used exactly like `dde23`.

`history`	Specify `history` in one of three ways: • A function of t such that `y = history(t)` returns the solution $y(t)$ for $t \le t_0$ as a column vector • A constant column vector, if $y(t)$ is constant • The solution `sol` from a previous integration, if this call continues that integration
`tspan`	Interval of integration as a vector `[t0,tf]` with `t0 < tf`.
`options`	Optional integration argument. A structure you create using the `ddeset` function. See `ddeset` for details.

Description

`sol = ddesd(ddefun,delays,history,tspan)` integrates the system of DDEs

$$y'(t) = f(t, y(t), y(d(1)), \ldots, y(d(k)))$$

on the interval $[t_0, t_f]$, where delays $d(j)$ can depend on both t and $y(t)$, and $t_0 < t_f$. Inputs `ddefun` and `delays` are function handles. See "Function Handles" in the MATLAB Programming documentation for more information.

"Parameterizing Functions Called by Function Functions" in the MATLAB Mathematics documentation, explains how to provide additional parameters to the functions `ddefun`, `delays`, and `history`, if necessary.

`ddesd` returns the solution as a structure `sol`. Use the auxiliary function `deval` and the output `sol` to evaluate the solution at specific points `tint` in the interval `tspan = [t0,tf]`.

```
yint = deval(sol,tint)
```

The structure `sol` returned by `ddesd` has the following fields.

`sol.x`	Mesh selected by `ddesd`
`sol.y`	Approximation to $y(x)$ at the mesh points in `sol.x`.
`sol.yp`	Approximation to $y'(x)$ at the mesh points in `sol.x`
`sol.solver`	Solver name, `'ddesd'`

`sol = ddesd(ddefun,delays,history,tspan,options)` solves as above with default integration properties replaced by values in `options`, an argument created with `ddeset`. See `ddeset` and "Initial Value Problems for DDEs" in the MATLAB documentation for details.

Commonly used options are scalar relative error tolerance `'RelTol'` (`1e-3` by default) and vector of absolute error tolerances `'AbsTol'` (all components are `1e-6` by default).

Use the `'Events'` option to specify a function that `ddesd` calls to find where functions $g(t, y(t), y(d(1)), \ldots, y(d(k)))$ vanish. This function must be of the form

```
[value,isterminal,direction] = events(t,y,Z)
```

and contain an event function for each event to be tested. For the `k`th event function in `events`:

- `value(k)` is the value of the `k`th event function.
- `isterminal(k) = 1` if you want the integration to terminate at a zero of this event function and `0` otherwise.
- `direction(k) = 0` if you want `ddesd` to compute all zeros of this event function, `+1` if only zeros where the event function increases, and `-1` if only zeros where the event function decreases.

If you specify the 'Events' option and events are detected, the output structure sol also includes fields:

sol.xe	Row vector of locations of all events, i.e., times when an event function vanished
sol.ye	Matrix whose columns are the solution values corresponding to times in sol.xe
sol.ie	Vector containing indices that specify which event occurred at the corresponding time in sol.xe

Examples

The equation

```
sol = ddesd(@ddex1de,@ddex1delays,@ddex1hist,[0,5]);
```

solves a DDE on the interval [0,5] with delays specified by the function ddex1delays and differential equations computed by ddex1de. The history is evaluated for $t \le 0$ by the function ddex1hist. The solution is evaluated at 100 equally spaced points in [0,5]:

```
tint = linspace(0,5);
yint = deval(sol,tint);
```

and plotted with

```
plot(tint,yint);
```

This problem involves constant delays. The delay function has the form

```
function d = ddex1delays(t,y)
%DDEX1DELAYS  Delays for using with DDEX1DE.
d = [ t - 1
      t - 0.2];
```

The problem can also be solved with the syntax corresponding to constant delays

```
delays = [1, 0.2];
```

```
sol = ddesd(@ddex1de,delays,@ddex1hist,[0, 5]);
```

or using dde23:

```
sol = dde23(@ddex1de,delays,@ddex1hist,[0, 5]);
```

For more examples of solving delay differential equations see ddex2 and ddex3.

ddeset

Purpose

Create or alter delay differential equations options structure

Syntax

```
options = ddeset('name1',value1,'name2',value2,...)
options = ddeset(oldopts,'name1',value1,...)
options = ddeset(oldopts,newopts)
ddeset
```

Description

`options = ddeset('name1',value1,'name2',value2,...)` creates an integrator options structure `options` in which the named properties have the specified values. Any unspecified properties have default values. It is sufficient to type only the leading characters that uniquely identify the property. `ddeset` ignores case for property names.

`options = ddeset(oldopts,'name1',value1,...)` alters an existing options structure `oldopts`. This overwrites any values in `oldopts` that are specified using name/value pairs and returns the modified structure as the output argument.

`options = ddeset(oldopts,newopts)` combines an existing options structure `oldopts` with a new options structure `newopts`. Any values set in `newopts` overwrite the corresponding values in `oldopts`.

`ddeset` with no input arguments displays all property names and their possible values, indicating defaults with braces `{}`.

You can use the function `ddeget` to query the `options` structure for the value of a specific property.

DDE Properties

The following sections describe the properties that you can set using `ddeset`. There are several categories of properties:

- Error control
- Solver output
- Step size
- Event location
- Discontinuities

Error Control Properties

At each step, solvers `dde23` and `ddesd` estimate an error `e`. `dde23` estimates the local truncation error, and `ddesd` estimates the residual. In either case, this error must be less than or equal to the acceptable error, which is a function of the specified relative tolerance, `RelTol`, and the specified absolute tolerance, `AbsTol`.

```
|e(i)| ≤ max(RelTol*abs(y(i)),AbsTol(i))
```

For routine problems, `dde23` and `ddesd` deliver accuracy roughly equivalent to the accuracy you request. They deliver less accuracy for problems integrated over "long" intervals and problems that are moderately unstable. Difficult problems may require tighter tolerances than the default values. For relative accuracy, adjust `RelTol`. For the absolute error tolerance, the scaling of the solution components is important: if `|y|` is somewhat smaller than `AbsTol`, the solver is not constrained to obtain any correct digits in `y`. You might have to solve a problem more than once to discover the scale of solution components.

Roughly speaking, this means that you want `RelTol` correct digits in all solution components except those smaller than thresholds `AbsTol(i)`. Even if you are not interested in a component `y(i)` when it is small, you may have to specify `AbsTol(i)` small enough to get some correct digits in `y(i)` so that you can accurately compute more interesting components

The following table describes the error control properties.

DDE Error Control Properties

Property	Value	Description
`RelTol`	Positive scalar {`1e-3`}	A relative error tolerance that applies to all components of the solution vector `y`. It is a measure of the error relative to the size of each solution component. Roughly, it controls the number of correct digits in all solution components except those smaller than thresholds `AbsTol(i)`. The default, `1e-3`, corresponds to 0.1% accuracy. The estimated error in each integration step satisfies `|e(i)|max(RelTol*abs(y(i)), AbsTol(i))`.
`AbsTol`	Positive scalar or vector {`1e-6`}	Absolute error tolerances that apply to the individual components of the solution vector. `AbsTol(i)` is a threshold below which the value of the `i`th solution component is unimportant. The absolute error tolerances determine the accuracy when the solution approaches zero. Even if you are not interested in a component `y(i)` when it is small, you may have to specify `AbsTol(i)` small enough to get some correct digits in `y(i)` so that you can accurately compute more interesting components. If `AbsTol` is a vector, the length of `AbsTol` must be the same as the length of the solution vector `y`. If `AbsTol` is a scalar, the value applies to all components of `y`.
`NormControl`	`on` | {`off`}	Control error relative to norm of solution. Set this property `on` to request that the solvers control the error in each integration step with `norm(e)<= max(RelTol*norm(y),AbsTol)`. By default, solvers `dde23` and `ddesd` use a more stringent component-wise error control.

Solver Output Properties

You can use the solver output properties to control the output that the solvers generate.

DDE Solver Output Properties

Property	Value	Description

`OutputFcn`	Function handle {`@odeplot`}	The output function is a function that the solver calls after every successful integration step. To specify an output function, set `'OutputFcn'` to a function handle. For example,
		`options = ddeset('OutputFcn',...`
		`@myfun)`
		sets 'OutputFcn' to @myfun, a handle to the function `myfun`. See "Function Handles" in the MATLAB Programming documentation for more information.
		The output function must be of the form
		`status = myfun(t,y,flag)`
		"Parameterizing Functions Called by Function Functions" in the MATLAB Mathematics documentation, explains how to provide additional parameters to `myfun`, if necessary.
		The solver calls the specified output function with the following flags. Note that the syntax of the call differs with the flag. The function must respond appropriately:

DDE Solver Output Properties (Continued)

Property	Value	Description
		• `init` — The solver calls `myfun(tspan,y0,'init')` before beginning the integration to allow the output function to initialize. `tspan` is the input argument to solvers `dde23` and `ddesd`. `y0` is the initial value of the solution, either from `history(t0)` or specified in the `initialY` option. • {none} — The solver calls `status = myfun(t,y)` after each integration step on which output is requested. `t` contains points where output was generated during the step, and `y` is the numerical solution at the points in `t`. If `t` is a vector, the `i`th column of `y` corresponds to the `i`th element of `t`. `myfun` must return a `status` output value of `0` or `1`. If literal > `status`, the solver halts integration. You can use this mechanism, for instance, to implement a **Stop** button. • done — The solver calls `myfun([],[],'done')` when integration is complete to allow the output function to perform any cleanup chores.
		You can use these general purpose output functions or you can edit them to create your own. Type `help functionname` at the command line for more information. • `odeplot` – time series plotting (default when you call the solver with no output argument and you have not specified an output function) • `odephas2` – two-dimensional phase plane plotting • `odephas3` – three-dimensional phase plane plotting • `odeprint` – print solution as the solver computes it

DDE Solver Output Properties (Continued)

Property	Value	Description

`OutputSel`	Vector of indices	Vector of indices specifying which components of the solution vector the `dde23` or `ddesd` solver passes to the output function. For example, if you want to use the `odeplot` output function, but you want to plot only the first and third components of the solution, you can do this using
		`options = ddeset...`
		`('OutputFcn',@odeplot,...`
		`'OutputSel',[1 3]);`
		By default, the solver passes all components of the solution to the output function.

`Stats`	`on` | {`off`}	Specifies whether the solver should display statistics about its computations. By default, `Stats` is `off`. If it is `on`, after solving the problem the solver displays: • The number of successful steps • The number of failed attempts • The number of times the DDE function was called

Step Size Properties

The step size properties let you specify the size of the first step the solver tries, potentially helping it to better recognize the scale of the problem. In addition, you can specify bounds on the sizes of subsequent time steps.

The following table describes the step size properties.

DDE Step Size Properties

Property	Value	Description
`InitialStep`	Positive scalar	Suggested initial step size. `InitialStep` sets an upper bound on the magnitude of the first step size the solver tries. If you do not set `InitialStep`, the solver bases the initial step size on the slope of the solution at the initial time `tspan(1)`. The initial step size is limited by the shortest delay. If the slope of all solution components is zero, the procedure might try a step size that is much too large. If you know this is happening or you want to be sure that the solver resolves important behavior at the start of the integration, help the code start by providing a suitable `InitialStep`.

DDE Step Size Properties (Continued)

Property	Value	Description
`MaxStep`	Positive scalar {`0.1* abs(t0-tf)`}	Upper bound on solver step size. If the differential equation has periodic coefficients or solutions, it may be a good idea to set `MaxStep` to some fraction (such as 1/4) of the period. This guarantees that the solver does not enlarge the time step too much and step over a period of interest. Do *not* reduce `MaxStep`: • When the solution does not appear to be accurate enough. Instead, reduce the relative error tolerance `RelTol`, and use the solution you just computed to determine appropriate values for the absolute error tolerance vector `AbsTol`. (See "Error Control Properties" on page 2-829 for a description of the error tolerance properties.)
		• To make sure that the solver doesn't step over some behavior that occurs only once during the simulation interval. If you know the time at which the change occurs, break the simulation interval into two pieces and call the solver (`dde23` or `ddesd`) twice. If you do not know the time at which the change occurs, try reducing the error tolerances `RelTol` and `AbsTol`. Use `MaxStep` as a last resort.

Event Location Property

In some DDE problems, the times of specific events are important. While solving a problem, the `dde23` and `ddesd` solvers can detect such events by locating transitions to, from, or through zeros of user-defined functions.

The following table describes the `Events` property.

DDE Events Property

String	Value	Description
`Events`	Function handle	Handle to a function that includes one or more event functions. See "Function Handles" in the MATLAB Programming documentation for more information. The function is of the form `[value,isterminal,direction] = events(t,y,Z)` `value`, `isterminal`, and `direction` are vectors for which the `i`th element corresponds to the `i`th event function:

DDE Events Property (Continued)

String	Value	Description
		• `value(i)` is the value of the `i`th event function. • `isterminal(i) = 1` if you want the integration to terminate at a zero of this event function, and `0` otherwise. • `direction(i) = 0` if you want the solver (`dde23` or `ddesd`) to locate all zeros (the default), `+1` if only zeros where the event function is increasing, and `-1` if only zeros where the event function is decreasing. If you specify an events function and events are detected, the solver returns three additional fields in the solution structure `sol`: • `sol.xe` is a row vector of times at which events occur. • `sol.ye` is a matrix whose columns are the solution values corresponding to times in `sol.xe`. • `sol.ie` is a vector containing indices that specify which event occurred at the corresponding time in `sol.xe`.
		For examples that use an event function while solving ordinary differential equation problems, see "Example: Simple Event Location" (`ballode`) and "Example: Advanced Event Location" (`orbitode`), in the MATLAB Mathematics documentation.

Discontinuity Properties

Solvers `dde23` and `ddesd` can solve problems with discontinuities in the history or in the coefficients of the equations. The following properties enable you to provide these solvers with a different initial value, and, for `dde23`, locations of known discontinuities. See "Discontinuities" in the MATLAB Mathematics documentation for more information.

The following table describes the discontinuity properties.

DDE Discontinuity Properties

String	Value	Description
`Jumps`	Vector	Location of discontinuities. Points t where the history or solution may have a jump discontinuity in a low-order derivative. This applies only to the `dde23` solver.
`InitialY`	Vector	Initial value of solution. By default the initial value of the solution is the value returned by `history` at the initial point. Supply a different initial value as the value of the `InitialY` property.

Example

To create an options structure that changes the relative error tolerance of the solver from the default value of `1e-3` to `1e-4`, enter

```
options = ddeset('RelTol', 1e-4);
```

To recover the value of `'RelTol'` from `options`, enter

```
ddeget(options, 'RelTol')

ans =

   1.0000e-004
```

See Also

`dde23`, `ddesd`, `ddeget`, `function_handle` (`@`)

Purpose

Terminate Dynamic Data Exchange (DDE) conversation

Syntax

Note Use COM, as described in COM Support in MATLAB. The ddeterm function will be removed in a future version of MATLAB.

```
rc = ddeterm(channel)
```

Description

`rc = ddeterm(channel)` accepts a channel handle returned by a previous call to `ddeinit` that established the DDE conversation. `ddeterm` terminates this conversation. `rc` is a return code where `0` indicates failure and `1` indicates success.

Examples

To close a conversation channel previously opened with `ddeinit`:

```
rc = ddeterm(channel)

rc =
1.00
```

See Also

`ddeadv`, `ddeexec`, `ddeinit`, `ddepoke`, `ddereq`, `ddeunadv`

ddeunadv

Purpose

Release advisory link

Syntax

```
rc = ddeunadv(channel,item,format,timeout)
```

Note Use COM, as described in COM Support in MATLAB. The ddeunadv function will be removed in a future version of MATLAB.

Description

`rc = ddeunadv(channel,item,format,timeout)` releases the advisory link between MATLAB and the server application established by an earlier `ddeadv` call. The `channel`, *`item`*, and `format` must be the same as those specified in the call to `ddeadv` that initiated the link. If you include the `timeout` argument but accept the default `format`, you must specify `format` as an empty matrix.

If successful, `ddeunadv` returns 1 in variable, `rc`. Otherwise it returns 0.

Arguments

`channel`	Conversation channel from `ddeinit`.
`item`	String specifying the DDE item name for the advisory link. Changing the data identified by `item` at the server triggers the advisory link.
format (*optional*)	Two-element array. This must be the same as the `format` argument for the corresponding `ddeadv` call.
timeout (*optional*)	Scalar specifying the time-out limit for this operation. `timeout` is specified in milliseconds. (1000 milliseconds = 1 second). The default value of `timeout` is three seconds.

Example

To release an advisory link established previously with `ddeadv`:

```
rc = ddeunadv(channel, 'r1c1:r5c5')
rc =
```

```
1.00
```

See Also

ddeadv, ddeexec, ddeinit, ddepoke, ddereq, ddeterm

deal

Purpose

Distribute inputs to outputs

Note As of MATLAB Version 7.0, you can access the contents of cell arrays and structure fields without using the `deal` function. See Example 3, below.

Syntax

```
[Y1, Y2, Y3, ...] = deal(X)
[Y1, Y2, Y3, ...] = deal(X1, X2, X3, ...)
[S.field] = deal(X)
[X{:}] = deal(A.field)
[Y1, Y2, Y3, ...] = deal(X{:})
[Y1, Y2, Y3, ...] = deal(S.field)
```

Description

`[Y1, Y2, Y3, ...] = deal(X)` copies the single input to all the requested outputs. It is the same as `Y1 = X, Y2 = X, Y3 = X, ...`

`[Y1, Y2, Y3, ...] = deal(X1, X2, X3, ...)` is the same as `Y1 = X1; Y2 = X2; Y3 = X3; ...`

Remarks

`deal` is most useful when used with cell arrays and structures via comma-separated list expansion. Here are some useful constructions:

`[S.field] = deal(X)` sets all the fields with the name `field` in the structure array `S` to the value `X`. If `S` doesn't exist, use `[S(1:m).field] = deal(X)`.

`[X{:}] = deal(A.field)` copies the values of the field with name `field` to the cell array `X`. If `X` doesn't exist, use `[X{1:m}] = deal(A.field)`.

`[Y1, Y2, Y3, ...] = deal(X{:})` copies the contents of the cell array `X` to the separate variables `Y1, Y2, Y3, ...`

`[Y1, Y2, Y3, ...] = deal(S.field)` copies the contents of the fields with the name `field` to separate variables `Y1, Y2, Y3, ...`

Examples

Example 1 — Assign Data From a Cell Array

Use `deal` to copy the contents of a 4-element cell array into four separate output variables.

```
C = {rand(3) ones(3,1) eye(3) zeros(3,1)};
[a,b,c,d] = deal(C{:})

a =
    0.9501    0.4860    0.4565
    0.2311    0.8913    0.0185
    0.6068    0.7621    0.8214

b =
    1
    1
    1

c =
    1    0    0
    0    1    0
    0    0    1

d =
    0
    0
    0
```

Example 2 — Assign Data From Structure Fields

Use `deal` to obtain the contents of all the name fields in a structure array:

```
A.name = 'Pat'; A.number = 176554;
A(2).name = 'Tony'; A(2).number = 901325;
[name1,name2] = deal(A(:).name)

name1 =
   Pat
```

```
name2 =
   Tony
```

Example 3 — Doing the Same Without deal

As of MATLAB Version 7.0, you can, in most cases, access the contents of cell arrays and structure fields without using the `deal` function. The two commands shown below perform the same operation as those used in the previous two examples, except that these commands do not require `deal`.

```
[a,b,c,d] = C{:}
[name1,name2] = A(:).name
```

See Also

`cell`, `iscell`, `celldisp`, `struct`, `isstruct`, `fieldnames`, `isfield`, `orderfields`, `rmfield`, `cell2struct`, `struct2cell`

Purpose

Strip trailing blanks from end of string

Syntax

```
str = deblank(str)
c = deblank(c)
```

Description

`str = deblank(str)` removes all trailing whitespace and null characters from the end of character string `str`. A whitespace is any character for which the `isspace` function returns logical 1 (`true`).

`c = deblank(c)` when `c` is a cell array of strings, applies `deblank` to each element of `c`.

The `deblank` function is useful for cleaning up the rows of a character array.

Examples

Example 1 – Removing Trailing Blanks From a String

Compose a string `str` that contains space, tab, and null characters:

```
NL = char(0);    TAB = char(9);
str = [NL 32 TAB NL 'AB' 32 NL 'CD' NL 32 TAB NL 32];
```

Display all characters of the string between | symbols:

```
['|' str '|']
ans =
    |    AB  CD       |
```

Remove trailing whitespace and null characters, and redisplay the string:

```
newstr = deblank(str);

['|' newstr '|']
ans =
    |    AB  CD|
```

Example 2– Removing Trailing Blanks From a Cell Array of Strings

```
A{1,1} = 'MATLAB    ';
A{1,2} = 'SIMULINK    ';
A{2,1} = 'Toolboxes    ';
A{2,2} = 'The MathWorks    ';
A =

    'MATLAB    '        'SIMULINK    '
    'Toolboxes    '    'The MathWorks    '

deblank(A)
ans =

    'MATLAB'            'SIMULINK'
    'Toolboxes'         'The MathWorks'
```

Purpose

List M-file debugging functions

GUI Alternatives

Use the **Debug** menu in most desktop tools, or use the Editor/Debugger.

Syntax

```
debug
```

Description

`debug` lists M-file debugging functions.

Use debugging functions (listed in the See Also section) to help you identify problems in your M-files. Set breakpoints using `dbstop`. When MATLAB encounters a breakpoint during execution, it enters debug mode, the Editor/Debugger becomes active, and the prompt in the Command Window changes to a `K>>`. Any MATLAB command is allowed at the prompt. To resume execution, use `dbcont` or `dbstep`. To exit from debug mode, use `dbquit`.

To open the M-File in the Editor/Debugger when execution reaches a breakpoint, select **Debug > Open M-Files When Debugging**.

`dbclear`, `dbcont`, `dbdown`, `dbquit`, `dbstack`, `dbstatus`, `dbstep`, `dbstop`, `dbtype`, `dbup`, `evalin`, `whos`

"Finding Errors, Debugging, and Correcting M-Files" in the MATLAB Desktop Tools and Development Environment documentation

dec2base

Purpose

Convert decimal to base N number in string

Syntax

```
str = dec2base(d, base)
str = dec2base(d, base, n)
```

Description

`str = dec2base(d, base)` converts the nonnegative integer `d` to the specified `base`. `d` must be a nonnegative integer smaller than 2^52, and `base` must be an integer between 2 and 36. The returned argument `str` is a string.

`str = dec2base(d, base, n)` produces a representation with at least `n` digits.

Examples

The expression `dec2base(23, 2)` converts 23_{10} to base 2, returning the string `'10111'`.

See Also

`base2dec`

Purpose

Convert decimal to binary number in string

Syntax

```
str = dec2bin(d)
str = dec2bin(d,n)
```

Description

returns the

`str = dec2bin(d)` binary representation of `d` as a string. `d` must be a nonnegative integer smaller than 2^52.

`str = dec2bin(d,n)` produces a binary representation with at least `n` bits.

Examples

Decimal 23 converts to binary 010111:

```
dec2bin(23)
ans =
    10111
```

See Also

`bin2dec`, `dec2hex`

dec2hex

Purpose

Convert decimal to hexadecimal number in string

Syntax

```
str = dec2hex(d)
str = dec2hex(d, n)
```

Description

`str = dec2hex(d)` converts the decimal integer `d` to its hexadecimal representation stored in a MATLAB string. `d` must be a nonnegative integer smaller than 2^52.

`str = dec2hex(d, n)` produces a hexadecimal representation with at least `n` digits.

Examples

To convert decimal 1023 to hexadecimal,

```
dec2hex(1023)

ans =
    3FF
```

See Also

`dec2bin`, `format`, `hex2dec`, `hex2num`

Purpose

Compute consistent initial conditions for `ode15i`

Syntax

```
[y0mod,yp0mod] = decic(odefun,t0,y0,fixed_y0,yp0,fixed_yp0)
[y0mod,yp0mod] = decic(odefun,t0,y0,fixed_y0,yp0,fixed_yp0,
   options)
[y0mod,yp0mod,resnrm] = decic(odefun,t0,y0,fixed_y0,yp0,
   fixed_yp0...)
```

Description

`[y0mod,yp0mod] = decic(odefun,t0,y0,fixed_y0,yp0,fixed_yp0)` uses the inputs `y0` and `yp0` as initial guesses for an iteration to find output values that satisfy the requirement $f(t0, y0mod, yp0mod) = 0$, i.e., `y0mod` and `yp0mod` are consistent initial conditions. `odefun` is a function handle. See "Function Handles" in the MATLAB Programming documentation for more information. The function `decic` changes as few components of the guesses as possible. You can specify that `decic` holds certain components fixed by setting `fixed_y0(i) = 1` if no change is permitted in the guess for `y0(i)` and 0 otherwise. `decic` interprets `fixed_y0 = []` as allowing changes in all entries. `fixed_yp0` is handled similarly.

"Parameterizing Functions Called by Function Functions" in the MATLAB Mathematics documentation, explains how to provide additional parameters to the function `odefun`, if necessary.

You cannot fix more than `length(y0)` components. Depending on the problem, it may not be possible to fix this many. It also may not be possible to fix certain components of `y0` or `yp0`. It is recommended that you fix no more components than necessary.

`[y0mod,yp0mod] = decic(odefun,t0,y0,fixed_y0,yp0,fixed_yp0,options)` computes as above with default tolerances for consistent initial conditions, `AbsTol` and `RelTol`, replaced by the values in options, a structure you create with the `odeset` function.

`[y0mod,yp0mod,resnrm] = decic(odefun,t0,y0,fixed_y0,yp0,fixed_yp0...)` returns the

norm of `odefun(t0,y0mod,yp0mod)` as `resnrm`. If the norm seems unduly large, use `options` to decrease `RelTol` (`1e-3` by default).

Examples

These demos provide examples of the use of `decic` in solving implicit ODEs: `ihb1dae`, `iburgersode`.

See Also

`ode15i`, `odeget`, `odeset`, `function_handle` (`@`)

Purpose

Deconvolution and polynomial division

Syntax

```
[q,r] = deconv(v,u)
```

Description

`[q,r] = deconv(v,u)` deconvolves vector `u` out of vector `v`, using long division. The quotient is returned in vector `q` and the remainder in vector `r` such that `v = conv(u,q)+r` .

If `u` and `v` are vectors of polynomial coefficients, convolving them is equivalent to multiplying the two polynomials, and deconvolution is polynomial division. The result of dividing `v` by `u` is quotient `q` and remainder `r`.

Examples

If

```
u = [1   2   3   4]
v = [10   20   30]
```

the convolution is

```
c = conv(u,v)
c =
    10     40     100     160     170     120
```

Use deconvolution to recover `u`:

```
[q,r] = deconv(c,u)
q =
    10    20    30
r =
    0     0     0     0     0     0
```

This gives a quotient equal to `v` and a zero remainder.

Algorithm

`deconv` uses the `filter` primitive.

See Also

`conv`, `residue`

Purpose

Discrete Laplacian

Syntax

```
L = del2(U)
-L = del2(U)
L = del2(U,h)
L = del2(U,hx,hy)
L = del2(U,hx,hy,hz,...)
```

Definition

If the matrix `U` is regarded as a function $u(x, y)$ evaluated at the point on a square grid, then `4*del2(U)` is a finite difference approximation of Laplace's differential operator applied to u, that is:

$$l = \frac{\nabla^2 u}{4} = \frac{1}{4}\left(\frac{d^2u}{dx^2} + \frac{d^2u}{dy^2}\right)$$

where:

$$l_{ij} = \frac{1}{4}(u_{i+1,j} + u_{i-1,j} + u_{i,j+1} + u_{i,j-1}) - u_{i,}$$

in the interior. On the edges, the same formula is applied to a cubic extrapolation.

For functions of more variables $u(x, y, z, \ldots)$, `del2(U)` is an approximation,

$$l = \frac{\nabla^2 u}{2N} = \frac{1}{2N}\left(\frac{d^2u}{dx^2} + \frac{d^2u}{dy^2} + \frac{d^2u}{dz^2} + \ldots\right)$$

where N is the number of variables in u.

Description

`L = del2(U)` where `U` is a rectangular array is a discrete approximation of

$$l = \frac{\nabla^2 u}{4} = \frac{1}{4}\left(\frac{d^2u}{dx^2} + \frac{d^2u}{dy^2}\right)$$

The matrix `L` is the same size as `U` with each element equal to the difference between an element of `U` and the average of its four neighbors.

`-L = del2(U)` when `U` is an multidimensional array, returns an approximation of

$$\frac{\nabla^2 u}{2N}$$

where N is `ndims(u)`.

`L = del2(U,h)` where `H` is a scalar uses `H` as the spacing between points in each direction (`h=1` by default).

`L = del2(U,hx,hy)` when `U` is a rectangular array, uses the spacing specified by `hx` and `hy`. If `hx` is a scalar, it gives the spacing between points in the x-direction. If `hx` is a vector, it must be of length `size(u,2)` and specifies the x-coordinates of the points. Similarly, if `hy` is a scalar, it gives the spacing between points in the y-direction. If `hy` is a vector, it must be of length `size(u,1)` and specifies the y-coordinates of the points.

`L = del2(U,hx,hy,hz,...)` where `U` is multidimensional uses the spacing given by `hx`, `hy`, `hz`, ...

Remarks

MATLAB computes the boundaries of the grid by extrapolating the second differences from the interior. The algorithm used for this computation can be seen in the `del2` M-file code. To view this code, type

```
type del2
```

Examples

The function

$$u(x, y) = x^2 + y^2$$

has

$$\nabla^2 u = 4$$

For this function, `4*del2(U)` is also `4`.

```
[x,y] = meshgrid(-4:4,-3:3);
U = x.*x+y.*y
U =
    25    18    13    10     9    10    13    18    25
    20    13     8     5     4     5     8    13    20
    17    10     5     2     1     2     5    10    17
    16     9     4     1     0     1     4     9    16
    17    10     5     2     1     2     5    10    17
    20    13     8     5     4     5     8    13    20
    25    18    13    10     9    10    13    18    25

V = 4*del2(U)
V =
     4     4     4     4     4     4     4     4     4
     4     4     4     4     4     4     4     4     4
     4     4     4     4     4     4     4     4     4
     4     4     4     4     4     4     4     4     4
     4     4     4     4     4     4     4     4     4
     4     4     4     4     4     4     4     4     4
     4     4     4     4     4     4     4     4     4
```

`diff`, `gradient`

Purpose

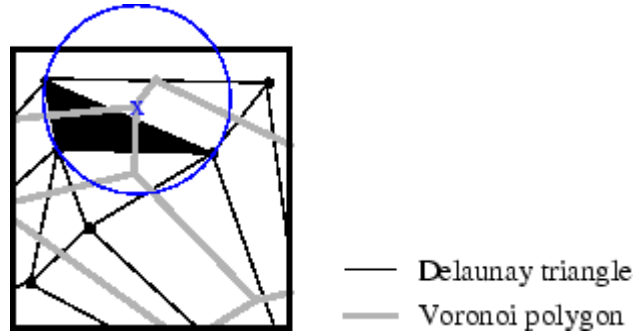
Delaunay triangulation

Syntax

```
TRI = delaunay(x,y)
TRI = delaunay(x,y,options)
```

Definition

Given a set of data points, the *Delaunay triangulation* is a set of lines connecting each point to its natural neighbors. The Delaunay triangulation is related to the Voronoi diagram — the circle circumscribed about a Delaunay triangle has its center at the vertex of a Voronoi polygon.



Description

`TRI = delaunay(x,y)` for the data points defined by vectors `x` and `y`, returns a set of triangles such that no data points are contained in any triangle's circumscribed circle. Each row of the `m`-by-3 matrix `TRI` defines one such triangle and contains indices into `x` and `y`. If the original data points are collinear or `x` is empty, the triangles cannot be computed and `delaunay` returns an empty matrix.

`delaunay` uses Qhull.

`TRI = delaunay(x,y,options)` specifies a cell array of strings `options` to be used in Qhull via `delaunayn`. The default options are `{'Qt','Qbb','Qc'}`.

If `options` is `[]`, the default options are used. If `options` is `{''}`, no options are used, not even the default. For more information on Qhull and its options, see `http://www.qhull.org`.

Remarks

The Delaunay triangulation is used by: `griddata` (to interpolate scattered data), `voronoi` (to compute the `voronoi` diagram), and is useful by itself to create a triangular grid for scattered data points.

The functions `dsearch` and `tsearch` search the triangulation to find nearest neighbor points or enclosing triangles, respectively.

Visualization

Use one of these functions to plot the output of `delaunay`:

`triplot` — Displays the triangles defined in the `m`-by-3 matrix `TRI`. See Example 1.

`trisurf` — Displays each triangle defined in the m-by-3 matrix TRI as a surface in 3-D space. To see a 2-D surface, you can supply a vector of some constant value for the third dimension. For example

```
trisurf(TRI,x,y,zeros(size(x)))
```

See Example 2.

`trimesh` — Displays each triangle defined in the m-by-3 matrix TRI as a mesh in 3-D space. To see a 2-D surface, you can supply a vector of some constant value for the third dimension. For example,

```
trimesh(TRI,x,y,zeros(size(x)))
```

produces almost the same result as `triplot`, except in 3-D space. See Example 2.

Examples

Example 1

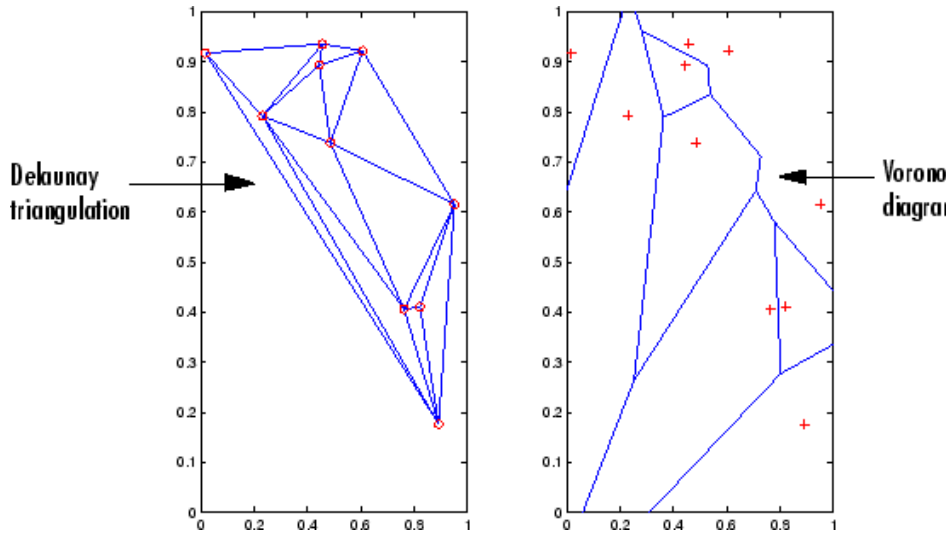
Plot the Delaunay triangulation for 10 randomly generated points.

```
rand('state',0);
x = rand(1,10);
y = rand(1,10);
```

```
TRI = delaunay(x,y);
subplot(1,2,1),...
triplot(TRI,x,y)
axis([0 1 0 1]);
hold on;
plot(x,y,'or');
hold off
```

Compare the Voronoi diagram of the same points:

```
[vx, vy] = voronoi(x,y,TRI);
subplot(1,2,2),...
plot(x,y,'r+',vx,vy,'b-'),...
axis([0 1 0 1])
```

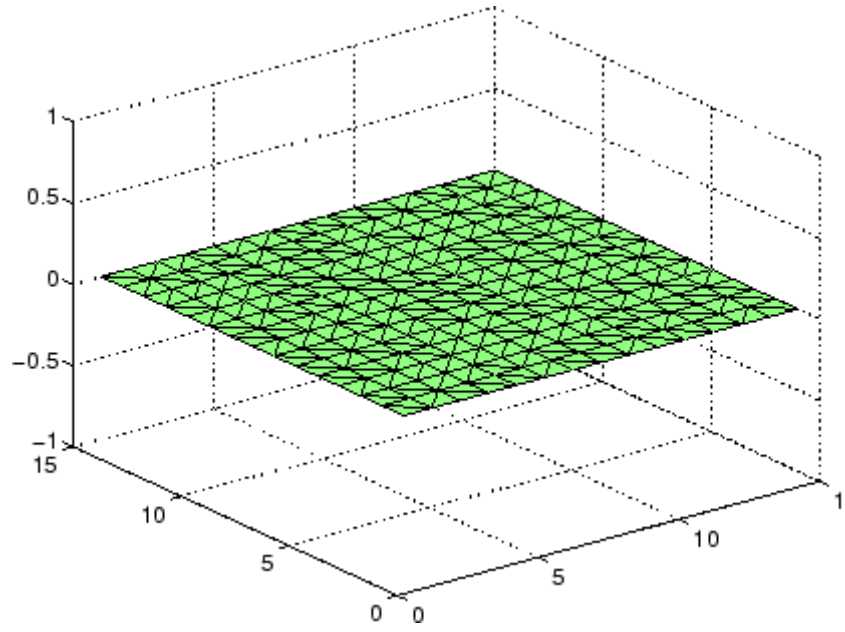


Example 2

Create a 2-D grid then use `trisurf` to plot its Delaunay triangulation in 3-D space by using `0`s for the third dimension.

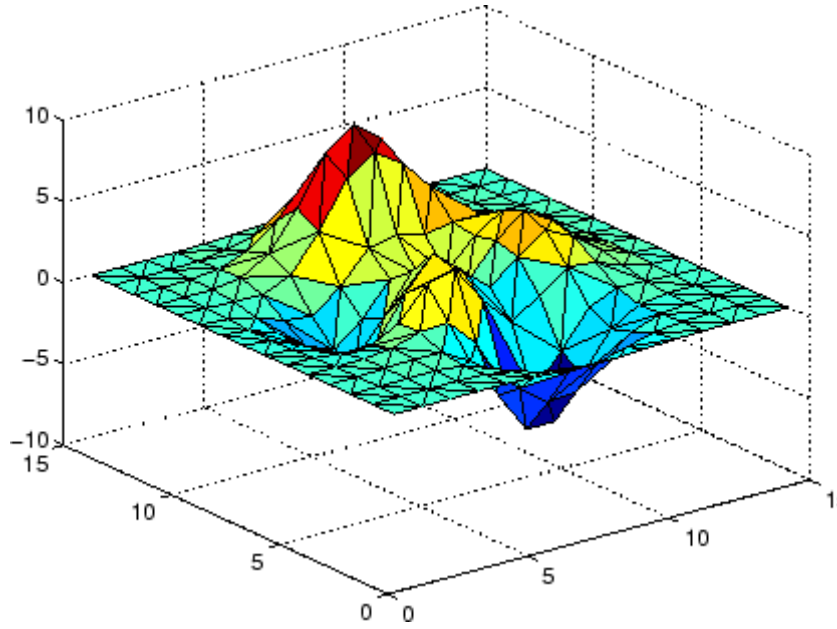
```
[x,y] = meshgrid(1:15,1:15);
```

```
tri = delaunay(x,y);
trisurf(tri,x,y,zeros(size(x)))
```



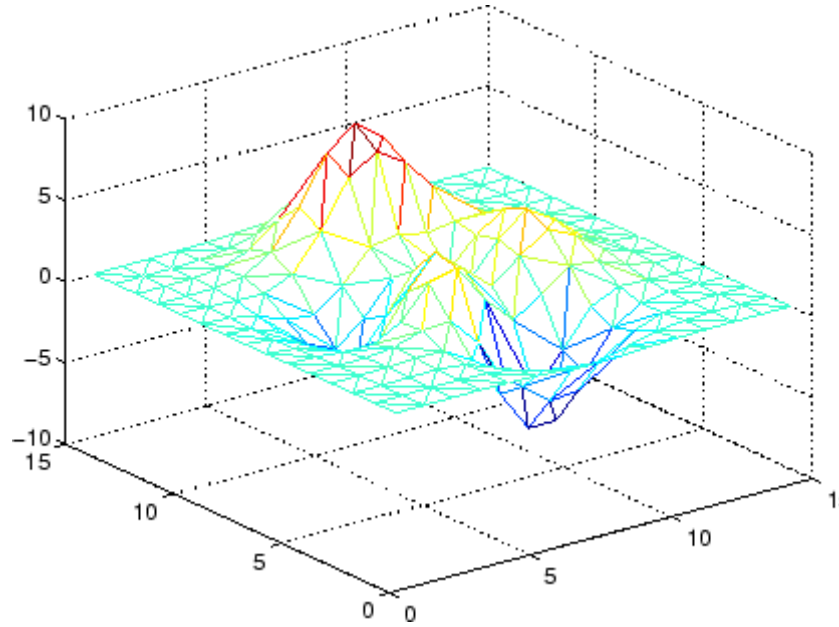
Next, generate `peaks` data as a 15-by-15 matrix, and use that data with the Delaunay triangulation to produce a surface in 3-D space.

```
z = peaks(15);
trisurf(tri,x,y,z)
```



You can use the same data with `trimesh` to produce a mesh in 3-D space.

```
trimesh(tri,x,y,z)
```



Example 3

The following example illustrates the `options` input for `delaunay`.

```
x = [-0.5 -0.5 0.5 0.5];
       y = [-0.5 0.5 0.5 -0.5];
```

The command

```
T = delaunay(X);
```

returns the following error message.

```
??? qhull input error: can not scale last coordinate. Input is
cocircular
   or cospherical. Use option 'Qz' to add a point at infinity.
```

The error message indicates that you should add `'Qz'` to the default Qhull options.

```
tri = delaunay(x,y,{'Qt','Qbb','Qc','Qz'})

tri =

     3     2     1
     3     4     1
```

Algorithm

`delaunay` is based on Qhull [1]. For information about Qhull, see `http://www.qhull.org/`. For copyright information, see `http://www.qhull.org/COPYING.txt`.

References

[1] Barber, C. B., D.P. Dobkin, and H.T. Huhdanpaa, "The Quickhull Algorithm for Convex Hulls," ACM Transactions on Mathematical Software, Vol. 22, No. 4, Dec. 1996, p. 469-483.

delaunay3

Purpose

3-D Delaunay tessellation

Syntax

```
T = delaunay3(x,y,z)
T = delaunay3(x,y,z,options)
```

Description

`T = delaunay3(x,y,z)` returns an array `T`, each row of which contains the indices of the points in `(x,y,z)` that make up a tetrahedron in the tessellation of `(x,y,z)`. `T` is a `numtes`-by-`4` array where `numtes` is the number of facets in the tessellation. `x`, `y`, and `z` are vectors of equal length. If the original data points are collinear or `x`, `y`, and `z` define an insufficient number of points, the triangles cannot be computed and `delaunay3` returns an empty matrix.

`delaunay3` uses Qhull.

`T = delaunay3(x,y,z,options)` specifies a cell array of strings `options` to be used in Qhull via `delaunay3`. The default options are `{'Qt','Qbb','Qc'}`.

If `options` is `[]`, the default options are used. If `options` is `{''}`, no options are used, not even the default. For more information on Qhull and its options, see `http://www.qhull.org`.

Visualization

Use `tetramesh` to plot `delaunay3` output. `tetramesh` displays the tetrahedrons defined in `T` as mesh. `tetramesh` uses the default transparency parameter value `'FaceAlpha' = 0.9`.

Examples

Example 1

This example generates a 3-dimensional Delaunay tessellation, then uses `tetramesh` to plot the tetrahedrons that form the corresponding simplex. `camorbit` rotates the camera position to provide a meaningful view of the figure.

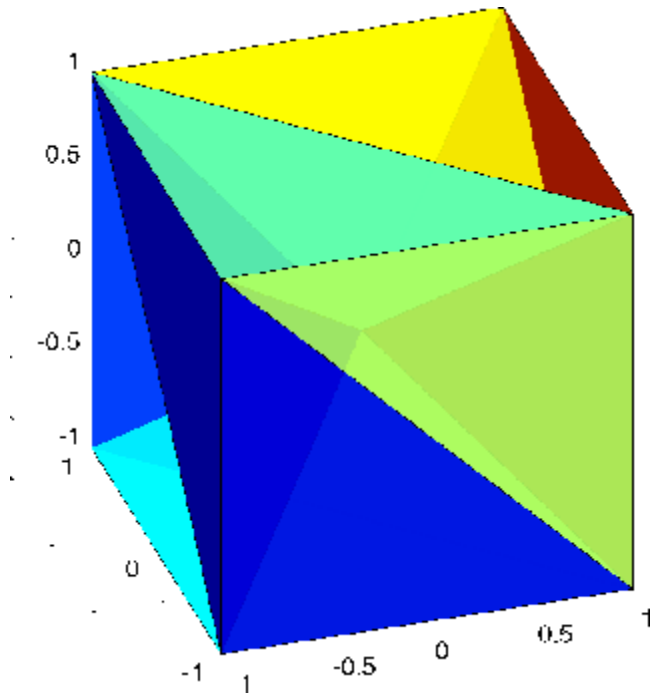
```
d = [-1 1];
[x,y,z] = meshgrid(d,d,d);  % A cube
x = [x(:);0];
y = [y(:);0];
z = [z(:);0];
```

```
% [x,y,z] are corners of a cube plus the center.
Tes = delaunay3(x,y,z)

Tes =

     9   1   5   6
     3   9   1   5
     2   9   1   6
     2   3   9   4
     2   3   9   1
     7   9   5   6
     7   3   9   5
     8   7   9   6
     8   2   9   6
     8   2   9   4
     8   3   9   4
     8   7   3   9

X = [x(:) y(:) z(:)];
tetramesh(Tes,X);camorbit(20,0)
```



Example 2

The following example illustrates the `options` input for `delaunay3`.

```
X = [-0.5 -0.5 -0.5 -0.5 0.5 0.5 0.5 0.5];
Y = [-0.5 -0.5 0.5 0.5 -0.5 -0.5 0.5 0.5];
Z = [-0.5 0.5 -0.5 0.5 -0.5 0.5 -0.5 0.5];
```

The command

```
T = delaunay3(X);
```

returns the following error message.

```
??? qhull input error: can not scale last coordinate. Input is
cocircular
```

```
    or cospherical. Use option 'Qz' to add a point at infinity.
```

The error message indicates that you should add `'Qz'` to the default Qhull options.

```
T = delaunay3( X, Y, Z, {'Qt', 'Qbb', 'Qc', 'Qz'} )

T =

     4     3     5     1
     4     2     5     1
     4     7     3     5
     4     7     8     5
     4     6     2     5
     4     6     8     5
```

Algorithm

`delaunay3` is based on Qhull [1]. For information about Qhull, see `http://www.qhull.org/`. For copyright information, see `http://www.qhull.org/COPYING.txt`.

See Also

`delaunay`, `delaunayn`

Reference

[1] Barber, C. B., D.P. Dobkin, and H.T. Huhdanpaa, "The Quickhull Algorithm for Convex Hulls," ACM Transactions on Mathematical Software, Vol. 22, No. 4, Dec. 1996, p. 469-483.

delaunayn

Purpose

N-D Delaunay tessellation

Syntax

```
T = delaunayn(X)
T = delaunayn(X, options)
```

Description

`T = delaunayn(X)` computes a set of simplices such that no data points of `X` are contained in any circumspheres of the simplices. The set of simplices forms the Delaunay tessellation. `X` is an `m`-by-`n` array representing m points in n-dimensional space. `T` is a `numt`-by-`(n+1)` array where each row contains the indices into `X` of the vertices of the corresponding simplex.

`delaunayn` uses Qhull.

`T = delaunayn(X, options)` specifies a cell array of strings `options` to be used as options in Qhull. The default options are:

- `{'Qt','Qbb','Qc'}` for 2- and 3-dimensional input
- `{'Qt','Qbb','Qc','Qx'}` for 4 and higher-dimensional input

If `options` is `[]`, the default options used. If `options` is `{''}`, no options are used, not even the default. For more information on Qhull and its options, see `http://www.qhull.org`.

Visualization

Plotting the output of `delaunayn` depends of the value of `n`:

- For `n = 2`, use `triplot`, `trisurf`, or `trimesh` as you would for `delaunay`.
- For `n = 3`, use `tetramesh` as you would for `delaunay3`.

  For more control over the color of the facets, use `patch` to plot the output. For an example, see “Tessellation and Interpolation of Scattered Data in Higher Dimensions” in the MATLAB documentation.
- You cannot plot `delaunayn` output for `n > 3`.

Examples

Example 1

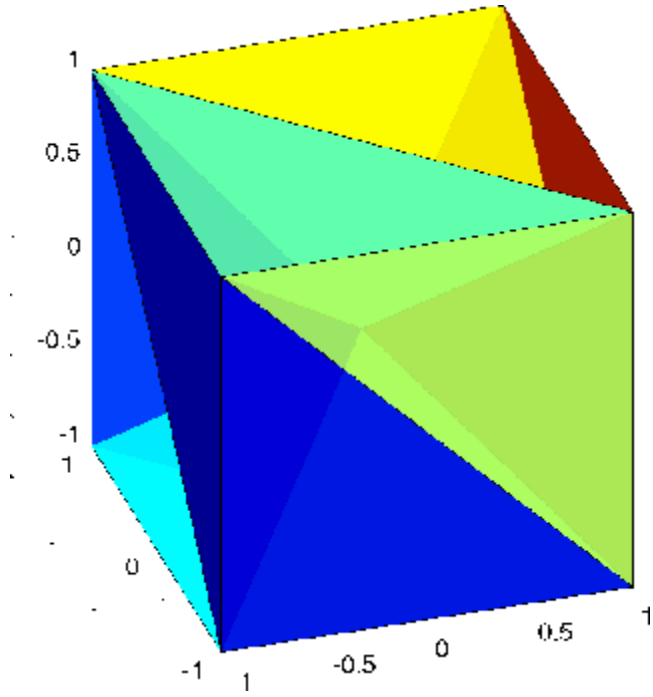
This example generates an n-dimensional Delaunay tessellation, where `n = 3`.

```
d = [-1 1];
[x,y,z] = meshgrid(d,d,d);  % A cube
x = [x(:);0];
y = [y(:);0];
z = [z(:);0];
% [x,y,z] are corners of a cube plus the center.
X = [x(:) y(:) z(:)];
Tes = delaunayn(X)

Tes =
   9  1  5  6
   3  9  1  5
   2  9  1  6
   2  3  9  4
   2  3  9  1
   7  9  5  6
   7  3  9  5
   8  7  9  6
   8  2  9  6
   8  2  9  4
   8  3  9  4
   8  7  3  9
```

You can use `tetramesh` to visualize the tetrahedrons that form the corresponding simplex. `camorbit` rotates the camera position to provide a meaningful view of the figure.

```
tetramesh(Tes,X);camorbit(20,0)
```



Example 2

The following example illustrates the `options` input for `delaunayn`.

```
X = [-0.5 -0.5  -0.5;...
            -0.5 -0.5   0.5;...
            -0.5  0.5  -0.5;...
            -0.5  0.5   0.5;...
             0.5 -0.5  -0.5;...
             0.5 -0.5   0.5;...
             0.5  0.5  -0.5;...
             0.5  0.5   0.5];
```

The command

```
T = delaunayn(X);
```

returns the following error message.

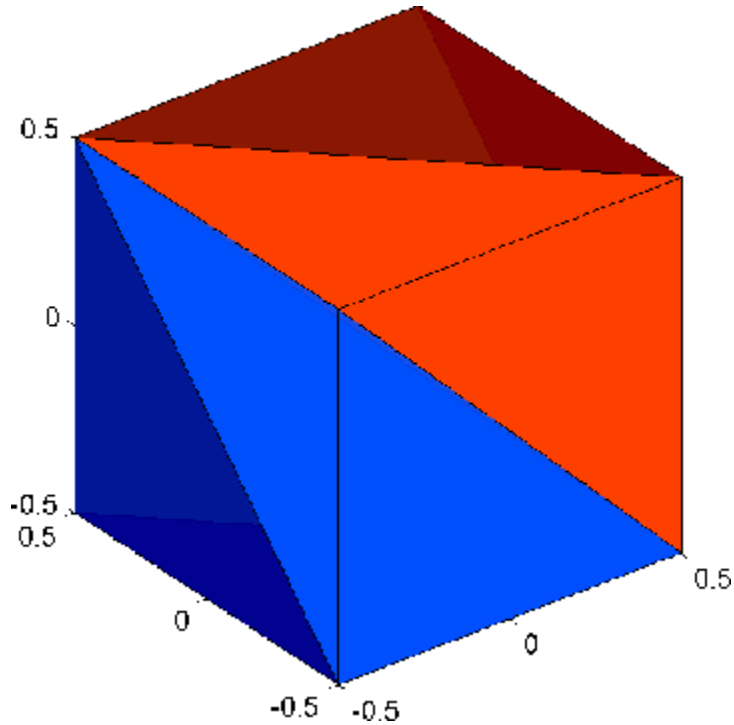
??? qhull input error: can not scale last coordinate. Input is cocircular or cospherical. Use option 'Qz' to add a point at infinity.

This suggests that you add `'Qz'` to the default options.

```
T = delaunayn(X,{'Qt','Qbb','Qc','Qz'});
```

To visualize this answer you can use the `tetramesh` function:

```
tetramesh(T,X)
```



Algorithm

`delaunayn` is based on Qhull [1]. For information about Qhull, see `http://www.qhull.org/`. For copyright information, see `http://www.qhull.org/COPYING.txt`.

`convhulln`, `delaunayn`, `delaunay3`, `tetramesh`, `voronoin`

Reference

[1] Barber, C. B., D.P. Dobkin, and H.T. Huhdanpaa, "The Quickhull Algorithm for Convex Hulls," ACM Transactions on Mathematical Software, Vol. 22, No. 4, Dec. 1996, p. 469-483.

Purpose

Remove files or graphics objects

Graphical Interface

As an alternative to the `delete` function, you can delete files using the "Current Directory Browser", as described in the Desktop Tools and Development Environment documentation.

Syntax

```
delete filename
delete(h)
delete('filename')
```

Description

`delete filename` deletes the named file from the disk. The `filename` may include an absolute pathname or a pathname relative to the current directory. The `filename` may also include wildcards, (`*`).

`delete(h)` deletes the graphics object with handle `h`. The function deletes the object without requesting verification even if the object is a window.

`delete('filename')` is the function form of `delete`. Use this form when the filename is stored in a string.

Note MATLAB does not ask for confirmation when you enter the `delete` command. To avoid accidentally losing files or graphics objects that you need, make sure that you have accurately specified the items you want deleted.

Remarks

The action that the delete function takes on deleted files depends upon the setting of the MATLAB recycle state. If you set the recycle state to `on`, MATLAB moves deleted files to your recycle bin or temporary directory. With the recycle state set to `off` (the default), deleted files are permanently removed from the system.

To set the recycle state for all MATLAB sessions, use the **Preferences** dialog box. Open the **Preferences** dialog and select **General**. To enable or disable recycling, click **Move files to the recycle bin** or **Delete files permanently**. See "General Preferences for MATLAB"

in the Desktop Tools and Development Environment documentation for more information.

The `delete` function deletes files and handles to graphics objects only. Use the `rmdir` function to delete directories.

Examples

To delete all files with a `.mat` extension in the `../mytests/` directory, type

```
delete('../mytests/*.mat')
```

To delete a directory, use `rmdir` rather than `delete`:

```
rmdir mydirectory
```

See Also

`recycle`, `dir`, `edit`, `fileparts`, `mkdir`, `rmdir`, `type`

Purpose

Remove COM control or server

Syntax

```
h.delete
delete(h)
```

Description

`h.delete` releases all interfaces derived from the specified COM server or control, and then deletes the server or control itself. This is different from releasing an interface, which releases and invalidates only that interface.

`delete(h)` is an alternate syntax for the same operation.

Examples

Create a Microsoft Calender application. Then create a `TitleFont` interface and use it to change the appearance of the font of the calendar's title:

```
f = figure('position',[300 300 500 500]);
cal = actxcontrol('mscal.calendar', [0 0 500 500], f);

TFont = cal.TitleFont
TFont =
   Interface.Standard_OLE_Types.Font

TFont.Name = 'Viva BoldExtraExtended';
TFont.Bold = 0;
```

When you're finished working with the title font, release the `TitleFont` interface:

```
TFont.release;
```

Now create a `GridFont` interface and use it to modify the size of the calendar's date numerals:

```
GFont = cal.GridFont
GFont =
   Interface.Standard_OLE_Types.Font
```

```
GFont.Size = 16;
```

When you're done, delete the `cal` object and the figure window. Deleting the `cal` object also releases all interfaces to the object (e.g., `GFont`):

```
cal.delete;
delete(f);
clear f;
```

Note that, although the object and interfaces themselves have been destroyed, the variables assigned to them still reside in the MATLAB workspace until you remove them with `clear`:

```
whos
  Name        Size                    Bytes  Class

  GFont       1x1                         0  handle
  TFone       1x1                         0  handle
  cal         1x1                         0  handle

Grand total is 3 elements using 0 bytes
```

See Also

`release`, `save`, `load`, `actxcontrol`, `actxserver`

Purpose

Remove file on FTP server

Syntax

```
delete(f,'filename')
```

Description

`delete(f,'filename')` removes the file `filename` from the current directory of the FTP server `f`, where `f` was created using `ftp`.

Examples

Connect to server `testsite`.

```
test=ftp('ftp.testsite.com')
```

Change the current directory to `testdir` and view the contents.

```
cd(test,'testdir');
dir(test)
```

See Also

`ftp`

delete (serial)

Purpose

Remove serial port object from memory

Syntax

```
delete(obj)
```

Arguments

`obj`	A serial port object or an array of serial port objects.

Description

`delete(obj)` removes `obj` from memory.

Remarks

When you delete `obj`, it becomes an *invalid* object. Because you cannot connect an invalid serial port object to the device, you should remove it from the workspace with the `clear` command. If multiple references to `obj` exist in the workspace, then deleting one reference invalidates the remaining references.

If `obj` is connected to the device, it has a `Status` property value of `open`. If you issue `delete` while `obj` is connected, then the connection is automatically broken. You can also disconnect `obj` from the device with the `fclose` function.

If you use the `help` command to display help for `delete`, then you need to supply the pathname shown below.

```
help serial/delete
```

Example

This example creates the serial port object `s`, connects `s` to the device, writes and reads text data, disconnects `s` from the device, removes `s` from memory using `delete`, and then removes `s` from the workspace using `clear`.

```
s = serial('COM1');
fopen(s)
fprintf(s,'*IDN?')
idn = fscanf(s);
fclose(s)
delete(s)
clear s
```

See Also

Functions

`clear`, `fclose`, `isvalid`

Properties

`Status`

delete (timer)

Purpose

Remove timer object from memory

Syntax

```
delete(obj)
```

Description

`delete(obj)` removes the timer object, `obj`, from memory. If `obj` is an array of timer objects, `delete` removes all the objects from memory.

When you delete a timer object, it becomes invalid and cannot be reused. Use the `clear` command to remove invalid timer objects from the workspace.

If multiple references to a timer object exist in the workspace, deleting the timer object invalidates the remaining references. Use the `clear` command to remove the remaining references to the object from the workspace.

See Also

`clear`, `isvalid(timer)`, `timer`

Purpose

Remove custom property from object

Syntax

```
h.deleteproperty('propertyname')
deleteproperty(h, 'propertyname')
```

Description

`h.deleteproperty('propertyname')` deletes the property specified in the string `propertyname` from the custom properties belonging to object or interface, `h`.

`deleteproperty(h, 'propertyname')` is an alternate syntax for the same operation.

Note You can only delete properties that have been created with `addproperty`.

Examples

Create an `mwsamp` control and add a new property named `Position` to it. Assign an array value to the property:

```
f = figure('position', [100 200 200 200]);
h = actxcontrol('mwsamp.mwsampctrl.2', [0 0 200 200], f);
h.get
     Label: 'Label'
    Radius: 20

h.addproperty('Position');
h.Position = [200 120];
h.get
       Label: 'Label'
      Radius: 20
    Position: [200 120]
```

Delete the custom `Position` property:

```
h.deleteproperty('Position');
h.get
     Label: 'Label'
```

```
                    Radius: 20
```

addproperty, get, set, inspect

Purpose

Remove `tsdata.event` objects from `timeseries` object

Syntax

```
ts = delevent(ts,event)
ts = delevent(ts,events)
ts = delevent(ts,event,n)
```

Description

`ts = delevent(ts,event)` removes the `tsdata.event` object from the `ts.events` property, where `event` is an event name string.

`ts = delevent(ts,events)` removes the `tsdata.event` object from the `ts.events` property, where `events` is a cell array of event name strings.

`ts = delevent(ts,event,n)` removes the nth `tsdata.event` object from the `ts.events` property. `event` is the name of the `tsdata.event` object.

Examples

The following example shows how to remove an event from a `timeseries` object:

1. Create a time series.

   ```
   ts = timeseries(rand(5,4))
   ```

2. Create an event object called `'test'` such that the event occurs at time 3.

   ```
   e = tsdata.event('test',3)
   ```

3. Add the event object to the time series `ts`.

   ```
   ts = addevent(ts,e)
   ```

4. Remove the event object from the time series `ts`.

   ```
   ts = delevent(ts,'test')
   ```

See Also

`addevent`, `timeseries`, `tsdata.event`, `tsprops`

delsample

Purpose

Remove sample from `timeseries` object

Syntax

```
ts = delsample(ts,'Index',N)
ts = delsample(ts,'Value',Time)
```

Description

`ts = delsample(ts,'Index',N)` deletes samples from the `timeseries` object `ts`. `N` specifies the indices of the `ts` time vector that correspond to the samples you want to delete.

`ts = delsample(ts,'Value',Time)` deletes samples from the `timeseries` object `ts`. `Time` specifies the time values that correspond to the samples you want to delete.

See Also

`addsample`

Purpose

Remove sample from `tscollection` object

Syntax

```
tsc = delsamplefromcollection(tsc,'Index',N)
tsc = delsamplefromcollection(tsc,'Value',Time)
```

Description

`tsc = delsamplefromcollection(tsc,'Index',N)` deletes samples from the `tscollection` object tsc. N specifies the indices of the tsc time vector that correspond to the samples you want to delete.

`tsc = delsamplefromcollection(tsc,'Value',Time)` deletes samples from the `tscollection` object tsc. Time specifies the time values that correspond to the samples you want to delete.

See Also

`addsampletocollection`, `tscollection`

demo

Purpose

Access product demos via Help browser

GUI Alternatives

As an alternative to the `demo` function, you can select **Help > Demos** from any desktop tool, or click the **Demos** tab when the Help browser is open.

Syntax

```
demo
demo subtopic
demo subtopic category
demo('subtopic', 'category')
```

Description

`demo` opens the **Demos** pane in the Help browser, listing demos for all installed products. The Help browser product filter preference applies to the demos listed, so installed products (and their categories) appear only if selected in the product filter. In the left pane, expand the listing for a product area (for example, MATLAB). Within that product area, expand the listing for a product or product category (for example, MATLAB Programming). Select a specific demo from the list (for example, Square Wave from Sine Waves). In the right pane, view instructions for using the demo. For more information, see the topic “Demos in the Help Browser” in the MATLAB Desktop Tools and Development Environment documentation. To run a demo from the command line, type the demo name. To run an M-file demo, open it in the Editor/Debugger and run it using **Cell > Evaluate Current Cell and Advance**, or run `echodemo` followed by the demo name.

`demo` *`subtopic`* opens the **Demos** pane in the Help browser with the specified subtopic expanded. Subtopics are `matlab`, `toolbox`, `simulink`, `blockset`, and `links and targets`. If no products in `subtopic` are installed, or if none are selected in the Help browser product filter preference, an error page appears.

`demo` *`subtopic category`* opens the **Demos** pane in the Help browser to the specified product or category within the subtopic. The `demo` function uses the full name displayed in the **Demo** pane for `category`. If the product specified by `category` is not installed, or is not selected in the Help browser product filter preference, an error page appears.

`demo('subtopic', 'category')` is the function form of the syntax. Use this form when `subtopic` or `category` is more than one word.

This illustration shows the result of running

```
demo matlab graphics
```

and then selecting the Square Wave from Sine Waves example.

Running a Demo from the Command Line

Type

```
vibes
```

to run a visualization demonstration showing an animated L-shaped membrane.

Running an M-File Demo from the Command Line

Type

```
quake
```

to run an earthquake data demo. Not much appears to happen because `quake` is an M-file demo and executes from start to end without stopping. Verify this by viewing the M-file, `quake.m`, for example, by typing

```
edit quake
```

The first line, that is, the H1 line for `quake`, is

```
%% Loma Prieta Earthquake
```

The `%%` indicates that `quake` is an M-file demo. To step through the demo cell-by-cell, from the Editor/Debugger select **Cell > Evaluate Current Cell and Advance**.

Alternatively, run

```
echodemo quake
```

and the `quake` demo runs step-by-step in the Command Window.

depdir

Purpose

List dependent directories of M-file or P-file

Syntax

```
list = depdir('file_name')
[list, prob_files, prob_sym,
   prob_strings] = depdir('file_name')
[...] = depdir('file_name1', 'file_name2',...)
```

Description

The `depdir` function lists the directories of all the functions that a specified M-file or P-file needs to operate. This function is useful for finding all the directories that need to be included with a run-time application and for determining the run-time path.

`list = depdir('file_name')` creates a cell array of strings containing the directories of all the M-files and P-files that `file_name.m` or `file_name.p` uses. This includes the second-level files that are called directly by `file_name`, as well as the third-level files that are called by the second-level files, and so on.

`[list, prob_files, prob_sym, prob_strings] = depdir('file_name')` creates three additional cell arrays containing information about any problems with the `depdir` search. `prob_files` contains filenames that `depdir` was unable to parse. `prob_sym` contains symbols that `depdir` was unable to find. `prob_strings` contains callback strings that `depdir` was unable to parse.

`[...] = depdir('file_name1', 'file_name2',...)` performs the same operation for multiple files. The dependent directories of all files are listed together in the output cell arrays.

Example

```
list = depdir('mesh')
```

See Also

`depfun`

Purpose

List dependencies of M-file or P-file

Syntax

```
list = depfun('fun')
[list, builtins, classes] = depfun('fun')
[list, builtins, classes, prob_files, prob_sym, eval_strings,
   ... called_from, java_classes] = depfun('fun')
[...] = depfun('fun1', 'fun2',...)
[...] = depfun({'fun1', 'fun2', ...})
[...] = depfun('fig_file')
[...] = depfun(..., options)
```

Description

The `depfun` function lists the paths of all files a specified M-file or P-file needs to operate.

Note It cannot be guaranteed that `depfun` will find every dependent file. Some dependent files can be hidden in callbacks, or can be constructed dynamically for evaluation, for example. Also note that the list of functions returned by `depfun` often includes extra files that would never be called if the specified function were actually evaluated.

`list = depfun('fun')` creates a cell array of strings containing the paths of all the files that function `fun` uses. This includes the second-level files that are called directly by `fun`, and the third-level files that are called by the second-level files, and so on.

Function `fun` must be on the MATLAB path, as determined by the `which` function. If the MATLAB path contains any relative directories, then files in those directories will also have a relative path.

Note If MATLAB returns a parse error for any of the input functions, or if the `prob_files` output below is nonempty, then the rest of the output of `depfun` might be incomplete. You should correct the problematic files and invoke `depfun` again.

`[list, builtins, classes] = depfun('fun')` creates three cell arrays containing information about dependent functions. `list` contains the paths of all the files that function `fun` and its subordinates use. `builtins` contains the built-in functions that `fun` and its subordinates use. `classes` contains the MATLAB classes that `fun` and its subordinates use.

`[list, builtins, classes, prob_files, prob_sym, eval_strings,... called_from, java_classes] = depfun('fun')` creates additional cell arrays or structure arrays containing information about any problems with the `depfun` search and about where the functions in `list` are invoked. The additional outputs are

- `prob_files` — Indicates which files `depfun` was unable to parse, find, or access. Parsing problems can arise from MATLAB syntax errors. `prob_files` is a structure array having these fields:
  - `name` (path to the file)
  - `listindex` (index of the file in `list`)
  - `errmsg` (problems encountered)
- *`unused`* — This is a placeholder for an output argument that is not fully implemented at this time. MATLAB returns an empty structure array for this output.
- `called_from` — Cell array of the same length as `list` that indicates which functions call other functions. This cell array is arranged so that the following statement returns all functions in function `fun` that invoke the function `list{`*`i`*`}`:

  ```
  list(called_from{i})
  ```

- `java_classes` — Cell array of Java class names used by `fun` and its subordinate functions.

`[...] = depfun('fun1', 'fun2',...)` performs the same operation for multiple functions. The dependent functions of all files are listed together in the output arrays.

`[...] = depfun({'fun1', 'fun2', ...})` performs the same operation, but on a cell array of functions. The dependent functions of all files are listed together in the output array.

`[...] = depfun('fig_file')` looks for dependent functions among the callback strings of the GUI elements that are defined in the figure file named `fig_file`.

`[...] = depfun(..., options)` modifies the `depfun` operation according to the *`options`* specified (see table below).

Option	Description
`'-all'`	Computes all possible left-side arguments and displays the results in the report(s). Only the specified arguments are returned.
`'-calltree'`	Returns a `call` list in place of a `called_from` list. This is derived from the `called_from` list as an extra step.
`'-expand'`	Includes both indices and full paths in the `call` or `called_from` list.
`'-print', 'file'`	Prints a full report to `file`.
`'-quiet'`	Displays only error and warning messages, and not a summary report.
`'-toponly'`	Examines *only* the files listed explicitly as input arguments. It does not examine the files on which they depend.
`'-verbose'`	Outputs additional internal messages.

Examples

```
list = depfun('mesh'); % Files mesh.m depends on
list = depfun('mesh','-toponly') % Files mesh.m depends on
directly
```

```
[list,builtins,classes] = depfun('gca');
```

See Also

depdir

Purpose

Matrix determinant

Syntax

```
d = det(X)
```

Description

`d = det(X)` returns the determinant of the square matrix `X`. If `X` contains only integer entries, the result `d` is also an integer.

Remarks

Using `det(X) == 0` as a test for matrix singularity is appropriate only for matrices of modest order with small integer entries. Testing singularity using `abs(det(X)) <= tolerance` is not recommended as it is difficult to choose the correct tolerance. The function `cond(X)` can check for singular and nearly singular matrices.

Algorithm

The determinant is computed from the triangular factors obtained by Gaussian elimination

```
[L,U] = lu(A)
s =  det(L)        % This is always +1 or -1
det(A) = s*prod(diag(U))
```

Examples

The statement `A = [1 2 3; 4 5 6; 7 8 9]`

produces

```
A =
     1     2     3
     4     5     6
     7     8     9
```

This happens to be a singular matrix, so `d = det(A)` produces `d = 0`. Changing `A(3,3)` with `A(3,3) = 0` turns `A` into a nonsingular matrix. Now `d = det(A)` produces `d = 27`.

`cond`, `condest`, `inv`, `lu`, `rref`

The arithmetic operators `\`, `/`

detrend

Purpose

Remove linear trends

Syntax

```
y = detrend(x)
y = detrend(x,'constant')
y = detrend(x,'linear',bp)
```

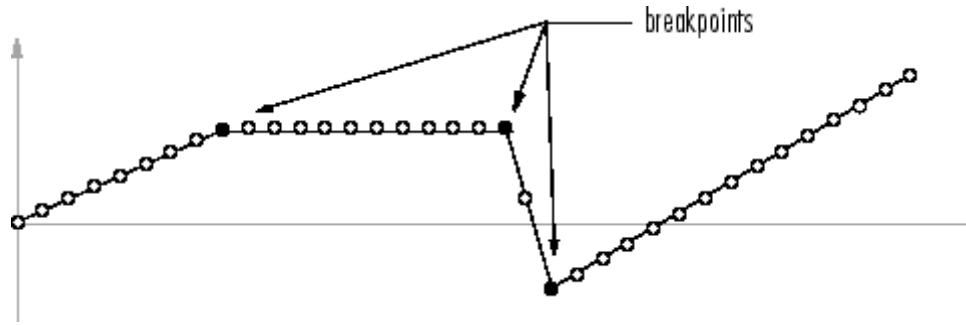
Description

`detrend` removes the mean value or linear trend from a vector or matrix, usually for FFT processing.

`y = detrend(x)` removes the best straight-line fit from vector `x` and returns it in `y`. If `x` is a matrix, `detrend` removes the trend from each column.

`y = detrend(x,'constant')` removes the mean value from vector `x` or, if `x` is a matrix, from each column of the matrix.

`y = detrend(x,'linear',bp)` removes a continuous, piecewise linear trend from vector `x` or, if `x` is a matrix, from each column of the matrix. Vector `bp` contains the indices of the breakpoints between adjacent linear segments. The breakpoint between two segments is defined as the data point that the two segments share.



`detrend(x,'linear')`, with no breakpoint vector specified, is the same as `detrend(x)`.

Example

```
sig = [0 1 -2 1 0 1 -2 1 0];      % signal with no linear trend
trend = [0 1 2 3 4 3 2 1 0];      % two-segment linear trend
```

```
x = sig+trend;                    % signal with added trend
y = detrend(x,'linear',5)         % breakpoint at 5th element

y =

   -0.0000
    1.0000
   -2.0000
    1.0000
    0.0000
    1.0000
   -2.0000
    1.0000
   -0.0000
```

Note that the breakpoint is specified to be the fifth element, which is the data point shared by the two segments.

Algorithm

`detrend` computes the least-squares fit of a straight line (or composite line for piecewise linear trends) to the data and subtracts the resulting function from the data. To obtain the equation of the straight-line fit, use `polyfit`.

See Also

`polyfit`

detrend (timeseries)

Purpose

Subtract mean or best-fit line and all NaNs from time series

Syntax

```
ts = detrend(ts1,method)
ts = detrend(ts1,Method,Index)
```

Description

`ts = detrend(ts1,method)` subtracts either a mean or a best-fit line from time-series data, usually for FFT processing. Method is a string that specifies the detrend method and has two possible values:

- `'constant'` — Subtracts the mean
- `'linear'` — Subtracts the best-fit line

`ts = detrend(ts1,Method,Index)` uses the optional `Index` integer array to specify the columns or rows to detrend. When `ts.IsTimeFirst` is `true`, `Index` specifies one or more data columns. When `ts.IsTimeFirst` is `false`, Index specifies one or more data rows.

Remarks

You cannot apply `detrend` to time-series data with more than two dimensions.

Purpose

Evaluate solution of differential equation problem

Syntax

```
sxint = deval(sol,xint)
sxint = deval(xint,sol)
sxint = deval(sol,xint,idx)
sxint = deval(xint,sol,idx)
[sxint, spxint] = deval(...)
```

Description

`sxint = deval(sol,xint)` and `sxint = deval(xint,sol)` evaluate the solution of a differential equation problem. `sol` is a structure returned by one of these solvers:

- An initial value problem solver (`ode45`, `ode23`, `ode113`, `ode15s`, `ode23s`, `ode23t`, `ode23tb`, `ode15i`)
- A delay differential equations solver (`dde23` or `ddesd`),
- The boundary value problem solver (`bvp4c`).

`xint` is a point or a vector of points at which you want the solution. The elements of `xint` must be in the interval `[sol.x(1),sol.x(end)]`. For each `i`, `sxint(:,i)` is the solution at `xint(i)`.

`sxint = deval(sol,xint,idx)` and `sxint = deval(xint,sol,idx)` evaluate as above but return only the solution components with indices listed in the vector `idx`.

`[sxint, spxint] = deval(...)` also returns `spxint`, the value of the first derivative of the polynomial interpolating the solution.

Note For multipoint boundary value problems, the solution obtained by `bvp4c` might be discontinuous at the interfaces. For an interface point `xc`, `deval` returns the average of the limits from the left and right of `xc`. To get the limit values, set the `xint` argument of `deval` to be slightly smaller or slightly larger than `xc`.

Example

This example solves the system $y' = \mathrm{vdp1}(t, y)$ using `ode45`, and evaluates and plots the first component of the solution at 100 points in the interval `[0,20]`.

```
sol = ode45(@vdp1,[0 20],[2 0]);
x = linspace(0,20,100);
y = deval(sol,x,1);
plot(x,y);
```

DDE solvers: `dde23`, `ddesd`

BVP solver: `bvp4c`

Purpose

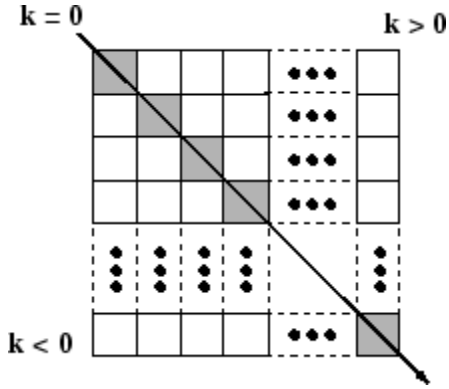
Diagonal matrices and diagonals of matrix

Syntax

```
X = diag(v,k)
X = diag(v)
v = diag(X,k)
v = diag(X)
```

Description

`X = diag(v,k)` when `v` is a vector of `n` components, returns a square matrix `X` of order `n+abs(k)`, with the elements of `v` on the `k`th diagonal. `k = 0` represents the main diagonal, `k > 0` above the main diagonal, and `k < 0` below the main diagonal.



`X = diag(v)` puts `v` on the main diagonal, same as above with `k = 0`.

`v = diag(X,k)` for matrix `X`, returns a column vector `v` formed from the elements of the `k`th diagonal of `X`.

`v = diag(X)` returns the main diagonal of `X`, same as above with `k = 0` .

Remarks

`(diag(X))` is a diagonal matrix.

`sum(diag(X))` is the trace of `X`.

`diag([])` generates an empty matrix, `([])`.

`diag(m-by-1,k)` generates a matrix of size `m+abs(k)`-by-`m+abs(k)`.

`diag(1-by-n,k)` generates a matrix of size `n+abs(k)`-by-`n+abs(k)`.

Examples

The statement

```
diag(-m:m)+diag(ones(2*m,1),1)+diag(ones(2*m,1),-1)
```

produces a tridiagonal matrix of order `2*m+1`.

See Also

`spdiags`, `tril`, `triu`, `blkdiag`

Purpose

Create and display dialog box

Syntax

```
h = dialog('PropertyName',PropertyValue,...)
```

Description

`h = dialog('PropertyName',PropertyValue,...)` returns a handle to a dialog box. This function creates a figure graphics object and sets the figure properties recommended for dialog boxes. You can specify any valid figure property value except `DockControls`, which is always `off`.

Note By default, the dialog box is modal. A modal dialog box prevents the user from interacting with other windows before responding. For more information, see `WindowStyle` in the MATLAB Figure Properties.

`figure`, `uiwait`, `uiresume`

"Predefined Dialog Boxes" on page 1-104 for related functions

diary

Purpose

Save session to file

Syntax

```
diary
diary('filename')
diary off
diary on
diary filename
```

Description

The `diary` function creates a log of keyboard input and the resulting text output, with some exceptions (see “Remarks” on page 2-906 for details). The output of `diary` is an ASCII file, suitable for searching in, printing, inclusion in most reports and other documents. If you do not specify `filename`, MATLAB creates a file named `diary` in the current directory.

`diary` toggles `diary` mode on and off. To see the status of `diary`, type `get(0,'Diary')`. MATLAB returns either `on` or `off` indicating the `diary` status.

`diary('filename')` writes a copy of all subsequent keyboard input and the resulting output (except it does not include graphics) to the named file, where `filename` is the full pathname or `filename` is in the current MATLAB directory. If the file already exists, output is appended to the end of the file. You cannot use a `filename` called `off` or `on`. To see the name of the `diary` file, use `get(0,'DiaryFile')`.

`diary off` suspends the diary.

`diary on` resumes diary mode using the current filename, or the default filename `diary` if none has yet been specified.

`diary filename` is the unquoted form of the syntax.

Remarks

Because the output of `diary` is plain text, the file does not exactly mirror input and output from the Command Window:

- Output does not include graphics (figure windows).
- Syntax highlighting and font preferences are not preserved.

- Hidden components of Command Window output such as hyperlink information generated with `matlab:` are shown in plain text. For example, if you enter the following statement

```
str = sprintf('%s%s', ...
   '<a href="matlab:magic(4)">', ...
   'Generate magic square</a>');
disp(str)
```

MATLAB displays

Generate magic square

However, the diary file, when viewed in a text editor, shows

```
str = sprintf('%s%s', ...
   '<a href="matlab:magic(4)">', ...
   'Generate magic square</a>');
disp(str)
<a href="matlab:magic(4)">Generate magic square</a>
```

If you view the output of diary in the Command Window, the Command Window interprets the `<a href ...>` statement and displays it as a hyperlink.

- Viewing the output of `diary` in a console window might produce different results compared to viewing `diary` output in the desktop Command Window. One example is using the `\r` option for the `fprintf` function; using the `\n` option might alleviate that problem.

See Also

`evalc`

"Command History Window" in the MATLAB Desktop Tools and Development Environment documentation

diff

Purpose

Differences and approximate derivatives

Syntax

```
Y = diff(X)
Y = diff(X,n)
Y = diff(X,n,dim)
```

Description

`Y = diff(X)` calculates differences between adjacent elements of `X`.

If `X` is a vector, then `diff(X)` returns a vector, one element shorter than `X`, of differences between adjacent elements:

```
[X(2)-X(1) X(3)-X(2) ... X(n)-X(n-1)]
```

If `X` is a matrix, then `diff(X)` returns a matrix of row differences:

```
[X(2:m,:)-X(1:m-1,:)]
```

In general, `diff(X)` returns the differences calculated along the first non-singleton (`size(X,dim) > 1`) dimension of `X`.

`Y = diff(X,n)` applies `diff` recursively `n` times, resulting in the nth difference. Thus, `diff(X,2)` is the same as `diff(diff(X))`.

`Y = diff(X,n,dim)` is the nth difference function calculated along the dimension specified by scalar `dim`. If order `n` equals or exceeds the length of dimension `dim`, `diff` returns an empty array.

Remarks

Since each iteration of `diff` reduces the length of `X` along dimension `dim`, it is possible to specify an order `n` sufficiently high to reduce `dim` to a singleton (`size(X,dim) = 1`) dimension. When this happens, `diff` continues calculating along the next nonsingleton dimension.

Examples

The quantity `diff(y)./diff(x)` is an approximate derivative.

```
x = [1 2 3 4 5];
y = diff(x)
y =
     1     1     1     1
```

```
z = diff(x,2)
z =
     0     0     0
```

Given,

```
A = rand(1,3,2,4);
```

`diff(A)` is the first-order difference along dimension `2`.

`diff(A,3,4)` is the third-order difference along dimension `4`.

See Also

`gradient`, `prod`, `sum`

diffuse

Purpose

Calculate diffuse reflectance

Syntax

```
R = diffuse(Nx,Ny,Nz,S)
```

Description

`R = diffuse(Nx,Ny,Nz,S)` returns the reflectance of a surface with normal vector components `[Nx,Ny,Nz]`. `S` specifies the direction to the light source. You can specify these directions as three vectors`[x,y,z]` or two vectors `[Theta Phi` (in spherical coordinates).

Lambert's Law: `R = cos(PSI)` where `PSI` is the angle between the surface normal and light source.

See Also

`specular`, `surfnorm`, `surfl`

"Lighting as a Visualization Tool"

Purpose

Directory listing

Graphical Interface

As an alternative to the `dir` function, use the "Current Directory Browser".

Syntax

```
dir
dir name
files = dir('dirname')
```

Description

`dir` lists the files in the current working directory. Results are not sorted, but presented in the order returned by the operating system.

`dir name` lists the specified files. The `name` argument can be a pathname, filename, or can include both. You can use absolute and relative pathnames and wildcards (`*`).

`files = dir('dirname')` returns the list of files in the specified directory (or the current directory, if `dirname` is not specified) to an `m`-by-`1` structure with the fields.

Fieldname	Description	Data Type
`name`	Filename	char array
`date`	Modification date timestamp	char array
`bytes`	Number of bytes allocated to the file	double
`isdir`	`1` if name is a directory; `0` if not	logical
`datenum`	Modification date as serial date number	double

Remarks

Listing Drives

On Windows, obtain a list of drives available using the DOS `net use` command. In the Command Window, run

```
dos('net use')
```

Or run

```
[s,r] = dos('net use')
```

to return the results to the character array `r`.

DOS Filenames

The MATLAB `dir` function is consistent with the Microsoft Windows OS `dir` command in that both support short filenames generated by DOS. For example, both of the following commands are equivalent in both Windows and MATLAB:

```
dir long_matlab_mfile_name.m
   long_matlab_mfile_name.m

dir long_m~1.m
   long_matlab_m-file_name.m
```

Examples

List Directory Contents

To view the contents of the `matlab/audiovideo` directory, type

```
dir(fullfile(matlabroot, 'toolbox/matlab/audiovideo'))
```

Using Wildcard and File Extension

To view the MAT files in your current working directory that include the term `java`, type

```
dir *java*.mat
```

MATLAB returns all filenames that match this specification:

```
java_array.mat  javafrmobj.mat  testjava.mat
```

Using Relative Pathname

To view the M-files in the MATLAB `audiovideo` directory, type

```
dir(fullfile(matlabroot,'toolbox/matlab/audiovideo/*.m'))
```

MATLAB returns

```
Contents.m           aviinfo.m                render_uimgraudiotoolbar.m
audiodevinfo.m       aviread.m                sound.m
audioplayerreg.m     lin2mu.m                 soundsc.m
audiorecorderreg.m   mmcompinfo.m             wavfinfo.m
audiouniquename.m    mmfileinfo.m             wavplay.m
aufinfo.m            movie2avi.m              wavread.m
auread.m             mu2lin.m                 wavrecord.m
auwrite.m            prefspanel.m             wavwrite.m
avifinfo.m           render_fullaudiotoolbar.m
```

Returning File List to Structure

To return the list of files to the variable `av_files`, type

```
av_files = dir(fullfile(matlabroot, ...
               'toolbox/matlab/audiovideo/*.m'))
```

MATLAB returns the information in a structure array.

```
av_files =
24x1 struct array with fields:
    name
    date
    bytes
    isdir
    datenum
```

Index into the structure to access a particular item. For example,

```
av_files(3).name
ans =
   audioplayerreg.m
```

dir (ftp)

Purpose

Directory contents on FTP server

Syntax

```
dir(f,'dirname')
d=dir(...)
```

Description

`dir(f,'dirname')` lists the files in the specified directory, `dirname`, on the FTP server `f`, where `f` was created using `ftp`. If `dirname` is unspecified, `dir` lists the files in the current directory of `f`.

`d=dir(...)` returns the results in an m-by-1 structure with the following fields for each file:

Fieldname	Description	Data Type
`name`	Filename	char array
`date`	Modification date timestamp	char array
`bytes`	Number of bytes allocated to the file	double
`isdir`	`1` if name is a directory; `0` if not	logical
`datenum`	Modification date as serial date number	char array

Examples

Connect to the MathWorks FTP server and view the contents.

```
tmw=ftp('ftp.mathworks.com');
dir(tmw)

README    incoming  matlab    outgoing  pub       pubs
```

Change to the directory `pub/pentium`.

```
cd(tmw,'pub/pentium')
```

View the contents of that directory.

```
dir(tmw)

Intel_replace.txt     Myths.txt             test
```

Or return the results to the structure `m`.

```
m=dir(tmw)

m =

37x1 struct array with fields:
    name
    date
    bytes
    isdir
    datanum
```

View element 17.

```
m(17)

ans =

     name: 'Moler_1.txt'
```

```
                date: '1995 Mar  27'
               bytes: 3427
               isdir: 0
             datenum: 728745
```

See Also

ftp, mkdir (ftp), rmdir (ftp)

Purpose

Display text or array

Syntax

```
disp(X)
```

Description

`disp(X)` displays an array, without printing the array name. If `X` contains a text string, the string is displayed.

Another way to display an array on the screen is to type its name, but this prints a leading `"X="` which is not always desirable.

Note that `disp` does not display empty arrays.

Examples

One use of `disp` in an M-file is to display a matrix with column labels:

```
disp('         Corn          Oats          Hay')
disp(rand(5,3))
```

which results in

```
     Corn         Oats         Hay
   0.2113       0.8474       0.2749
   0.0820       0.4524       0.8807
   0.7599       0.8075       0.6538
   0.0087       0.4832       0.4899
   0.8096       0.6135       0.7741
```

You can also use the `disp` command to display a hyperlink in the Command Window. Include the full hypertext string on a single line as input to `disp`.

```
disp('<a href = "http://www.mathworks.com">The MathWorks Web Site</a>')
```

generates this hyperlink in the Command Window:

```
The MathWorks Web Site
```

Click on this link to display The MathWorks home page in a MATLAB Web browser.

See Also format, int2str, matlabcolon, num2str, rats, sprintf

Purpose

Information about memmapfile object

Syntax

```
disp(obj)
```

Description

`disp(obj)` displays all properties and their values for `memmapfile` object `obj`.

MATLAB also displays this information when you construct a `memmapfile` object or set any of the object's property values, provided you do not terminate the command to do so with a semicolon.

Examples

Construct an object `m` of class `memmapfile`:

```
m = memmapfile('records.dat',                    ...
               'Offset', 2048,                   ...
               'Format', {                       ...
                  'int16'  [2 2] 'model';        ...
                  'uint32' [1 1] 'serialno';     ...
                  'single' [1 3] 'expenses'});
```

Use `disp` to display all the object's current properties:

```
disp(m)
    Filename: 'd:\matlab\mfiles\records.dat'
    Writable: false
      Offset: 2048
      Format: {'int16' [2 2] 'model'
               'uint32' [1 1] 'serialno'
               'single' [1 3] 'expenses'}
      Repeat: Inf
        Data: 753x1 struct array with fields:
            model
         serialno
         expenses
```

See Also

`memmapfile`, `get(memmapfile)`

disp (MException)

Purpose

Display `MException` object

Syntax

```
disp(ME)
disp(ME.property)
```

Description

`disp(ME)` displays all properties (fields) of `MException` object `ME`.

`disp(ME.property)` displays the specified property of `MException` object `ME`.

Examples

Using the `surf` command without input arguments throws an exception. Use `disp` to display the `identifier`, `message`, `stack`, and `cause` properties of the `MException` object:

```
try
   surf
catch ME
   disp(ME)
end

 MException object with properties:

    identifier: 'MATLAB:nargchk:notEnoughInputs'
       message: 'Not enough input arguments.'
         stack: [1x1 struct]
         cause: {}
```

Display only the `stack` property:

```
disp(ME.stack)
    file: 'X:\bat\Akernel\perfect\matlab\toolbox\matlab\
graph3d\surf.m'
    name: 'surf'
    line: 54
```

See Also

`try`, `catch`, `error`, `assert`, `MException`, `getReport(MException)`, `throw(MException)`, `rethrow(MException)`,

`throwAsCaller(MException)`, `addCause(MException)`, `isequal(MException)`, `eq(MException)`, `ne(MException)`, `last(MException)`,

disp (serial)

Purpose

Serial port object summary information

Syntax

```
obj
disp(obj)
```

Arguments

`obj`	A serial port object or an array of serial port objects.

Description

`obj` or `disp(obj)` displays summary information for `obj`.

Remarks

In addition to the syntax shown above, you can display summary information for `obj` by excluding the semicolon when:

- Creating a serial port object
- Configuring property values using the dot notation

Use the display summary to quickly view the communication settings, communication state information, and information associated with read and write operations.

Example

The following commands display summary information for the serial port object `s`.

```
s = serial('COM1')
s.BaudRate = 300
s
```

Purpose

Information about timer object

Syntax

```
disp(obj)
obj
```

Description

`disp(obj)` displays summary information for the timer object, `obj`.

If `obj` is an array of timer objects, `disp` outputs a table of summary information about the timer objects in the array.

`obj`, that is, typing the object name alone, does the same as `disp(obj)`

In addition to the syntax shown above, you can display summary information for `obj` by excluding the semicolon when

- Creating a timer object, using the `timer` function
- Configuring property values using the dot notation

Examples

The following commands display summary information for timer object `t`.

```
t = timer

Timer Object: timer-1

   Timer Settings
      ExecutionMode: singleShot
             Period: 1
           BusyMode: drop
            Running: off

   Callbacks
           TimerFcn: []
           ErrorFcn: []
           StartFcn: []
            StopFcn: []
```

This example shows the format of summary information displayed for an array of timer objects.

```
t2 = timer;
disp(timerfind)

Timer Object Array
Timer Object Array

   Index:  ExecutionMode:  Period:  TimerFcn:     Name:
   1       singleShot      1        ''            timer-1
   2       singleShot      1        ''            timer-2
```

See Also

`timer`, `get(timer)`

Purpose

Display text or array (overloaded method)

Syntax

```
display(X)
```

Description

`display(X)` prints the value of a variable or expression, `X`. MATLAB calls `display(X)` when it interprets a variable or expression, `X`, that is not terminated by a semicolon. For example, `sin(A)` calls `display`, while `sin(A);` does not.

If `X` is an instance of a MATLAB class, then MATLAB calls the `display` method of that class, if such a method exists. If the class has no `display` method or if `X` is not an instance of a MATLAB class, then the MATLAB built-in `display` function is called.

Examples

A typical implementation of `display` calls `disp` to do most of the work and looks like this.

```
function display(X)
if isequal(get(0,'FormatSpacing'),'compact')
   disp([inputname(1) ' =']);
   disp(X)
else
   disp(' ')
   disp([inputname(1) ' =']);
   disp(' ');
   disp(X)
end
```

The expression `magic(3)`, with no terminating semicolon, calls this function as `display(magic(3))`.

```
magic(3)

ans =

     8     1     6
     3     5     7
     4     9     2
```

As an example of a class `display` method, the function below implements the `display` method for objects of the MATLAB class `polynom`.

```
function display(p)
% POLYNOM/DISPLAY Command window display of a polynom
disp(' ');
disp([inputname(1),' = '])
disp(' ');
disp(['    ' char(p)])
disp(' ');
```

The statement

```
p = polynom([1 0 -2 -5])
```

creates a `polynom` object. Since the statement is not terminated with a semicolon, the MATLAB interpreter calls `display(p)`, resulting in the output

```
p =

    x^3 - 2*x - 5
```

See Also

`disp`, `ans`, `sprintf`, special characters

Purpose

Compute divergence of vector field

Syntax

```
div = divergence(X,Y,Z,U,V,W)
div = divergence(U,V,W)
div = divergence(X,Y,U,V)
div = divergence(U,V)
```

Description

`div = divergence(X,Y,Z,U,V,W)` computes the divergence of a 3-D vector field `U`, `V`, `W`. The arrays `X`, `Y`, `Z` define the coordinates for `U`, `V`, `W` and must be monotonic and 3-D plaid (as if produced by `meshgrid`).

`div = divergence(U,V,W)` assumes `X`, `Y`, and `Z` are determined by the expression

```
[X Y Z] = meshgrid(1:n,1:m,1:p)
```

where `[m,n,p] = size(U)`.

`div = divergence(X,Y,U,V)` computes the divergence of a 2-D vector field `U`, `V`. The arrays `X`, `Y` define the coordinates for `U`, `V` and must be monotonic and 2-D plaid (as if produced by `meshgrid`).

`div = divergence(U,V)` assumes `X` and `Y` are determined by the expression

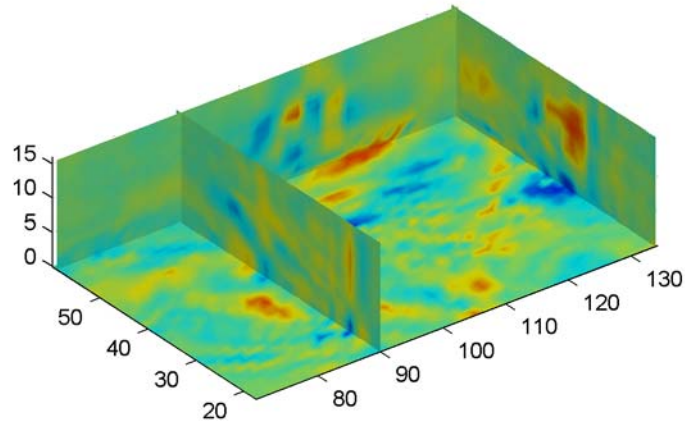
```
[X Y] = meshgrid(1:n,1:m)
```

where `[m,n] = size(U)`.

Examples

This example displays the divergence of vector volume data as slice planes, using color to indicate divergence.

```
load wind
div = divergence(x,y,z,u,v,w);
slice(x,y,z,div,[90 134],[59],[0]);
shading interp
daspect([1 1 1])
camlight
```



See Also

`streamtube`, `curl`, `isosurface`

"Volume Visualization" on page 1-102 for related functions

"Example — Displaying Divergence with Stream Tubes" for another example

Purpose

Read ASCII-delimited file of numeric data into matrix

Graphical Interface

As an alternative to `dlmread`, use the Import Wizard. To activate the Import Wizard, select **Import data** from the **File** menu.

Syntax

```
M = dlmread(filename)
M = dlmread(filename, delimiter)
M = dlmread(filename, delimiter, R, C)
M = dlmread(filename, delimiter, range)
```

Description

`M = dlmread(filename)` reads from the ASCII-delimited numeric data file `filename` to output matrix `M`. The `filename` input is a string enclosed in single quotes. The delimiter separating data elements is inferred from the formatting of the file. Comma (`,`) is the default delimiter.

`M = dlmread(filename, delimiter)` reads numeric data from the ASCII-delimited file `filename`, using the specified `delimiter`. Use `\t` to specify a tab delimiter.

Note When a delimiter is inferred from the formatting of the file, consecutive whitespaces are treated as a single delimiter. By contrast, if a delimiter is specified by the `delimiter` input, any repeated delimiter character is treated as a separate delimiter.

`M = dlmread(filename, delimiter, R, C)` reads numeric data from the ASCII-delimited file `filename`, using the specified `delimiter`. The values `R` and `C` specify the row and column where the upper left corner of the data lies in the file. `R` and `C` are zero based, so that `R=0`, `C=0` specifies the first value in the file, which is the upper left corner.

Note dlmread reads numeric data only. The file being read may contain nonnumeric data, but this nonnumeric data cannot be within the range being imported.

`M = dlmread(filename, delimiter, range)` reads the range specified by `range = [R1 C1 R2 C2]` where `(R1,C1)` is the upper left corner of the data to be read and `(R2,C2)` is the lower right corner. You can also specify the range using spreadsheet notation, as in `range = 'A1..B7'`.

Remarks

If you want to specify an `R`, `C`, or `range` input, but not a `delimiter`, set the `delimiter` argument to the empty string, (two consecutive single quotes with no spaces in between, `''`). For example,

```
M = dlmread('myfile.dat', '', 5, 2)
```

Using this syntax enables you to specify the starting row and column or range to read while having `dlmread` treat repeated whitespaces as a single delimiter.

`dlmread` fills empty delimited fields with zero. Data files having lines that end with a nonspace delimiter, such as a semicolon, produce a result that has an additional last column of zeros.

`dlmread` imports any complex number as a whole into a complex numeric field, converting the real and imaginary parts to the specified numeric type. Valid forms for a complex number are

Form	Example
`–<real>–<imag>i|j`	`5.7-3.1i`
`–<imag>i|j`	`-7j`

Embedded white-space in a complex number is invalid and is regarded as a field delimiter.

Examples

Example 1

Export the 5-by-8 matrix `M` to a file, and read it with `dlmread`, first with no arguments other than the filename:

```
rand('state', 0);   M = rand(5,8);   M = floor(M * 100);
dlmwrite('myfile.txt', M, 'delimiter', '\t')

dlmread('myfile.txt')
ans =
    95    76    61    40     5    20     1    41
    23    45    79    93    35    19    74    84
    60     1    92    91    81    60    44    52
    48    82    73    41     0    27    93    20
    89    44    17    89    13    19    46    67
```

Now read a portion of the matrix by specifying the row and column of the upper left corner:

```
dlmread('myfile.txt', '\t', 2, 3)
ans =
    91    81    60    44    52
    41     0    27    93    20
    89    13    19    46    67
```

This time, read a different part of the matrix using a range specifier:

```
dlmread('myfile.txt', '\t', 'C1..G4')
ans =
    61    40     5    20     1
    79    93    35    19    74
    92    91    81    60    44
    73    41     0    27    93
```

Example 2

Export matrix `M` to a file, and then append an additional matrix to the file that is offset one row below the first:

```
M = magic(3);
```

```
dlmwrite('myfile.txt', [M*5 M/5], ' ')

dlmwrite('myfile.txt', rand(3), '-append', ...
   'roffset', 1, 'delimiter', ' ')

type myfile.txt

80 10 15 65 3.2 0.4 0.6 2.6
25 55 50 40 1 2.2 2 1.6
45 35 30 60 1.8 1.4 1.2 2.4
20 70 75 5 0.8 2.8 3 0.2

0.99008 0.49831 0.32004
0.78886 0.21396 0.9601
0.43866 0.64349 0.72663
```

When `dlmread` imports these two matrices from the file, it pads the smaller matrix with zeros:

```
dlmread('myfile.txt')
   40.0000    5.0000   30.0000   1.6000   0.2000   1.2000
   15.0000   25.0000   35.0000   0.6000   1.0000   1.4000
   20.0000   45.0000   10.0000   0.8000   1.8000   0.4000
    0.6038    0.0153    0.9318        0        0        0
    0.2722    0.7468    0.4660        0        0        0
    0.1988    0.4451    0.4187        0        0        0
```

See Also

`dlmwrite`, `textscan`, `csvread`, `csvwrite`, `wk1read`, `wk1write`

Purpose

Write matrix to ASCII-delimited file

Syntax

```
dlmwrite(filename, M)
dlmwrite(filename, M, 'D')
dlmwrite(filename, M, 'D', R, C)
dlmwrite(filename, M, 'attrib1', value1, 'attrib2', value2,
   ...)
dlmwrite(filename, M, '-append')
dlmwrite(filename, M, '-append', attribute-value list)
```

Description

`dlmwrite(filename, M)` writes matrix `M` into an ASCII format file using the default delimiter (`,`) to separate matrix elements. The data is written starting at the first column of the first row in the destination file, `filename`. The `filename` input is a string enclosed in single quotes.

`dlmwrite(filename, M, 'D')` writes matrix `M` into an ASCII format file, using delimiter `D` to separate matrix elements. The data is written starting at the first column of the first row in the destination file, `filename`. A comma (`,`) is the default delimiter. Use `\t` to produce tab-delimited files.

`dlmwrite(filename, M, 'D', R, C)` writes matrix `M` into an ASCII format file, using delimiter `D` to separate matrix elements. The data is written starting at row `R` and column `C` in the destination file, `filename`. `R` and `C` are zero based, so that `R=0`, `C=0` specifies the first value in the file, which is the upper left corner.

`dlmwrite(filename, M, 'attrib1', value1, 'attrib2', value2, ...)` is an alternate syntax to those shown above, in which you specify any number of attribute-value pairs in any order in the argument list. Each attribute must be immediately followed by a corresponding value (see the table below).

Attribute	Value
`delimiter`	Delimiter string to be used in separating matrix elements

Attribute	Value
newline	Character(s) to use in terminating each line (see table below)
roffset	Offset, in rows, from the top of the destination file to where matrix data is to be written. Offset is zero based.
coffset	Offset, in columns, from the left side of the destination file to where matrix data is to be written. Offset is zero based.
precision	Numeric precision to use in writing data to the file. Specify the number of significant digits or a C-style format string starting in %, such as `'%10.5f'`.

This table shows which values you can use when setting the **newline** attribute.

Line Terminator	Description
'pc'	PC terminator (implies carriage return/line feed (CR/LF))
'unix'	UNIX terminator (implies line feed (LF))

`dlmwrite(filename, M, '-append')` appends the matrix to the file. If you do not specify `'-append'`, `dlmwrite` overwrites any existing data in the file.

`dlmwrite(filename, M, '-append', attribute-value list)` is the same as the syntax shown above, but accepts a list of `attribute-value` pairs. You can place the `'-append'` flag in the argument list anywhere between `attribute-value` pairs, but not in between an `attribute` and its `value`.

Remarks

The resulting file is readable by spreadsheet programs.

Examples

Example 1

Export matrix `M` to a file delimited by the tab character and using a precision of six significant digits:

```
dlmwrite('myfile.txt', M, 'delimiter', '\t', ...
         'precision', 6)
type myfile.txt

0.893898      0.284409      0.582792      0.432907
0.199138      0.469224      0.423496      0.22595
0.298723      0.0647811     0.515512      0.579807
0.661443      0.988335      0.333951      0.760365
```

Example 2

Export matrix `M` to a file using a precision of six decimal places and the conventional line terminator for the PC platform:

```
dlmwrite('myfile.txt', m, 'precision', '%.6f', ...
         'newline', 'pc')
type myfile.txt

16.000000,2.000000,3.000000,13.000000
5.000000,11.000000,10.000000,8.000000
9.000000,7.000000,6.000000,12.000000
4.000000,14.000000,15.000000,1.000000
```

Example 3

Export matrix `M` to a file, and then append an additional matrix to the file that is offset one row below the first:

```
M = magic(3);
dlmwrite('myfile.txt', [M*5 M/5], ' ')

dlmwrite('myfile.txt', rand(3), '-append', ...
   'roffset', 1, 'delimiter', ' ')

type myfile.txt
```

```
80 10 15 65 3.2 0.4 0.6 2.6
25 55 50 40 1 2.2 2 1.6
45 35 30 60 1.8 1.4 1.2 2.4
20 70 75 5 0.8 2.8 3 0.2

0.99008 0.49831 0.32004
0.78886 0.21396 0.9601
0.43866 0.64349 0.72663
```

When `dlmread` imports these two matrices from the file, it pads the smaller matrix with zeros:

```
dlmread('myfile.txt')
   40.0000    5.0000   30.0000   1.6000   0.2000   1.2000
   15.0000   25.0000   35.0000   0.6000   1.0000   1.4000
   20.0000   45.0000   10.0000   0.8000   1.8000   0.4000
    0.6038    0.0153    0.9318        0        0        0
    0.2722    0.7468    0.4660        0        0        0
    0.1988    0.4451    0.4187        0        0        0
```

See Also

`dlmread`, `csvwrite`, `csvread`, `wk1write`, `wk1read`

Purpose

Dulmage-Mendelsohn decomposition

Syntax

```
p = dmperm(A)
[p,q,r,s,cc,rr] = dmperm(A)
```

Description

`p = dmperm(A)` finds a vector `p` such that `p(j) = i` if column `j` is matched to row `i`, or zero if column `j` is unmatched. If `A` is a square matrix with full structural rank, `p` is a maximum matching row permutation and `A(p,:)` has a zero-free diagonal. The structural rank of `A` is `sprank(A) = sum(p>0)`.

`[p,q,r,s,cc,rr] = dmperm(A)` where `A` need not be square or full structural rank, finds the Dulmage-Mendelsohn decomposition of `A`. `p` and `q` are row and column permutation vectors, respectively, such that `A(p,q)` has a block upper triangular form. `r` and `s` are index vectors indicating the block boundaries for the fine decomposition. `cc` and `rr` are vectors of length five indicating the block boundaries of the coarse decomposition.

`C = A(p,q)` is split into a 4-by-4 set of coarse blocks:

```
A11 A12 A13 A14
0    0  A23 A24
0    0   0  A34
0    0   0  A44
```

where `A12`, `A23`, and `A34` are square with zero-free diagonals. The columns of `A11` are the unmatched columns, and the rows of `A44` are the unmatched rows. Any of these blocks can be empty. In the coarse decomposition, the `(i,j)th` block is `C(rr(i):rr(i+1)-1,cc(j):cc(j+1)-1)`. For a linear system,

- `[A11 A12]` is the underdetermined part of the system—it is always rectangular and with more columns and rows, or 0-by-0,
- `A23` is the well-determined part of the system—it is always square, and

- `[A34 ; A44]` is the overdetermined part of the system—it is always rectangular with more rows than columns, or `0`-by-`0`.

The structural rank of `A` is `sprank(A) = rr(4)-1`, which is an upper bound on the numerical rank of `A`. `sprank(A) = rank(full(sprand(A)))` with probability 1 in exact arithmetic.

The `A23` submatrix is further subdivided into block upper triangular form via the fine decomposition (the strongly connected components of `A23`). If `A` is square and structurally nonsingular, `A23` is the entire matrix.

`C(r(i):r(i+1)-1,s(j):s(j+1)-1)` is the `(i,j)`th block of the fine decomposition. The `(1,1)` block is the rectangular block `[A11 A12]`, unless this block is `0`-by-`0`. The `(b,b)` block is the rectangular block `[A34 ; A44]`, unless this block is `0`-by-`0`, where `b = length(r)-1`. All other blocks of the form `C(r(i):r(i+1)-1,s(i):s(i+1)-1)` are diagonal blocks of `A23`, and are square with a zero-free diagonal.

Remarks

If `A` is a reducible matrix, the linear system $Ax=b$ can be solved by permuting `A` to a block upper triangular form, with irreducible diagonal blocks, and then performing block backsubstitution. Only the diagonal blocks of the permuted matrix need to be factored, saving fill and arithmetic in the blocks above the diagonal.

In graph theoretic terms, `dmperm` finds a maximum-size matching in the bipartite graph of `A`, and the diagonal blocks of `A(p,q)` correspond to the strong Hall components of that graph. The output of `dmperm` can also be used to find the connected or strongly connected components of an undirected or directed graph. For more information see Pothen and Fan [1].

`dmperm` uses CSparse [2].

`sprank`

Purpose

Reference page in Help browser

GUI Alternatives

As an alternative to the `doc` function, use the Help browser **Search for** field. Type the function name and click **Go**.

Syntax

```
doc
doc functionname
doc toolboxname
doc toolboxname/functionname
doc classname.methodname
```

Description

`doc` opens the Help browser, if it is not already running, or brings the window to the top, displaying the **Contents** pane when the Help browser is already open.

`doc functionname` displays the reference page for the MATLAB function `functionname` in the Help browser. For example, you are looking at the reference page for the `doc` function. Here `functionname` can be a function, block, property, method, or object. If `functionname` is overloaded, that is, if `functionname` appears in multiple directories on the MATLAB search path, `doc` displays the reference page for the first `functionname` on the search path and displays a hyperlinked list of the other functions and their directories in the MATLAB Command Window. Overloaded functions within the same product are not listed — use the `overloaddirectory` form of the syntax. If a reference page for `functionname` does not exist, `doc` displays its M-file help in the Help browser. The `doc` function is intended only for help files supplied by The MathWorks, and is not supported for use with HTML files you create yourself.

`doc toolboxname` displays the roadmap page for `toolboxname` in the Help browser, which provides a summary of the most pertinent documentation for that product.

`doc toolboxname/functionname` displays the reference page for the `functionname` that belongs to the specified `toolboxname`, in the Help browser. This is useful for overloaded functions.

`doc classname.methodname` displays the reference page for the `methodname` that is a member of `classname`.

Note If there is a function called `name` as well as a toolbox called `name`, the roadmap page for the toolbox called `name` displays. To see the reference page for the function called `name`, use `doc toolboxname/name`, where `toolboxname` is the name of the toolbox in which the function `name` resides. For example, `doc matlab` displays the roadmap page for MATLAB (that is, the `matlab` toolbox), while `doc matlab/matlabunix` displays the reference page for the `matlab` startup function for UNIX, which is in MATLAB.

Examples

Type `doc abs` to display the reference page for the `abs` function. If Simulink and Signal Processing Toolbox are installed and on the search path, the Command Window lists hyperlinks for the `abs` function in those products:

```
doc signal/abs
doc simulink/abs
```

Type `doc signal/abs` to display the reference page for the `abs` function in Signal Processing Toolbox.

Type `doc signal` to display the roadmap page for Signal Processing Toolbox.

Type `doc serial.get` to display the reference page for the `get` method located in the `serial` directory of MATLAB. This syntax is required because there is at least one other `get` function in MATLAB.

"Help for Using MATLAB" in the MATLAB Desktop Tools and Development Environment documentation.

docopt

Purpose

Web browser for UNIX platforms

Syntax

```
docopt
doccmd = docopt
```

Description

`docopt` displays the Web browser used with MATLAB on non-Macintosh UNIX platforms, with the default being `netscape` (for Netscape). For non-Macintosh UNIX platforms, you can modify the `docopt.m` file to specify the Web browser MATLAB uses. The Web browser is used with the `web` function and its `-browser` option. It is also used for links to external Web sites from the Help.

`doccmd = docopt` returns a string containing the command that `web -browser` uses to invoke a Web browser.

To change the browser, edit the `docopt.m` file and change line 51. For example,

```
50 elseif isunix                    % UNIX
51 %   doccmd = '';
```

Remove the comment symbol. In the quote, enter the command that starts your Web browser, and save the file. For example,

```
51     doccmd = 'mozilla';
```

specifies Mozilla as the Web browser MATLAB uses.

`doc`, `edit`, `helpbrowser`, `web`

Purpose

Open Help browser **Search** pane and search for specified term

GUI Alternatives

As an alternative to the `docsearch` function, select **Desktop > Help**, type in the **Search for** field, and click **Go**.

Syntax

```
docsearch
docsearch word
docsearch('word1 word2 ...')
docsearch('"word1 word2" ...')
docsearch('wo*rd ...')
docsearch('word1 word2 BOOLEANOP word3')
```

Description

`docsearch` opens the Help browser to the **Search Results** pane, or if the Help browser is already open to that pane, brings it to the top.

`docsearch word` executes a Help browser full-text search for `word`, displaying results in the Help browser **Search Results** pane. If `word` is a `functionname` or `blockname`, the first entry in **Search Results** is the reference page, or reference pages for overloaded functions.

`docsearch('word1 word2 ...')` executes a Help browser full-text search for pages containing `word1` and `word2` and any other specified words, displaying results in the Help browser **Search Results** pane.

`docsearch('"word1 word2" ...')` executes a Help browser full-text search for pages containing the exact phrase `word1 word2` and any other specified words, displaying results in the Help browser **Search Results** pane.

`docsearch('wo*rd ...')` executes a Help browser full-text search for pages containing words that begin with `wo` and end with `rd`, and any other specified words, displaying results in the Help browser **Search Results** pane. This is also called a wildcard or partial word search. You can use a wildcard symbol (`*`) multiple times within a word. You cannot use the wildcard symbol within an exact phrase. You must use at least two letters or digits with a wildcard symbol.

`docsearch('word1 word2 BOOLEANOP word3')` executes a Help browser full-text search for the term `word1 word2 BOOLEANOP word3`,

where BOOLEANOP is a Boolean operator (AND, NOT, OR) used to refine the search. docsearch evaluates NOTs first, then ORs, and finally ANDs. Results display in the Help browser **Search Results** pane.

Examples

`docsearch plot` finds all pages that contain the word `plot`.

`docsearch('plot tools')` finds all pages that contain the words `plot` and `tools` anywhere in the page.

`docsearch('"plot tools"')` finds all pages that contain the exact phrase `plot tools`.

`docsearch('plot* tools')` finds all pages that contain the word `tools` and the word `plot` or variations of `plot`, such as `plotting`, and `plots`.

`docsearch('"plot tools" NOT "time series"')` finds all pages that contain the exact phrase `plot tools`, but only if the pages do not contain the exact phrase `time series`.

`builddocsearchdb`, `doc`, `helpbrowser`

"Search Documentation and Demos with the Help Browser" in the MATLAB Desktop Tools and Development Environment documentation

Purpose

Execute DOS command and return result

Syntax

```
dos command
status = dos('command')
[status,result] = dos('command')
[status,result] = dos('command','-echo')
```

Description

`dos command` calls upon the shell to execute the given command for Windows systems.

`status = dos('command')` returns completion status to the `status` variable.

`[status,result] = dos('command')` in addition to completion status, returns the result of the command to the `result` variable.

`[status,result] = dos('command','-echo')` forces the output to the Command Window, even though it is also being assigned into a variable.

Both console (DOS) programs and Windows programs may be executed, but the syntax causes different results based on the type of programs. Console programs have `stdout` and their output is returned to the result variable. They are always run in an iconified DOS or Command Prompt Window except as noted below. Console programs never execute in the background. Also, MATLAB will always wait for the `stdout` pipe to close before continuing execution. Windows programs may be executed in the background as they have no `stdout`.

The ampersand, `&`, character has special meaning. For console programs this causes the console to open. Omitting this character will cause console programs to run iconically. For Windows programs, appending this character will cause the application to run in the background. MATLAB will continue processing.

Note Running `dos` with a `command` that relies upon the current directory will fail when the current directory is specified using a UNC pathname. This is because DOS does not support UNC pathnames. In that event, MATLAB returns this error: `??? Error using ==> dos DOS commands may not be executed when the current directory is a UNC pathname`. To work around this limitation, change the directory to a mapped drive prior to running `dos` or a function that calls `dos`.

Examples

The following example performs a directory listing, returning a zero (success) in `s` and the string containing the listing in `w`.

```
[s, w] = dos('dir');
```

To open the DOS 5.0 editor in a DOS window

```
dos('edit &')
```

To open the notepad editor and return control immediately to MATLAB

```
dos('notepad file.m &')
```

The next example returns a one in `s` and an error message in `w` because `foo` is not a valid shell command.

```
[s, w] = dos('foo')
```

This example echoes the results of the `dir` command to the Command Window as it executes as well as assigning the results to `w`.

```
[s, w] = dos('dir', '-echo');
```

`!` (exclamation point), `perl`, `system`, `unix`, `winopen`

"Running External Programs" in the MATLAB Desktop Tools and Development Environment documentation

Purpose

Vector dot product

Syntax

```
C = dot(A,B)
C = dot(A,B,dim)
```

Description

`C = dot(A,B)` returns the scalar product of the vectors `A` and `B`. `A` and `B` must be vectors of the same length. When `A` and `B` are both column vectors, `dot(A,B)` is the same as `A'*B`.

For multidimensional arrays `A` and `B`, `dot` returns the scalar product along the first non-singleton dimension of `A` and `B`. `A` and `B` must have the same size.

`C = dot(A,B,dim)` returns the scalar product of `A` and `B` in the dimension `dim`.

Examples

The dot product of two vectors is calculated as shown:

```
a = [1 2 3]; b = [4 5 6];
c = dot(a,b)

c =
      32
```

See Also

`cross`

double

Purpose

Convert to double precision

Syntax

```
double(x)
```

Description

`double(x)` returns the double-precision value for `X`. If `X` is already a double-precision array, `double` has no effect.

Remarks

`double` is called for the expressions in `for`, `if`, and `while` loops if the expression isn't already double-precision. `double` should be overloaded for any object when it makes sense to convert it to a double-precision value.

Purpose

Drag rectangles with mouse

Syntax

```
[finalrect] = dragrect(initialrect)
[finalrect] = dragrect(initialrect,stepsize)
```

Description

`[finalrect] = dragrect(initialrect)` tracks one or more rectangles anywhere on the screen. The n-by-4 matrix `initialrect` defines the rectangles. Each row of `initialrect` must contain the initial rectangle position as `[left bottom width height]` values. `dragrect` returns the final position of the rectangles in `finalrect`.

`[finalrect] = dragrect(initialrect,stepsize)` moves the rectangles in increments of `stepsize`. The lower left corner of the first rectangle is constrained to a grid of size equal to `stepsize` starting at the lower left corner of the figure, and all other rectangles maintain their original offset from the first rectangle.

`[finalrect] = dragrect(...)` returns the final positions of the rectangles when the mouse button is released. The default step size is `1`.

Remarks

`dragrect` returns immediately if a mouse button is not currently pressed. Use `dragrect` in a `ButtonDownFcn`, or from the command line in conjunction with `waitforbuttonpress`, to ensure that the mouse button is down when `dragrect` is called. `dragrect` returns when you release the mouse button.

If the drag ends over a figure window, the positions of the rectangles are returned in that figure's coordinate system. If the drag ends over a part of the screen not contained within a figure window, the rectangles are returned in the coordinate system of the figure over which the drag began.

Note You cannot use normalized figure units with `dragrect`.

Example

Drag a rectangle that is 50 pixels wide and 100 pixels in height.

```
waitforbuttonpress
point1 = get(gcf,'CurrentPoint') % button down detected
rect = [point1(1,1) point1(1,2) 50 100]
[r2] = dragrect(rect)
```

`rbbox`, `waitforbuttonpress`

"Selecting Region of Interest" on page 1-101 for related functions

Purpose

Flushes event queue and updates figure window

Syntax

```
drawnow
drawnow expose
drawnow update
```

Description

`drawnow` causes figure windows and their children to update and flushes the system event queue. Any callbacks generated by incoming events (e.g. mouse or key events) are dispatched before `drawnow` returns.

`drawnow expose` causes only graphics objects to refresh, if needed. It does not allow callbacks to execute and does not process other events in the queue.

`drawnow update` causes only non-graphics objects to refresh, if needed. It does not allow callbacks to execute and does not process other events in the queue.

You can combine the `expose` and `update` options to obtain both effects.

```
drawnow expose update
```

Other Events That Cause Event Queue Processing

Other events that cause MATLAB to flush the event queue and draw the figure includes:

- Returning to the MATLAB prompt
- Executing the following functions
  - `figure`
  - `getframe`
  - `input`
  - `keyboard`
  - `pause`
- Functions that wait for user input (i.e., `waitforbuttonpress`, `waitfor`, `ginput`)

Examples

Using drawnow in a loop causes the display to update while the loop executes:

```
t = 0:pi/20:2*pi;
y = exp(sin(t));
h = plot(t,y,'YDataSource','y');
for k = 1:.1:10
 y = exp(sin(t.*k));
 refreshdata(h,'caller') % Evaluate y in the function workspace
 drawnow; pause(.1)
end
```

waitfor, waitforbuttonpress

"Figure Windows" on page 1-95 for related functions

Purpose

Search Delaunay triangulation for nearest point

Syntax

```
K = dsearch(x,y,TRI,xi,yi)
K = dsearch(x,y,TRI,xi,yi,S)
```

Description

`K = dsearch(x,y,TRI,xi,yi)` returns the index into `x` and `y` of the nearest point to the point (`xi`,`yi`). `dsearch` requires a triangulation `TRI` of the points `x`,`y` obtained using `delaunay`. If `xi` and `yi` are vectors, `K` is a vector of the same size.

`K = dsearch(x,y,TRI,xi,yi,S)` uses the sparse matrix `S` instead of computing it each time:

```
S = sparse(TRI(:,[1 1 2 2 3 3]),TRI(:,[2 3 1 3 1 2]),1,nxy,nxy)
```

where `nxy = prod(size(x))`.

`delaunay`, `tsearch`, `voronoi`

dsearchn

Purpose

N-D nearest point search

Syntax

```
k = dsearchn(X,T,XI)
k = dsearchn(X,T,XI,outval)
k = dsearchn(X,XI)
[k,d] = dsearchn(X,...)
```

Description

`k = dsearchn(X,T,XI)` returns the indices `k` of the closest points in `X` for each point in `XI`. `X` is an `m`-by-`n` matrix representing `m` points in n-dimensional space. `XI` is a `p`-by-`n` matrix, representing `p` points in n-dimensional space. `T` is a `numt`-by-`n+1` matrix, a tessellation of the data `X` generated by `delaunayn`. The output `k` is a column vector of length `p`.

`k = dsearchn(X,T,XI,outval)` returns the indices `k` of the closest points in `X` for each point in `XI`, unless a point is outside the convex hull. If `XI(J,:)` is outside the convex hull, then `K(J)` is assigned `outval`, a scalar double. `Inf` is often used for `outval`. If `outval` is `[]`, then `k` is the same as in the case `k = dsearchn(X,T,XI)`.

`k = dsearchn(X,XI)` performs the search without using a tessellation. With large `X` and small `XI`, this approach is faster and uses much less memory.

`[k,d] = dsearchn(X,...)` also returns the distances `d` to the closest points. `d` is a column vector of length `p`.

Algorithm

`dsearchn` is based on Qhull [1]. For information about Qhull, see `http://www.qhull.org/`. For copyright information, see `http://www.qhull.org/COPYING.txt`.

Purpose

Echo M-files during execution

Syntax

```
echo on
echo off
echo
echo fcnname on
echo fcnname off
echo fcnname
echo on all
echo off all
```

Description

The `echo` command controls the echoing of M-files during execution. Normally, the commands in M-files are not displayed on the screen during execution. Command echoing is useful for debugging or for demonstrations, allowing the commands to be viewed as they execute.

The `echo` command behaves in a slightly different manner for script files and function files. For script files, the use of `echo` is simple; echoing can be either `on` or `off`, in which case any script used is affected.

`echo on`	Turns on the echoing of commands in all script files
`echo off`	Turns off the echoing of commands in all script files
`echo`	Toggles the echo state

With function files, the use of `echo` is more complicated. If `echo` is enabled on a function file, the file is interpreted, rather than compiled. Each input line is then displayed as it is executed. Since this results in inefficient execution, use `echo` only for debugging.

`echo fcnname on`	Turns on echoing of the named function file
`echo fcnname off`	Turns off echoing of the named function file
`echo fcnname`	Toggles the echo state of the named function file

`echo on all`	Sets echoing on for all function files
`echo off all`	Sets echoing off for all function files

`function`

Purpose

Run M-file demo step-by-step in Command Window

GUI Alternatives

As an alternative to the `echodemo` function, select the demo in the Help browser **Demos** tab and click the **Run in the Command Window** link.

Syntax

```
echodemo filename
echodemo('filename', cellindex)
```

Description

`echodemo filename` runs the M-file demo `filename` step-by-step in the Command Window. At each step, follow links in the Command Window to proceed. Depending on the size of the Command Window, you might have to scroll up to see the links. The script `filename` was created in the Editor/Debugger using cells. (The associated HTML demo file for `filename` that appears in the Help browser **Demos** pane was created using the MATLAB cell publishing feature.) The link to `filename` also shows the current cell number, `n`, and the total number of cells, `m`, as `n/m`, and when clicked, opens `filename` in the Editor/Debugger. To end the demo, click the **Stop** link.

`echodemo('filename', cellindex)` runs the M-file type demo `filename`, starting with the cell number specified by `cellindex`. Because steps prior to `cellindex` are not run, this statement might produce an error or unexpected result, depending on the demo.

Note M-file demos run as scripts. Therefore, the variables are part of the base workspace, which could result in problems if you have any variables of the same name. For more information, see “Running Demos and Base Workspace Variables” in the Desktop Tools and Development Environment documentation.

Examples

`echodemo quake` runs the MATLAB Loma Prieta Earthquake demo.

`echodemo ('quake', 6)` runs the MATLAB Loma Prieta Earthquake demo, starting at cell 6.

`echodemo ('intro', 3)` produces an error because cell 3 of the MATLAB demo `intro` requires data created when cells 1 and 2 run.

`demo`, `helpbrowser`

Purpose

Edit or create M-file

GUI Alternatives

As an alternative to the `edit` function, select **File > New** or **Open** in the MATLAB desktop or any desktop tool.

Syntax

```
edit
edit fun.m
edit file.ext
edit fun1 fun2 fun3 ...
edit class/fun
edit private/fun
edit class/private/fun
edit('my file.m')
```

Description

`edit` opens a new editor window.

`edit fun.m` opens the M-file `fun.m` in the default editor. Note that `fun.m` can be a MATLAB `partialpath` or a complete path. If `fun.m` does not exist, a prompt appears asking if you want to create a new file titled `fun.m`. After you click **Yes**, the Editor/Debugger creates a blank file titled `fun.m`. If you do not want the prompt to appear in this situation, select that check box in the prompt. Then when you type `edit fun.m`, where `fun.m` did not previously exist, a new file called `fun.m` is automatically opened in the Editor/Debugger. To make the prompt appear, specify it in preferences for Prompt.

`edit file.ext` opens the specified file.

`edit fun1 fun2 fun3 ...` opens `fun1.m`, `fun2.m`, `fun3.m`, and so on, in the default editor.

`edit class/fun`, or `edit private/fun`, or `edit class/private/fun` edit a method, private function, or private method for the class named `class`.

`edit('my file.m')` opens the M-file `my file.m` in the default editor. This form of the `edit` function is useful when a filename contains a space, for example, because you cannot use the command form in such a case.

Remarks

To specify the default editor for MATLAB, select **Preferences** from the **File** menu. On the **Editor/Debugger** pane, select **MATLAB editor** or specify another.

UNIX Users

If you run MATLAB with the `-nodisplay` startup option, or run without the `DISPLAY` environment variable set, `edit` uses the `External Editor` command. It does not use the MATLAB Editor/Debugger, but instead uses the default editor defined for your system in *`matlabroot`*`/X11/app-defaults/Matlab`.

You can specify the editor that the `edit` function uses or specify editor options by adding the following line to your own `.Xdefaults` file, located in `~home`:

```
matlab*externalEditorCommand: $EDITOR -option $FILE
```

where

- `$EDITOR` is the name of your default editor, for example, `emacs`; leaving it as `$EDITOR` means your default system editor will be used.
- `-option` is a valid option flag you can include for the specified editor.
- **`$FILE`** means the filename you type with the `edit` command will open in the specified editor.

For example,

```
emacs $FILE
```

means that when you type `edit foo`, the file `foo` will open in the `emacs` editor.

After adding the line to your `.Xdefaults` file, you must run the following before starting MATLAB:

```
xrdb -merge ~home/.Xdefaults
```

`open`, `type`

Purpose

Find eigenvalues and eigenvectors

Syntax

```
d = eig(A)
d = eig(A,B)
[V,D] = eig(A)
[V,D] = eig(A,'nobalance')
[V,D] = eig(A,B)
[V,D] = eig(A,B,flag)
```

Description

`d = eig(A)` returns a vector of the eigenvalues of matrix `A`.

`d = eig(A,B)` returns a vector containing the generalized eigenvalues, if `A` and `B` are square matrices.

Note If `S` is sparse and symmetric, you can use `d = eig(S)` to returns the eigenvalues of `S`. If `S` is sparse but not symmetric, or if you want to return the eigenvectors of `S`, use the function `eigs` instead of `eig`.

`[V,D] = eig(A)` produces matrices of eigenvalues (`D`) and eigenvectors (`V`) of matrix `A`, so that `A*V = V*D`. Matrix `D` is the *canonical form* of `A` — a diagonal matrix with `A`'s eigenvalues on the main diagonal. Matrix `V` is the *modal matrix* — its columns are the eigenvectors of `A`.

If `W` is a matrix such that `W'*A = D*W'`, the columns of `W` are the *left eigenvectors* of `A`. Use `[W,D] = eig(A.'); W = conj(W)` to compute the left eigenvectors.

`[V,D] = eig(A,'nobalance')` finds eigenvalues and eigenvectors without a preliminary balancing step. This may give more accurate results for certain problems with unusual scaling. Ordinarily, balancing improves the conditioning of the input matrix, enabling more accurate computation of the eigenvectors and eigenvalues. However, if a matrix contains small elements that are really due to roundoff error, balancing may scale them up to make them as significant as the other elements of the original matrix, leading to incorrect eigenvectors. Use the

nobalance option in this event. See the balance function for more details.

[V,D] = eig(A,B) produces a diagonal matrix D of generalized eigenvalues and a full matrix V whose columns are the corresponding eigenvectors so that A*V = B*V*D .

[V,D] = eig(A,B,*flag*) specifies the algorithm used to compute eigenvalues and eigenvectors. *flag* can be:

'chol'	Computes the generalized eigenvalues of A and B using the Cholesky factorization of B. This is the default for symmetric (Hermitian) A and symmetric (Hermitian) positive definite B.
'qz'	Ignores the symmetry, if any, and uses the QZ algorithm as it would for nonsymmetric (non-Hermitian) A and B.

Note For eig(A), the eigenvectors are scaled so that the norm of each is 1.0. For eig(A,B), eig(A,'nobalance'), and eig(A,B,flag), the eigenvectors are not normalized.

Also note that if A is symmetric, eig(A,'nobalance') ignores the nobalance option since A is already balanced.

Remarks

The eigenvalue problem is to determine the nontrivial solutions of the equation

$$Ax = \lambda x$$

where A is an n-by-n matrix, x is a length n column vector, and λ is a scalar. The n values of λ that satisfy the equation are the *eigenvalues*, and the corresponding values of x are the *right eigenvectors*. In MATLAB, the function eig solves for the eigenvalues λ, and optionally the eigenvectors x.

The *generalized* eigenvalue problem is to determine the nontrivial solutions of the equation

$$Ax = \lambda Bx$$

where both A and B are n-by-n matrices and λ is a scalar. The values of λ that satisfy the equation are the *generalized eigenvalues* and the corresponding values of x are the *generalized right eigenvectors*.

If B is nonsingular, the problem could be solved by reducing it to a standard eigenvalue problem

$$B^{-1}Ax = \lambda x$$

Because B can be singular, an alternative algorithm, called the QZ method, is necessary.

When a matrix has no repeated eigenvalues, the eigenvectors are always independent and the eigenvector matrix `V` *diagonalizes* the original matrix `A` if applied as a similarity transformation. However, if a matrix has repeated eigenvalues, it is not similar to a diagonal matrix unless it has a full (independent) set of eigenvectors. If the eigenvectors are not independent then the original matrix is said to be *defective*. Even if a matrix is defective, the solution from `eig` satisfies `A*X = X*D`.

Examples

The matrix

```
B = [ 3     -2      -.9    2*eps
      -2     4       1    -eps
      -eps/4  eps/2  -1     0
      -.5    -.5      .1    1   ];
```

has elements on the order of roundoff error. It is an example for which the `nobalance` option is necessary to compute the eigenvectors correctly. Try the statements

```
[VB,DB] = eig(B)
B*VB - VB*DB
[VN,DN] = eig(B,'nobalance')
```

```
B*VN - VN*DN
```

Algorithm

Inputs of Type Double

For inputs of type `double`, MATLAB uses the following LAPACK routines to compute eigenvalues and eigenvectors.

Case	Routine
Real symmetric `A`	`DSYEV`
Real nonsymmetric `A`:	
• With preliminary balance step	`DGEEV` (with the scaling factor `SCLFAC = 2` in `DGEBAL`, instead of the LAPACK default value of `8`)
• `d = eig(A,'nobalance')`	`DGEHRD`, `DHSEQR`
• `[V,D] = eig(A,'nobalance')`	`DGEHRD`, `DORGHR`, `DHSEQR`, `DTREVC`
Hermitian `A`	`ZHEEV`
Non-Hermitian `A`:	
• With preliminary balance step	`ZGEEV` (with `SCLFAC = 2` instead of `8` in `ZGEBAL`)
• `d = eig(A,'nobalance')`	`ZGEHRD`, `ZHSEQR`
• `[V,D] = eig(A,'nobalance')`	`ZGEHRD`, `ZUNGHR`, `ZHSEQR`, `ZTREVC`
Real symmetric `A`, symmetric positive definite `B`.	`DSYGV`
Special case: `eig(A,B,'qz')` for real `A`, `B` (same as real nonsymmetric `A`, real general `B`)	`DGGEV`
Real nonsymmetric `A`, real general `B`	`DGGEV`
Complex Hermitian `A`, Hermitian positive definite `B`.	`ZHEGV`

Case	Routine
Special case: `eig(A,B,'qz')` for complex `A` or `B` (same as complex non-Hermitian `A`, complex `B`)	`ZGGEV`
Complex non-Hermitian `A`, complex `B`	`ZGGEV`

Inputs of Type Single

For inputs of type `single`, MATLAB uses the following LAPACK routines to compute eigenvalues and eigenvectors.

Case	Routine
Real symmetric `A`	`SSYEV`
Real nonsymmetric `A`:	
• With preliminary balance step	`SGEEV` (with the scaling factor `SCLFAC = 2` in `SGEBAL`, instead of the LAPACK default value of `8`)
• `d = eig(A,'nobalance')`	`SGEHRD`, `SHSEQR`
• `[V,D] = eig(A,'nobalance')`	`SGEHRD`, `SORGHR`, `SHSEQR`, `STREVC`
Hermitian `A`	`CHEEV`
Non-Hermitian `A`:	
• With preliminary balance step	`CGEEV`
• `d = eig(A,'nobalance')`	`CGEHRD`, `CHSEQR`
• `[V,D] = eig(A,'nobalance')`	`CGEHRD`, `CUNGHR`, `CHSEQR`, `CTREVC`
Real symmetric `A`, symmetric positive definite `B`.	`CSYGV`
Special case: `eig(A,B,'qz')` for real `A`, `B` (same as real nonsymmetric `A`, real general `B`)	`SGGEV`

Case	Routine
Real nonsymmetric `A`, real general `B`	`SGGEV`
Complex Hermitian `A`, Hermitian positive definite `B`.	`CHEGV`
Special case: `eig(A,B,'qz')` for complex `A` or `B` (same as complex non-Hermitian `A`, complex `B`)	`CGGEV`
Complex non-Hermitian `A`, complex `B`	`CGGEV`

[1] Anderson, E., Z. Bai, C. Bischof, S. Blackford, J. Demmel, J. Dongarra, J. Du Croz, A. Greenbaum, S. Hammarling, A. McKenney, and D. Sorensen, *LAPACK User's Guide* (`http://www.netlib.org/lapack/lug/lapack_lug.html`), Third Edition, SIAM, Philadelphia, 1999.

Purpose

Find largest eigenvalues and eigenvectors of sparse matrix

Syntax

```
d = eigs(A)
[V,D] = eigs(A)
[V,D,flag] = eigs(A)
eigs(A,B)
eigs(A,k)
eigs(A,B,k)
eigs(A,k,sigma)
eigs(A,B,k,sigma)
eigs(A,K,sigma,opts)
eigs(A,B,k,sigma,opts)
eigs(Afun,n,...)
```

Description

`d = eigs(A)` returns a vector of `A`'s six largest magnitude eigenvalues. `A` must be a square matrix, and should be large and sparse.

`[V,D] = eigs(A)` returns a diagonal matrix `D` of `A`'s six largest magnitude eigenvalues and a matrix `V` whose columns are the corresponding eigenvectors.

`[V,D,flag] = eigs(A)` also returns a convergence flag. If `flag` is `0` then all the eigenvalues converged; otherwise not all converged.

`eigs(A,B)` solves the generalized eigenvalue problem `A*V == B*V*D`. `B` must be symmetric (or Hermitian) positive definite and the same size as `A`. `eigs(A,[],...)` indicates the standard eigenvalue problem `A*V == V*D`.

`eigs(A,k)` and `eigs(A,B,k)` return the `k` largest magnitude eigenvalues.

`eigs(A,k,sigma)` and `eigs(A,B,k,sigma)` return `k` eigenvalues based on *`sigma`*, which can take any of the following values:

scalar (real or complex, including 0)	The eigenvalues closest to *sigma*. If A is a function, Afun must return Y = (A-*sigma**B)\x (i.e., Y = A\x when *sigma* = 0). Note, B need only be symmetric (Hermitian) positive semi-definite.
'lm'	Largest magnitude (default).
'sm'	Smallest magnitude. Same as *sigma* = 0. If A is a function, Afun must return Y = A\x. Note, B need only be symmetric (Hermitian) positive semi-definite.

For real symmetric problems, the following are also options:

'la'	Largest algebraic ('lr' in MATLAB 5)
'sa'	Smallest algebraic ('sr' in MATLAB 5)
'be'	Both ends (one more from high end if k is odd)

For nonsymmetric and complex problems, the following are also options:

'lr'	Largest real part
'sr'	Smallest real part
'li'	Largest imaginary part
'si'	Smallest imaginary part

Note The syntax eigs(A,k,...) is not valid when A is scalar. To pass a value for k, you must specify B as the second argument and k as the third (eigs(A,B,k,...)). If necessary, you can set B equal to [], the default.

---

eigs(A,K,*sigma*,opts) and eigs(A,B,k,*sigma*,opts) specify an options structure. Default values are shown in brackets ({}).

Parameter	Description	Values
`options.issym`	`1` if `A` or `A-sigma*B` represented by `Afun` is symmetric, `0` otherwise.	`[{0} | 1]`
`options.isreal`	`1` if `A` or `A-sigma*B` represented by `Afun` is real, `0` otherwise.	`[0 | {1}]`
`options.tol`	Convergence: Ritz estimate residual `<= tol*norm(A)`.	`[scalar | {eps}]`
`options.maxit`	Maximum number of iterations.	`[integer | {300}]`
`options.p`	Number of Lanczos basis vectors. `p >= 2k` (`p >= 2k+1` real nonsymmetric) advised. `p` must satisfy `k < p <= n` for real symmetric, `k+1 < p <= n` otherwise. Note: If you do not specify a `p` value, the default algorithm uses at least 20 Lanczos vectors.	`[integer | {2*k}]`
`options.v0`	Starting vector.	Randomly generated by ARPACK
`options.disp`	Diagnostic information display level.	`[0 | {1} | 2]`
`options.cholB`	`1` if `B` is really its Cholesky factor `chol(B)`, `0` otherwise.	`[{0} | 1]`
`options.permB`	Permutation vector `permB` if sparse `B` is really `chol(B(permB,permB))`.	`[permB | {1:n}]`

`eigs(Afun,n,...)` accepts the function handle `Afun` instead of the matrix `A`. See "Function Handles" in the MATLAB Programming documentation for more information. `Afun` must accept an input vector of size `n`.

`y = Afun(x)` should return:

`A*x`	if *`sigma`* is not specified, or is a string other than `'sm'`
`A\x`	if *`sigma`* is `0` or `'sm'`
`(A-`*`sigma`*`*I)\x`	if *`sigma`* is a nonzero scalar (standard eigenvalue problem). `I` is an identity matrix of the same size as `A`.
`(A-`*`sigma`*`*B)\x`	if *`sigma`* is a nonzero scalar (generalized eigenvalue problem)

"Parameterizing Functions Called by Function Functions" in the MATLAB Mathematics documentation, explains how to provide additional parameters to the function `Afun`, if necessary.

The matrix `A`, `A-`*`sigma`*`*I` or `A-`*`sigma`*`*B` represented by `Afun` is assumed to be real and nonsymmetric unless specified otherwise by `opts.isreal` and `opts.issym`. In all the `eigs` syntaxes, `eigs(A,...)` can be replaced by `eigs(Afun,n,...)`.

Remarks

`d = eigs(A,k)` is not a substitute for

```
d = eig(full(A))
d = sort(d)
d = d(end-k+1:end)
```

but is most appropriate for large sparse matrices. If the problem fits into memory, it may be quicker to use `eig(full(A))`.

Algorithm

`eigs` provides the reverse communication required by the Fortran library ARPACK, namely the routines `DSAUPD`, `DSEUPD`, `DNAUPD`, `DNEUPD`, `ZNAUPD`, and `ZNEUPD`.

Examples

Example 1

```
A = delsq(numgrid('C',15));
d1 = eigs(A,5,'sm')
```

returns

```
Iteration 1: a few Ritz values of the 20-by-20 matrix:
     0
     0
     0
     0
     0

Iteration 2: a few Ritz values of the 20-by-20 matrix:
    1.8117
    2.0889
    2.8827
    3.7374
    7.4954

Iteration 3: a few Ritz values of the 20-by-20 matrix:
    1.8117
    2.0889
    2.8827
    3.7374
    7.4954

d1 =

    0.5520
    0.4787
    0.3469
    0.2676
    0.1334
```

Example 2

This example replaces the matrix `A` in example 1 with a handle to a function `dnRk`. The example is contained in an M-file `run_eigs` that

- Calls `eigs` with the function handle `@dnRk` as its first argument.
- Contains `dnRk` as a nested function, so that all variables in `run_eigs` are available to `dnRk`.

The following shows the code for `run_eigs`:

```
function d2 = run_eigs
n = 139;
opts.issym = 1;
R = 'C';
k = 15;
d2 = eigs(@dnRk,n,5,'sm',opts);

    function y = dnRk(x)
        y = (delsq(numgrid(R,k))) \ x;
    end
end
```

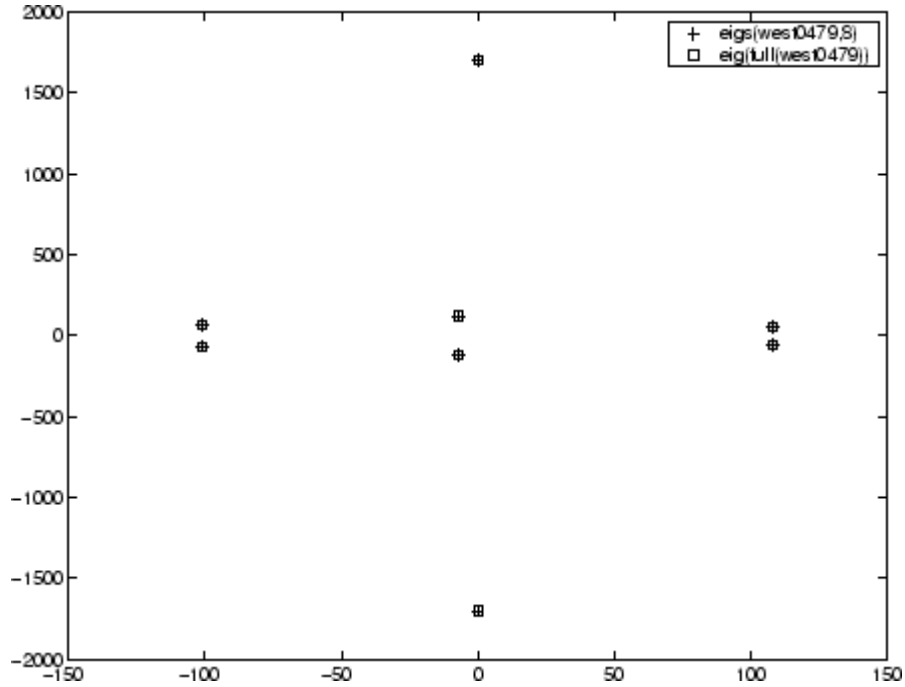
Example 3

`west0479` is a real 479-by-479 sparse matrix with both real and pairs of complex conjugate eigenvalues. `eig` computes all 479 eigenvalues. `eigs` easily picks out the largest magnitude eigenvalues.

This plot shows the 8 largest magnitude eigenvalues of `west0479` as computed by `eig` and `eigs`.

```
load west0479
d = eig(full(west0479))
dlm = eigs(west0479,8)
[dum,ind] = sort(abs(d));
plot(dlm,'k+')
hold on
plot(d(ind(end-7:end)),'ks')
```

```
hold off
legend('eigs(west0479,8)','eig(full(west0479))')
```



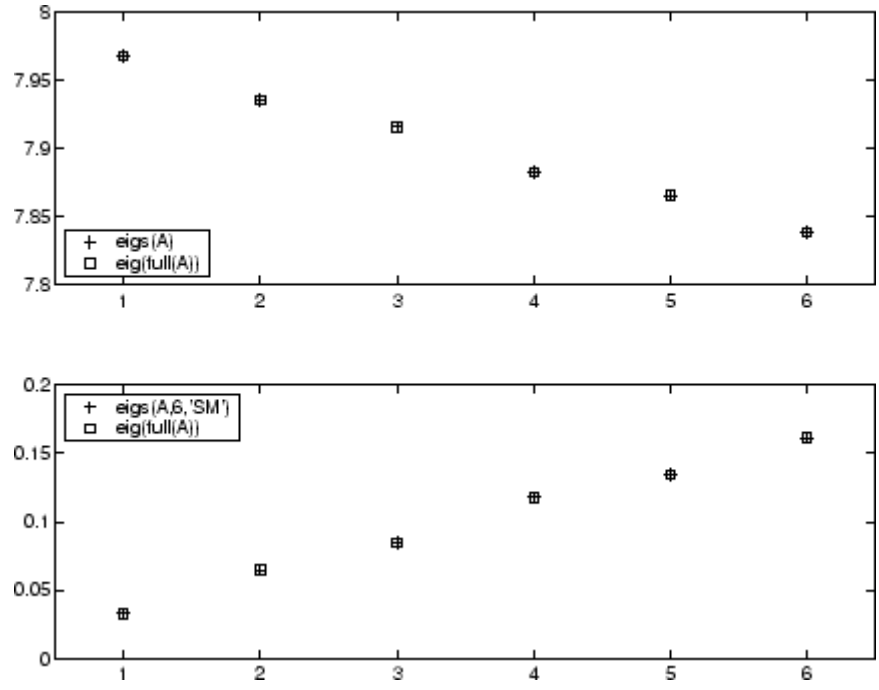
Example 4

`A = delsq(numgrid('C',30))` is a symmetric positive definite matrix of size 632 with eigenvalues reasonably well-distributed in the interval (0 8), but with 18 eigenvalues repeated at 4. The `eig` function computes all 632 eigenvalues. It computes and plots the six largest and smallest magnitude eigenvalues of `A` successfully with:

```
A = delsq(numgrid('C',30));
d = eig(full(A));
[dum,ind] = sort(abs(d));
dlm = eigs(A);
dsm = eigs(A,6,'sm');
```

```
subplot(2,1,1)
plot(dlm,'k+')
hold on
plot(d(ind(end:-1:end-5)),'ks')
hold off
legend('eigs(A)','eig(full(A))',3)
set(gca,'XLim',[0.5 6.5])

subplot(2,1,2)
plot(dsm,'k+')
hold on
plot(d(ind(1:6)),'ks')
hold off
legend('eigs(A,6,''sm'')','eig(full(A))',2)
set(gca,'XLim',[0.5 6.5])
```



However, the repeated eigenvalue at 4 must be handled more carefully. The call `eigs(A,18,4.0)` to compute 18 eigenvalues near 4.0 tries to find eigenvalues of `A - 4.0*I`. This involves divisions of the form `1/(lambda - 4.0)`, where `lambda` is an estimate of an eigenvalue of `A`. As `lambda` gets closer to 4.0, `eigs` fails. We must use `sigma` near but not equal to 4 to find those 18 eigenvalues.

```
sigma = 4 - 1e-6
[V,D] = eigs(A,18,sigma)
```

The plot shows the 20 eigenvalues closest to 4 that were computed by `eig`, along with the 18 eigenvalues closest to `4 - 1e-6` that were computed by `eigs`.

Purpose

Jacobi elliptic functions

Syntax

```
[SN,CN,DN] = ellipj(U,M)
[SN,CN,DN] = ellipj(U,M,tol)
```

Definition

The Jacobi elliptic functions are defined in terms of the integral:

$$u = \int_0^{\phi} \frac{d\theta}{(1 - m\sin^2\theta)^{\frac{1}{2}}}$$

Then

$$sn(u) = \sin\phi,\ cn(u) = \cos\phi,\ dn(u) = (1 - m\sin^2\phi)^{\frac{1}{2}},\ am(u) = \phi$$

Some definitions of the elliptic functions use the modulus k instead of the parameter m. They are related by

$$k^2 = m = \sin^2\alpha$$

The Jacobi elliptic functions obey many mathematical identities; for a good sample, see [1].

Description

`[SN,CN,DN] = ellipj(U,M)` returns the Jacobi elliptic functions `SN`, `CN`, and `DN`, evaluated for corresponding elements of argument `U` and parameter `M`. Inputs `U` and `M` must be the same size (or either can be scalar).

`[SN,CN,DN] = ellipj(U,M,tol)` computes the Jacobi elliptic functions to accuracy `tol`. The default is `eps`; increase this for a less accurate but more quickly computed answer.

Algorithm

`ellipj` computes the Jacobi elliptic functions using the method of the arithmetic-geometric mean [1]. It starts with the triplet of numbers:

$$a_0 = 1,\ b_0 = (1 - m)^{\frac{1}{2}},\ c_0 = (m)^{\frac{1}{2}}$$

`ellipj` computes successive iterates with

$$a_i = \frac{1}{2}(a_{i-1} + b_{i-1})$$
$$b_i = (a_{i-1}b_{i-1})^{\frac{1}{2}}$$
$$c_i = \frac{1}{2}(a_{i-1} - b_{i-1})$$

Next, it calculates the amplitudes in radians using:

$$\sin(2\phi_{n-1} - \phi_n) = \frac{c_n}{a_n}\sin(\phi_n)$$

being careful to unwrap the phases correctly. The Jacobian elliptic functions are then simply:

$$sn(u) = \sin\phi_0$$
$$cn(u) = \cos\phi_0$$
$$dn(u) = (1 - m \cdot sn(u)^2)^{\frac{1}{2}}$$

Limitations

The `ellipj` function is limited to the input domain $0 \le m \le 1$. Map other values of `M` into this range using the transformations described in [1], equations 16.10 and 16.11. `U` is limited to real values.

`ellipke`

References

[1] Abramowitz, M. and I.A. Stegun, *Handbook of Mathematical Functions*, Dover Publications, 1965, 17.6.

Purpose

Complete elliptic integrals of first and second kind

Syntax

```
K = ellipke(M)
[K,E] = ellipke(M)
[K,E] = ellipke(M,tol)
```

Definition

The *complete* elliptic integral of the first kind [1] is

$$K(m) = F(\pi/2|m)$$

where F, the elliptic integral of the first kind, is

$$K(m) = \int_0^1 [(1-t^2)(1-mt^2)]^{\frac{-1}{2}}\, dt = \int_0^{\frac{\pi}{2}} (1-m\sin^2\theta)^{\frac{-1}{2}}\, d\theta$$

The complete elliptic integral of the second kind

$$E(m) = E(K(m)) = E\langle\pi/2|m\rangle$$

is

$$E(m) = \int_0^1 (1-t^2)^{\frac{-1}{2}}(1-mt^2)^{\frac{1}{2}} dt = \int_0^{\frac{\pi}{2}} (1-m\sin^2\theta)^{\frac{1}{2}} d\theta$$

Some definitions of `K` and `E` use the modulus k instead of the parameter m. They are related by

$$k^2 = m = \sin^2\alpha$$

Description

`K = ellipke(M)` returns the complete elliptic integral of the first kind for the elements of `M`.

`[K,E] = ellipke(M)` returns the complete elliptic integral of the first and second kinds.

`[K,E] = ellipke(M,tol)` computes the complete elliptic integral to accuracy `tol`. The default is `eps`; increase this for a less accurate but more quickly computed answer.

Algorithm

`ellipke` computes the complete elliptic integral using the method of the arithmetic-geometric mean described in [1], section 17.6. It starts with the triplet of numbers

$$a_0 = 1,\ b_0 = (1-m)^{\frac{1}{2}},\ c_0 = (m)^{\frac{1}{2}}$$

`ellipke` computes successive iterations of a_i, b_i, and c_i with

$$a_i = \frac{1}{2}(a_{i-1} + b_{i-1})$$
$$b_i = (a_{i-1}b_{i-1})^{\frac{1}{2}}$$
$$c_i = \frac{1}{2}(a_{i-1} - b_{i-1})$$

stopping at iteration n when $cn \approx 0$, within the tolerance specified by `eps`. The complete elliptic integral of the first kind is then

$$K(m) = \frac{\pi}{2a_n}$$

Limitations

`ellipke` is limited to the input domain $0 \le m \le 1$.

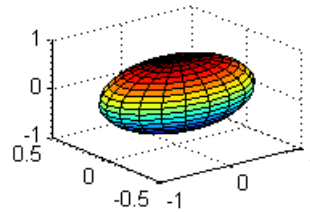
`ellipj`

References

[1] Abramowitz, M. and I.A. Stegun, *Handbook of Mathematical Functions*, Dover Publications, 1965, 17.6.

Purpose

Generate ellipsoid



Syntax

```
[x,y,z] = ellipsoid(xc,yc,zc,xr,yr,zr,n)
[x,y,z] = ellipsoid(xc,yc,zc,xr,yr,zr)
ellipsoid(axes_handle,...)
ellipsoid(...)
```

Description

`[x,y,z] = ellipsoid(xc,yc,zc,xr,yr,zr,n)` generates a surface mesh described by three `n+1`-by-`n+1` matrices, enabling `surf(x,y,z)` to plot an ellipsoid with center `(xc,yc,zc)` and semi-axis lengths `(xr,yr,zr)`.

`[x,y,z] = ellipsoid(xc,yc,zc,xr,yr,zr)` uses `n = 20`.

`ellipsoid(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`ellipsoid(...)` with no output arguments plots the ellipsoid as a surface.

Algorithm

`ellipsoid` generates the data using the following equation:

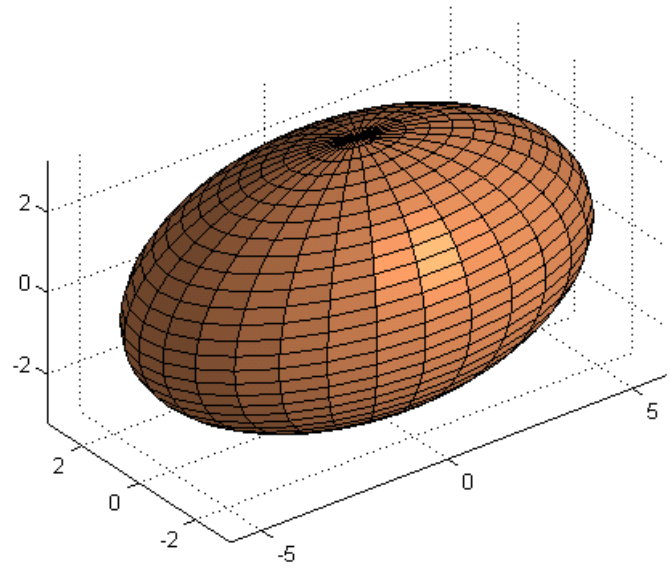
$$\frac{(x-xc)^2}{xr^2}+\frac{(y-yc)^2}{yr^2}+\frac{(z-zc)^2}{zr^2}$$

Note that `ellipsoid(0,0,0, .5,.5,.5)` is equivalent to a unit sphere.

Example

Generate ellipsoid with size and proportions of a standard U.S. football:

```
[x, y, z] = ellipsoid(0,0,0,5.9,3.25,3.25,30);
surfl(x, y, z)
colormap copper
axis equal
```



See Also

`cylinder`, `sphere`, `surf`

"Polygons and Surfaces" on page 1-90 for related functions

Purpose

Execute statements if condition is false

Syntax

```
if expression, statements1, else statements2, end
```

Description

`if` *`expression`*`,` *`statements1`*`, else` *`statements2`*`, end` evaluates *`expression`* and, if the evaluation yields logical `1` (`true`) or a nonzero result, executes one or more MATLAB commands denoted here as *`statements1`* or, if the evaluation yields logical `0` (`false`), executes the commands in *`statements2`*. `else` is used to delineate the alternate block of statements..

A `true` expression has either a logical `1` (`true`) or nonzero value. For nonscalar expressions, (for example, "if (matrix A is less than matrix B)"), `true` means that every element of the resulting matrix has a `true` or nonzero value.

Expressions usually involve relational operations such as `(count < limit)` or `isreal(A)`. Simple expressions can be combined by logical operators (`&`,`|`,`~`) into compound expressions such as `(count < limit) & ((height - offset) >= 0)`.

See "Program Control Statements" in the MATLAB Programming documentation for more information on controlling the flow of your program code.

Examples

In this example, if both of the conditions are not satisfied, then the student fails the course.

```
if ((attendance >= 0.90) & (grade_average >= 60))
   pass = 1;
else
   fail = 1;
end;
```

See Also

`if`, `elseif`, `end`, `for`, `while`, `switch`, `break`, `return`, relational operators, logical operators (elementwise and short-circuit)

elseif

Purpose

Execute statements if additional condition is true

Syntax

```
if expression1, statements1, elseif expression2,
statements2,
   end
```

Description

`if` *`expression1`*`, `*`statements1`*`, elseif` *`expression2`*`, `*`statements2`*`, end` evaluates *`expression1`* and, if the evaluation yields logical 1 (`true`) or a nonzero result, executes one or more MATLAB commands denoted here as *`statements1`*. If *`expression1`* is `false`, MATLAB evaluates the `elseif` expression, *`expression2`*. If *`expression2`* evaluates to `true` or a nonzero result, executes the commands in *`statements2`*.

A `true` expression has either a logical 1 (`true`) or nonzero value. For nonscalar expressions, (for example, is matrix A less then matrix B), `true` means that every element of the resulting matrix has a `true` or nonzero value.

Expressions usually involve relational operations such as `(count < limit)` or `isreal(A)`. Simple expressions can be combined by logical operators (`&`,`|`,`~`) into compound expressions such as `(count < limit) & ((height - offset) >= 0)`.

See "Program Control Statements" in the MATLAB Programming documentation for more information on controlling the flow of your program code.

Remarks

`elseif` , with a space between the `else` and the `if`, differs from `elseif`, with no space. The former introduces a new, nested `if`, which must have a matching `end`. The latter is used in a linear sequence of conditional statements with only one terminating `end`.

The two segments shown below produce identical results. Exactly one of the four assignments to `x` is executed, depending upon the values of the three logical expressions, `A`, `B`, and `C`.

```
if A                            if A
   x = a                            x = a
```

```
else                                elseif B
   if B                                 x = b
      x = b                         elseif C
   else                                 x = c
       if C                         else
          x = c                         x = d
       else                         end
           x = d
       end
   end
end
```

Examples

Here is an example showing `if`, `else`, and `elseif`.

```
for m = 1:k
    for n = 1:k
        if m == n
            a(m,n) = 2;
        elseif abs(m-n) == 2
            a(m,n) = 1;
        else
            a(m,n) = 0;
        end
    end
end
```

For `k=5` you get the matrix

```
a =

     2     0     1     0     0
     0     2     0     1     0
     1     0     2     0     1
     0     1     0     2     0
     0     0     1     0     2
```

`if`, `else`, `end`, `for`, `while`, `switch`, `break`, `return`, relational operators, logical operators (elementwise and short-circuit)

enableservice

Purpose

Enable, disable, or report status of Automation server

Syntax

```
state = enableservice('AutomationServer',enable)
state = enableservice('AutomationServer')
enableservice('DDEServer',enable)
```

Note Use COM, as described in COM Support in MATLAB. The `enableservice('DDEServer',enable)` syntax will be removed in a future version of MATLAB.

Description

`state = enableservice('AutomationServer',enable)` enables or disables the MATLAB Automation server.

If `enable` is logical `1` (`true`), `enableservice` converts an existing MATLAB session into an Automation server. If `enable` is logical `0` (`false`), `enableservice` disables the MATLAB Automation server.

`state` indicates the previous state of the Automation server. If `state = 1`, MATLAB was an Automation server. If `state` is logical `0` (`false`), MATLAB was not an Automation server.

`state = enableservice('AutomationServer')` returns the current state of the Automation server. If `state` is logical `1` (`true`), MATLAB is an Automation server.

`enableservice('DDEServer',enable)` enables the MATLAB DDE server. You cannot disable a DDE server once it has been enabled. Therefore, the only allowed value for `enable` is logical `1` (`true`).

Examples

Enable an Automation Server Example

Enable the Automation server in the current MATLAB session:

```
state = enableservice('AutomationServer',true);
```

Next, show the current state of the MATLAB session:

```
state = enableservice('AutomationServer')
```

MATLAB displays `state = 1 (true)`, showing that MATLAB is an Automation server.

Finally, enable the Automation server and show the previous state by typing

```
state = enableservice('AutomationServer',true)
```

MATLAB displays `state = 1 (true)`, showing that MATLAB previously was an Automation server.

Note the previous state may be the same as the current state. As seen in this case, `state = 1` shows MATLAB was, and still is, an Automation server.

end

Purpose

Terminate block of code, or indicate last array index

Syntax

```
end
```

Description

`end` is used to terminate `for`, `while`, `switch`, `try`, and `if` statements. Without an `end` statement, `for`, `while`, `switch`, `try`, and `if` wait for further input. Each `end` is paired with the closest previous unpaired `for`, `while`, `switch`, `try`, or `if` and serves to delimit its scope.

`end` also marks the termination of an M-file function, although in most cases, it is optional. `end` statements are required only in M-files that employ one or more nested functions. Within such an M-file, *every* function (including primary, nested, private, and subfunctions) must be terminated with an `end` statement. You can terminate any function type with `end`, but doing so is not required unless the M-file contains a nested function.

The `end` function also serves as the last index in an indexing expression. In that context, `end = (size(x,k))` when used as part of the `k`th index. Examples of this use are `X(3:end)` and `X(1,1:2:end-1)`. When using `end` to grow an array, as in `X(end+1)=5`, make sure `X` exists first.

You can overload the `end` statement for a user object by defining an `end` method for the object. The `end` method should have the calling sequence `end(obj,k,n)`, where `obj` is the user object, `k` is the index in the expression where the `end` syntax is used, and `n` is the total number of indices in the expression. For example, consider the expression

```
A(end-1,:)
```

MATLAB will call the `end` method defined for `A` using the syntax

```
end(A,1,2)
```

Examples

This example shows `end` used with the `for` and `if` statements.

```
for k = 1:n
 if a(k) == 0
  a(k) = a(k) + 2;
```

```
    end
end
```

In this example, `end` is used in an indexing expression.

```
A = magic(5)

A =

    17    24     1     8    15
    23     5     7    14    16
     4     6    13    20    22
    10    12    19    21     3
    11    18    25     2     9

B = A(end,2:end)

B =

    18    25     2     9
```

See Also

`break`, `for`, `if`, `return`, `switch`, `try`, `while`

eomday

Purpose

Last day of month

Syntax

```
E = eomday(Y, M)
```

Description

`E = eomday(Y, M)` returns the last day of the year and month given by corresponding elements of arrays `Y` and `M`.

Examples

Because 1996 is a leap year, the statement `eomday(1996,2)` returns `29`.

To show all the leap years in this century, try:

```
y = 1900:1999;
E = eomday(y, 2);
y(find(E == 29))

ans =
  Columns 1 through 6
     1904     1908     1912     1916     1920     1924

  Columns 7 through 12
     1928     1932     1936     1940     1944     1948

  Columns 13 through 18
     1952     1956     1960     1964     1968     1972

  Columns 19 through 24
     1976     1980     1984     1988     1992     1996
```

See Also

`datenum`, `datevec`, `weekday`

Purpose

Floating-point relative accuracy

Syntax

```
eps
d = eps(X)
eps('double')
eps('single')
```

Description

`eps` returns the distance from 1.0 to the next largest double-precision number, that is `eps = 2^(-52)`.

`d = eps(X)` is the positive distance from `abs(X)` to the next larger in magnitude floating point number of the same precision as `X`. `X` may be either double precision or single precision. For all `X`,

```
eps(X) = eps(-X) = eps(abs(X))
```

`eps('double')` is the same as `eps` or `eps(1.0)`.

`eps('single')` is the same as `eps(single(1.0))` or `single(2^-23)`.

Except for numbers whose absolute value is smaller than `realmin` , if `2^E <= abs(X) < 2^(E+1)`, then

```
eps(X) = 2^(E-23) if isa(X,'single')
eps(X) = 2^(E-52) if isa(X,'double')
```

For all `X` of class `double` such that `abs(X) <= realmin`, `eps(X) = 2^(-1074)`. Similarly, for all `X` of class `single` such that `abs(X) <= realmin('single')`, `eps(X) = 2^(-149)`.

Replace expressions of the form

```
if Y < eps * ABS(X)
```

with

```
if Y < eps(X)
```

Examples

```
double precision
eps(1/2) = 2^(-53)
```

```
eps(1) = 2^(-52)
eps(2) = 2^(-51)
eps(realmax) = 2^971
eps(0) = 2^(-1074)

if(abs(x)) <= realmin, eps(x) = 2^(-1074)
eps(realmin/2) = 2^(-1074)
eps(realmin/16) = 2^(-1074)
eps(Inf) = NaN
eps(NaN) = NaN

single precision
eps(single(1/2)) = 2^(-24)
eps(single(1)) = 2^(-23)
eps(single(2)) = 2^(-22)
eps(realmax('single')) = 2^104
eps(single(0)) = 2^(-149)
eps(realmin('single')/2) = 2^(-149)
eps(realmin('single')/16) = 2^(-149)
if(abs(x)) <= realmin('single'), eps(x) = 2^(-149)
eps(single(Inf)) = single(NaN)
eps(single(NaN)) = single(NaN)
```

See Also

`realmax`, `realmin`

Purpose

Test for equality

Syntax

```
A == B
eq(A, B)
```

Description

`A == B` compares each element of array `A` for equality with the corresponding element of array `B`, and returns an array with elements set to logical 1 (`true`) where `A` and `B` are equal, or logical 0 (`false`) where they are not equal. Each input of the expression can be an array or a scalar value.

If both `A` and `B` are scalar (i.e., 1-by-1 matrices), then MATLAB returns a scalar value.

If both `A` and `B` are nonscalar arrays, then these arrays must have the same dimensions, and MATLAB returns an array of the same dimensions as `A` and `B`.

If one input is scalar and the other a nonscalar array, then the scalar input is treated as if it were an array having the same dimensions as the nonscalar input array. In other words, if input `A` is the number 100, and `B` is a 3-by-5 matrix, then `A` is treated as if it were a 3-by-5 matrix of elements, each set to 100. MATLAB returns an array of the same dimensions as the nonscalar input array.

`eq(A, B)` is called for the syntax `A == B` when either `A` or `B` is an object.

Examples

Create two 6-by-6 matrices, `A` and `B`, and locate those elements of `A` that are equal to the corresponding elements of `B`:

```
A = magic(6);
B = repmat(magic(3), 2, 2);

A == B
ans =
     0     1     1     0     0     0
     1     0     1     0     0     0
     0     1     1     0     0     0
     1     0     0     0     0     0
```

```
     0     1     0     0     0     0
     1     0     0     0     0     0
```

See Also

`ne`, `le`, `ge`, `lt`, `gt`, relational operators

Purpose

Compare `MException` objects for equality

Syntax

```
eObj1 == eObj2
```

Description

`eObj1 == eObj2` tests scalar `MException` objects `eObj1` and `eObj2` for equality, returning logical 1 (`true`) if the two objects are identical, otherwise returning logical 0 (`false`).

See Also

`try`, `catch`, `error`, `assert`, `MException`, `isequal(MException)`, `ne(MException)`, `getReport(MException)`, `disp(MException)`, `throw(MException)`, `rethrow(MException)`, `throwAsCaller(MException)`, `addCause(MException)`, `last(MException)`

Purpose

Error functions

Syntax

```
Y = erf(X)
Y = erfc(X)
Y = erfcx(X)
X = erfinv(Y)
X = erfcinv(Y)
```

Definition

The error function `erf(X)` is twice the integral of the Gaussian distribution with 0 mean and variance of $1/2$.

$$\mathrm{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt$$

The complementary error function `erfc(X)` is defined as

$$\mathrm{erfc}(x) = \frac{2}{\sqrt{\pi}} \int_x^\infty e^{-t^2} dt = 1 - \mathrm{erf}(x)$$

The scaled complementary error function `erfcx(X)` is defined as

$$\mathrm{erfcx}(x) = e^{x^2} \mathrm{erfc}(x)$$

For large `X`, `erfcx(X)` is approximately $\left(\frac{1}{\sqrt{\pi}}\right)\frac{1}{x}$

Description

`Y = erf(X)` returns the value of the error function for each element of real array `X`.

`Y = erfc(X)` computes the value of the complementary error function.

`Y = erfcx(X)` computes the value of the scaled complementary error function.

`X = erfinv(Y)` returns the value of the inverse error function for each element of `Y`. Elements of `Y` must be in the interval `[-1 1]`. The function `erfinv` satisfies $y = \mathrm{erf}(x)$ for $-1 \le y \le 1$ and $-\infty \le x \le \infty$.

`X = erfcinv(Y)` returns the value of the inverse of the complementary error function for each element of `Y`. Elements of `Y` must be in the interval `[0 2]`. The function `erfcinv` satisfies $y = \text{erfc}(x)$ for $2 \geq y \geq 0$ and $-\infty \leq x \leq \infty$.

Remarks

The relationship between the complementary error function `erfc` and the standard normal probability distribution returned by the Statistics Toolbox function `normcdf` is

$$\text{normcdf}(x) = 0.5 * \text{erfc}(-x/\sqrt{2})$$

The relationship between the inverse complementary error function `erfcinv` and the inverse standard normal probability distribution returned by the Statistics Toolbox function `norminv` is

$$\text{norminv}(p) = -\sqrt{2} * \text{erfcinv}(2p)$$

Examples

`erfinv(1)` is `Inf`

`erfinv(-1)` is `-Inf`.

For `abs(Y) > 1`, `erfinv(Y)` is `NaN`.

Algorithms

For the error functions, the MATLAB code is a translation of a Fortran program by W. J. Cody, Argonne National Laboratory, NETLIB/SPECFUN, March 19, 1990. The main computation evaluates near-minimax rational approximations from [1].

For the inverse of the error function, rational approximations accurate to approximately six significant digits are used to generate an initial approximation, which is then improved to full accuracy by one step of Halley's method.

References

[1] Cody, W. J., "Rational Chebyshev Approximations for the Error Function," *Math. Comp.*, pgs. 631-638, 1969

Purpose

Display message and abort function

Syntax

```
error('message')
error('message', a1, a2, ...)
error('message_id', 'message')
error('message_id', 'message', a1, a2, ...)
error(message_struct)
```

Description

`error('message')` displays an error message and returns control to the keyboard. The error message contains the input string `message`.

The `error` command has no effect if `message` is an empty string.

`error('message', a1, a2, ...)` displays a message string that contains formatting conversion characters, such as those used with the MATLAB `sprintf` function. Each conversion character in `message` is converted to one of the values `a1, a2, ...` in the argument list.

Note MATLAB converts special characters (like `\n` and `%d`) in the error message string only when you specify more than one input argument with `error`. See Example 3 below.

`error('message_id', 'message')` attaches a unique message identifier, or `message_id`, to the error message. The identifier enables you to better identify the source of an error. See and in the MATLAB documentation for more information on the `message_id` argument and how to use it.

`error('message_id', 'message', a1, a2, ...)` includes formatting conversion characters in `message`, and the character translations `a1, a2, ...`.

`error(message_struct)` accepts a scalar error structure input `message_struct` with at least one of the fields `message`, `identifier`, and `stack`. (See the help for `lasterror` for more information on these fields.) If the `message_struct` input includes a `stack` field, then the `stack` field of the error will be set according to the contents of the `stack`

input. As a special case, if `message_struct` is an empty structure, no action is taken and `error` returns without exiting from the M-file.

Remarks

In addition to the `message_id` and `message`, the `error` function also determines where the error occurred, and provides this information using the `stack` field of the structure returned by `lasterror`. The `stack` field contains a structure array in the same format as the output of `dbstack`. This stack points to the line, function, and M-file in which the error occurred.

Examples

Example 1

The `error` function provides an error return from M-files:

```
function foo(x,y)
if nargin ~= 2
     error('Wrong number of input arguments')
end
```

The returned error message looks like this:

```
foo(pi)

??? Error using ==> foo
Wrong number of input arguments
```

Example 2

Specify a message identifier and error message string with `error`:

```
error('MyToolbox:angleTooLarge', ...
      'The angle specified must be less than 90 degrees.');
```

In your error handling code, use `lasterror` to determine the message identifier and error message string for the failing operation:

```
err = lasterror;

err.message
```

```
ans =
   The angle specified must be less than 90 degrees.

err.identifier
ans =
   MyToolbox:angleTooLarge
```

If this error is thrown from code in an M-file, you can find the M-file name, function, and line number using the `stack` field of the structure returned by `lasterror`:

```
err.stack
ans =
    file: 'd:\mytools\plotshape.m'
    name: 'check_angles'
    line: 26
```

Example 3

MATLAB converts special characters (like `\n` and `%d`) in the error message string only when you specify more than one input argument with `error`. In the single-argument case shown below, `\n` is taken to mean `backslash-n`. It is not converted to a newline character:

```
error('In this case, the newline \n is not converted.')
??? In this case, the newline \n is not converted.
```

But, when more than one argument is specified, MATLAB does convert special characters. This holds true regardless of whether the additional argument supplies conversion values or is a message identifier:

```
error('ErrorTests:convertTest', ...
      'In this case, the newline \n is converted.')
??? In this case, the newline
 is converted.
```

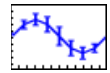
Purpose

Plot error bars along curve



GUI Alternatives

To graph selected variables, use the Plot Selector in the Workspace Browser, or use the Figure Palette Plot Catalog. Manipulate graphs in *plot edit* mode with the Property Editor. For details, see Plotting Tools — Interactive Plotting in the MATLAB Graphics documentation and Creating Graphics from the Workspace Browser in the MATLAB Desktop Tools documentation.

Syntax

```
errorbar(Y,E)
errorbar(X,Y,E)
errorbar(X,Y,L,U)
errorbar(...,LineSpec)
h = errorbar(...)
hlines = errorbar('v6',...)
```

Description

Error bars show the confidence level of data or the deviation along a curve.

`errorbar(Y,E)` plots `Y` and draws an error bar at each element of `Y`. The error bar is a distance of `E(i)` above and below the curve so that each bar is symmetric and `2*E(i)` long.

`errorbar(X,Y,E)` plots `Y` versus `X` with symmetric error bars `2*E(i)` long. `X`, `Y`, `E` must be the same size. When they are vectors, each error bar is a distance of `E(i)` above and below the point defined by `(X(i),Y(i))`. When they are matrices, each error bar is a distance of `E(i,j)` above and below the point defined by `(X(i,j),Y(i,j))`.

`errorbar(X,Y,L,U)` plots `X` versus `Y` with error bars `L(i)+U(i)` long specifying the lower and upper error bars. `X`, `Y`, `L`, and `U` must be the same size. When they are vectors, each error bar is a distance of `L(i)` below and `U(i)` above the point defined by `(X(i),Y(i))`. When they are matrices, each error bar is a distance of `L(i,j)` below and `U(i,j)` above the point defined by `(X(i,j),Y(i,j))`.

`errorbar(...,LineSpec)` uses the color and linestyle specified by the string `'LineSpec'`. The color is applied to the data line and error bars. The linestyle and marker are applied to the data line only. See `plot` for examples of styles.

`h = errorbar(...)` returns handles to the errorbarseries objects created. `errorbar` creates one object for vector input arguments and one object per column for matrix input arguments. See `errorbarseries properties` for more information.

Backward-Compatible Version

`hlines = errorbar('v6',...)` returns the handles of line objects instead of errorbarseries objects for compatibility with MATLAB 6.5 and earlier.

Note The `v6` option enables users of Version 7.x of MATLAB to create FIG-files that previous versions can open. It is obsolete and will be removed in a future version of MATLAB.

See Plot Objects and Backward Compatibility for more information.

Remarks

When the arguments are all matrices, `errorbar` draws one line per matrix column. If `X` and `Y` are vectors, they specify one curve.

Examples

Draw symmetric error bars that are two standard deviation units in length.

```
X = 0:pi/10:pi;
Y = sin(X);
E = std(Y)*ones(size(X));
errorbar(X,Y,E)
```

See `Errorbarseries Properties` for property descriptions

Errorbarseries Properties

Purpose

Define errorbarseries properties

Modifying Properties

You can set and query graphics object properties using the `set` and `get` commands or the Property editor (`propertyeditor`).

Note that you cannot define default property values for errorbarseries objects. See “Plot Objects” for more information on errorbarseries objects.

Errorbarseries Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

`Annotation`

`hg.Annotation` object Read Only

Control the display of errorbarseries objects in legends. The `Annotation` property enables you to specify whether this errorbarseries object is represented in a figure legend.

Querying the `Annotation` property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the errorbarseries object is displayed in a figure legend:

IconDisplayStyle Value	Purpose
`on`	Include the errorbarseries object in a legend as one entry, but not its children objects

IconDisplayStyle Value	Purpose
`off`	Do not include the errorbarseries or its children in a legend (default)
`children`	Include only the children of the errorbarseries as separate entries in the legend

Setting the `IconDisplayStyle` property

These commands set the `IconDisplayStyle` of a graphics object with handle `hobj` to `children`, which causes each child object to have an entry in the legend:

```
hAnnotation = get(hobj,'Annotation');
hLegendEntry = get(hAnnotation','LegendInformation');
set(hLegendEntry,'IconDisplayStyle','children')
```

Using the `IconDisplayStyle` property

See “Controlling Legends” for more information and examples.

`BeingDeleted`
`on | {off}` Read Only

This object is being deleted. The `BeingDeleted` property provides a mechanism that you can use to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object's delete function might call other functions that act on a number of different objects. These functions might not need to perform actions on objects if the objects are going to

be deleted, and therefore, can check the object's `BeingDeleted` property before acting.

`BusyAction`
`cancel | {queue}`

Callback routine interruption. The `BusyAction` property enables you to control how MATLAB handles events that potentially interrupt executing callbacks. If there is a callback function executing, callbacks invoked subsequently always attempt to interrupt it.

If the `Interruptible` property of the object whose callback is executing is set to `on` (the default), then interruption occurs at the next point where the event queue is processed. If the `Interruptible` property is `off`, the `BusyAction` property (of the object owning the executing callback) determines how MATLAB handles the event. The choices are

- `cancel` — Discard the event that attempted to execute a second callback routine.
- `queue` — Queue the event that attempted to execute a second callback routine until the current callback finishes.

`ButtonDownFcn`
string or function handle

Button press callback function. A callback that executes whenever you press a mouse button while the pointer is over this object, but not over another graphics object. See the `HitTestArea` property for information about selecting objects of this type.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

This property can be

- A string that is a valid MATLAB expression

- The name of an M-file
- A function handle

Set this property to a function handle that references the callback. The expressions execute in the MATLAB workspace.

See “Function Handle Callbacks” for information on how to use function handles to define the callbacks.

`Children`
array of graphics object handles

Children of this object. The handle of a patch object that is the child of this object (whether visible or not).

Note that if a child object's `HandleVisibility` property is set to `callback` or `off`, its handle does not show up in this object's `Children` property unless you set the root `ShowHiddenHandles` property to `on`:

```
set(0,'ShowHiddenHandles','on')
```

`Clipping`
`{on} | off`

Clipping mode. MATLAB clips graphs to the axes plot box by default. If you set `Clipping` to `off`, portions of graphs can be displayed outside the axes plot box. This can occur if you create a plot object, set `hold` to `on`, freeze axis scaling (`axis manual`), and then create a larger plot object.

`Color`
ColorSpec

Color of the object. A three-element RGB vector or one of the MATLAB predefined names, specifying the object's color.

See the ColorSpec reference page for more information on specifying color.

`CreateFcn`
string or function handle

Not available on errorbarseries objects.

`DeleteFcn`
string or function handle

Callback executed during object deletion. A callback that executes when this object is deleted (e.g., this might happen when you issue a `delete` command on the object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object's properties so the callback routine can query these values.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which can be queried using `gcbo`.

See "Function Handle Callbacks" for information on how to use function handles to define the callback function.

See the `BeingDeleted` property for related information.

`DisplayName`
string (default is empty string)

String used by legend for this errorbarseries object. The `legend` function uses the string defined by the `DisplayName` property to label this errorbarseries object in the legend.

- If you specify string arguments with the `legend` function, `DisplayName` is set to this errorbarseries object's corresponding string and that string is used for the legend.

- If `DisplayName` is empty, legend creates a string of the form, `['data' n]`, where *n* is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, `DisplayName` is set to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add programmatically a legend that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See “Controlling Legends” for more examples.

`EraseMode`

```
{normal} | none | xor | background
```

Erase mode. This property controls the technique MATLAB uses to draw and erase objects and their children. Alternative erase modes are useful for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to ensure that all objects are rendered correctly. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- `none` — Do not erase objects when they are moved or destroyed. While the objects are still visible on the screen after erasing with `EraseMode none`, you cannot print these objects because MATLAB stores no information about their former locations.
- `xor` — Draw and erase the object by performing an exclusive OR (XOR) with each pixel index of the screen behind it. Erasing

the object does not damage the color of the objects behind it. However, the color of the erased object depends on the color of the screen behind it and it is correctly colored only when it is over the axes background color (or the figure background color if the axes `Color` property is set to `none`). That is, it isn't erased correctly if there are objects behind it.

- `background` — Erase the graphics objects by redrawing them in the axes background color, (or the figure background color if the axes `Color` property is set to `none`). This damages other graphics objects that are behind the erased object, but the erased object is always properly colored.

Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB can mathematically combine layers of colors (e.g., performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

Set the axes background color with the axes `Color` property. Set the figure background color with the figure `Color` property.

You can use the MATLAB `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

`HandleVisibility`
`{on} | callback | off`

Control access to object's handle by command-line users and GUIs. This property determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for

preventing command-line users from accidentally accessing objects that you need to protect for some reason.

- `on` — Handles are always visible when `HandleVisibility` is `on`.
- `callback` — Setting `HandleVisibility` to `callback` causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Setting `HandleVisibility` to `off` makes handles invisible at all times. This might be necessary when a callback invokes a function that might potentially damage the GUI (such as evaluating a user-typed string) and so temporarily hides its own handles during the execution of that function.

Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Properties Affected by Handle Visibility

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

Overriding Handle Visibility

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility`

settings (this does not affect the values of the `HandleVisibility` properties). See also `findall`.

Handle Validity

Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

`HitTest`

`{on} | off`

Selectable by mouse click. `HitTest` determines whether this object can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the objects that compose the area graph. If `HitTest` is `off`, clicking this object selects the object below it (which is usually the axes containing it).

`HitTestArea`

`on | {off}`

Select the object by clicking lines or area of extent. This property enables you to select plot objects in two ways:

- Select by clicking lines or markers (default).
- Select by clicking anywhere in the extent of the plot.

When `HitTestArea` is `off`, you must click th eobject's lines or markers (excluding the baseline, if any) to select the object. When

HitTestArea is on, you can select this object by clicking anywhere within the extent of the plot (i.e., anywhere within a rectangle that encloses it).

`Interruptible`
`{on} | off`

Callback routine interruption mode. The `Interruptible` property controls whether an object's callback can be interrupted by callbacks invoked subsequently.

Only callbacks defined for the `ButtonDownFcn` property are affected by the `Interruptible` property. MATLAB checks for events that can interrupt a callback only when it encounters a `drawnow`, `figure`, `getframe`, or `pause` command in the routine. See the `BusyAction` property for related information.

Setting `Interruptible` to `on` allows any graphics object's callback to interrupt callback routines originating from a bar property. Note that MATLAB does not save the state of variables or the display (e.g., the handle returned by the `gca` or `gcf` command) when an interruption occurs.

`LData`
array equal in size to `XData` and `YData`

Errorbar length below data point. The `errorbar` function uses this data to determine the length of the errorbar below each data point. Specify these values in data units. See also `UData`.

`LDataSource`
string (MATLAB variable)

Link `LData` to MATLAB variable. Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `LData`.

MATLAB reevaluates this property only when you set it. Therefore, a change to workspace variables appearing in an expression does not change `LData`.

You can use the `refreshdata` function to force an update of the object's data. `refreshdata` also enables you to specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

See the `refreshdata` reference page for more information.

`LineStyle`

`{-} | -- | : | -. | none`

Line style. This property specifies the line style of the object. Available line styles are shown in the following table.

Specifier String	Line Style
`-`	Solid line (default)
`--`	Dashed line
`:`	Dotted line
`-.`	Dash-dot line
`none`	No line

You can use `LineStyle none` when you want to place a marker at each point but do not want the points connected with a line (see the `Marker` property).

`LineWidth`

scalar

The width of linear objects and edges of filled areas. Specify this value in points (1 point = $^1/_{72}$ inch). The default `LineWidth` is 0.5 points.

`Marker`
character (see table)

Marker symbol. The `Marker` property specifies the type of markers that are displayed at plot vertices. You can set values for the `Marker` property independently from the `LineStyle` property. Supported markers include those shown in the following table.

Marker Specifier	Description
`+`	Plus sign
`o`	Circle
`*`	Asterisk
`.`	Point
`x`	Cross
`s`	Square
`d`	Diamond
`^`	Upward-pointing triangle
`v`	Downward-pointing triangle
`>`	Right-pointing triangle
`<`	Left-pointing triangle
`p`	Five-pointed star (pentagram)
`h`	Six-pointed star (hexagram)
`none`	No marker (default)

`MarkerEdgeColor`
`ColorSpec | none | {auto}`

Marker edge color. The color of the marker or the edge color for filled markers (circle, square, diamond, pentagram, hexagram, and the four triangles). `ColorSpec` defines the color to use. `none`

specifies no color, which makes nonfilled markers invisible. `auto` sets `MarkerEdgeColor` to the same color as the `Color` property.

`MarkerFaceColor`
`ColorSpec | {none} | auto`

Marker face color. The fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles). `ColorSpec` defines the color to use. `none` makes the interior of the marker transparent, allowing the background to show through. `auto` sets the fill color to the axes color, or to the figure color if the axes `Color` property is set to `none` (which is the factory default for axes objects).

`MarkerSize`
size in points

Marker size. A scalar specifying the size of the marker in points. The default value for `MarkerSize` is 6 points (1 point = 1/72 inch). Note that MATLAB draws the point marker (specified by the `'.'` symbol) at one-third the specified size.

`Parent`
handle of parent axes, hggroup, or hgtransform

Parent of this object. This property contains the handle of the object's parent. The parent is normally the axes, hggroup, or hgtransform object that contains the object.

See "Objects That Can Contain Other Objects" for more information on parenting graphics objects.

`Selected`
`on | {off}`

Is object selected? When you set this property to `on`, MATLAB displays selection "handles" at the corners and midpoints if the `SelectionHighlight` property is also `on` (the default). You can, for example, define the `ButtonDownFcn` callback to set this

property to `on`, thereby indicating that this particular object is selected. This property is also set to `on` when an object is manually selected in plot edit mode.

`SelectionHighlight`
`{on} | off`

Objects are highlighted when selected. When the `Selected` property is `on`, MATLAB indicates the selected state by drawing selection handles on the curve and error bars. When `SelectionHighlight` is `off`, MATLAB does not draw the handles.

`Tag`
string

User-specified object label. The `Tag` property provides a means to identify graphics objects with a user-specified label. This is particularly useful when you are constructing interactive graphics programs that would otherwise need to define object handles as global variables or pass them as arguments between callbacks.

For example, you might create an errorbarseries object and set the `Tag` property:

```
t = errorbar(Y,E,'Tag','errorbar1')
```

When you want to access the errorbarseries object, you can use `findobj` to find the errorbarseries object's handle.

The following statement changes the `MarkerFaceColor` property of the object whose `Tag` is `errorbar1`.

```
set(findobj('Tag','errorbar1'),'MarkerFaceColor','red')
```

`Type`
string (read only)

Type of graphics object. This property contains a string that identifies the class of the graphics object. For errorbarseries objects, `Type` is 'hggroup'. The following statement finds all the hggroup objects in the current axes.

```
t = findobj(gca,'Type','hggroup');
```

`UData`
array equal in size to `XData` and `YData`

Errorbar length above data point. The `errorbar` function uses this data to determine the length of the errorbar above each data point. Specify these values in data units.

`UDataSource`
string (MATLAB variable)

Link `UData` to MATLAB variable. Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `UData`.

MATLAB reevaluates this property only when you set it. Therefore, a change to workspace variables appearing in an expression does not change `UData`.

You can use the `refreshdata` function to force an update of the object's data. `refreshdata` also enables you to specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

See the `refreshdata` reference page for more information.

`UIContextMenu`
handle of a uicontextmenu object

Associate a context menu with the errorbarseries object. Assign this property the handle of a uicontextmenu object created in the errorbarseries object's parent figure. Use the `uicontextmenu`

function to create the context menu. MATLAB displays the context menu whenever you right-click over the errorbarseries object.

`UserData`
array

User-specified data. This property can be any data you want to associate with the errorbarseries object (including cell arrays and structures). The errorbarseries object does not set values for this property, but you can access it using the `set` and `get` functions.

`Visible`
`{on} | off`

Visibility of errorbarseries object and its children. By default, errorbarseries object visibility is `on`. This means all children of the errorbarseries object are visible unless the child object's `Visible` property is set to `off`. Setting an errorbarseries object's `Visible` property to `off` also makes its children invisible.

`XData`
array

X-coordinates of the curve. The `errorbar` function plots a curve using the *x*-axis coordinates in the `XData` array. `XData` must be the same size as `YData`.

If you do not specify `XData` (i.e., the input argument `x`), the `errorbar` function uses the indices of `YData` to create the curve. See the `XDataMode` property for related information.

`XDataMode`
{auto} | manual

Use automatic or user-specified x-axis values. If you specify `XData` (by setting the `XData` property or specifying the input argument `x`), the `errorbar` function sets this property to `manual`.

If you set `XDataMode` to `auto` after having specified `XData`, the `errorbar` function resets the *x* tick-mark labels to the indices of the `YData`.

`XDataSource`
string (MATLAB variable)

Link `XData` to MATLAB variable. Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `XData`.

MATLAB reevaluates this property only when you set it. Therefore, a change to workspace variables appearing in an expression does not change `XData`.

You can use the `refreshdata` function to force an update of the object's data. `refreshdata` also enables you to specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

See the `refreshdata` reference page for more information.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

`YData`
scalar, vector, or matrix

Data defining curve. `YData` contains the data defining the curve. If `YData` is a matrix, the `errorbar` function displays a curve with error bars for each column in the matrix.

The input argument `Y` in the `errorbar` function calling syntax assigns values to `YData`.

`YDataSource`
string (MATLAB variable)

Link `YData` to MATLAB variable. Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `YData`.

MATLAB reevaluates this property only when you set it. Therefore, a change to workspace variables appearing in an expression does not change `YData`.

You can use the `refreshdata` function to force an update of the object's data. `refreshdata` also enables you to specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

See the `refreshdata` reference page for more information.

Purpose

Create and open error dialog box

Syntax

```
h = errordlg
h = errordlg(errorstring)
h = errordlg(errorstring,dlgname)
h = errordlg(errorstring,dlgname,createmode)
```

Description

`h = errordlg` creates and displays a dialog box with title `Error Dialog` that contains the string `This is the default error string.` The `errordlg` function returns the handle of the dialog box in `h`.

`h = errordlg(errorstring)` displays a dialog box with title `Error Dialog` that contains the string `errorstring`.

`h = errordlg(errorstring,dlgname)` displays a dialog box with title`dlgname` that contains the string `errorstring`.

`h = errordlg(errorstring,dlgname,createmode)` specifies whether the error dialog box is modal or nonmodal. Optionally, it can also specify an interpreter for `errorstring` and `dlgname`. The *`createmode`* argument can be a string or a structure.

If *`createmode`* is a string, it must be one of the values shown in the following table.

createmode Value	Description
`modal`	Replaces the error dialog box having the specified `Title`, that was last created or clicked on, with a modal error dialog box as specified. All other error dialog boxes with the same title are deleted. The dialog box which is replaced can be either modal or nonmodal.

createmode Value	Description
`non-modal` (default)	Creates a new nonmodal error dialog box with the specified parameters. Existing error dialog boxes with the same title are not deleted.
`replace`	Replaces the error dialog box having the specified `Title`, that was last created or clicked on, with a nonmodal error dialog boxbox as specified. All other error dialog boxes with the same title are deleted. The dialog box which is replaced can be either modal or nonmodal.

Note A modal dialog box prevents the user from interacting with other windows before responding. To block MATLAB program execution as well, use the`uiwait` function. For more information about modal dialog boxes, see `WindowStyle` in theFigure Properties.

If `CreateMode` is a structure, it can have fields `WindowStyle` and `Interpreter`. `WindowStyle` must be one of the options shown in the table above. `Interpreter` is one of the strings `'tex'` or `'none'`. The default value for `Interpreter` is `'none'`.

Remarks

MATLAB sizes the dialog box to fit the string `'errorstring'`. The error dialog box has an **OK** push button and remains on the screen until you press the **OK** button or the **Return** key. After pressing the button, the error dialog box disappears.

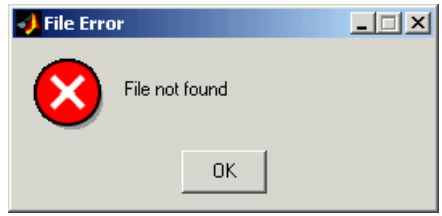
The appearance of the dialog box depends on the platform you use.

Examples

The function

```
errordlg('File not found','File Error');
```

displays this dialog box:



See Also

`dialog`, `helpdlg`, `inputdlg`, `listdlg`, `msgbox`, `questdlg`, `warndlg`

`figure`, `uiwait`, `uiresume`

“Predefined Dialog Boxes” on page 1-104 for related functions

Purpose

Time elapsed between date vectors

Syntax

```
e = etime(t2, t1)
```

Description

`e = etime(t2, t1)` returns the time in seconds between vectors `t1` and `t2`. The two vectors must be six elements long, in the format returned by `clock`:

```
T = [Year Month Day Hour Minute Second]
```

Remarks

When timing the duration of an event, use the `tic` and `toc` functions instead of `clock` or `etime`. These latter two functions are based on the system time which can be adjusted periodically by the operating system and thus might not be reliable in time comparison operations.

The `etime` function measures time elapsed between two points in time, and does not take into account differences in those points brought about by daylight savings time or changes in time zone.

Examples

Calculate how long a 2048-point real FFT takes.

```
x = rand(2048, 1);
t = clock;  fft(x);  etime(clock, t)
ans =
      0.4167
```

Limitations

As currently implemented, the `etime` function fails across month and year boundaries. Since `etime` is an M-file, you can modify the code to work across these boundaries if needed.

See Also

`clock`, `cputime`, `tic`, `toc`

Purpose

Elimination tree

Syntax

```
p = etree(A)
p = etree(A,'col')
p = etree(A,'sym')
[p,q] = etree(...)
```

Description

`p = etree(A)` returns an elimination tree for the square symmetric matrix whose upper triangle is that of `A`. `p(j)` is the parent of column `j` in the tree, or `0` if `j` is a root.

`p = etree(A,'col')` returns the elimination tree of `A'*A`.

`p = etree(A,'sym')` is the same as `p = etree(A)`.

`[p,q] = etree(...)` also returns a postorder permutation `q` of the tree.

See Also

`treelayout`, `treeplot`, `etreeplot`

Purpose

Plot elimination tree

Syntax

```
etreeplot(A)
etreeplot(A,nodeSpec,edgeSpec)
```

Description

`etreeplot(A)` plots the elimination tree of `A` (or `A+A'`, if non-symmetric).

`etreeplot(A,nodeSpec,edgeSpec)` allows optional parameters `nodeSpec` and `edgeSpec` to set the node or edge color, marker, and linestyle. Use `''` to omit one or both.

See Also

`etree`, `treeplot`, `treelayout`

Purpose

Execute string containing MATLAB expression

Syntax

```
eval(expression)
[a1, a2, a3, ...] = eval(function(b1, b2, b3, ...))
```

Description

`eval(expression)` executes `expression`, a string containing any valid MATLAB expression. You can construct `expression` by concatenating substrings and variables inside square brackets:

```
expression = [string1, int2str(var), string2, ...]
```

`[a1, a2, a3, ...] = eval(function(b1, b2, b3, ...))` executes `function` with arguments `b1, b2, b3, ...`, and returns the results in the specified output variables.

Remarks

Using the `eval` output argument list is recommended over including the output arguments in the expression string. The first syntax below avoids strict checking by the MATLAB parser and can produce untrapped errors and other unexpected behavior. Use the second syntax instead:

```
% Not recommended
  eval('[a1, a2, a3, ...] = function(var)')

% Recommended syntax
  [a1, a2, a3, ...] = eval('function(var)')
```

Examples

Example 1 – Working with a Series of Files

Load MAT-files `August1.mat` to `August10.mat` into the MATLAB workspace:

```
for d=1:10
   s = ['load August' int2str(d) '.mat']
   eval(s)
end
```

These are the strings being evaluated:

```
s =
   load August1.mat
s =
   load August2.mat
s =
   load August3.mat
      - etc. -
```

Example 2 – Assigning to Variables with Generated Names

Generate variable names that are unique in the MATLAB workspace and assign a value to each using `eval`:

```
for k = 1:5
   t = clock;
   pause(uint8(rand * 10));
   v = genvarname('time_elapsed', who);
   eval([v ' = etime(clock,t)'])
   end
```

As this code runs, `eval` creates a unique statement for each assignment:

```
time_elapsed =
    5.0070
time_elapsed1 =
    2.0030
time_elapsed2 =
    7.0010
time_elapsed3 =
    8.0010
time_elapsed4 =
    3.0040
```

Example 3 – Evaluating a Returned Function Name

The following command removes a figure by evaluating its `CloseRequestFcn` property as returned by `get`.

```
eval(get(h,'CloseRequestFcn'))
```

See Also

evalc, evalin, assignin, feval, catch, lasterror, try

Purpose

Evaluate MATLAB expression with capture

Syntax

```
T = evalc(S)
[T, X, Y, Z, ...] = evalc(S)
```

Description

`T = evalc(S)` is the same as `eval(S)` except that anything that would normally be written to the command window, except for error messages, is captured and returned in the character array `T` (lines in `T` are separated by `\n` characters).

`[T, X, Y, Z, ...] = evalc(S)` is the same as `[X, Y, Z, ...] = eval(S)` except that any output is captured into `T`.

Remark

When you are using `evalc`, `diary`, `more`, and `input` are disabled.

See Also

`eval`, `evalin`, `assignin`, `feval`, `diary`, `input`, `more`

evalin

Purpose

Execute MATLAB expression in specified workspace

Syntax

```
evalin(ws, expression)
[a1, a2, a3, ...] = evalin(ws, expression)
```

Description

`evalin(ws, expression)` executes *`expression`*, a string containing any valid MATLAB expression, in the context of the workspace `ws`. `ws` can have a value of `'base'` or `'caller'` to denote the MATLAB base workspace or the workspace of the caller function. You can construct *`expression`* by concatenating substrings and variables inside square brackets:

```
expression = [string1, int2str(var), string2,...]
```

`[a1, a2, a3, ...] = evalin(ws, expression)` executes *`expression`* and returns the results in the specified output variables. Using the `evalin` output argument list is recommended over including the output arguments in the expression string:

```
evalin(ws,'[a1, a2, a3, ...] = function(var)')
```

The above syntax avoids strict checking by the MATLAB parser and can produce untrapped errors and other unexpected behavior.

Remarks

The MATLAB base workspace is the workspace that is seen from the MATLAB command line (when not in the debugger). The caller workspace is the workspace of the function that called the M-file. Note, the base and caller workspaces are equivalent in the context of an M-file that is invoked from the MATLAB command line.

If you use `evalin('caller', ws)` in the MATLAB debugger after having changed your local workspace context with `dbup` or `dbdown`, MATLAB evaluates the expression in the context of the function that is one level up in the stack from your current workspace context.

Examples

This example extracts the value of the variable `var` in the MATLAB base workspace and captures the value in the local variable `v`:

```
v = evalin('base', 'var');
```

Limitation

`evalin` cannot be used recursively to evaluate an expression. For example, a sequence of the form `evalin('caller', 'evalin(''caller'', ''x'')')` doesn't work.

See Also

`assignin`, `eval`, `evalc`, `feval`, `catch`, `lasterror`, `try`

eventlisteners

Purpose

List of events attached to listeners

Syntax

```
C = h.eventlisteners
C = eventlisteners(h)
```

Description

`C = h.eventlisteners` lists any events, along with their event handler routines, that have been registered with control, `h`. The function returns cell array of strings `C`, with each row containing the name of a registered event and the handler routine for that event. If the control has no registered events, then `eventlisteners` returns an empty cell array.

Events and their event handler routines must be registered in order for the control to respond to them. You can register events either when you create the control, using `actxcontrol`, or at any time afterwards, using `registerevent`.

`C = eventlisteners(h)` is an alternate syntax for the same operation.

Examples

mwsamp Control Example

Create an `mwsamp` control, registering only the `Click` event. `eventlisteners` returns the name of the event and its event handler routine, `myclick`:

```
f = figure('position', [100 200 200 200]);
h = actxcontrol('mwsamp.mwsampctrl.2', ...
    [0 0 200 200], f, ...
    {'Click' 'myclick'});

h.eventlisteners
ans =
    'click'    'myclick'
```

Register two more events: `DblClick` and `MouseDown`. `eventlisteners` returns the names of the three registered events along with their respective handler routines:

```
h.registerevent({'DblClick', 'my2click'; ...
    'MouseDown' 'mymoused'});
```

```
h.eventlisteners
ans =
    'click'        'myclick'
    'dblclick'     'my2click'
    'mousedown'    'mymoused'
```

Now unregister all events for the control. `eventlisteners` returns an empty cell array, indicating that no events have been registered for the control:

```
h.unregisterallevents

h.eventlisteners
ans =
     {}
```

Excel Workbook Example

```
excel = actxserver('Excel.Application');
wbs = excel.Workbooks;
wb = wbs.Add;
wb.registerevent({'Activate' 'EvtActivateHandler'})
wb.eventlisteners

ans =

    'Activate'    'EvtActivateHandler'
```

See Also

`events`, `registerevent`, `unregisterevent`, `unregisterallevents`, `isevent`

Purpose

List of events control can trigger

Syntax

```
S = h.events
S = events(h)
```

Description

`S = h.events` returns structure array `S` containing all events, both registered and unregistered, known to the control, and the function prototype used when calling the event handler routine. For each array element, the structure field is the event name and the contents of that field is the function prototype for that event's handler.

`S = events(h)` is an alternate syntax for the same operation.

Examples

List Control Events Example

Create an `mwsamp` control and list all events:

```
f = figure ('position', [100 200 200 200]);
h = actxcontrol ('mwsamp.mwsampctrl.2', [0 0 200 200], f);

h.events
   Click = void Click()
   DblClick = void DblClick()
   MouseDown = void MouseDown(int16 Button, int16 Shift,
      Variant x, Variant y)
```

Assign the output to a variable and get one field of the returned structure:

```
ev = h.events;

ev.MouseDown
ans =
   void MouseDown(int16 Button, int16 Shift, ...
                  Variant x, Variant y)
```

List Excel Workbook Events Example

Open Excel and list all events for a Workbook object:

```
excel = actxserver('Excel.Application');
wbs = excel.Workbooks;
wb = wbs.Add;
wb.events
```

MATLAB displays all events supported by the Workbook object.

```
 Open = void Open()
 Activate = void Activate()
 Deactivate = void Deactivate()
 BeforeClose = void BeforeClose(bool Cancel)
                 .
                 .
```

See Also

isevent, eventlisteners, registerevent, unregisterevent, unregisterallevents

Execute

Purpose

Execute MATLAB command in server

Syntax

MATLAB Client

```
result = h.Execute('command')
result = Execute(h, 'command')
result = invoke(h, 'Execute', 'command')
```

Method Signature

```
BSTR Execute([in] BSTR command)
```

Visual Basic Client

```
Execute(command As String) As String
```

Description

The `Execute` function executes the MATLAB statement specified by the string `command` in the MATLAB Automation server attached to handle `h`.

The server returns output from the command in the string, `result`. The `result` string also contains any warning or error messages that might have been issued by MATLAB as a result of the command.

Note that if you terminate the MATLAB command string with a semicolon and there are no warnings or error messages, `result` might be returned empty.

Remarks

If you want to be able to display output from `Execute` in the client window, you must specify an output variable (i.e., `result` in the above syntax statements).

Server function names, like `Execute`, are case sensitive when used with dot notation (the first syntax shown).

All three versions of the MATLAB client syntax perform the same operation.

Examples

Execute the MATLAB `version` function in the server and return the output to the MATLAB client.

MATLAB Client

```
h = actxserver('matlab.application');
server_version = h.Execute('version')
server_version =
ans =
   6.5.0.180913a (R13)
```

Visual Basic .NET Client

```
Dim Matlab As Object
Dim server_version As String
Matlab = CreateObject("matlab.application")
server_version = Matlab.Execute("version")
```

See Also

Feval, PutFullMatrix, GetFullMatrix, PutCharArray, GetCharArray

exifread

Purpose

Read EXIF information from JPEG and TIFF image files

Syntax

```
output = exifread(filename)
```

Description

`output = exifread(filename)` reads the Exchangeable Image File Format (EXIF) data from the file specified by the string `filename`. `filename` must specify a JPEG or TIFF image file. `output` is a structure containing metadata values about the image or images in `imagefile`.

Note `exifread` returns all EXIF tags and does not process them in any way.

EXIF is a standard used by digital camera manufacturers to store information in the image file, such as, the make and model of a camera, the time the picture was taken and digitized, the resolution of the image, exposure time, and focal length. For more information about EXIF and the meaning of metadata attributes, see `http://www.exif.org/`.

See Also

`imfinfo`, `imread`

Purpose

Check existence of variable, function, directory, or Java class

Graphical Interface

As an alternative to the `exist` function, use the Workspace Browser or the Current Directory Browser.

Syntax

```
exist name
exist name kind
A = exist('name','kind')
```

Description

`exist name` returns the status of `name`:

`0`	If `name` does not exist.
`1`	If `name` is a variable in the workspace.
`2`	If `name` is an M-file on your MATLAB search path. It also returns 2 when `name` is the full pathname to a file or the name of an ordinary file on your MATLAB search path.
`3`	If `name` is a MEX- or DLL-file on your MATLAB search path.
`4`	If `name` is an MDL-file on your MATLAB search path.
`5`	If `name` is a built-in MATLAB function.
`6`	If `name` is a P-file on your MATLAB search path.
`7`	If `name` is a directory.
`8`	If `name` is a Java class. (`exist` returns 0 if you start MATLAB with the `-nojvm` option.)

`exist name kind` returns the status of `name` for the specified *`kind`*. If `name` of type *`kind`* does not exist, it returns `0`. The *`kind`* argument may be one of the following:

`builtin`	Checks only for built-in functions.
`class`	Checks only for Java classes.
`dir`	Checks only for directories.

`file`	Checks only for files or directories.
`var`	Checks only for variables.

If `name` belongs to more than one category (e.g., if there are both an M-file and variable of the given name) and you do not specify a *`kind`* argument, `exist` returns one value according to the order of evaluation shown in the table below. For example, if `name` matches both a directory and M-file name, `exist` returns `7`, identifying it as a directory.

Order of Evaluation	Return Value	Type of Entity
1	1	Variable
2	5	Built-in
3	7	Directory
4	3	MEX or DLL-file
5	4	MDL-file
6	6	P-file
7	2	M-file
8	8	Java class

`A = exist('name','kind')` is the function form of the syntax.

Remarks

If `name` specifies a filename, that filename may include an extension to preclude conflicting with other similar filenames. For example, `exist('file.ext')`.

If `name` specifies a filename, MATLAB attempts to locate the file, examines the filename extension, and determines the value to return based on the extension alone. MATLAB does not examine the contents or internal structure of the file.

You can specify a partial path to a directory or file. A partial pathname is a pathname relative to the MATLAB path that contains only the trailing one or more components of the full pathname. For example,

both of the following commands return 2, identifying `mkdir.m` as an M-file. The first uses a partial pathname:

```
exist('matlab/general/mkdir.m')
exist([matlabroot '/toolbox/matlab/general/mkdir.m'])
```

If a file or directory is not on the search path, then `name` must specify either a full pathname, a partial pathname relative to `MATLABPATH`, a partial pathname relative to your current directory, or the file or directory must reside in your current working directory.

If `name` is a Java class, then `exist('name')` returns an `8`. However, if `name` is a Java class file, then `exist('name')` returns a `2`.

Remarks

To check for the existence of more than one variable, use the `ismember` function. For example,

```
a = 5.83;
c = 'teststring';
ismember({'a','b','c'},who)

ans =

     1     0     1
```

Examples

This example uses `exist` to check whether a MATLAB function is a built-in function or a file:

```
type = exist('plot')
type =
5
```

This indicates that `plot` is a built-in function.

In the next example, `exist` returns `8` on the Java class, `Welcome`, and returns `2` on the Java class file, `Welcome.class`:

```
exist Welcome
ans =
```

```
     8

exist javaclasses/Welcome.class
ans =
     2
```

indicates there is a Java class Welcome and a Java class file Welcome.class.

The following example indicates that `testresults` is both a variable in the workspace and a directory on the search path:

```
exist('testresults','var')
ans =
     1
exist('testresults','dir')
ans =
     7
```

See Also

`assignin`, `computer`, `dir`, `evalin`, `help`, `inmem`, `isfield`, `isempty`, `lookfor`, `mfilename`, `partialpath`, `what`, `which`, `who`

Purpose

Terminate MATLAB (same as `quit`)

GUI Alternatives

As an alternative to the `exit` function, select **File > Exit MATLAB** or click the Close box in the MATLAB desktop.

Syntax

```
exit
```

Description

`exit` terminates the current MATLAB session after running `finish.m`, if the file `finish.m` exists. It performs the same as `quit` and takes the same termination options, such as **`force`**. For more information, see `quit`.

See Also

`quit`, `finish`

Purpose

Exponential

Syntax

```
Y = exp(X)
```

Description

The `exp` function is an elementary function that operates element-wise on arrays. Its domain includes complex numbers.

`Y = exp(X)` returns the exponential for each element of `X`.
For complex $z = x + i*y$, it returns the complex exponential $e^z = e^x(\cos(y) + i\sin(y))$.

Remark

Use `expm` for matrix exponentials.

See Also

`expm`, `log`, `log10`, `expint`

Purpose

Exponential integral

Syntax

```
Y = expint(X)
```

Definitions

The exponential integral computed by this function is defined as

$$E_1(x) = \int_x^\infty \frac{e^{-t}}{t} dt$$

Another common definition of the exponential integral function is the Cauchy principal value integral

$$Ei(x) = \int_{-\infty}^x \frac{e^t}{t} dt$$

which, for real positive `x`, is related to `expint` as

$$E_1(-x) = -Ei(x) - i\pi$$

Description

`Y = expint(X)` evaluates the exponential integral for each element of `X`.

References

[1] Abramowitz, M. and I. A. Stegun. *Handbook of Mathematical Functions*. Chapter 5, New York: Dover Publications, 1965.

Purpose

Matrix exponential

Syntax

```
Y = expm(X)
```

Description

`Y = expm(X)` raises the constant e to the matrix power `X`.

Although it is not computed this way, if `X` has a full set of eigenvectors `V` with corresponding eigenvalues `D`, then

```
[V,D] = EIG(X) and EXPM(X) = V*diag(exp(diag(D)))/V
```

Use `exp` for the element-by-element exponential.

Algorithm

`expm` uses the Padé approximation with scaling and squaring. See reference [3], below.

Note The `expmdemo1`, `expmdemo2`, and `expmdemo3` demos illustrate the use of Padé approximation, Taylor series approximation, and eigenvalues and eigenvectors, respectively, to compute the matrix exponential. References [1] and [2] describe and compare many algorithms for computing a matrix exponential.

Examples

This example computes and compares the matrix exponential of `A` and the exponential of `A`.

```
A = [1         1         0
     0         0         2
     0         0        -1 ];

expm(A)
ans =
    2.7183    1.7183         1.0862
    0         1.0000         1.2642
    0              0         0.3679
```

```
exp(A)
ans =
    2.7183        2.7183        1.0000
    1.0000        1.0000        7.3891
    1.0000        1.0000        0.3679
```

Notice that the diagonal elements of the two results are equal. This would be true for any triangular matrix. But the off-diagonal elements, including those below the diagonal, are different.

expm1

Purpose

Compute `exp(x)-1` accurately for small values of `x`

Syntax

```
y = expm1(x)
```

Description

`y = expm1(x)` computes `exp(x)-1`, compensating for the roundoff in `exp(x)`.

For small `x`, `expm1(x)` is approximately `x`, whereas `exp(x)-1` can be zero.

See Also

`exp`, `expm`, `log1p`

Purpose

Export variables to workspace

Syntax

```
export2wsdlg(checkboxlabels,defaultvariablenames,
itemstoexport)
export2wsdlg(checkboxlabels,defaultvariablenames,
itemstoexport,title)
export2wsdlg(checkboxlabels,defaultvariablenames,
itemstoexport,title,selected)
export2wsdlg(checkboxlabels,defaultvariablenames,
itemstoexport,title,selected,helpfunction)
export2wsdlg(checkboxlabels,defaultvariablenames,
itemstoexport,title,selected,helpfunction,functionlist)
hdialog = export2wsdlg(...)
[hdialog,ok_pressed] = export2wsdlg(...)
```

Description

`export2wsdlg(checkboxlabels,defaultvariablenames, itemstoexport)` creates a dialog with a series of check boxes and edit fields. `checkboxlabels` is a cell array of labels for the check boxes. `defaultvariablenames` is a cell array of strings that serve as a basis for variable names that appear in the edit fields. `itemstoexport` is a cell array of the values to be stored in the variables. If there is only one item to export, `export2wsdlg` creates a text control instead of a check box.

Note By default, the dialog box is modal. A modal dialog box prevents the user from interacting with other windows before responding.

`export2wsdlg(checkboxlabels,defaultvariablenames, itemstoexport,title)` creates the dialog with `title` as its title.

`export2wsdlg(checkboxlabels,defaultvariablenames, itemstoexport,title,selected)` creates the dialog allowing the user to control which check boxes are checked. `selected` is a logical array whose length is the same as `checkboxlabels`. True indicates that the check box should initially be checked, false unchecked.

`export2wsdlg(checkboxlabels,defaultvariablenames, itemstoexport,title,selected,helpfunction)` creates the dialog with a help button. `helpfunction` is a callback that displays help.

`export2wsdlg(checkboxlabels,defaultvariablenames, itemstoexport,title,selected,helpfunction,functionlist)` creates a dialog that enables the user to pass in `functionlist`, a cell array of functions and optional arguments that calculate, then return the value to export. `functionlist` should be the same length as `checkboxlabels`.

`hdialog = export2wsdlg(...)` returns the handle of the dialog.

`[hdialog,ok_pressed] = export2wsdlg(...)` sets `ok_pressed` to true if the OK button is pressed, or false otherwise. If two return arguments are requested, `hdialog` is `[]` and the function does not return until the dialog is closed.

The user can edit the text fields to modify the default variable names. If the same name appears in multiple edit fields, `export2wsdlg` creates a structure using that name. It then uses the `defaultvariablenames` as fieldnames for that structure.

The lengths of `checkboxlabels`, `defaultvariablenames`, `itemstoexport` and `selected` must all be equal.

The strings in `defaultvariablenames` must be unique.

Examples

This example creates a dialog box that enables the user to save the variables `sumA` and/or `meanA` to the workspace. The dialog box title is Save Sums to Workspace.

```
A = randn(10,1);
checkLabels = {'Save sum of A to variable named:' ...
               'Save mean of A to variable named:'};
varNames = {'sumA','meanA'};
items = {sum(A),mean(A)};
export2wsdlg(checkLabels,varNames,items,...
             'Save Sums to Workspace');
```

Purpose

Identity matrix

Syntax

```
Y = eye(n)
Y = eye(m,n)
eye([m n])
Y = eye(size(A))
eye(m, n, classname)
eye([m,n],classname)
```

Description

`Y = eye(n)` returns the `n`-by-`n` identity matrix.

`Y = eye(m,n)` or `eye([m n])` returns an `m`-by-`n` matrix with 1's on the diagonal and 0's elsewhere.

Note The size inputs `m` and `n` should be nonnegative integers. Negative integers are treated as 0.

`Y = eye(size(A))` returns an identity matrix the same size as `A`.

`eye(m, n, classname)` or `eye([m,n],classname)` is an m-by-n matrix with 1's of class `classname` on the diagonal and zeros of class `classname` elsewhere. `classname` is a string specifying the data type of the output. `classname` can have the following values: `'double'`, `'single'`, `'int8'`, `'uint8'`, `'int16'`, `'uint16'`, `'int32'`, `'uint32'`, `'int64'`, or `'uint64'`.

Example:

```
x = eye(2,3,'int8');
```

Limitations

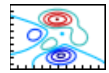
The identity matrix is not defined for higher-dimensional arrays. The assignment `y = eye([2,3,4])` results in an error.

See Also

`ones`, `rand`, `randn`, `zeros`

Purpose

Easy-to-use contour plotter



Syntax

```
ezcontour(fun)
ezcontour(fun,domain)
ezcontour(...,n)
ezcontour(axes_handle,...)
h = ezcontour(...)
```

Description

`ezcontour(fun)` plots the contour lines of `fun(x,y)` using the `contour` function. `fun` is plotted over the default domain: $-2\pi < x < 2\pi$, $-2\pi < y < 2\pi$.

`fun` can be a function handle for an M-file function or an anonymous function (see "Function Handles" and "Anonymous Functions") or a string (see Remarks).

`ezcontour(fun,domain)` plots `fun(x,y)` over the specified `domain`. `domain` can be either a 4-by-1 vector `[xmin, xmax, ymin, ymax]` or a 2-by-1 vector `[min, max]` (where `min` < x < `max`, `min` < y < `max`).

`ezcontour(...,n)` plots `fun` over the default domain using an `n`-by-`n` grid. The default value for `n` is 60.

`ezcontour(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ezcontour(...)` returns the handles to contour objects in `h`.

`ezcontour` automatically adds a title and axis labels.

Remarks

Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the string expression you pass to `ezcontour`. For example, the MATLAB syntax for a contour plot of the expression

```
sqrt(x.^2 + y.^2)
```

is written as

```
ezcontour('sqrt(x^2 + y^2)')
```

That is, `x^2` is interpreted as `x.^2` in the string you pass to `ezcontour`.

If the function to be plotted is a function of the variables u and v (rather than x and y), the domain endpoints `umin`, `umax`, `vmin`, and `vmax` are sorted alphabetically. Thus, `ezcontour('u^2 - v^3',[0,1],[3,6])` plots the contour lines for $u^2 - v^3$ over $0 < u < 1$, $3 < v < 6$.

Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezcontour`.

```
fh = @(x,y) sqrt(x.^2 + y.^2);
ezcontour(fh)
```

When using function handles, you must use the array power, array multiplication, and array division operators (`.^, .*, ./`) since `ezcontour` does not alter the syntax, as in the case with string inputs.

Passing Additional Arguments

If your function has additional parameters, for example, `k` in `myfun`:

```
function z = myfun(x,y,k)
z = x.^k - y.^k - 1;
```

then use an anonymous function to specify that parameter:

```
ezcontour(@(x,y)myfun(x,y,2))
```

Examples

The following mathematical expression defines a function of two variables, x and y.

$$f(x,y) = 3(1-x)^2 e^{-x^2-(y+1)^2} - 10\left(\frac{x}{5} - x^3 - y^5\right)e^{-x^2-y^2} - \frac{1}{3}e^{-(x+1)^2-y^2}$$

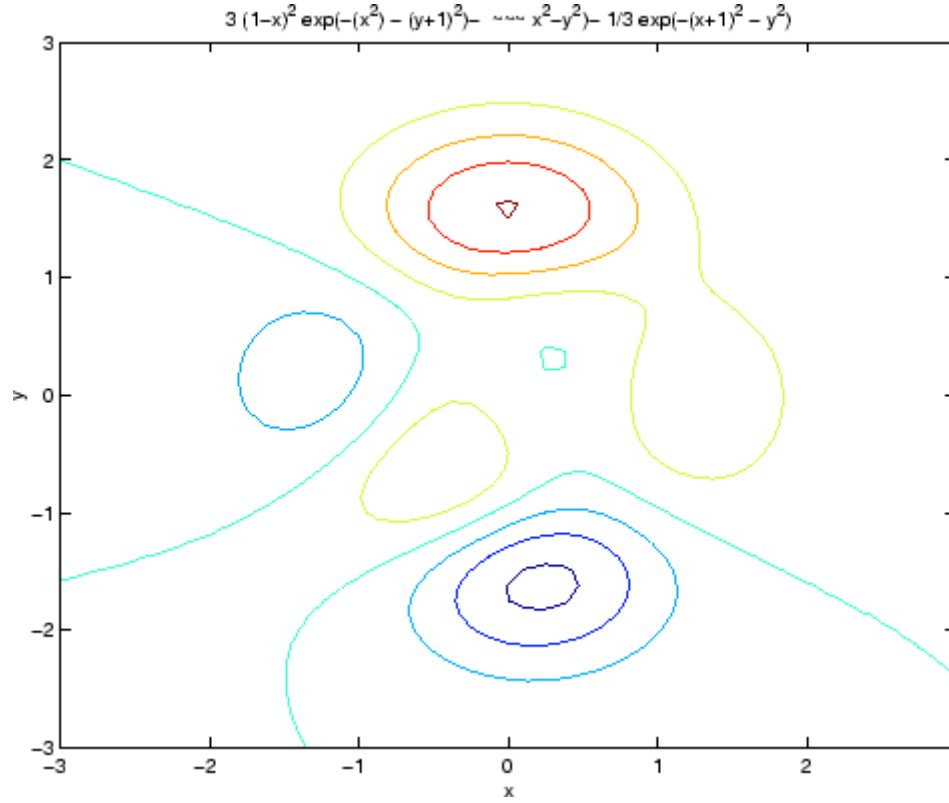
`ezcontour` requires a function handle argument that expresses this function using MATLAB syntax. This example uses an anonymous function, which you can define in the command window without creating an M-file.

```
f=@(x,y) 3*(1-x).^2.*exp(-(x.^2) - (y+1).^2) ...
   - 10*(x/5 - x.^3 - y.^5).*exp(-x.^2-y.^2) ...
   - 1/3*exp(-(x+1).^2 - y.^2);
```

For convenience, this function is written on three lines. The MATLAB `peaks` function evaluates this expression for different sizes of grids.

Pass the function handle `f` to `ezcontour` along with a domain ranging from -3 to 3 in both *x* and *y* and specify a computational grid of 49-by-49:

```
ezcontour(f,[-3,3],49)
```



In this particular case, the title is too long to fit at the top of the graph, so MATLAB abbreviates the string.

See Also

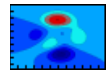
`contour`, `ezcontourf`, `ezmesh`, `ezmeshc`, `ezplot`, `ezplot3`, `ezpolar`, `ezsurf`, `ezsurfc`, `function_handle`

“Contour Plots” on page 1-89 for related functions

ezcontourf

Purpose

Easy-to-use filled contour plotter



Syntax

```
ezcontourf(fun)
ezcontourf(fun,domain)
ezcontourf(...,n)
ezcontourf(axes_handle,...)
h = ezcontourf(...)
```

Description

`ezcontourf(fun)` plots the contour lines of `fun(x,y)` using the `contourf` function. `fun` is plotted over the default domain: $-2\pi < x < 2\pi$, $-2\pi < y < 2\pi$.

`fun` can be a function handle for an M-file function or an anonymous function (see "Function Handles" and Anonymous Functions) or a string (see Remarks).

`ezcontourf(fun,domain)` plots `fun(x,y)` over the specified `domain`. `domain` can be either a 4-by-1 vector `[xmin, xmax, ymin, ymax]` or a 2-by-1 vector `[min, max]`, where `min` $< x <$ `max`, `min` $< y <$ `max`).

`ezcontourf(...,n)` plots `fun` over the default domain using an `n`-by-`n` grid. The default value for `n` is 60.

`ezcontourf(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = ezcontourf(...)` returns the handles to contour objects in `h`.

`ezcontourf` automatically adds a title and axis labels.

Remarks

Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the string expression you pass to `ezcontourf`. For example, the MATLAB syntax for a filled contour plot of the expression

```
sqrt(x.^2 + y.^2);
```

is written as

```
ezcontourf('sqrt(x^2 + y^2)')
```

That is, `x^2` is interpreted as `x.^2` in the string you pass to `ezcontourf`.

If the function to be plotted is a function of the variables u and v (rather than x and y), then the domain endpoints `umin`, `umax`, `vmin`, and `vmax` are sorted alphabetically. Thus, `ezcontourf('u^2 - v^3',[0,1],[3,6])` plots the contour lines for $u^2 - v^3$ over $0 < u < 1$, $3 < v < 6$.

Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezcontourf`.

```
fh = @(x,y) sqrt(x.^2 + y.^2);
ezcontourf(fh)
```

When using function handles, you must use the array power, array multiplication, and array division operators (`.^`, `.*`, `./`) since `ezcontourf` does not alter the syntax, as in the case with string inputs.

Passing Additional Arguments

If your function has additional parameters, for example, `k` in `myfun`:

```
function z = myfun(x,y,k)
z = x.^k - y.^k - 1;
```

then you can use an anonymous function to specify that parameter:

```
ezcontourf(@(x,y)myfun(x,y,2))
```

Examples

The following mathematical expression defines a function of two variables, x and y.

$$f(x,y) = 3(1-x)^2 e^{-x^2-(y+1)^2} - 10\left(\frac{x}{5} - x^3 - y^5\right)e^{-x^2-y^2} - \frac{1}{3}e^{-(x+1)^2-y^2}$$

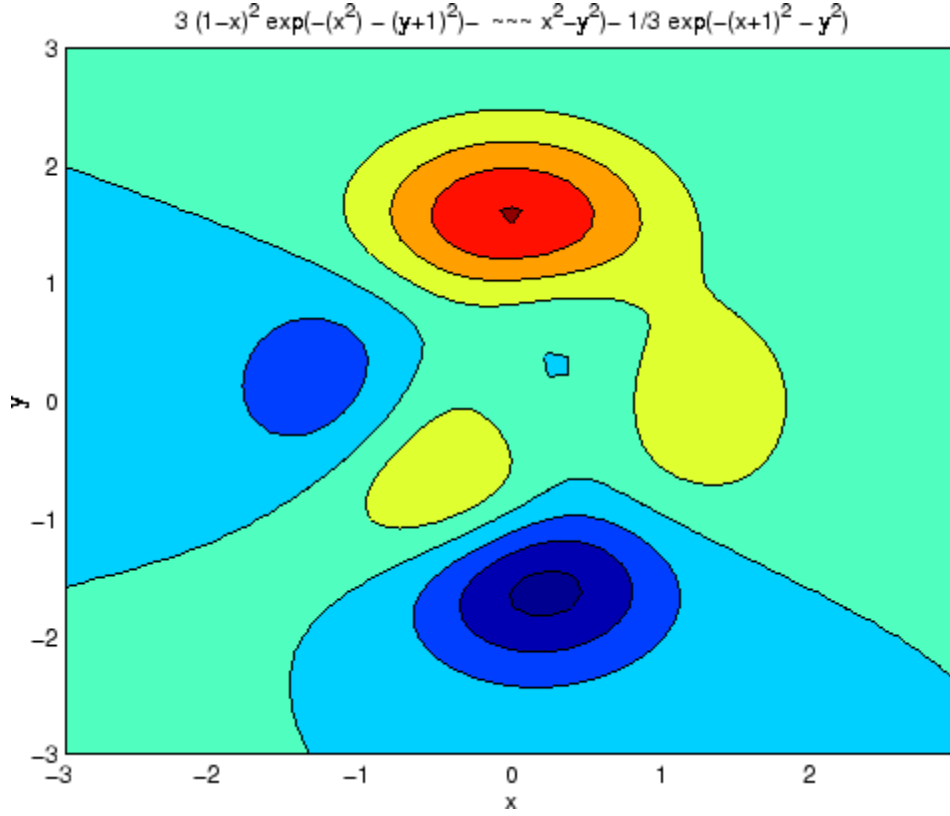
`ezcontourf` requires a string argument that expresses this function using MATLAB syntax to represent exponents, natural logs, etc. This function is represented by the string

```
f = ['3*(1-x)^2*exp(-(x^2)-(y+1)^2)',...
     '- 10*(x/5 - x^3 - y^5)*exp(-x^2-y^2)',...
     '- 1/3*exp(-(x+1)^2 - y^2)'];
```

For convenience, this string is written on three lines and concatenated into one string using square brackets.

Pass the string variable `f` to `ezcontourf` along with a domain ranging from -3 to 3 and specify a grid of 49-by-49:

```
ezcontourf(f,[-3,3],49)
```



In this particular case, the title is too long to fit at the top of the graph, so MATLAB abbreviates the string.

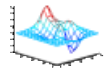
“Contour Plots” on page 1-89 for related functions

ezmesh

Purpose

Easy-to-use 3-D mesh plotter



Syntax

```
ezmesh(fun)
ezmesh(fun,domain)
ezmesh(funx,funy,funz)
ezmesh(funx,funy,funz,[smin,smax,tmin,tmax])
ezmesh(funx,funy,funz,[min,max]
ezmesh(...,n)
ezmesh(...,'circ')
ezmesh(axes_handle,...)
h = ezmesh(...)
```

Description

`ezmesh(fun)` creates a graph of `fun(x,y)` using the `mesh` function. `fun` is plotted over the default domain: $-2\pi < x < 2\pi$, $-2\pi < y < 2\pi$.

`fun` can be a function handle for an M-file function or an anonymous function (see "Function Handles" and Anonymous Functions) or a string (see the Remarks section).

`ezmesh(fun,domain)` plots `fun` over the specified `domain`. `domain` can be either a 4-by-1 vector [`xmin`, `xmax`, `ymin`, `ymax`] or a 2-by-1 vector [`min`, `max`] (where `min` < `x` < `max`, `min` < `y` < `max`).

`ezmesh(funx,funy,funz)` plots the parametric surface `funx(s,t)`, `funy(s,t)`, and `funz(s,t)` over the square: $-2\pi < s < 2\pi$, $-2\pi < t < 2\pi$.

`ezmesh(funx,funy,funz,[smin,smax,tmin,tmax])` or `ezmesh(funx,funy,funz,[min,max])` plots the parametric surface using the specified domain.

`ezmesh(...,n)` plots `fun` over the default domain using an `n`-by-`n` grid. The default value for `n` is 60.

`ezmesh(...,'circ')` plots `fun` over a disk centered on the domain.

`ezmesh(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ezmesh(...)` returns the handle to a surface object in `h`.

Remarks

Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the string expression you pass to `ezmesh`. For example, the MATLAB syntax for a mesh plot of the expression

```
sqrt(x.^2 + y.^2);
```

is written as

```
ezmesh('sqrt(x^2 + y^2)')
```

That is, `x^2` is interpreted as `x.^2` in the string you pass to `ezmesh`.

If the function to be plotted is a function of the variables u and v (rather than x and y), then the domain endpoints `umin`, `umax`, `vmin`, and `vmax` are sorted alphabetically. Thus, `ezmesh('u^2 - v^3',[0,1],[3,6])` plots $u^2 - v^3$ over $0 < u < 1$, $3 < v < 6$.

Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezmesh`.

```
fh = @(x,y) sqrt(x.^2 + y.^2);
ezmesh(fh)
```

Note that when using function handles, you must use the array power, array multiplication, and array division operators (`.^, .*, ./`) since `ezmesh` does not alter the syntax, as in the case with string inputs.

Passing Additional Arguments

If your function has additional parameters, for example `k` in `myfun`:

```
function z = myfun(x,y,k)
z = x.^k - y.^k - 1;
```

then you can use an anonymous function to specify that parameter:

```
ezmesh(@(x,y)myfun(x,y,2))
```

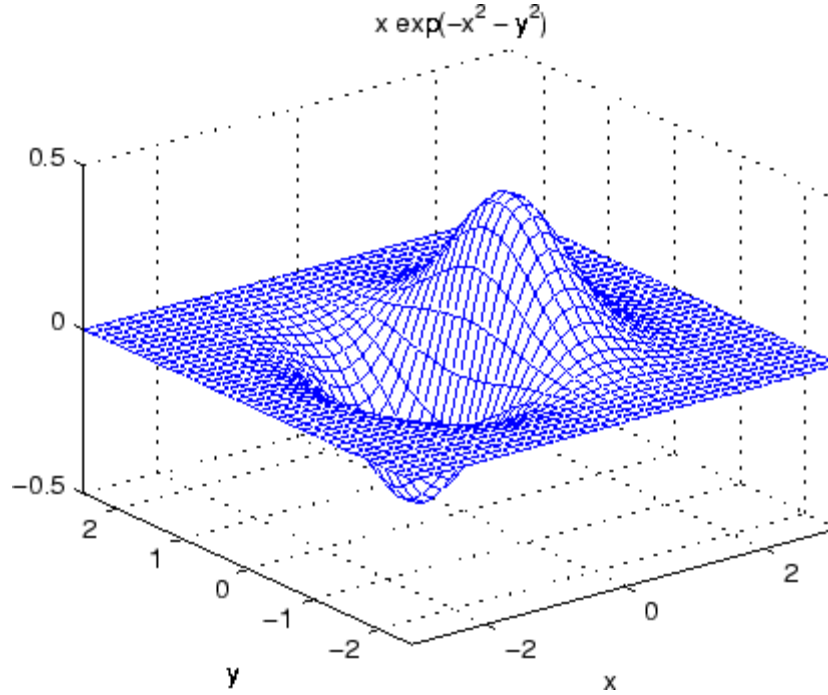
Examples

This example visualizes the function

$$f(x, y) = xe^{-x^2 - y^2}$$

with a mesh plot drawn on a 40-by-40 grid. The mesh lines are set to a uniform blue color by setting the colormap to a single color:

```
fh = @(x,y) x.*exp(-x.^2-y.^2);
ezmesh(fh,40)
colormap([0 0 1])
```



See Also

`ezmeshc`, `function_handle`, `mesh`

"Function Plots" on page 1-89 for related functions

ezmeshc

Purpose

Easy-to-use combination mesh/contour plotter

Syntax

```
ezmeshc(fun)
ezmeshc(fun,domain)
ezmeshc(funx,funy,funz)
ezmeshc(funx,funy,funz,[smin,smax,tmin,tmax])
ezmeshc(funx,funy,funz,[min,max])
ezmeshc(...,n)
ezmeshc(...,'circ')
ezmesh(axes_handle,...)
h = ezmeshc(...)
```

Description

`ezmeshc(fun)` creates a graph of `fun(x,y)` using the `meshc` function. `fun` is plotted over the default domain $-2\pi < x < 2\pi$, $-2\pi < y < 2\pi$.

`fun` can be a function handle for an M-file function or an anonymous function (see "Function Handles" and "Anonymous Functions") or a string (see the Remarks section).

`ezmeshc(fun,domain)` plots `fun` over the specified `domain`. `domain` can be either a 4-by-1 vector [`xmin`, `xmax`, `ymin`, `ymax`] or a 2-by-1 vector [`min`, `max`] (where `min` $< x <$ `max`, `min` $< y <$ `max`).

`ezmeshc(funx,funy,funz)` plots the parametric surface `funx(s,t)`, `funy(s,t)`, and `funz(s,t)` over the square: $-2\pi <$ `s` $< 2\pi$, $-2\pi <$ `t` $< 2\pi$.

`ezmeshc(funx,funy,funz,[smin,smax,tmin,tmax])` or `ezmeshc(funx,funy,funz,[min,max])` plots the parametric surface using the specified domain.

`ezmeshc(...,n)` plots `fun` over the default domain using an `n`-by-`n` grid. The default value for `n` is 60.

`ezmeshc(...,'circ')` plots `fun` over a disk centered on the domain.

`ezmesh(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ezmeshc(...)` returns the handle to a surface object in `h`.

Remarks

Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the string expression you pass to `ezmeshc`. For example, the MATLAB syntax for a mesh/contour plot of the expression

```
sqrt(x.^2 + y.^2);
```

is written as

```
ezmeshc('sqrt(x^2 + y^2)')
```

That is, `x^2` is interpreted as `x.^2` in the string you pass to `ezmeshc`.

If the function to be plotted is a function of the variables u and v (rather than x and y), then the domain endpoints `umin`, `umax`, `vmin`, and `vmax` are sorted alphabetically. Thus, `ezmeshc('u^2 - v^3',[0,1],[3,6])` plots $u^2 - v^3$ over $0 < u < 1$, $3 < v < 6$.

Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezmeshc`.

```
fh = @(x,y) sqrt(x.^2 + y.^2);
ezmeshc(fh)
```

Note that when using function handles, you must use the array power, array multiplication, and array division operators (`.^, .*, ./`) since `ezmeshc` does not alter the syntax, as in the case with string inputs.

Passing Additional Arguments

If your function has additional parameters, for example `k` in `myfun`:

```
function z = myfun(x,y,k)
z = x.^k - y.^k - 1;
```

then you can use an anonymous function to specify that parameter:

```
ezmeshc(@(x,y)myfun(x,y,2))
```

Examples

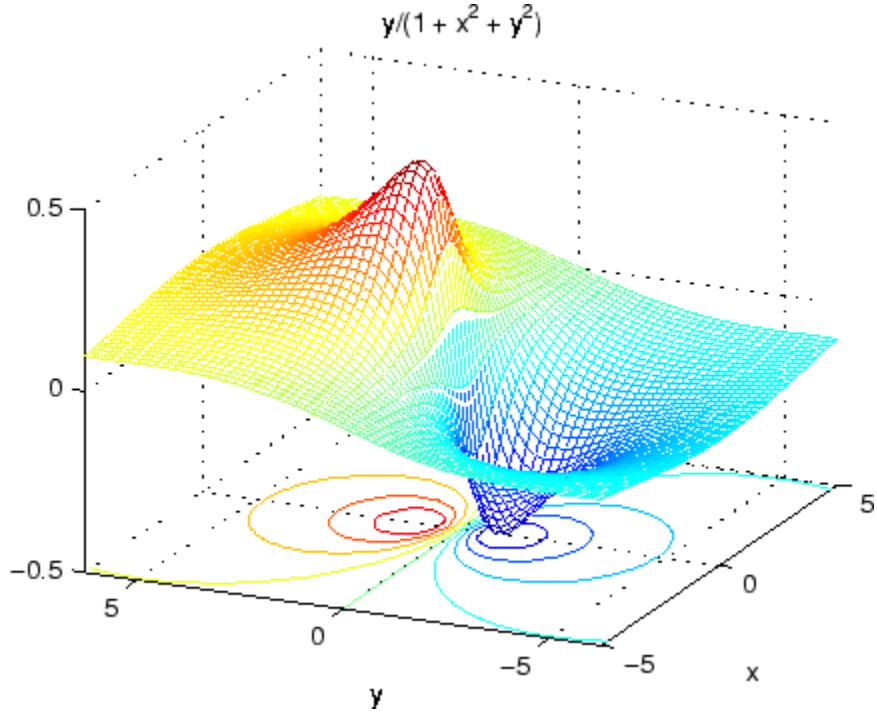
Create a mesh/contour graph of the expression

$$f(x, y) = \frac{y}{1 + x^2 + y^2}$$

over the domain -5 < x < 5, -2*pi < y < 2*pi:

```
ezmeshc('y/(1 + x^2 + y^2)',[-5,5,-2*pi,2*pi])
```

Use the mouse to rotate the axes to better observe the contour lines (this picture uses a view of azimuth = -65.5 and elevation = 26)



See Also

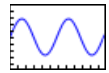
`ezmesh`, `ezsurfc`, `function_handle`, `meshc`

“Function Plots” on page 1-89 for related functions

ezplot

Purpose

Easy-to-use function plotter



Syntax

```
ezplot(fun)
ezplot(fun,[min,max])
ezplot(fun2)
ezplot(fun2,[xmin,xmax,ymin,ymax])
ezplot(fun2,[min,max])
ezplot(funx,funy)
ezplot(funx,funy,[tmin,tmax])
ezplot(...,figure_handle)
ezplot(axes_handle,...)
h = ezplot(...)
```

Description

`ezplot(fun)` plots the expression `fun(x)` over the default domain $-2\pi < x < 2\pi$.

`fun` can be a function handle for an M-file function or an anonymous function (see "Function Handles" and Anonymous Functions) or a string (see the Remarks section).

`ezplot(fun,[min,max])` plots `fun(x)` over the domain: `min` $< x <$ `max`.

For implicitly defined functions, `fun2(x,y)`:

`ezplot(fun2)` plots `fun2(x,y) = 0` over the default domain $-2\pi < x < 2\pi$, $-2\pi < y < 2\pi$.

`ezplot(fun2,[xmin,xmax,ymin,ymax])` plots `fun2(x,y) = 0` over `xmin` < `x` < `xmax` and `ymin` < `y` < `ymax`.

`ezplot(fun2,[min,max])` plots `fun2(x,y) = 0` over `min` < `x` < `max` and `min` < `y` < `max`.

`ezplot(funx,funy)` plots the parametrically defined planar curve `funx(t)` and `funy(t)` over the default domain 0 < `t` < 2π.

`ezplot(funx,funy,[tmin,tmax])` plots `funx(t)` and `funy(t)` over `tmin < t < tmax`.

`ezplot(...,figure_handle)` plots the given function over the specified domain in the figure window identified by the handle `figure`.

`ezplot(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ezplot(...)` returns the handle to a line objects in `h`.

Remarks

Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the expression you pass to `ezplot`. For example, the MATLAB syntax for a plot of the expression

```
x.^2 - y.^2
```

which represents an implicitly defined function, is written as

```
ezplot('x^2 - y^2')
```

That is, `x^2` is interpreted as `x.^2` in the string you pass to `ezplot`.

Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezplot`,

```
fh = @(x,y) sqrt(x.^2 + y.^2 - 1);
ezplot(fh)
axis equal
```

which plots a circle. Note that when using function handles, you must use the array power, array multiplication, and array division operators (`.^, .*, ./`) since `ezplot` does not alter the syntax, as in the case with string inputs.

Passing Additional Arguments

If your function has additional parameters, for example `k` in `myfun`:

```
function z = myfun(x,y,k)
z = x.^k - y.^k - 1;
```

then you can use an anonymous function to specify that parameter:

```
ezplot(@(x,y)myfun(x,y,2))
```

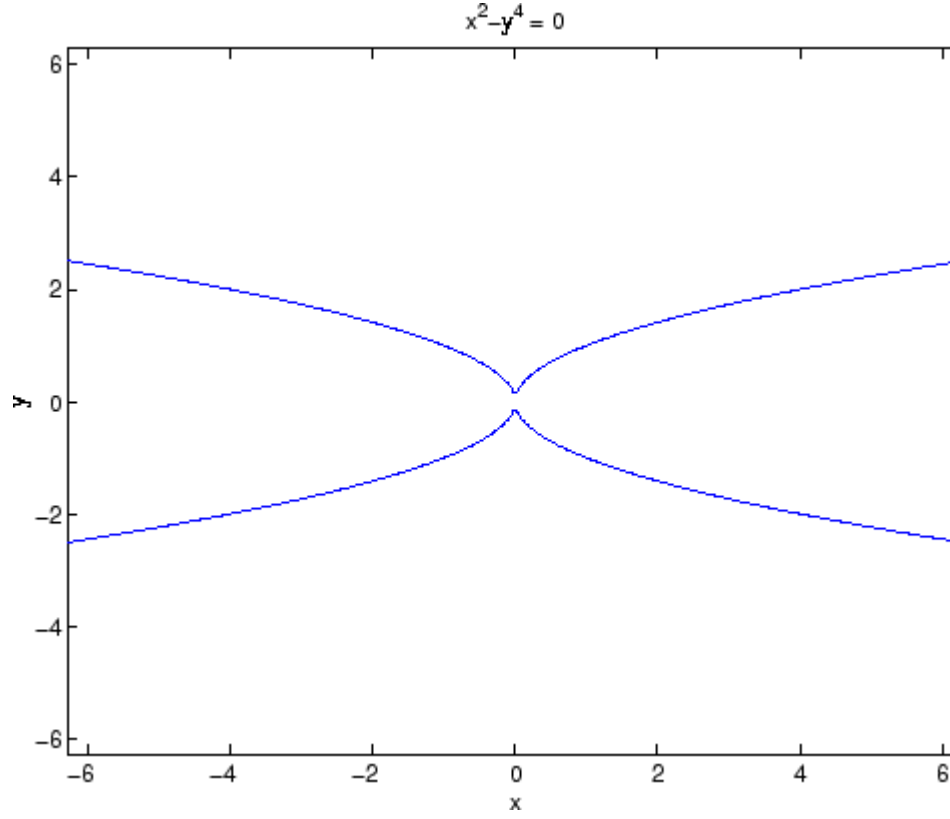
Examples

This example plots the implicitly defined function

$x^2 - y^4 = 0$

over the domain $[-2\pi, 2\pi]$:

```
ezplot('x^2-y^4')
```



See Also

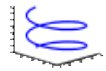
`ezplot3`, `ezpolar`, `function_handle`, `plot`

"Function Plots" on page 1-89 for related functions

ezplot3

Purpose

Easy-to-use 3-D parametric curve plotter



Syntax

```
ezplot3(funx,funy,funz)
ezplot3(funx,funy,funz,[tmin,tmax])
ezplot3(...,'animate')
ezplot3(axes_handle,...)
h = ezplot3(...)
```

Description

`ezplot3(funx,funy,funz)` plots the spatial curve `funx(t)`, `funy(t)`, and `funz(t)` over the default domain $0 < t < 2\pi$.

`funx`, `funy`, and `funz` can be function handles for M-file functions or an anonymous functions (see "Function Handles" and "Anonymous Functions") or strings (see the Remarks section).

`ezplot3(funx,funy,funz,[tmin,tmax])` plots the curve `funx(t)`, `funy(t)`, and `funz(t)` over the domain `tmin` < `t` < `tmax`.

`ezplot3(...,'animate')` produces an animated trace of the spatial curve.

`ezplot3(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ezplot3(...)` returns the handle to the plotted objects in `h`.

Remarks

Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the expression you pass to `ezplot3`. For example, the MATLAB syntax for a plot of the expression

```
x = s./2, y = 2.*s, z = s.^2;
```

which represents a parametric function, is written as

```
ezplot3('s/2','2*s','s^2')
```

That is, `s/2` is interpreted as `s./2` in the string you pass to `ezplot3`.

Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezplot3`.

```
fh1 = @(s) s./2; fh2 = @(s) 2.*s; fh3 = @(s) s.^2;
ezplot3(fh1,fh2,fh3)
```

Note that when using function handles, you must use the array power, array multiplication, and array division operators (`.^, .*, ./`) since `ezplot` does not alter the syntax, as in the case with string inputs.

Passing Additional Arguments

If your function has additional parameters, for example `k` in `myfuntk`:

```
function s = myfuntk(t,k)
s = t.^k.*sin(t);
```

then you can use an anonymous function to specify that parameter:

```
ezplot3(@cos,@(t)myfuntk(t,1),@sqrt)
```

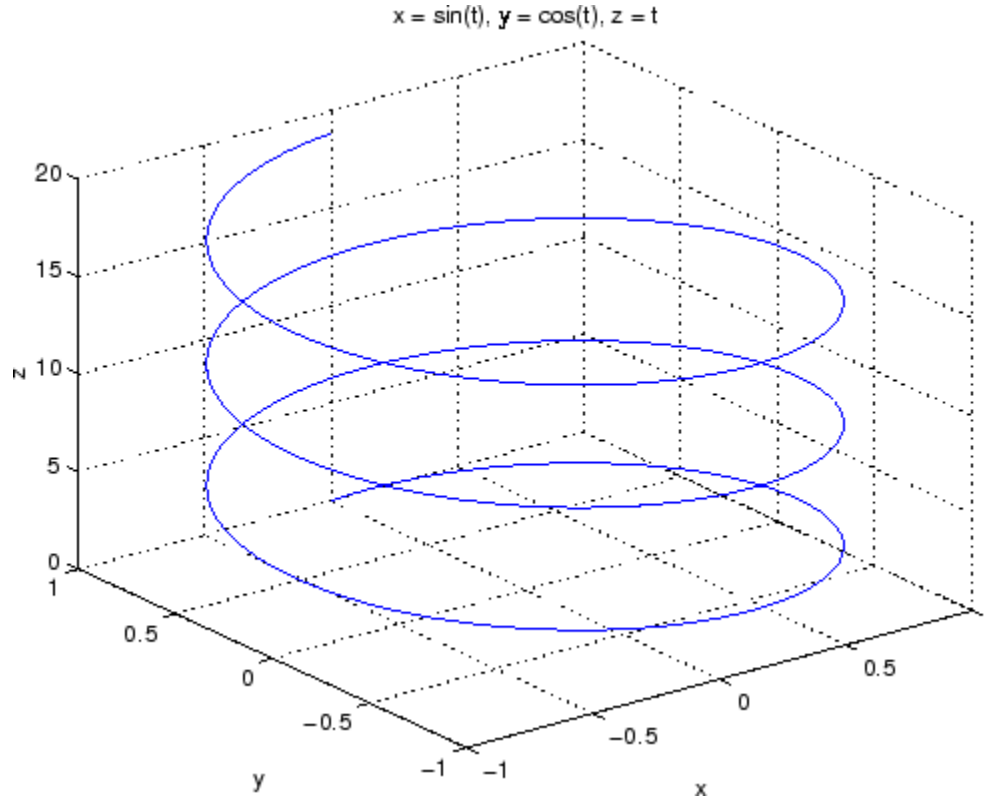
Examples

This example plots the parametric curve

$$x = \sin t, \quad y = \cos t, \quad z = t$$

over the domain [0,6π]:

```
ezplot3('sin(t)','cos(t)','t',[0,6*pi])
```



See Also

`ezplot`, `ezpolar`, `function_handle`, `plot3`

"Function Plots" on page 1-89 for related functions

Purpose

Easy-to-use polar coordinate plotter

Syntax

```
ezpolar(fun)
ezpolar(fun,[a,b])
ezpolar(axes_handle,...)
h = ezpolar(...)
```

Description

`ezpolar(fun)` plots the polar curve `rho = fun(theta)` over the default domain $0 <$ `theta` $< 2\pi$.

`fun` can be a function handle for an M-file function or an anonymous function (see "Function Handles" and "Function Handles") or a string (see the Remarks section).

`ezpolar(fun,[a,b])` plots `fun` for `a` < `theta` < `b`.

`ezpolar(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ezpolar(...)` returns the handle to a line object in `h`.

Remarks

Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the expression you pass to `ezpolar`. For example, the MATLAB syntax for a plot of the expression

```
t.^2.*cos(t)
```

which represents an implicitly defined function, is written as

```
ezpolar('t^2*cos(t)')
```

That is, `t^2` is interpreted as `t.^2` in the string you pass to `ezpolar`.

Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezpolar`.

```
fh = @(t) t.^2.*cos(t);
ezpolar(fh)
```

Note that when using function handles, you must use the array power, array multiplication, and array division operators (`.^`, `.*`, `./`) since `ezpolar` does not alter the syntax, as in the case with string inputs.

Passing Additional Arguments

If your function has additional parameters, for example `k1` and `k2` in `myfun`:

```
function s = myfun(t,k1,k2)
s = sin(k1*t).*cos(k2*t);
```

then you can use an anonymous function to specify the parameters:

```
ezpolar(@(t)myfun(t,2,3))
```

Examples

This example creates a polar plot of the function

1 + cos(t)

over the domain [0, 2π]:

```
ezpolar('1+cos(t)')
```

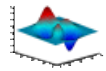
`ezplot`, `ezplot3`, `function_handle`, `plot`, `plot3`, `polar`

"Function Plots" on page 1-89 for related functions

ezsurf

Purpose

Easy-to-use 3-D colored surface plotter



Syntax

```
ezsurf(fun)
ezsurf(fun,domain)
ezsurf(funx,funy,funz)
ezsurf(funx,funy,funz,[smin,smax,tmin,tmax])
ezsurf(funx,funy,funz,[min,max]
ezsurf(...,n)
ezsurf(...,'circ')
ezsurf(axes_handle,...)
h = ezsurf(...)
```

Description

`ezsurf(fun)` creates a graph of `fun(x,y)` using the `surf` function. `fun` is plotted over the default domain: $-2\pi < x < 2\pi$, $-2\pi < y < 2\pi$.

`fun` can be a function handle for an M-file function or an anonymous function (see "Function Handles" and "Anonymous Functions") or a string (see the Remarks section).

`ezsurf(fun,domain)` plots `fun` over the specified `domain`. `domain` can be either a 4-by-1 vector [`xmin`, `xmax`, `ymin`, `ymax`] or a 2-by-1 vector [`min`, `max`] (where `min` < `x` < `max`, `min` < `y` < `max`).

`ezsurf(funx,funy,funz)` plots the parametric surface `funx(s,t)`, `funy(s,t)`, and `funz(s,t)` over the square: $-2\pi < s < 2\pi$, $-2\pi < t < 2\pi$.

`ezsurf(funx,funy,funz,[smin,smax,tmin,tmax])` or `ezsurf(funx,funy,funz,[min,max])` plots the parametric surface using the specified domain.

`ezsurf(...,n)` plots `fun` over the default domain using an `n`-by-`n` grid. The default value for `n` is 60.

`ezsurf(...,'circ')` plots `fun` over a disk centered on the domain.

`ezsurf(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ezsurf(...)` returns the handle to a surface object in `h`.

Remarks

`ezsurf` and `ezsurfc` do not accept complex inputs.

Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the expression you pass to `ezmesh`. For example, the MATLAB syntax for a surface plot of the expression

```
sqrt(x.^2 + y.^2);
```

is written as

```
ezsurf('sqrt(x^2 + y^2)')
```

That is, `x^2` is interpreted as `x.^2` in the string you pass to `ezsurf`.

If the function to be plotted is a function of the variables u and v (rather than x and y), then the domain endpoints `umin`, `umax`, `vmin`, and `vmax` are sorted alphabetically. Thus, `ezsurf('u^2 - v^3',[0,1],[3,6])` plots u^2 - v^3 over $0 < u < 1$, $3 < v < 6$.

Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezsurf`.

```
fh = @(x,y) sqrt(x.^2 + y.^2);
ezsurf(fh)
```

Note that when using function handles, you must use the array power, array multiplication, and array division operators (`.^, .*, ./`) since `ezsurf` does not alter the syntax, as in the case with string inputs.

Passing Additional Arguments

If your function has additional parameters, for example `k` in `myfun`:

```
function z = myfun(x,y,k1,k2,k3)
z = x.*(y.^k1)./(x.^k2 + y.^k3);
```

then you can use an anonymous function to specify that parameter:

```
ezsurf(@(x,y)myfun(x,y,2,2,4))
```

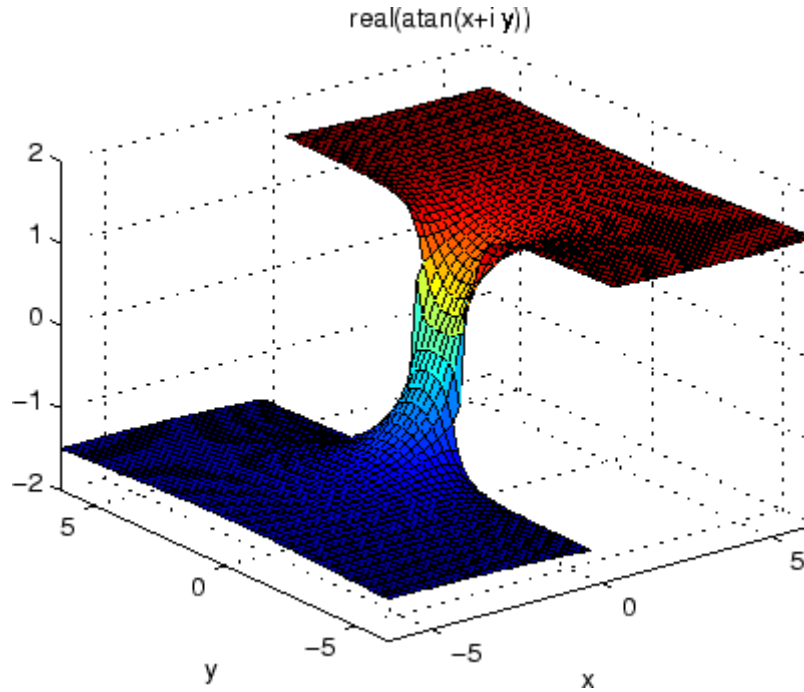
Examples

`ezsurf` does not graph points where the mathematical function is not defined (these data points are set to `NaN`s, which MATLAB does not plot). This example illustrates this filtering of singularities/discontinuous points by graphing the function

$$f(x, y) = real(atan(x + iy))$$

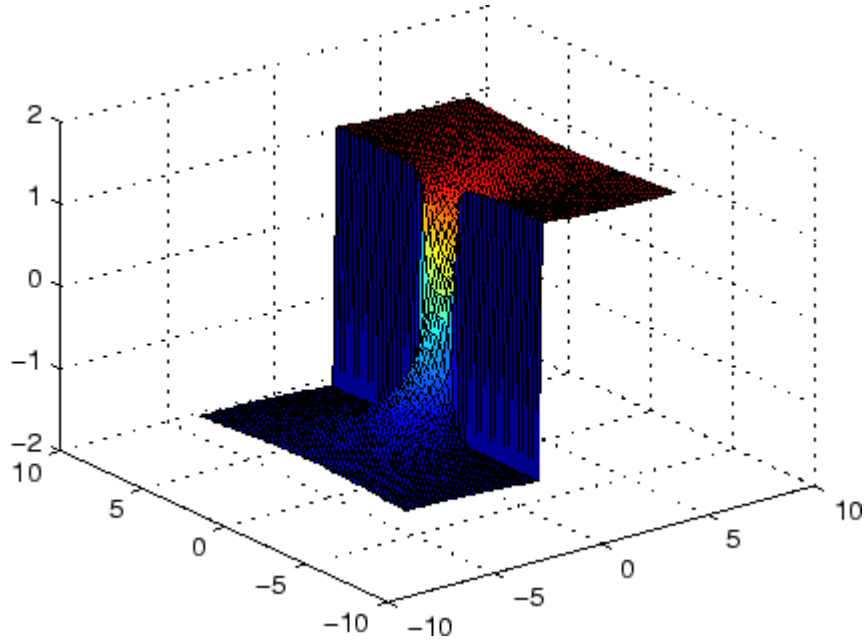
over the default domain $-2\pi < x < 2\pi$, $-2\pi < y < 2\pi$:

```
ezsurf('real(atan(x+i*y))')
```



Using `surf` to plot the same data produces a graph without filtering of discontinuities (as well as requiring more steps):

```
[x,y] = meshgrid(linspace(-2*pi,2*pi,60));
z = real(atan(x+i.*y));
surf(x,y,z)
```



Note also that `ezsurf` creates graphs that have axis labels, a title, and extend to the axis limits.

See Also

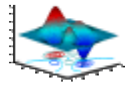
`ezmesh`, `ezsurfc`, `function_handle`, `surf`

"Function Plots" on page 1-89 for related functions

ezsurfc

Purpose

Easy-to-use combination surface/contour plotter



Syntax

```
ezsurfc(fun)
ezsurfc(fun,domain)
ezsurfc(funx,funy,funz)
ezsurfc(funx,funy,funz,[smin,smax,tmin,tmax])
ezsurfc(funx,funy,funz,[min,max]
ezsurfc(...,n)
ezsurfc(...,'circ')
ezsurfc(axes_handle,...)
h = ezsurfc(...)
```

Description

`ezsurfc(fun)` creates a graph of `fun(x,y)` using the `surfc` function. The function `fun` is plotted over the default domain: $-2\pi < x < 2\pi$, $-2\pi < y < 2\pi$.

`fun` can be a function handle for an M-file function or an anonymous function (see "Function Handles" and "Anonymous Functions") or a string (see the Remarks section).

`ezsurfc(fun,domain)` plots `fun` over the specified `domain`. `domain` can be either a 4-by-1 vector [`xmin`, `xmax`, `ymin`, `ymax`] or a 2-by-1 vector [`min`, `max`] (where $min < x < max$, $min < y < max$).

`ezsurfc(funx,funy,funz)` plots the parametric surface `funx(s,t)`, `funy(s,t)`, and `funz(s,t)` over the square: $-2\pi < s < 2\pi$, $-2\pi < t < 2\pi$.

`ezsurfc(funx,funy,funz,[smin,smax,tmin,tmax])` or `ezsurfc(funx,funy,funz,[min,max])` plots the parametric surface using the specified domain.

`ezsurfc(...,n)` plots *f* over the default domain using an `n`-by-`n` grid. The default value for `n` is 60.

`ezsurfc(...,'circ')` plots *f* over a disk centered on the domain.

`ezsurfc(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ezsurfc(...)` returns the handles to the graphics objects in `h`.

Remarks

`ezsurf` and `ezsurfc` do not accept complex inputs.

Passing the Function as a String

Array multiplication, division, and exponentiation are always implied in the expression you pass to `ezsurfc`. For example, the MATLAB syntax for a surface/contour plot of the expression

```
sqrt(x.^2 + y.^2);
```

is written as

```
ezsurfc('sqrt(x^2 + y^2)')
```

That is, `x^2` is interpreted as `x.^2` in the string you pass to `ezsurfc`.

If the function to be plotted is a function of the variables u and v (rather than x and y), then the domain endpoints `umin`, `umax`, `vmin`, and `vmax` are sorted alphabetically. Thus, `ezsurfc('u^2 - v^3',[0,1],[3,6])` plots $u^2 - v^3$ over $0 < u < 1$, $3 < v < 6$.

Passing a Function Handle

Function handle arguments must point to functions that use MATLAB syntax. For example, the following statements define an anonymous function and pass the function handle `fh` to `ezsurfc`.

```
fh = @(x,y) sqrt(x.^2 + y.^2);
ezsurf(fh)
```

Note that when using function handles, you must use the array power, array multiplication, and array division operators (`.^, .*, ./`) since `ezsurfc` does not alter the syntax, as in the case with string inputs.

Passing Additional Arguments

If your function has additional parameters, for example `k` in `myfun`:

```
function z = myfun(x,y,k1,k2,k3)
z = x.*(y.^k1)./(x.^k2 + y.^k3);
```

then you can use an anonymous function to specify that parameter:

```
ezsurfc(@(x,y)myfun(x,y,2,2,4))
```

Examples

Create a surface/contour plot of the expression

$$f(x, y) = \frac{y}{1 + x^2 + y^2}$$

over the domain -5 < x < 5, -2*pi < y < 2*pi, with a computational grid of size 35-by-35:

```
ezsurfc('y/(1 + x^2 + y^2)',[-5,5,-2*pi,2*pi],35)
```

Use the mouse to rotate the axes to better observe the contour lines (this picture uses a view of azimuth = -65.5 and elevation = 26).

Revision History

December 1996	First printing	For MATLAB 5.0 (Release 8)
June 1997	Online only	Revised for MATLAB 5.1 (Release 9)
October 1997	Online only	Revised for MATLAB 5.2 (Release 10)
January 1999	Online only	Revised for MATLAB 5.3 (Release 11)
June 1999	Second printing	For MATLAB 5.3 (Release 11)
June 2001	Online only	Revised for MATLAB 6.1 (Release 12.1)
July 2002	Online only	Revised for 6.5 (Release 13)
June 2004	Online only	Revised for 7.0 (Release 14)
September 2006	Online only	Revised for 7.3 (Release 2006b)
September 2007	Online only	Revised for 7.5 (Release 2007b)

Contents

1 Functions — By Category

Functions — By Category

Creating Graphical User Interfaces (p. 1-104)	GUIDE, programming graphical user interfaces
External Interfaces (p. 1-109)	Interfaces to DLLs, Java, COM and ActiveX, Web services, and serial port devices, and C and Fortran routines

Desktop Tools and Development Environment

Startup and Shutdown

exit	Terminate MATLAB (same as `quit`)
finish	MATLAB termination M-file
matlab (UNIX)	Start MATLAB (UNIX systems)
matlab (Windows)	Start MATLAB (Windows systems)
matlabrc	MATLAB startup M-file for single-user systems or system administrators
prefdir	Directory containing preferences, history, and layout files
preferences	Open Preferences dialog box for MATLAB and related products

quit	Terminate MATLAB
startup	MATLAB startup M-file for user-defined options

Command Window and History

clc	Clear Command Window
commandhistory	Open Command History window, or select it if already open
commandwindow	Open Command Window, or select it if already open
diary	Save session to file
dos	Execute DOS command and return result
format	Set display format for output
home	Move cursor to upper-left corner of Command Window
matlabcolon (matlab:)	Run specified function via hyperlink
more	Control paged output for Command Window
perl	Call Perl script using appropriate operating system executable
system	Execute operating system command and return result
unix	Execute UNIX command and return result

Help for Using MATLAB

builddocsearchdb	Build searchable documentation database
demo	Access product demos via Help browser
doc	Reference page in Help browser
docopt	Web browser for UNIX platforms
docsearch	Open Help browser **Search** pane and search for specified term
echodemo	Run M-file demo step-by-step in Command Window
help	Help for MATLAB functions in Command Window
helpbrowser	Open Help browser to access all online documentation and demos
helpwin	Provide access to M-file help for all functions
info	Information about contacting The MathWorks
lookfor	Search for keyword in all help entries
playshow	Run M-file demo (deprecated; use `echodemo` instead)
support	Open MathWorks Technical Support Web page
web	Open Web site or file in Web browser or Help browser
whatsnew	Release Notes for MathWorks products

Workspace, Search Path, and File Operations

Workspace

assignin	Assign value to variable in specified workspace
clear	Remove items from workspace, freeing up system memory
evalin	Execute MATLAB expression in specified workspace
exist	Check existence of variable, function, directory, or Java class
openvar	Open workspace variable in Array Editor or other tool for graphical editing
pack	Consolidate workspace memory
uiimport	Open Import Wizard to import data
which	Locate functions and files
workspace	Open Workspace browser to manage workspace

Search Path

addpath	Add directories to MATLAB search path
genpath	Generate path string
partialpath	Partial pathname description

path	View or change MATLAB directory search path
path2rc	Save current MATLAB search path to `pathdef.m` file
pathdef	Directories in MATLAB search path
pathsep	Path separator for current platform
pathtool	Open Set Path dialog box to view and change MATLAB path
restoredefaultpath	Restore default MATLAB search path
rmpath	Remove directories from MATLAB search path
savepath	Save current MATLAB search path to `pathdef.m` file

File Operations

See also "File I/O" on page 1-76 functions.

cd	Change working directory
copyfile	Copy file or directory
delete	Remove files or graphics objects
dir	Directory listing
exist	Check existence of variable, function, directory, or Java class
fileattrib	Set or get attributes of file or directory
filebrowser	Current Directory browser
isdir	Determine whether input is a directory
lookfor	Search for keyword in all help entries

ls	Directory contents on UNIX system
matlabroot	Root directory of MATLAB installation
mkdir	Make new directory
movefile	Move file or directory
pwd	Identify current directory
recycle	Set option to move deleted files to recycle folder
rehash	Refresh function and file system path caches
rmdir	Remove directory
toolboxdir	Root directory for specified toolbox
type	Display contents of file
web	Open Web site or file in Web browser or Help browser
what	List MATLAB files in current directory
which	Locate functions and files

Programming Tools

Edit and Debug M-Files (p. 1-9)	Edit and debug M-files
Improve Performance and Tune M-Files (p. 1-9)	Improve performance and find potential problems in M-files
Source Control (p. 1-10)	Interface MATLAB with source control system
Publishing (p. 1-10)	Publish M-file code and results

Edit and Debug M-Files

clipboard	Copy and paste strings to and from system clipboard
datatipinfo	Produce short description of input variable
dbclear	Clear breakpoints
dbcont	Resume execution
dbdown	Change local workspace context when in debug mode
dbquit	Quit debug mode
dbstack	Function call stack
dbstatus	List all breakpoints
dbstep	Execute one or more lines from current breakpoint
dbstop	Set breakpoints
dbtype	List M-file with line numbers
dbup	Change local workspace context
debug	List M-file debugging functions
edit	Edit or create M-file
keyboard	Input from keyboard

Improve Performance and Tune M-Files

memory	Help for memory limitations
mlint	Check M-files for possible problems
mlintrpt	Run `mlint` for file or directory, reporting results in browser
pack	Consolidate workspace memory
profile	Profile execution time for function

profsave	Save profile report in HTML format
rehash	Refresh function and file system path caches
sparse	Create sparse matrix
zeros	Create array of all zeros

Source Control

checkin	Check files into source control system (UNIX)
checkout	Check files out of source control system (UNIX)
cmopts	Name of source control system
customverctrl	Allow custom source control system (UNIX)
undocheckout	Undo previous checkout from source control system (UNIX)
verctrl	Source control actions (Windows)

Publishing

grabcode	MATLAB code from M-files published to HTML
notebook	Open M-book in Microsoft Word (Windows)
publish	Publish M-file containing cells, saving output to file of specified type

System

Operating System Interface (p. 1-11)	Exchange operating system information and commands with MATLAB
MATLAB Version and License (p. 1-12)	Information about MATLAB version and license

Operating System Interface

clipboard	Copy and paste strings to and from system clipboard
computer	Information about computer on which MATLAB is running
dos	Execute DOS command and return result
getenv	Environment variable
hostid	MATLAB server host identification number
maxNumCompThreads	Controls maximum number of computational threads
perl	Call Perl script using appropriate operating system executable
setenv	Set environment variable
system	Execute operating system command and return result
unix	Execute UNIX command and return result
winqueryreg	Item from Microsoft Windows registry

MATLAB Version and License

ismac	Determine whether running Macintosh OS X versions of MATLAB
ispc	Determine whether PC (Windows) version of MATLAB
isstudent	Determine whether Student Version of MATLAB
isunix	Determine whether UNIX version of MATLAB
javachk	Generate error message based on Java feature support
license	Return license number or perform licensing task
prefdir	Directory containing preferences, history, and layout files
usejava	Determine whether Java feature is supported in MATLAB
ver	Version information for MathWorks products
verLessThan	Compare toolbox version to specified version string
version	Version number for MATLAB

Mathematics

Arrays and Matrices (p. 1-14)	Basic array operators and operations, creation of elementary and specialized arrays and matrices
Linear Algebra (p. 1-19)	Matrix analysis, linear equations, eigenvalues, singular values, logarithms, exponentials, factorization
Elementary Math (p. 1-23)	Trigonometry, exponentials and logarithms, complex values, rounding, remainders, discrete math
Polynomials (p. 1-28)	Multiplication, division, evaluation, roots, derivatives, integration, eigenvalue problem, curve fitting, partial fraction expansion
Interpolation and Computational Geometry (p. 1-28)	Interpolation, Delaunay triangulation and tessellation, convex hulls, Voronoi diagrams, domain generation
Cartesian Coordinate System Conversion (p. 1-31)	Conversions between Cartesian and polar or spherical coordinates
Nonlinear Numerical Methods (p. 1-31)	Differential equations, optimization, integration
Specialized Math (p. 1-35)	Airy, Bessel, Jacobi, Legendre, beta, elliptic, error, exponential integral, gamma functions
Sparse Matrices (p. 1-36)	Elementary sparse matrices, operations, reordering algorithms, linear algebra, iterative methods, tree operations
Math Constants (p. 1-39)	Pi, imaginary unit, infinity, Not-a-Number, largest and smallest positive floating point numbers, floating point relative accuracy

Arrays and Matrices

Basic Information (p. 1-14)	Display array contents, get array information, determine array type
Operators (p. 1-15)	Arithmetic operators
Elementary Matrices and Arrays (p. 1-16)	Create elementary arrays of different types, generate arrays for plotting, array indexing, etc.
Array Operations (p. 1-17)	Operate on array content, apply function to each array element, find cumulative product or sum, etc.
Array Manipulation (p. 1-17)	Create, sort, rotate, permute, reshape, and shift array contents
Specialized Matrices (p. 1-18)	Create Hadamard, Companion, Hankel, Vandermonde, Pascal matrices, etc.

Basic Information

disp	Display text or array
display	Display text or array (overloaded method)
isempty	Determine whether array is empty
isequal	Test arrays for equality
isequalwithequalnans	Test arrays for equality, treating NaNs as equal
isfinite	Array elements that are finite
isfloat	Determine whether input is floating-point array
isinf	Array elements that are infinite
isinteger	Determine whether input is integer array

islogical	Determine whether input is logical array
isnan	Array elements that are NaN
isnumeric	Determine whether input is numeric array
isscalar	Determine whether input is scalar
issparse	Determine whether input is sparse
isvector	Determine whether input is vector
length	Length of vector
max	Largest elements in array
min	Smallest elements in array
ndims	Number of array dimensions
numel	Number of elements in array or subscripted array expression
size	Array dimensions

Operators

+	Addition
+	Unary plus
-	Subtraction
-	Unary minus
*	Matrix multiplication
^	Matrix power
\	Backslash or left matrix divide
/	Slash or right matrix divide
’	Transpose
.’	Nonconjugated transpose
.*	Array multiplication (element-wise)

.^	Array power (element-wise)
.\	Left array divide (element-wise)
./	Right array divide (element-wise)

Elementary Matrices and Arrays

blkdiag	Construct block diagonal matrix from input arguments
diag	Diagonal matrices and diagonals of matrix
eye	Identity matrix
freqspace	Frequency spacing for frequency response
ind2sub	Subscripts from linear index
linspace	Generate linearly spaced vectors
logspace	Generate logarithmically spaced vectors
meshgrid	Generate `X` and `Y` arrays for 3-D plots
ndgrid	Generate arrays for N-D functions and interpolation
ones	Create array of all ones
rand	Uniformly distributed pseudorandom numbers
randn	Normally distributed random numbers
sub2ind	Single index from subscripts
zeros	Create array of all zeros

Array Operations

See “Linear Algebra” on page 1-19 and “Elementary Math” on page 1-23 for other array operations.

accumarray	Construct array with accumulation
arrayfun	Apply function to each element of array
bsxfun	Apply element-by-element binary operation to two arrays with singleton expansion enabled
cast	Cast variable to different data type
cross	Vector cross product
cumprod	Cumulative product
cumsum	Cumulative sum
dot	Vector dot product
idivide	Integer division with rounding option
kron	Kronecker tensor product
prod	Product of array elements
sum	Sum of array elements
tril	Lower triangular part of matrix
triu	Upper triangular part of matrix

Array Manipulation

blkdiag	Construct block diagonal matrix from input arguments
cat	Concatenate arrays along specified dimension
circshift	Shift array circularly

diag	Diagonal matrices and diagonals of matrix
end	Terminate block of code, or indicate last array index
flipdim	Flip array along specified dimension
fliplr	Flip matrix left to right
flipud	Flip matrix up to down
horzcat	Concatenate arrays horizontally
inline	Construct inline object
ipermute	Inverse permute dimensions of N-D array
permute	Rearrange dimensions of N-D array
repmat	Replicate and tile array
reshape	Reshape array
rot90	Rotate matrix 90 degrees
shiftdim	Shift dimensions
sort	Sort array elements in ascending or descending order
sortrows	Sort rows in ascending order
squeeze	Remove singleton dimensions
vectorize	Vectorize expression
vertcat	Concatenate arrays vertically

Specialized Matrices

compan	Companion matrix
gallery	Test matrices
hadamard	Hadamard matrix
hankel	Hankel matrix

hilb	Hilbert matrix
invhilb	Inverse of Hilbert matrix
magic	Magic square
pascal	Pascal matrix
rosser	Classic symmetric eigenvalue test problem
toeplitz	Toeplitz matrix
vander	Vandermonde matrix
wilkinson	Wilkinson's eigenvalue test matrix

Linear Algebra

Matrix Analysis (p. 1-19)	Compute norm, rank, determinant, condition number, etc.
Linear Equations (p. 1-20)	Solve linear systems, least squares, LU factorization, Cholesky factorization, etc.
Eigenvalues and Singular Values (p. 1-21)	Eigenvalues, eigenvectors, Schur decomposition, Hessenburg matrices, etc.
Matrix Logarithms and Exponentials (p. 1-22)	Matrix logarithms, exponentials, square root
Factorization (p. 1-22)	Cholesky, LU, and QR factorizations, diagonal forms, singular value decomposition

Matrix Analysis

cond	Condition number with respect to inversion
condeig	Condition number with respect to eigenvalues

det	Matrix determinant
norm	Vector and matrix norms
normest	2-norm estimate
null	Null space
orth	Range space of matrix
rank	Rank of matrix
rcond	Matrix reciprocal condition number estimate
rref	Reduced row echelon form
subspace	Angle between two subspaces
trace	Sum of diagonal elements

Linear Equations

chol	Cholesky factorization
cholinc	Sparse incomplete Cholesky and Cholesky-Infinity factorizations
cond	Condition number with respect to inversion
condest	1-norm condition number estimate
funm	Evaluate general matrix function
ilu	Sparse incomplete LU factorization
inv	Matrix inverse
linsolve	Solve linear system of equations
lscov	Least-squares solution in presence of known covariance
lsqnonneg	Solve nonnegative least-squares constraints problem
lu	LU matrix factorization

luinc	Sparse incomplete LU factorization
pinv	Moore-Penrose pseudoinverse of matrix
qr	Orthogonal-triangular decomposition
rcond	Matrix reciprocal condition number estimate

Eigenvalues and Singular Values

balance	Diagonal scaling to improve eigenvalue accuracy
cdf2rdf	Convert complex diagonal form to real block diagonal form
condeig	Condition number with respect to eigenvalues
eig	Find eigenvalues and eigenvectors
eigs	Find largest eigenvalues and eigenvectors of sparse matrix
gsvd	Generalized singular value decomposition
hess	Hessenberg form of matrix
ordeig	Eigenvalues of quasitriangular matrices
ordqz	Reorder eigenvalues in QZ factorization
ordschur	Reorder eigenvalues in Schur factorization
poly	Polynomial with specified roots
polyeig	Polynomial eigenvalue problem

rsf2csf	Convert real Schur form to complex Schur form
schur	Schur decomposition
sqrtm	Matrix square root
ss2tf	Convert state-space filter parameters to transfer function form
svd	Singular value decomposition
svds	Find singular values and vectors

Matrix Logarithms and Exponentials

expm	Matrix exponential
logm	Matrix logarithm
sqrtm	Matrix square root

Factorization

balance	Diagonal scaling to improve eigenvalue accuracy
cdf2rdf	Convert complex diagonal form to real block diagonal form
chol	Cholesky factorization
cholinc	Sparse incomplete Cholesky and Cholesky-Infinity factorizations
cholupdate	Rank 1 update to Cholesky factorization
gsvd	Generalized singular value decomposition
ilu	Sparse incomplete LU factorization
lu	LU matrix factorization

luinc	Sparse incomplete LU factorization
planerot	Givens plane rotation
qr	Orthogonal-triangular decomposition
qrdelete	Remove column or row from QR factorization
qrinsert	Insert column or row into QR factorization
qrupdate	
qz	QZ factorization for generalized eigenvalues
rsf2csf	Convert real Schur form to complex Schur form
svd	Singular value decomposition

Elementary Math

Trigonometric (p. 1-24)	Trigonometric functions with results in radians or degrees
Exponential (p. 1-25)	Exponential, logarithm, power, and root functions
Complex (p. 1-26)	Numbers with real and imaginary components, phase angles
Rounding and Remainder (p. 1-27)	Rounding, modulus, and remainder
Discrete Math (e.g., Prime Factors) (p. 1-27)	Prime factors, factorials, permutations, rational fractions, least common multiple, greatest common divisor

Trigonometric

acos	Inverse cosine; result in radians
acosd	Inverse cosine; result in degrees
acosh	Inverse hyperbolic cosine
acot	Inverse cotangent; result in radians
acotd	Inverse cotangent; result in degrees
acoth	Inverse hyperbolic cotangent
acsc	Inverse cosecant; result in radians
acscd	Inverse cosecant; result in degrees
acsch	Inverse hyperbolic cosecant
asec	Inverse secant; result in radians
asecd	Inverse secant; result in degrees
asech	Inverse hyperbolic secant
asin	Inverse sine; result in radians
asind	Inverse sine; result in degrees
asinh	Inverse hyperbolic sine
atan	Inverse tangent; result in radians
atan2	Four-quadrant inverse tangent
atand	Inverse tangent; result in degrees
atanh	Inverse hyperbolic tangent
cos	Cosine of argument in radians
cosd	Cosine ofo argument in degrees
cosh	Hyperbolic cosine
cot	Cotangent of argument in radians
cotd	Cotangent of argument in degrees
coth	Hyperbolic cotangent
csc	Cosecant of argument in radians

cscd	Cosecant of argument in degrees
csch	Hyperbolic cosecant
hypot	Square root of sum of squares
sec	Secant of argument in radians
secd	Secant of argument in degrees
sech	Hyperbolic secant
sin	Sine of argument in radians
sind	Sine of argument in degrees
sinh	Hyperbolic sine of argument in radians
tan	Tangent of argument in radians
tand	Tangent of argument in degrees
tanh	Hyperbolic tangent

Exponential

exp	Exponential
expm1	Compute `exp(x)-1` accurately for small values of `x`
log	Natural logarithm
log10	Common (base 10) logarithm
log1p	Compute `log(1+x)` accurately for small values of `x`
log2	Base 2 logarithm and dissect floating-point numbers into exponent and mantissa
nextpow2	Next higher power of 2
nthroot	Real `n`th root of real numbers
pow2	Base 2 power and scale floating-point numbers

reallog	Natural logarithm for nonnegative real arrays
realpow	Array power for real-only output
realsqrt	Square root for nonnegative real arrays
sqrt	Square root

Complex

abs	Absolute value and complex magnitude
angle	Phase angle
complex	Construct complex data from real and imaginary components
conj	Complex conjugate
cplxpair	Sort complex numbers into complex conjugate pairs
i	Imaginary unit
imag	Imaginary part of complex number
isreal	Determine whether input is real array
j	Imaginary unit
real	Real part of complex number
sign	Signum function
unwrap	Correct phase angles to produce smoother phase plots

Rounding and Remainder

ceil	Round toward infinity
fix	Round toward zero
floor	Round toward minus infinity
idivide	Integer division with rounding option
mod	Modulus after division
rem	Remainder after division
round	Round to nearest integer

Discrete Math (e.g., Prime Factors)

factor	Prime factors
factorial	Factorial function
gcd	Greatest common divisor
isprime	Array elements that are prime numbers
lcm	Least common multiple
nchoosek	Binomial coefficient or all combinations
perms	All possible permutations
primes	Generate list of prime numbers
rat, rats	Rational fraction approximation

Polynomials

conv	Convolution and polynomial multiplication
deconv	Deconvolution and polynomial division
poly	Polynomial with specified roots
polyder	Polynomial derivative
polyeig	Polynomial eigenvalue problem
polyfit	Polynomial curve fitting
polyint	Integrate polynomial analytically
polyval	Polynomial evaluation
polyvalm	Matrix polynomial evaluation
residue	Convert between partial fraction expansion and polynomial coefficients
roots	Polynomial roots

Interpolation and Computational Geometry

Interpolation (p. 1-29)	Data interpolation, data gridding, polynomial evaluation, nearest point search
Delaunay Triangulation and Tessellation (p. 1-30)	Delaunay triangulation and tessellation, triangular surface and mesh plots
Convex Hull (p. 1-30)	Plot convex hull, plotting functions
Voronoi Diagrams (p. 1-30)	Plot Voronoi diagram, patch graphics object, plotting functions
Domain Generation (p. 1-31)	Generate arrays for 3-D plots, or for N-D functions and interpolation

Interpolation

dsearch	Search Delaunay triangulation for nearest point
dsearchn	N-D nearest point search
griddata	Data gridding
griddata3	Data gridding and hypersurface fitting for 3-D data
griddatan	Data gridding and hypersurface fitting (dimension >= 2)
interp1	1-D data interpolation (table lookup)
interp1q	Quick 1-D linear interpolation
interp2	2-D data interpolation (table lookup)
interp3	3-D data interpolation (table lookup)
interpft	1-D interpolation using FFT method
interpn	N-D data interpolation (table lookup)
meshgrid	Generate `X` and `Y` arrays for 3-D plots
mkpp	Make piecewise polynomial
ndgrid	Generate arrays for N-D functions and interpolation
padecoef	Padé approximation of time delays
pchip	Piecewise Cubic Hermite Interpolating Polynomial (PCHIP)
ppval	Evaluate piecewise polynomial
spline	Cubic spline data interpolation
tsearchn	N-D closest simplex search
unmkpp	Piecewise polynomial details

Delaunay Triangulation and Tessellation

delaunay	Delaunay triangulation
delaunay3	3-D Delaunay tessellation
delaunayn	N-D Delaunay tessellation
dsearch	Search Delaunay triangulation for nearest point
dsearchn	N-D nearest point search
tetramesh	Tetrahedron mesh plot
trimesh	Triangular mesh plot
triplot	2-D triangular plot
trisurf	Triangular surface plot
tsearch	Search for enclosing Delaunay triangle
tsearchn	N-D closest simplex search

Convex Hull

convhull	Convex hull
convhulln	N-D convex hull
patch	Create patch graphics object
plot	2-D line plot
trisurf	Triangular surface plot

Voronoi Diagrams

dsearch	Search Delaunay triangulation for nearest point
patch	Create patch graphics object
plot	2-D line plot

voronoi	Voronoi diagram
voronoin	N-D Voronoi diagram

Domain Generation

meshgrid	Generate `X` and `Y` arrays for 3-D plots
ndgrid	Generate arrays for N-D functions and interpolation

Cartesian Coordinate System Conversion

cart2pol	Transform Cartesian coordinates to polar or cylindrical
cart2sph	Transform Cartesian coordinates to spherical
pol2cart	Transform polar or cylindrical coordinates to Cartesian
sph2cart	Transform spherical coordinates to Cartesian

Nonlinear Numerical Methods

Ordinary Differential Equations (IVP) (p. 1-32)	Solve stiff and nonstiff differential equations, define the problem, set solver options, evaluate solution
Delay Differential Equations (p. 1-33)	Solve delay differential equations with constant and general delays, set solver options, evaluate solution
Boundary Value Problems (p. 1-33)	Solve boundary value problems for ordinary differential equations, set solver options, evaluate solution

Partial Differential Equations (p. 1-34)	Solve initial-boundary value problems for parabolic-elliptic PDEs, evaluate solution
Optimization (p. 1-34)	Find minimum of single and multivariable functions, solve nonnegative least-squares constraint problem
Numerical Integration (Quadrature) (p. 1-34)	Evaluate Simpson, Lobatto, and vectorized quadratures, evaluate double and triple integrals

Ordinary Differential Equations (IVP)

decic	Compute consistent initial conditions for `ode15i`
deval	Evaluate solution of differential equation problem
ode15i	Solve fully implicit differential equations, variable order method
ode23, ode45, ode113, ode15s, ode23s, ode23t, ode23tb	Solve initial value problems for ordinary differential equations
odefile	Define differential equation problem for ordinary differential equation solvers
odeget	Ordinary differential equation options parameters
odeset	Create or alter options structure for ordinary differential equation solvers
odextend	Extend solution of initial value problem for ordinary differential equation

Delay Differential Equations

dde23	Solve delay differential equations (DDEs) with constant delays
ddeget	Extract properties from delay differential equations options structure
ddesd	Solve delay differential equations (DDEs) with general delays
ddeset	Create or alter delay differential equations options structure
deval	Evaluate solution of differential equation problem

Boundary Value Problems

bvp4c	Solve boundary value problems for ordinary differential equations
bvp5c	Solve boundary value problems for ordinary differential equations
bvpget	Extract properties from options structure created with `bvpset`
bvpinit	Form initial guess for `bvp4c`
bvpset	Create or alter options structure of boundary value problem
bvpxtend	Form guess structure for extending boundary value solutions
deval	Evaluate solution of differential equation problem

Partial Differential Equations

pdepe	Solve initial-boundary value problems for parabolic-elliptic PDEs in 1-D
pdeval	Evaluate numerical solution of PDE using output of pdepe

Optimization

fminbnd	Find minimum of single-variable function on fixed interval
fminsearch	Find minimum of unconstrained multivariable function using derivative-free method
fzero	Find root of continuous function of one variable
lsqnonneg	Solve nonnegative least-squares constraints problem
optimget	Optimization options values
optimset	Create or edit optimization options structure

Numerical Integration (Quadrature)

dblquad	Numerically evaluate double integral
quad	Numerically evaluate integral, adaptive Simpson quadrature
quadgk	Numerically evaluate integral, adaptive Gauss-Kronrod quadrature
quadl	Numerically evaluate integral, adaptive Lobatto quadrature

quadv	Vectorized quadrature
triplequad	Numerically evaluate triple integral

Specialized Math

airy	Airy functions
besselh	Bessel function of third kind (Hankel function)
besseli	Modified Bessel function of first kind
besselj	Bessel function of first kind
besselk	Modified Bessel function of second kind
bessely	Bessel function of second kind
beta	Beta function
betainc	Incomplete beta function
betaln	Logarithm of beta function
ellipj	Jacobi elliptic functions
ellipke	Complete elliptic integrals of first and second kind
erf, erfc, erfcx, erfinv, erfcinv	Error functions
expint	Exponential integral
gamma, gammainc, gammaln	Gamma functions
legendre	Associated Legendre functions
psi	Psi (polygamma) function

Sparse Matrices

Elementary Sparse Matrices (p. 1-36)	Create random and nonrandom sparse matrices
Full to Sparse Conversion (p. 1-37)	Convert full matrix to sparse, sparse matrix to full
Working with Sparse Matrices (p. 1-37)	Test matrix for sparseness, get information on sparse matrix, allocate sparse matrix, apply function to nonzero elements, visualize sparsity pattern.
Reordering Algorithms (p. 1-37)	Random, column, minimum degree, Dulmage-Mendelsohn, and reverse Cuthill-McKee permutations
Linear Algebra (p. 1-38)	Compute norms, eigenvalues, factorizations, least squares, structural rank
Linear Equations (Iterative Methods) (p. 1-38)	Methods for conjugate and biconjugate gradients, residuals, lower quartile
Tree Operations (p. 1-39)	Elimination trees, tree plotting, factorization analysis

Elementary Sparse Matrices

spdiags	Extract and create sparse band and diagonal matrices
speye	Sparse identity matrix
sprand	Sparse uniformly distributed random matrix
sprandn	Sparse normally distributed random matrix
sprandsym	Sparse symmetric random matrix

Full to Sparse Conversion

find	Find indices and values of nonzero elements
full	Convert sparse matrix to full matrix
sparse	Create sparse matrix
spconvert	Import matrix from sparse matrix external format

Working with Sparse Matrices

issparse	Determine whether input is sparse
nnz	Number of nonzero matrix elements
nonzeros	Nonzero matrix elements
nzmax	Amount of storage allocated for nonzero matrix elements
spalloc	Allocate space for sparse matrix
spfun	Apply function to nonzero sparse matrix elements
spones	Replace nonzero sparse matrix elements with ones
spparms	Set parameters for sparse matrix routines
spy	Visualize sparsity pattern

Reordering Algorithms

amd	Approximate minimum degree permutation
colamd	Column approximate minimum degree permutation

colperm	Sparse column permutation based on nonzero count
dmperm	Dulmage-Mendelsohn decomposition
ldl	Block ldl' factorization for Hermitian indefinite matrices
randperm	Random permutation
symamd	Symmetric approximate minimum degree permutation
symrcm	Sparse reverse Cuthill-McKee ordering

Linear Algebra

cholinc	Sparse incomplete Cholesky and Cholesky-Infinity factorizations
condest	1-norm condition number estimate
eigs	Find largest eigenvalues and eigenvectors of sparse matrix
ilu	Sparse incomplete LU factorization
luinc	Sparse incomplete LU factorization
normest	2-norm estimate
spaugment	Form least squares augmented system
sprank	Structural rank
svds	Find singular values and vectors

Linear Equations (Iterative Methods)

bicg	Biconjugate gradients method
bicgstab	Biconjugate gradients stabilized method

cgs	Conjugate gradients squared method
gmres	Generalized minimum residual method (with restarts)
lsqr	LSQR method
minres	Minimum residual method
pcg	Preconditioned conjugate gradients method
qmr	Quasi-minimal residual method
symmlq	Symmetric LQ method

Tree Operations

etree	Elimination tree
etreeplot	Plot elimination tree
gplot	Plot nodes and links representing adjacency matrix
symbfact	Symbolic factorization analysis
treelayout	Lay out tree or forest
treeplot	Plot picture of tree

Math Constants

eps	Floating-point relative accuracy
i	Imaginary unit
Inf	Infinity
intmax	Largest value of specified integer type
intmin	Smallest value of specified integer type
j	Imaginary unit

NaN	Not-a-Number
pi	Ratio of circle's circumference to its diameter, π
realmax	Largest positive floating-point number
realmin	Smallest positive normalized floating-point number

Data Analysis

Basic Operations

cumprod	Cumulative product
cumsum	Cumulative sum
prod	Product of array elements
sort	Sort array elements in ascending or descending order
sortrows	Sort rows in ascending order
sum	Sum of array elements

Descriptive Statistics

corrcoef	Correlation coefficients
cov	Covariance matrix
max	Largest elements in array
mean	Average or mean value of array
median	Median value of array

min	Smallest elements in array
mode	Most frequent values in array
std	Standard deviation
var	Variance

Filtering and Convolution

conv	Convolution and polynomial multiplication
conv2	2-D convolution
convn	N-D convolution
deconv	Deconvolution and polynomial division
detrend	Remove linear trends
filter	1-D digital filter
filter2	2-D digital filter

Interpolation and Regression

interp1	1-D data interpolation (table lookup)
interp2	2-D data interpolation (table lookup)
interp3	3-D data interpolation (table lookup)
interpn	N-D data interpolation (table lookup)
mldivide \, mrdivide /	Left or right matrix division
polyfit	Polynomial curve fitting
polyval	Polynomial evaluation

Fourier Transforms

abs	Absolute value and complex magnitude
angle	Phase angle
cplxpair	Sort complex numbers into complex conjugate pairs
fft	Discrete Fourier transform
fft2	2-D discrete Fourier transform
fftn	N-D discrete Fourier transform
fftshift	Shift zero-frequency component to center of spectrum
fftw	Interface to FFTW library run-time algorithm tuning control
ifft	Inverse discrete Fourier transform
ifft2	2-D inverse discrete Fourier transform
ifftn	N-D inverse discrete Fourier transform
ifftshift	Inverse FFT shift
nextpow2	Next higher power of 2
unwrap	Correct phase angles to produce smoother phase plots

Derivatives and Integrals

cumtrapz	Cumulative trapezoidal numerical integration
del2	Discrete Laplacian
diff	Differences and approximate derivatives

gradient	Numerical gradient
polyder	Polynomial derivative
polyint	Integrate polynomial analytically
trapz	Trapezoidal numerical integration

Time Series Objects

General Purpose (p. 1-44)	Combine `timeseries` objects, query and set `timeseries` object properties, plot `timeseries` objects
Data Manipulation (p. 1-45)	Add or delete data, manipulate `timeseries` objects
Event Data (p. 1-46)	Add or delete events, create new `timeseries` objects based on event data
Descriptive Statistics (p. 1-46)	Descriptive statistics for `timeseries` objects

General Purpose

get (timeseries)	Query `timeseries` object property values
getdatasamplesize	Size of data sample in `timeseries` object
getqualitydesc	Data quality descriptions
isempty (timeseries)	Determine whether `timeseries` object is empty
length (timeseries)	Length of time vector
plot (timeseries)	Plot time series
set (timeseries)	Set properties of `timeseries` object
size (timeseries)	Size of `timeseries` object

timeseries	Create `timeseries` object
tsdata.event	Construct event object for `timeseries` object
tsprops	Help on `timeseries` object properties
tstool	Open Time Series Tools GUI

Data Manipulation

addsample	Add data sample to `timeseries` object
ctranspose (timeseries)	Transpose `timeseries` object
delsample	Remove sample from `timeseries` object
detrend (timeseries)	Subtract mean or best-fit line and all `NaN`s from time series
filter (timeseries)	Shape frequency content of time series
getabstime (timeseries)	Extract date-string time vector into cell array
getinterpmethod	Interpolation method for `timeseries` object
getsampleusingtime (timeseries)	Extract data samples into new `timeseries` object
idealfilter (timeseries)	Apply ideal (noncausal) filter to `timeseries` object
resample (timeseries)	Select or interpolate `timeseries` data using new time vector
setabstime (timeseries)	Set times of `timeseries` object as date strings
setinterpmethod	Set default interpolation method for `timeseries` object

synchronize	Synchronize and resample two `timeseries` objects using common time vector
transpose (timeseries)	Transpose `timeseries` object
vertcat (timeseries)	Vertical concatenation of `timeseries` objects

Event Data

addevent	Add event to `timeseries` object
delevent	Remove `tsdata.event` objects from `timeseries` object
gettsafteratevent	New `timeseries` object with samples occurring at or after event
gettsafterevent	New `timeseries` object with samples occurring after event
gettsatevent	New `timeseries` object with samples occurring at event
gettsbeforeatevent	New `timeseries` object with samples occurring before or at event
gettsbeforeevent	New `timeseries` object with samples occurring before event
gettsbetweenevents	New `timeseries` object with samples occurring between events

Descriptive Statistics

iqr (timeseries)	Interquartile range of `timeseries` data
max (timeseries)	Maximum value of `timeseries` data
mean (timeseries)	Mean value of `timeseries` data
median (timeseries)	Median value of `timeseries` data

min (timeseries)	Minimum value of `timeseries` data
std (timeseries)	Standard deviation of `timeseries` data
sum (timeseries)	Sum of `timeseries` data
var (timeseries)	Variance of `timeseries` data

Time Series Collections

General Purpose (p. 1-47)	Query and set `tscollection` object properties, plot `tscollection` objects
Data Manipulation (p. 1-48)	Add or delete data, manipulate `tscollection` objects

General Purpose

get (tscollection)	Query `tscollection` object property values
isempty (tscollection)	Determine whether `tscollection` object is empty
length (tscollection)	Length of time vector
plot (timeseries)	Plot time series
set (tscollection)	Set properties of `tscollection` object
size (tscollection)	Size of `tscollection` object
tscollection	Create `tscollection` object
tstool	Open Time Series Tools GUI

Data Manipulation

addsampletocollection	Add sample to `tscollection` object
addts	Add `timeseries` object to `tscollection` object
delsamplefromcollection	Remove sample from `tscollection` object
getabstime (tscollection)	Extract date-string time vector into cell array
getsampleusingtime (tscollection)	Extract data samples into new `tscollection` object
gettimeseriesnames	Cell array of names of `timeseries` objects in `tscollection` object
horzcat (tscollection)	Horizontal concatenation for `tscollection` objects
removets	Remove `timeseries` objects from `tscollection` object
resample (tscollection)	Select or interpolate data in `tscollection` using new time vector
setabstime (tscollection)	Set times of `tscollection` object as date strings
settimeseriesnames	Change name of `timeseries` object in `tscollection`
vertcat (tscollection)	Vertical concatenation for `tscollection` objects

Programming and Data Types

Data Types

Cell Arrays (p. 1-53)	Data of varying types and sizes stored in cells of array
Function Handles (p. 1-54)	Invoke a function indirectly via handle
MATLAB Classes and Objects (p. 1-55)	MATLAB object-oriented class system
Java Classes and Objects (p. 1-55)	Access Java classes through MATLAB interface
Data Type Identification (p. 1-57)	Determine data type of a variable

Numeric Types

arrayfun	Apply function to each element of array
cast	Cast variable to different data type
cat	Concatenate arrays along specified dimension
class	Create object or return class of object
find	Find indices and values of nonzero elements
intmax	Largest value of specified integer type
intmin	Smallest value of specified integer type
intwarning	Control state of integer warnings
ipermute	Inverse permute dimensions of N-D array
isa	Determine whether input is object of given class
isequal	Test arrays for equality

isequalwithequalnans	Test arrays for equality, treating NaNs as equal
isfinite	Array elements that are finite
isinf	Array elements that are infinite
isnan	Array elements that are NaN
isnumeric	Determine whether input is numeric array
isreal	Determine whether input is real array
isscalar	Determine whether input is scalar
isvector	Determine whether input is vector
permute	Rearrange dimensions of N-D array
realmax	Largest positive floating-point number
realmin	Smallest positive normalized floating-point number
reshape	Reshape array
squeeze	Remove singleton dimensions
zeros	Create array of all zeros

Characters and Strings

See “String Functions” on page 1-63 for all string-related functions.

cellstr	Create cell array of strings from character array
char	Convert to character array (string)
eval	Execute string containing MATLAB expression
findstr	Find string within another, longer string

isstr	Determine whether input is character array
regexp, regexpi	Match regular expression
sprintf	Write formatted data to string
sscanf	Read formatted data from string
strcat	Concatenate strings horizontally
strcmp, strcmpi	Compare strings
strings	MATLAB string handling
strjust	Justify character array
strmatch	Find possible matches for string
strread	Read formatted data from string
strrep	Find and replace substring
strtrim	Remove leading and trailing white space from string
strvcat	Concatenate strings vertically

Structures

arrayfun	Apply function to each element of array
cell2struct	Convert cell array to structure array
class	Create object or return class of object
deal	Distribute inputs to outputs
fieldnames	Field names of structure, or public fields of object
getfield	Field of structure array
isa	Determine whether input is object of given class
isequal	Test arrays for equality

isfield	Determine whether input is structure array field
isscalar	Determine whether input is scalar
isstruct	Determine whether input is structure array
isvector	Determine whether input is vector
orderfields	Order fields of structure array
rmfield	Remove fields from structure
setfield	Set value of structure array field
struct	Create structure array
struct2cell	Convert structure to cell array
structfun	Apply function to each field of scalar structure

Cell Arrays

cell	Construct cell array
cell2mat	Convert cell array of matrices to single matrix
cell2struct	Convert cell array to structure array
celldisp	Cell array contents
cellfun	Apply function to each cell in cell array
cellplot	Graphically display structure of cell array
cellstr	Create cell array of strings from character array
class	Create object or return class of object
deal	Distribute inputs to outputs

isa	Determine whether input is object of given class
iscell	Determine whether input is cell array
iscellstr	Determine whether input is cell array of strings
isequal	Test arrays for equality
isscalar	Determine whether input is scalar
isvector	Determine whether input is vector
mat2cell	Divide matrix into cell array of matrices
num2cell	Convert numeric array to cell array
struct2cell	Convert structure to cell array

Function Handles

class	Create object or return class of object
feval	Evaluate function
func2str	Construct function name string from function handle
functions	Information about function handle
function_handle (@)	Handle used in calling functions indirectly
isa	Determine whether input is object of given class
isequal	Test arrays for equality
str2func	Construct function handle from function name string

MATLAB Classes and Objects

class	Create object or return class of object
fieldnames	Field names of structure, or public fields of object
inferiorto	Establish inferior class relationship
isa	Determine whether input is object of given class
isobject	Determine whether input is MATLAB OOPs object
loadobj	User-defined extension of `load` function for user objects
methods	Information on class methods
methodsview	Information on class methods in separate window
saveobj	User-defined extension of `save` function for user objects
subsasgn	Subscripted assignment for objects
subsindex	Subscripted indexing for objects
subsref	Subscripted reference for objects
substruct	Create structure argument for `subsasgn` or `subsref`
superiorto	Establish superior class relationship

Java Classes and Objects

cell	Construct cell array
class	Create object or return class of object
clear	Remove items from workspace, freeing up system memory
depfun	List dependencies of M-file or P-file

exist	Check existence of variable, function, directory, or Java class
fieldnames	Field names of structure, or public fields of object
im2java	Convert image to Java image
import	Add package or class to current Java import list
inmem	Names of M-files, MEX-files, Java classes in memory
isa	Determine whether input is object of given class
isjava	Determine whether input is Java object
javaaddpath	Add entries to dynamic Java class path
javaArray	Construct Java array
javachk	Generate error message based on Java feature support
javaclasspath	Set and get dynamic Java class path
javaMethod	Invoke Java method
javaObject	Construct Java object
javarmpath	Remove entries from dynamic Java class path
methods	Information on class methods
methodsview	Information on class methods in separate window
usejava	Determine whether Java feature is supported in MATLAB
which	Locate functions and files

Data Type Identification

is*	Detect state
isa	Determine whether input is object of given class
iscell	Determine whether input is cell array
iscellstr	Determine whether input is cell array of strings
ischar	Determine whether item is character array
isfield	Determine whether input is structure array field
isfloat	Determine whether input is floating-point array
isinteger	Determine whether input is integer array
isjava	Determine whether input is Java object
islogical	Determine whether input is logical array
isnumeric	Determine whether input is numeric array
isobject	Determine whether input is MATLAB OOPs object
isreal	Determine whether input is real array
isstr	Determine whether input is character array
isstruct	Determine whether input is structure array

validateattributes	Check validity of array
who, whos	List variables in workspace

Data Type Conversion

Numeric (p. 1-58)	Convert data of one numeric type to another numeric type
String to Numeric (p. 1-58)	Convert characters to numeric equivalent
Numeric to String (p. 1-59)	Convert numeric to character equivalent
Other Conversions (p. 1-59)	Convert to structure, cell array, function handle, etc.

Numeric

cast	Cast variable to different data type
double	Convert to double precision
int8, int16, int32, int64	Convert to signed integer
single	Convert to single precision
typecast	Convert data types without changing underlying data
uint8, uint16, uint32, uint64	Convert to unsigned integer

String to Numeric

base2dec	Convert base N number string to decimal number
bin2dec	Convert binary number string to decimal number
cast	Cast variable to different data type

hex2dec	Convert hexadecimal number string to decimal number
hex2num	Convert hexadecimal number string to double-precision number
str2double	Convert string to double-precision value
str2num	Convert string to number
unicode2native	Convert Unicode characters to numeric bytes

Numeric to String

cast	Cast variable to different data type
char	Convert to character array (string)
dec2base	Convert decimal to base N number in string
dec2bin	Convert decimal to binary number in string
dec2hex	Convert decimal to hexadecimal number in string
int2str	Convert integer to string
mat2str	Convert matrix to string
native2unicode	Convert numeric bytes to Unicode characters
num2str	Convert number to string

Other Conversions

cell2mat	Convert cell array of matrices to single matrix
cell2struct	Convert cell array to structure array

datestr	Convert date and time to string format
func2str	Construct function name string from function handle
logical	Convert numeric values to logical
mat2cell	Divide matrix into cell array of matrices
num2cell	Convert numeric array to cell array
num2hex	Convert singles and doubles to IEEE hexadecimal strings
str2func	Construct function handle from function name string
str2mat	Form blank-padded character matrix from strings
struct2cell	Convert structure to cell array

Operators and Special Characters

Arithmetic Operators (p. 1-60)	Plus, minus, power, left and right divide, transpose, etc.
Relational Operators (p. 1-61)	Equal to, greater than, less than or equal to, etc.
Logical Operators (p. 1-61)	Element-wise and short circuit and, or, not
Special Characters (p. 1-62)	Array constructors, line continuation, comments, etc.

Arithmetic Operators

+	Plus
-	Minus

.	Decimal point
=	Assignment
*	Matrix multiplication
/	Matrix right division
\	Matrix left division
^	Matrix power
'	Matrix transpose
.*	Array multiplication (element-wise)
./	Array right division (element-wise)
.\	Array left division (element-wise)
.^	Array power (element-wise)
.'	Array transpose

Relational Operators

<	Less than
<=	Less than or equal to
>	Greater than
>=	Greater than or equal to
==	Equal to
~=	Not equal to

Logical Operators

See also "Logical Functions" on page 1-66 for functions like `xor`, `all`, `any`, etc.

&&	Logical AND
||	Logical OR
&	Logical AND for arrays

|	Logical OR for arrays
~	Logical NOT

Special Characters

:	Create vectors, subscript arrays, specify for-loop iterations
( )	Pass function arguments, prioritize operators
[ ]	Construct array, concatenate elements, specify multiple outputs from function
{ }	Construct cell array, index into cell array
.	Insert decimal point, define structure field, reference methods of object
.( )	Reference dynamic field of structure
..	Reference parent directory
...	Continue statement to next line
,	Separate rows of array, separate function input/output arguments, separate commands
;	Separate columns of array, suppress output from current command
%	Insert comment line into code
%{ %}	Insert block of comments into code
!	Issue command to operating system
' '	Construct character array
@	Construct function handle, reference class directory

String Functions

Description of Strings in MATLAB

strings	MATLAB string handling

String Creation

blanks	Create string of blank characters
cellstr	Create cell array of strings from character array
char	Convert to character array (string)
sprintf	Write formatted data to string
strcat	Concatenate strings horizontally
strvcat	Concatenate strings vertically

String Identification

class	Create object or return class of object
isa	Determine whether input is object of given class
iscellstr	Determine whether input is cell array of strings
ischar	Determine whether item is character array
isletter	Array elements that are alphabetic letters
isscalar	Determine whether input is scalar
isspace	Array elements that are space characters
isstrprop	Determine whether string is of specified category
isvector	Determine whether input is vector
validatestring	Check validity of text string

String Manipulation

deblank	Strip trailing blanks from end of string
lower	Convert string to lowercase
strjust	Justify character array
strrep	Find and replace substring
strtrim	Remove leading and trailing white space from string
upper	Convert string to uppercase

String Parsing

findstr	Find string within another, longer string
regexp, regexpi	Match regular expression
regexprep	Replace string using regular expression
regexptranslate	Translate string into regular expression
sscanf	Read formatted data from string
strfind	Find one string within another
strread	Read formatted data from string
strtok	Selected parts of string

String Evaluation

eval	Execute string containing MATLAB expression
evalc	Evaluate MATLAB expression with capture
evalin	Execute MATLAB expression in specified workspace

String Comparison

strcmp, strcmpi	Compare strings
strmatch	Find possible matches for string
strncmp, strncmpi	Compare first n characters of strings

Bit-wise Functions

bitand	Bitwise AND
bitcmp	Bitwise complement
bitget	Bit at specified position
bitmax	Maximum double-precision floating-point integer
bitor	Bitwise OR
bitset	Set bit at specified position
bitshift	Shift bits specified number of places
bitxor	Bitwise XOR
swapbytes	Swap byte ordering

Logical Functions

all	Determine whether all array elements are nonzero
and	Find logical AND of array or scalar inputs
any	Determine whether any array elements are nonzero
false	Logical 0 (false)
find	Find indices and values of nonzero elements
isa	Determine whether input is object of given class
iskeyword	Determine whether input is MATLAB keyword
isvarname	Determine whether input is valid variable name
logical	Convert numeric values to logical

not	Find logical NOT of array or scalar input
or	Find logical OR of array or scalar inputs
true	Logical 1 (true)
xor	Logical exclusive-OR

See “Operators and Special Characters” on page 1-60 for logical operators.

Relational Functions

eq	Test for equality
ge	Test for greater than or equal to
gt	Test for greater than
le	Test for less than or equal to
lt	Test for less than
ne	Test for inequality

See “Operators and Special Characters” on page 1-60 for relational operators.

Set Functions

intersect	Find set intersection of two vectors
ismember	Array elements that are members of set
issorted	Determine whether set elements are in sorted order
setdiff	Find set difference of two vectors
setxor	Find set exclusive OR of two vectors
union	Find set union of two vectors
unique	Find unique elements of vector

Date and Time Functions

addtodate	Modify date number by field
calendar	Calendar for specified month
clock	Current time as date vector
cputime	Elapsed CPU time
date	Current date string
datenum	Convert date and time to serial date number
datestr	Convert date and time to string format
datevec	Convert date and time to vector of components
eomday	Last day of month
etime	Time elapsed between date vectors
now	Current date and time
weekday	Day of week

Programming in MATLAB

M-File Functions and Scripts (p. 1-69)	Declare functions, handle arguments, identify dependencies, etc.
Evaluation of Expressions and Functions (p. 1-70)	Evaluate expression in string, apply function to array, run script file, etc.
Timer Functions (p. 1-71)	Schedule execution of MATLAB commands
Variables and Functions in Memory (p. 1-72)	List files in memory, clear M-files in memory, assign to variable in nondefault workspace, refresh caches

Control Flow (p. 1-73)	if-then-else, for loops, switch-case, try-catch
Error Handling (p. 1-74)	Generate warnings and errors, test for and catch errors, retrieve most recent error message
MEX Programming (p. 1-75)	Compile MEX function from C or Fortran code, list MEX-files in memory, debug MEX-files

M-File Functions and Scripts

addOptional (inputParser)	Add optional argument to `inputParser` schema
addParamValue (inputParser)	Add parameter-value argument to `inputParser` schema
addRequired (inputParser)	Add required argument to `inputParser` schema
createCopy (inputParser)	Create copy of `inputParser` object
depdir	List dependent directories of M-file or P-file
depfun	List dependencies of M-file or P-file
echo	Echo M-files during execution
end	Terminate block of code, or indicate last array index
function	Declare M-file function
input	Request user input
inputname	Variable name of function input
inputParser	Construct input parser object
mfilename	Name of currently running M-file
namelengthmax	Maximum identifier length
nargchk	Validate number of input arguments

nargin, nargout	Number of function arguments
nargoutchk	Validate number of output arguments
parse (inputParser)	Parse and validate named inputs
pcode	Create preparsed pseudocode file (P-file)
script	Script M-file description
syntax	Two ways to call MATLAB functions
varargin	Variable length input argument list
varargout	Variable length output argument list

Evaluation of Expressions and Functions

ans	Most recent answer
arrayfun	Apply function to each element of array
assert	Generate error when condition is violated
builtin	Execute built-in function from overloaded method
cellfun	Apply function to each cell in cell array
echo	Echo M-files during execution
eval	Execute string containing MATLAB expression
evalc	Evaluate MATLAB expression with capture
evalin	Execute MATLAB expression in specified workspace
feval	Evaluate function

iskeyword	Determine whether input is MATLAB keyword
isvarname	Determine whether input is valid variable name
pause	Halt execution temporarily
run	Run script that is not on current path
script	Script M-file description
structfun	Apply function to each field of scalar structure
symvar	Determine symbolic variables in expression
tic, toc	Measure performance using stopwatch timer

Timer Functions

delete (timer)	Remove timer object from memory
disp (timer)	Information about timer object
get (timer)	Timer object properties
isvalid (timer)	Determine whether timer object is valid
set (timer)	Configure or display timer object properties
start	Start timer(s) running
startat	Start timer(s) running at specified time
stop	Stop timer(s)
timer	Construct timer object
timerfind	Find timer objects

timerfindall	Find timer objects, including invisible objects
wait	Wait until timer stops running

Variables and Functions in Memory

ans	Most recent answer
assignin	Assign value to variable in specified workspace
datatipinfo	Produce short description of input variable
genvarname	Construct valid variable name from string
global	Declare global variables
inmem	Names of M-files, MEX-files, Java classes in memory
isglobal	Determine whether input is global variable
mislocked	Determine whether M-file or MEX-file cannot be cleared from memory
mlock	Prevent clearing M-file or MEX-file from memory
munlock	Allow clearing M-file or MEX-file from memory
namelengthmax	Maximum identifier length
pack	Consolidate workspace memory
persistent	Define persistent variable
rehash	Refresh function and file system path caches

Control Flow

break	Terminate execution of `for` or `while` loop
case	Execute block of code if condition is `true`
catch	Specify how to respond to error in `try` statement
continue	Pass control to next iteration of `for` or `while` loop
else	Execute statements if condition is false
elseif	Execute statements if additional condition is true
end	Terminate block of code, or indicate last array index
error	Display message and abort function
for	Execute block of code specified number of times
if	Execute statements if condition is true
otherwise	Default part of switch statement
return	Return to invoking function
switch	Switch among several cases, based on expression
try	Attempt to execute block of code, and catch errors
while	Repeatedly execute statements while condition is true

Error Handling

addCause (MException)	Append `MException` objects
assert	Generate error when condition is violated
catch	Specify how to respond to error in `try` statement
disp (MException)	Display `MException` object
eq (MException)	Compare `MException` objects for equality
error	Display message and abort function
ferror	Query MATLAB about errors in file input or output
getReport (MException)	Get error message for exception
intwarning	Control state of integer warnings
isequal (MException)	Compare `MException` objects for equality
last (MException)	Last uncaught exception
lasterr	Last error message
lasterror	Last error message and related information
lastwarn	Last warning message
MException	Construct `MException` object
ne (MException)	Compare `MException` objects for inequality
rethrow	Reissue error
rethrow (MException)	Reissue existing exception
throw (MException)	Terminate function and issue exception

try	Attempt to execute block of code, and catch errors
warning	Warning message

MEX Programming

dbmex	Enable MEX-file debugging
inmem	Names of M-files, MEX-files, Java classes in memory
mex	Compile MEX-function from C, C++, or Fortran source code
mexext	MEX-filename extension

File I/O

File Name Construction (p. 1-76)	Get path, directory, filename information; construct filenames
Opening, Loading, Saving Files (p. 1-77)	Open files; transfer data between files and MATLAB workspace
Memory Mapping (p. 1-77)	Access file data via memory map using MATLAB array indexing
Low-Level File I/O (p. 1-77)	Low-level operations that use a file identifier
Text Files (p. 1-78)	Delimited or formatted I/O to text files
XML Documents (p. 1-79)	Documents written in Extensible Markup Language
Spreadsheets (p. 1-79)	Excel and Lotus 1-2-3 files
Scientific Data (p. 1-80)	CDF, FITS, HDF formats
Audio and Audio/Video (p. 1-81)	General audio functions; SparcStation, WAVE, AVI files
Images (p. 1-83)	Graphics files
Internet Exchange (p. 1-84)	URL, FTP, zip, tar, and e-mail

To see a listing of file formats that are readable from MATLAB, go to file formats.

File Name Construction

filemarker	Character to separate file name and internal function name
fileparts	Parts of file name and path
filesep	Directory separator for current platform
fullfile	Build full filename from parts

tempdir	Name of system's temporary directory
tempname	Unique name for temporary file

Opening, Loading, Saving Files

daqread	Read Data Acquisition Toolbox (.daq) file
filehandle	Construct file handle object
importdata	Load data from disk file
load	Load workspace variables from disk
open	Open files based on extension
save	Save workspace variables to disk
uiimport	Open Import Wizard to import data
winopen	Open file in appropriate application (Windows)

Memory Mapping

disp (memmapfile)	Information about memmapfile object
get (memmapfile)	Memmapfile object properties
memmapfile	Construct memmapfile object

Low-Level File I/O

fclose	Close one or more open files
feof	Test for end-of-file
ferror	Query MATLAB about errors in file input or output

fgetl	Read line from file, discarding newline character
fgets	Read line from file, keeping newline character
fopen	Open file, or obtain information about open files
fprintf	Write formatted data to file
fread	Read binary data from file
frewind	Move file position indicator to beginning of open file
fscanf	Read formatted data from file
fseek	Set file position indicator
ftell	File position indicator
fwrite	Write binary data to file

Text Files

csvread	Read comma-separated value file
csvwrite	Write comma-separated value file
dlmread	Read ASCII-delimited file of numeric data into matrix
dlmwrite	Write matrix to ASCII-delimited file
textread	Read data from text file; write to multiple outputs
textscan	Read formatted data from text file or string

XML Documents

xmlread	Parse XML document and return Document Object Model node
xmlwrite	Serialize XML Document Object Model node
xslt	Transform XML document using XSLT engine

Spreadsheets

Microsoft Excel Functions (p. 1-79)	Read and write Microsoft Excel spreadsheet
Lotus 1-2-3 Functions (p. 1-79)	Read and write Lotus WK1 spreadsheet

Microsoft Excel Functions

xlsfinfo	Determine whether file contains Microsoft Excel (`.xls`) spreadsheet
xlsread	Read Microsoft Excel spreadsheet file (`.xls`)
xlswrite	Write Microsoft Excel spreadsheet file (`.xls`)

Lotus 1-2-3 Functions

wk1finfo	Determine whether file contains 1-2-3 WK1 worksheet
wk1read	Read Lotus 1-2-3 WK1 spreadsheet file into matrix
wk1write	Write matrix to Lotus 1-2-3 WK1 spreadsheet file

Scientific Data

Common Data Format (CDF) (p. 1-80)	Work with CDF files
Flexible Image Transport System (p. 1-80)	Work with FITS files
Hierarchical Data Format (HDF) (p. 1-81)	Work with HDF files
Band-Interleaved Data (p. 1-81)	Work with band-interleaved files

Common Data Format (CDF)

cdfepoch	Construct `cdfepoch` object for Common Data Format (CDF) export
cdfinfo	Information about Common Data Format (CDF) file
cdfread	Read data from Common Data Format (CDF) file
cdfwrite	Write data to Common Data Format (CDF) file
todatenum	Convert CDF epoch object to MATLAB datenum

Flexible Image Transport System

fitsinfo	Information about FITS file
fitsread	Read data from FITS file

Hierarchical Data Format (HDF)

hdf	Summary of MATLAB HDF4 capabilities
hdf5	Summary of MATLAB HDF5 capabilities
hdf5info	Information about HDF5 file
hdf5read	Read HDF5 file
hdf5write	Write data to file in HDF5 format
hdfinfo	Information about HDF4 or HDF-EOS file
hdfread	Read data from HDF4 or HDF-EOS file
hdftool	Browse and import data from HDF4 or HDF-EOS files

Band-Interleaved Data

multibandread	Read band-interleaved data from binary file
multibandwrite	Write band-interleaved data to file

Audio and Audio/Video

General (p. 1-82)	Create audio player object, obtain information about multimedia files, convert to/from audio signal
SPARCstation-Specific Sound Functions (p. 1-82)	Access NeXT/SUN (`.au`) sound files

Microsoft WAVE Sound Functions (p. 1-83)	Access Microsoft WAVE (`.wav`) sound files
Audio/Video Interleaved (AVI) Functions (p. 1-83)	Access Audio/Video interleaved (`.avi`) sound files

General

audioplayer	Create audio player object
audiorecorder	Create audio recorder object
beep	Produce beep sound
lin2mu	Convert linear audio signal to mu-law
mmfileinfo	Information about multimedia file
mmreader	Create multimedia reader object for reading video files
mu2lin	Convert mu-law audio signal to linear
read	Read video frame data from multimedia reader object
sound	Convert vector into sound
soundsc	Scale data and play as sound

SPARCstation-Specific Sound Functions

aufinfo	Information about NeXT/SUN (`.au`) sound file
auread	Read NeXT/SUN (`.au`) sound file
auwrite	Write NeXT/SUN (`.au`) sound file

Microsoft WAVE Sound Functions

wavfinfo	Information about Microsoft WAVE (`.wav`) sound file
wavplay	Play recorded sound on PC-based audio output device
wavread	Read Microsoft WAVE (`.wav`) sound file
wavrecord	Record sound using PC-based audio input device
wavwrite	Write Microsoft WAVE (`.wav`) sound file

Audio/Video Interleaved (AVI) Functions

addframe	Add frame to Audio/Video Interleaved (AVI) file
avifile	Create new Audio/Video Interleaved (AVI) file
aviinfo	Information about Audio/Video Interleaved (AVI) file
aviread	Read Audio/Video Interleaved (AVI) file
close (avifile)	Close Audio/Video Interleaved (AVI) file
movie2avi	Create Audio/Video Interleaved (AVI) movie from MATLAB movie

Images

exifread	Read EXIF information from JPEG and TIFF image files
im2java	Convert image to Java image

imfinfo	Information about graphics file
imread	Read image from graphics file
imwrite	Write image to graphics file

Internet Exchange

URL, Zip, Tar, E-Mail (p. 1-84)	Send e-mail, read from given URL, extract from tar or zip file, compress and decompress files
FTP Functions (p. 1-84)	Connect to FTP server, download from server, manage FTP files, close server connection

URL, Zip, Tar, E-Mail

gunzip	Uncompress GNU zip files
gzip	Compress files into GNU zip files
sendmail	Send e-mail message to address list
tar	Compress files into tar file
untar	Extract contents of tar file
unzip	Extract contents of zip file
urlread	Read content at URL
urlwrite	Save contents of URL to file
zip	Compress files into zip file

FTP Functions

ascii	Set FTP transfer type to ASCII
binary	Set FTP transfer type to binary

cd (ftp)	Change current directory on FTP server
close (ftp)	Close connection to FTP server
delete (ftp)	Remove file on FTP server
dir (ftp)	Directory contents on FTP server
ftp	Connect to FTP server, creating FTP object
mget	Download file from FTP server
mkdir (ftp)	Create new directory on FTP server
mput	Upload file or directory to FTP server
rename	Rename file on FTP server
rmdir (ftp)	Remove directory on FTP server

Graphics

Basic Plots and Graphs (p. 1-86)	Linear line plots, log and semilog plots
Plotting Tools (p. 1-87)	GUIs for interacting with plots
Annotating Plots (p. 1-87)	Functions for and properties of titles, axes labels, legends, mathematical symbols
Specialized Plotting (p. 1-88)	Bar graphs, histograms, pie charts, contour plots, function plotters
Bit-Mapped Images (p. 1-92)	Display image object, read and write graphics file, convert to movie frames
Printing (p. 1-92)	Printing and exporting figures to standard formats
Handle Graphics (p. 1-93)	Creating graphics objects, setting properties, finding handles

Basic Plots and Graphs

box	Axes border
errorbar	Plot error bars along curve
hold	Retain current graph in figure
LineSpec	Line specification string syntax
loglog	Log-log scale plot
plot	2-D line plot
plot3	3-D line plot
plotyy	2-D line plots with y-axes on both left and right side
polar	Polar coordinate plot

semilogx, semilogy	Semilogarithmic plots
subplot	Create axes in tiled positions

Plotting Tools

figurepalette	Show or hide figure palette
pan	Pan view of graph interactively
plotbrowser	Show or hide figure plot browser
plotedit	Interactively edit and annotate plots
plottools	Show or hide plot tools
propertyeditor	Show or hide property editor
rotate3d	Rotate 3-D view using mouse
showplottool	Show or hide figure plot tool
zoom	Turn zooming on or off or magnify by factor

Annotating Plots

annotation	Create annotation objects
clabel	Contour plot elevation labels
datacursormode	Enable or disable interactive data cursor mode
datetick	Date formatted tick labels
gtext	Mouse placement of text in 2-D view
legend	Graph legend for lines and patches
line	Create line object
rectangle	Create 2-D rectangle object
texlabel	Produce TeX format from character string

title	Add title to current axes
xlabel, ylabel, zlabel	Label *x*-, *y*-, and *z*-axis

Specialized Plotting

Area, Bar, and Pie Plots (p. 1-88)	1-D, 2-D, and 3-D graphs and charts
Contour Plots (p. 1-89)	Unfilled and filled contours in 2-D and 3-D
Direction and Velocity Plots (p. 1-89)	Comet, compass, feather and quiver plots
Discrete Data Plots (p. 1-89)	Stair, step, and stem plots
Function Plots (p. 1-89)	Easy-to-use plotting utilities for graphing functions
Histograms (p. 1-90)	Plots for showing distributions of data
Polygons and Surfaces (p. 1-90)	Functions to generate and plot surface patches in two or more dimensions
Scatter/Bubble Plots (p. 1-91)	Plots of point distributions
Animation (p. 1-91)	Functions to create and play movies of plots

Area, Bar, and Pie Plots

area	Filled area 2-D plot
bar, barh	Plot bar graph (vertical and horizontal)
bar3, bar3h	Plot 3-D bar chart
pareto	Pareto chart
pie	Pie chart
pie3	3-D pie chart

Contour Plots

contour	Contour plot of matrix
contour3	3-D contour plot
contourc	Low-level contour plot computation
contourf	Filled 2-D contour plot
ezcontour	Easy-to-use contour plotter
ezcontourf	Easy-to-use filled contour plotter

Direction and Velocity Plots

comet	2-D comet plot
comet3	3-D comet plot
compass	Plot arrows emanating from origin
feather	Plot velocity vectors
quiver	Quiver or velocity plot
quiver3	3-D quiver or velocity plot

Discrete Data Plots

stairs	Stairstep graph
stem	Plot discrete sequence data
stem3	Plot 3-D discrete sequence data

Function Plots

ezcontour	Easy-to-use contour plotter
ezcontourf	Easy-to-use filled contour plotter
ezmesh	Easy-to-use 3-D mesh plotter

ezmeshc	Easy-to-use combination mesh/contour plotter
ezplot	Easy-to-use function plotter
ezplot3	Easy-to-use 3-D parametric curve plotter
ezpolar	Easy-to-use polar coordinate plotter
ezsurf	Easy-to-use 3-D colored surface plotter
ezsurfc	Easy-to-use combination surface/contour plotter
fplot	Plot function between specified limits

Histograms

hist	Histogram plot
histc	Histogram count
rose	Angle histogram plot

Polygons and Surfaces

convhull	Convex hull
cylinder	Generate cylinder
delaunay	Delaunay triangulation
delaunay3	3-D Delaunay tessellation
delaunayn	N-D Delaunay tessellation
dsearch	Search Delaunay triangulation for nearest point
dsearchn	N-D nearest point search
ellipsoid	Generate ellipsoid

fill	Filled 2-D polygons
fill3	Filled 3-D polygons
inpolygon	Points inside polygonal region
pcolor	Pseudocolor (checkerboard) plot
polyarea	Area of polygon
rectint	Rectangle intersection area
ribbon	Ribbon plot
slice	Volumetric slice plot
sphere	Generate sphere
tsearch	Search for enclosing Delaunay triangle
tsearchn	N-D closest simplex search
voronoi	Voronoi diagram
waterfall	Waterfall plot

Scatter/Bubble Plots

plotmatrix	Scatter plot matrix
scatter	Scatter plot
scatter3	3-D scatter plot

Animation

frame2im	Convert movie frame to indexed image
getframe	Capture movie frame
im2frame	Convert image to movie frame

movie	Play recorded movie frames
noanimate	Change `EraseMode` of all objects to `normal`

Bit-Mapped Images

frame2im	Convert movie frame to indexed image
im2frame	Convert image to movie frame
im2java	Convert image to Java image
image	Display image object
imagesc	Scale data and display image object
imfinfo	Information about graphics file
imformats	Manage image file format registry
imread	Read image from graphics file
imwrite	Write image to graphics file
ind2rgb	Convert indexed image to RGB image

Printing

frameedit	Edit print frames for Simulink and Stateflow block diagrams
hgexport	Export figure
orient	Hardcopy paper orientation
print, printopt	Print figure or save to file and configure printer defaults
printdlg	Print dialog box

printpreview	Preview figure to print
saveas	Save figure or Simulink block diagram using specified format

Handle Graphics

Finding and Identifying Graphics Objects (p. 1-93)	Find and manipulate graphics objects via their handles
Object Creation Functions (p. 1-94)	Constructors for core graphics objects
Plot Objects (p. 1-94)	Property descriptions for plot objects
Figure Windows (p. 1-95)	Control and save figures
Axes Operations (p. 1-96)	Operate on axes objects
Operating on Object Properties (p. 1-96)	Query, set, and link object properties

Finding and Identifying Graphics Objects

allchild	Find all children of specified objects
ancestor	Ancestor of graphics object
copyobj	Copy graphics objects and their descendants
delete	Remove files or graphics objects
findall	Find all graphics objects
findfigs	Find visible offscreen figures
findobj	Locate graphics objects with specific properties
gca	Current axes handle
gcbf	Handle of figure containing object whose callback is executing

gcbo	Handle of object whose callback is executing
gco	Handle of current object
get	Query object properties
ishandle	Is object handle valid
propedit	Open Property Editor
set	Set object properties

Object Creation Functions

axes	Create axes graphics object
figure	Create figure graphics object
hggroup	Create hggroup object
hgtransform	Create hgtransform graphics object
image	Display image object
light	Create light object
line	Create line object
patch	Create patch graphics object
rectangle	Create 2-D rectangle object
root object	Root object properties
surface	Create surface object
text	Create text object in current axes
uicontextmenu	Create context menu

Plot Objects

Annotation Arrow Properties	Define annotation arrow properties
Annotation Doublearrow Properties	Define annotation doublearrow properties

Annotation Ellipse Properties	Define annotation ellipse properties
Annotation Line Properties	Define annotation line properties
Annotation Rectangle Properties	Define annotation rectangle properties
Annotation Textarrow Properties	Define annotation textarrow properties
Annotation Textbox Properties	Define annotation textbox properties
Areaseries Properties	Define areaseries properties
Barseries Properties	Define barseries properties
Contourgroup Properties	Define contourgroup properties
Errorbarseries Properties	Define errorbarseries properties
Image Properties	Define image properties
Lineseries Properties	Define lineseries properties
Quivergroup Properties	Define quivergroup properties
Scattergroup Properties	Define scattergroup properties
Stairseries Properties	Define stairseries properties
Stemseries Properties	Define stemseries properties
Surfaceplot Properties	Define surfaceplot properties

Figure Windows

clf	Clear current figure window
close	Remove specified figure
closereq	Default figure close request function
drawnow	Flushes event queue and updates figure window
gcf	Current figure handle
hgload	Load Handle Graphics object hierarchy from file

hgsave	Save Handle Graphics object hierarchy to file
newplot	Determine where to draw graphics objects
opengl	Control OpenGL rendering
refresh	Redraw current figure
saveas	Save figure or Simulink block diagram using specified format

Axes Operations

axis	Axis scaling and appearance
box	Axes border
cla	Clear current axes
gca	Current axes handle
grid	Grid lines for 2-D and 3-D plots
ishold	Current hold state
makehgtform	Create 4-by-4 transform matrix

Operating on Object Properties

get	Query object properties
linkaxes	Synchronize limits of specified 2-D axes
linkprop	Keep same value for corresponding properties
refreshdata	Refresh data in graph when data source is specified
set	Set object properties

3-D Visualization

Surface and Mesh Plots

Creating Surfaces and Meshes

hidden	Remove hidden lines from mesh plot
mesh, meshc, meshz	Mesh plots
peaks	Example function of two variables
surf, surfc	3-D shaded surface plot
surface	Create surface object
surfl	Surface plot with colormap-based lighting

tetramesh	Tetrahedron mesh plot
trimesh	Triangular mesh plot
triplot	2-D triangular plot
trisurf	Triangular surface plot

Domain Generation

griddata	Data gridding
meshgrid	Generate `X` and `Y` arrays for 3-D plots

Color Operations

brighten	Brighten or darken colormap
caxis	Color axis scaling
colorbar	Colorbar showing color scale
colordef	Set default property values to display different color schemes
colormap	Set and get current colormap
colormapeditor	Start colormap editor
ColorSpec	Color specification
graymon	Set default figure properties for grayscale monitors
hsv2rgb	Convert HSV colormap to RGB colormap
rgb2hsv	Convert RGB colormap to HSV colormap
rgbplot	Plot colormap
shading	Set color shading properties
spinmap	Spin colormap

surfnorm	Compute and display 3-D surface normals
whitebg	Change axes background color

Colormaps

contrast	Grayscale colormap for contrast enhancement

View Control

Controlling the Camera Viewpoint (p. 1-99)	Orbiting, dollying, pointing, rotating camera positions and setting fields of view
Setting the Aspect Ratio and Axis Limits (p. 1-100)	Specifying what portions of axes to view and how to scale them
Object Manipulation (p. 1-100)	Panning, rotating, and zooming views
Selecting Region of Interest (p. 1-101)	Interactively identifying rectangular regions

Controlling the Camera Viewpoint

camdolly	Move camera position and target
cameratoolbar	Control camera toolbar programmatically
camlookat	Position camera to view object or group of objects
camorbit	Rotate camera position around camera target
campan	Rotate camera target around camera position

campos	Set or query camera position
camproj	Set or query projection type
camroll	Rotate camera about view axis
camtarget	Set or query location of camera target
camup	Set or query camera up vector
camva	Set or query camera view angle
camzoom	Zoom in and out on scene
makehgtform	Create 4-by-4 transform matrix
view	Viewpoint specification
viewmtx	View transformation matrices

Setting the Aspect Ratio and Axis Limits

daspect	Set or query axes data aspect ratio
pbaspect	Set or query plot box aspect ratio
xlim, ylim, zlim	Set or query axis limits

Object Manipulation

pan	Pan view of graph interactively
reset	Reset graphics object properties to their defaults
rotate	Rotate object in specified direction
rotate3d	Rotate 3-D view using mouse
selectmoveresize	Select, move, resize, or copy axes and uicontrol graphics objects
zoom	Turn zooming on or off or magnify by factor

Selecting Region of Interest

dragrect	Drag rectangles with mouse
rbbox	Create rubberband box for area selection

Lighting

camlight	Create or move light object in camera coordinates
diffuse	Calculate diffuse reflectance
light	Create light object
lightangle	Create or position `light` object in spherical coordinates
lighting	Specify lighting algorithm
material	Control reflectance properties of surfaces and patches
specular	Calculate specular reflectance

Transparency

alim	Set or query axes alpha limits
alpha	Set transparency properties for objects in current axes
alphamap	Specify figure alphamap (transparency)

Volume Visualization

coneplot	Plot velocity vectors as cones in 3-D vector field
contourslice	Draw contours in volume slice planes
curl	Compute curl and angular velocity of vector field
divergence	Compute divergence of vector field
flow	Simple function of three variables
interpstreamspeed	Interpolate stream-line vertices from flow speed
isocaps	Compute isosurface end-cap geometry
isocolors	Calculate isosurface and patch colors
isonormals	Compute normals of isosurface vertices
isosurface	Extract isosurface data from volume data
reducepatch	Reduce number of patch faces
reducevolume	Reduce number of elements in volume data set
shrinkfaces	Reduce size of patch faces
slice	Volumetric slice plot
smooth3	Smooth 3-D data
stream2	Compute 2-D streamline data
stream3	Compute 3-D streamline data
streamline	Plot streamlines from 2-D or 3-D vector data
streamparticles	Plot stream particles
streamribbon	3-D stream ribbon plot from vector volume data

streamslice	Plot streamlines in slice planes
streamtube	Create 3-D stream tube plot
subvolume	Extract subset of volume data set
surf2patch	Convert surface data to patch data
volumebounds	Coordinate and color limits for volume data

Creating Graphical User Interfaces

Predefined Dialog Boxes

dialog	Create and display dialog box
errordlg	Create and open error dialog box
export2wsdlg	Export variables to workspace
helpdlg	Create and open help dialog box
inputdlg	Create and open input dialog box
listdlg	Create and open list-selection dialog box
msgbox	Create and open message box
printdlg	Print dialog box
printpreview	Preview figure to print
questdlg	Create and open question dialog box
uigetdir	Open standard dialog box for selecting a directory

uigetfile	Open standard dialog box for retrieving files
uigetpref	Open dialog box for retrieving preferences
uiopen	Open file selection dialog box with appropriate file filters
uiputfile	Open standard dialog box for saving files
uisave	Open standard dialog box for saving workspace variables
uisetcolor	Open standard dialog box for setting object's `ColorSpec`
uisetfont	Open standard dialog box for setting object's font characteristics
waitbar	Open waitbar
warndlg	Open warning dialog box

Deploying User Interfaces

guidata	Store or retrieve GUI data
guihandles	Create structure of handles
movegui	Move GUI figure to specified location on screen
openfig	Open new copy or raise existing copy of saved figure

Developing User Interfaces

addpref	Add preference
getappdata	Value of application-defined data
getpref	Preference

ginput	Graphical input from mouse or cursor
guidata	Store or retrieve GUI data
guide	Open GUI Layout Editor
inspect	Open Property Inspector
isappdata	True if application-defined data exists
ispref	Test for existence of preference
rmappdata	Remove application-defined data
rmpref	Remove preference
setappdata	Specify application-defined data
setpref	Set preference
uigetpref	Open dialog box for retrieving preferences
uisetpref	Manage preferences used in `uigetpref`
waitfor	Wait for condition before resuming execution
waitforbuttonpress	Wait for key press or mouse-button click

User Interface Objects

menu	Generate menu of choices for user input
uibuttongroup	Create container object to exclusively manage radio buttons and toggle buttons
uicontextmenu	Create context menu
uicontrol	Create user interface control object

uimenu	Create menus on figure windows
uipanel	Create panel container object
uipushtool	Create push button on toolbar
uitoggletool	Create toggle button on toolbar
uitoolbar	Create toolbar on figure

Finding Objects from Callbacks

findall	Find all graphics objects
findfigs	Find visible offscreen figures
findobj	Locate graphics objects with specific properties
gcbf	Handle of figure containing object whose callback is executing
gcbo	Handle of object whose callback is executing

GUI Utility Functions

align	Align user interface controls (uicontrols) and axes
getpixelposition	Get component position in pixels
listfonts	List available system fonts
selectmoveresize	Select, move, resize, or copy axes and uicontrol graphics objects
setpixelposition	Set component position in pixels
textwrap	Wrapped string matrix for given uicontrol
uistack	Reorder visual stacking order of objects

Controlling Program Execution

uiresume, uiwait	Control program execution

External Interfaces

Dynamic Link Libraries (p. 1-109)	Access functions stored in external shared library (.dll) files
Java (p. 1-110)	Work with objects constructed from Java API and third-party class packages
Component Object Model and ActiveX (p. 1-111)	Integrate COM components into your application
Web Services (p. 1-113)	Communicate between applications over a network using SOAP and WSDL
Serial Port Devices (p. 1-113)	Read and write to devices connected to your computer's serial port

See also MATLAB C and Fortran API Reference for functions you can use in external routines that interact with MATLAB programs and the data in MATLAB workspaces.

Dynamic Link Libraries

calllib	Call function in external library
libfunctions	Information on functions in external library
libfunctionsview	Create window displaying information on functions in external library
libisloaded	Determine whether external library is loaded
libpointer	Create pointer object for use with external libraries
libstruct	Construct structure as defined in external library

loadlibrary	Load external library into MATLAB
unloadlibrary	Unload external library from memory

Java

class	Create object or return class of object
fieldnames	Field names of structure, or public fields of object
import	Add package or class to current Java import list
inspect	Open Property Inspector
isa	Determine whether input is object of given class
isjava	Determine whether input is Java object
ismethod	Determine whether input is object method
isprop	Determine whether input is object property
javaaddpath	Add entries to dynamic Java class path
javaArray	Construct Java array
javachk	Generate error message based on Java feature support
javaclasspath	Set and get dynamic Java class path
javaMethod	Invoke Java method
javaObject	Construct Java object
javarmpath	Remove entries from dynamic Java class path
methods	Information on class methods

methodsview	Information on class methods in separate window
usejava	Determine whether Java feature is supported in MATLAB

Component Object Model and ActiveX

actxcontrol	Create ActiveX control in figure window
actxcontrollist	List all currently installed ActiveX controls
actxcontrolselect	Open GUI to create ActiveX control
actxGetRunningServer	Get handle to running instance of Automation server
actxserver	Create COM server
addproperty	Add custom property to object
class	Create object or return class of object
delete (COM)	Remove COM control or server
deleteproperty	Remove custom property from object
enableservice	Enable, disable, or report status of Automation server
eventlisteners	List of events attached to listeners
events	List of events control can trigger
Execute	Execute MATLAB command in server
Feval (COM)	Evaluate MATLAB function in server
fieldnames	Field names of structure, or public fields of object
get (COM)	Get property value from interface, or display properties

GetCharArray	Get character array from server
GetFullMatrix	Get matrix from server
GetVariable	Get data from variable in server workspace
GetWorkspaceData	Get data from server workspace
inspect	Open Property Inspector
interfaces	List custom interfaces to COM server
invoke	Invoke method on object or interface, or display methods
isa	Determine whether input is object of given class
iscom	Is input COM object
isevent	Is input event
isinterface	Is input COM interface
ismethod	Determine whether input is object method
isprop	Determine whether input is object property
load (COM)	Initialize control object from file
MaximizeCommandWindow	Open server window on Windows desktop
methods	Information on class methods
methodsview	Information on class methods in separate window
MinimizeCommandWindow	Minimize size of server window
move	Move or resize control in parent window
propedit (COM)	Open built-in property page for control
PutCharArray	Store character array in server

PutFullMatrix	Store matrix in server
PutWorkspaceData	Store data in server workspace
Quit (COM)	Terminate MATLAB server
registerevent	Register event handler with control's event
release	Release interface
save (COM)	Serialize control object to file
set (COM)	Set object or interface property to specified value
unregisterallevents	Unregister all events for control
unregisterevent	Unregister event handler with control's event

Web Services

callSoapService	Send SOAP message off to endpoint
createClassFromWsdl	Create MATLAB object based on WSDL file
createSoapMessage	Create SOAP message to send to server
parseSoapResponse	Convert response string from SOAP server into MATLAB data types

Serial Port Devices

clear (serial)	Remove serial port object from MATLAB workspace
delete (serial)	Remove serial port object from memory
disp (serial)	Serial port object summary information

fclose (serial)	Disconnect serial port object from device
fgetl (serial)	Read line of text from device and discard terminator
fgets (serial)	Read line of text from device and include terminator
fopen (serial)	Connect serial port object to device
fprintf (serial)	Write text to device
fread (serial)	Read binary data from device
fscanf (serial)	Read data from device, and format as text
fwrite (serial)	Write binary data to device
get (serial)	Serial port object properties
instrcallback	Event information when event occurs
instrfind	Read serial port objects from memory to MATLAB workspace
instrfindall	Find visible and hidden serial port objects
isvalid (serial)	Determine whether serial port objects are valid
length (serial)	Length of serial port object array
load (serial)	Load serial port objects and variables into MATLAB workspace
readasync	Read data asynchronously from device
record	Record data and event information to file
save (serial)	Save serial port objects and variables to MAT-file
serial	Create serial port object

serialbreak	Send break to device connected to serial port
set (serial)	Configure or display serial port object properties
size (serial)	Size of serial port object array
stopasync	Stop asynchronous read and write operations

factor

Purpose

Prime factors

Syntax

```
f = factor(n)
```

Description

`f = factor(n)` returns a row vector containing the prime factors of `n`.

Examples

```
f = factor(123)
f =
     3    41
```

See Also

`isprime`, `primes`

Purpose

Factorial function

Syntax

```
factorial(N)
```

Description

`factorial(N)`, for scalar `N`, is the product of all the integers from `1` to `N`, i.e. `prod(1:n)`. When `N` is an `N`-dimensional array, `factorial(N)` is the factorial for each element of `N`.

Since double precision numbers only have about 15 digits, the answer is only accurate for `n <= 21`. For larger `n`, the answer will have the right magnitude, and is accurate for the first 15 digits.

See Also

`prod`

false

Purpose

Logical 0 (false)

Syntax

```
false
false(n)
false(m, n)
false(m, n, p, ...)
false(size(A))
```

Description

`false` is shorthand for `logical(0)`.

`false(n)` is an `n`-by-`n` matrix of logical zeros.

`false(m, n)` or `false([m, n])` is an `m`-by-`n` matrix of logical zeros.

`false(m, n, p, ...)` or `false([m n p ...])` is an `m`-by-`n`-by-`p`-by-`...` array of logical zeros.

Note The size inputs `m`, `n`, `p`, `...` should be nonnegative integers. Negative integers are treated as 0.

`false(size(A))` is an array of logical zeros that is the same size as array `A`.

Remarks

`false(n)` is much faster and more memory efficient than `logical(zeros(n))`.

See Also

`true`, `logical`

Purpose

Close one or more open files

Syntax

```
status = fclose(fid)
status = fclose('all')
```

Description

`status = fclose(fid)` closes the specified file if it is open, returning `0` if successful and `-1` if unsuccessful. Argument `fid` is a file identifier associated with an open file. (See `fopen` for a complete description of `fid`).

If `fid` does not represent an open file, or if it is equal to 0, 1, or 2, then `fclose` throws an error.

`status = fclose('all')` closes all open files (except standard input, output, and error), returning `0` if successful and `-1` if unsuccessful.

See Also

`ferror`, `fopen`, `fprintf`, `fread`, `frewind`, `fscanf`, `fseek`, `ftell`, `fwrite`

fclose (serial)

Purpose

Disconnect serial port object from device

Syntax

```
fclose(obj)
```

Arguments

`obj`	A serial port object or an array of serial port objects.

Description

`fclose(obj)` disconnects `obj` from the device.

Remarks

If `obj` was successfully disconnected, then the `Status` property is configured to `closed` and the `RecordStatus` property is configured to `off`. You can reconnect `obj` to the device using the `fopen` function.

An error is returned if you issue `fclose` while data is being written asynchronously. In this case, you should abort the write operation with the `stopasync` function, or wait for the write operation to complete.

If you use the `help` command to display help for `fclose`, then you need to supply the pathname shown below.

```
help serial/fclose
```

Example

This example creates the serial port object `s`, connects `s` to the device, writes and reads text data, and then disconnects `s` from the device using `fclose`.

```
s = serial('COM1');
fopen(s)
fprintf(s, '*IDN?')
idn = fscanf(s);
fclose(s)
```

At this point, the device is available to be connected to a serial port object. If you no longer need `s`, you should remove from memory with the `delete` function, and remove it from the workspace with the `clear` command.

See Also

Functions

clear, delete, fopen, stopasync

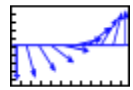
Properties

RecordStatus, Status

feather

Purpose

Plot velocity vectors



GUI Alternatives

Use the Plot Selector  to graph selected variables in the Workspace Browser and the Plot Catalog, accessed from the Figure Palette. Directly manipulate graphs in *plot edit* mode, and modify them using the Property Editor. For details, see "Working in Plot Edit Mode", and "The Figure Palette" in the MATLAB Graphics documentation, and also Creating Graphics from the Workspace Browser in the MATLAB Desktop documentation.

Syntax

```
feather(U,V)
feather(Z)
feather(...,LineSpec)
feather(axes_handle,...)
h = feather(...)
```

Description

A feather plot displays vectors emanating from equally spaced points along a horizontal axis. You express the vector components relative to the origin of the respective vector.

`feather(U,V)` displays the vectors specified by `U` and `V`, where `U` contains the x components as relative coordinates, and `V` contains the y components as relative coordinates.

`feather(Z)` displays the vectors specified by the complex numbers in `Z`. This is equivalent to `feather(real(Z),imag(Z))`.

`feather(...,LineSpec)` draws a feather plot using the line type, marker symbol, and color specified by `LineSpec`.

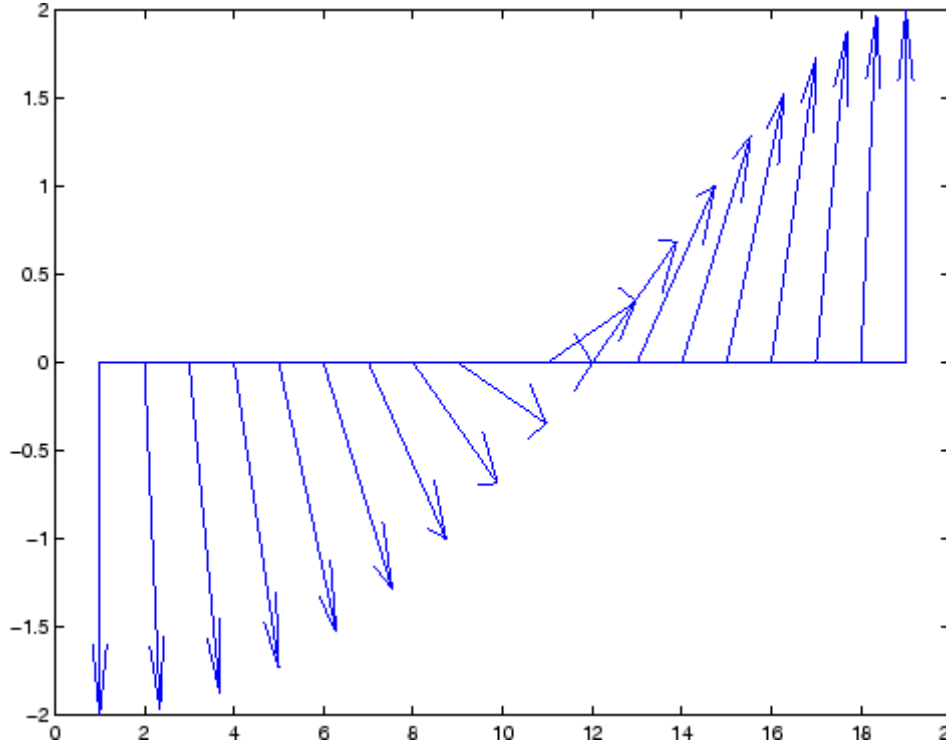
`feather(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = feather(...)` returns the handles to line objects in `h`.

Examples

Create a feather plot showing the direction of `theta`.

```
theta = (-90:10:90)*pi/180;
r = 2*ones(size(theta));
[u,v] = pol2cart(theta,r);
feather(u,v);
```



See Also

`compass`, `LineSpec`, `rose`

"Direction and Velocity Plots" on page 1-89 for related functions

feof

Purpose

Test for end-of-file

Syntax

```
eofstat = feof(fid)
```

Description

`eofstat = feof(fid)` returns `1` if the end-of-file indicator for the file `fid` has been set and `0` otherwise. (See `fopen` for a complete description of `fid`.)

The end-of-file indicator is set when there is no more input from the file.

See Also

`fopen`

Purpose

Query MATLAB about errors in file input or output

Syntax

```
message = ferror(fid)
message = ferror(fid, 'clear')
[message,errnum] = ferror(...)
```

Description

`message = ferror(fid)` returns the error string `message`. Argument `fid` is a file identifier associated with an open file (see `fopen` for a complete description of `fid`).

`message = ferror(fid, 'clear')` clears the error indicator for the specified file.

`[message,errnum] = ferror(...)` returns the error status number `errnum` of the most recent file I/O operation associated with the specified file.

If the most recent I/O operation performed on the specified file was successful, the value of `message` is empty and `ferror` returns an `errnum` value of `0`.

A nonzero `errnum` indicates that an error occurred in the most recent file I/O operation. The value of `message` is a string that can contain information about the nature of the error. If the message is not helpful, consult the C run-time library manual for your host operating system for further details.

feval

Purpose

Evaluate function

Syntax

```
[y1, y2, ...] = feval(fhandle, x1, ..., xn)
[y1, y2, ...] = feval(function, x1, ..., xn)
```

Description

`[y1, y2, ...] = feval(fhandle, x1, ..., xn)` evaluates the function handle, `fhandle`, using arguments `x1` through `xn`. If the function handle is bound to more than one built-in or M-file, (that is, it represents a set of overloaded functions), then the data type of the arguments `x1` through `xn` determines which function is dispatched to.

Note It is not necessary to use `feval` to call a function by means of a function handle. This is explained in "Calling a Function Using Its Handle" in the MATLAB Programming documentation.

`[y1, y2, ...] = feval(function, x1, ..., xn)`. If `function` is a quoted string containing the name of a function (usually defined by an M-file), then `feval(function, x1, ..., xn)` evaluates that function at the given arguments. The `function` parameter must be a simple function name; it cannot contain path information.

Remarks

The following two statements are equivalent.

```
[V,D] = eig(A)
[V,D] = feval(@eig, A)
```

Examples

The following example passes a function handle, `fhandle`, in a call to `fminbnd`. The `fhandle` argument is a handle to the `humps` function.

```
fhandle = @humps;
x = fminbnd(fhandle, 0.3, 1);
```

The `fminbnd` function uses `feval` to evaluate the function handle that was passed in.

```
function [xf, fval, exitflag, output] = ...
    fminbnd(funfcn, ax, bx, options, varargin)
            .
            .
            .
fx = feval(funfcn, x, varargin{:});
```

assignin, function_handle, functions, builtin, eval, evalin

Purpose

Evaluate MATLAB function in server

Syntax

MATLAB Client

```
result = h.Feval('functionname', numout, arg1, arg2, ...)
result = Feval(h, 'functionname', numout, arg1, arg2, ...)
result = invoke(h, 'Feval', 'functionname', numout, ...
arg1, arg2, ...)
```

Method Signatures

```
HRESULT Feval([in] BSTR functionname, [in] long nargout,
[out] VARIANT* result, [in, optional] VARIANT arg1, arg2, ...)
```

Visual Basic Client

```
Feval(String functionname, long numout,
arg1, arg2, ...) As Object
```

Description

`Feval` executes the MATLAB function specified by the string `functionname` in the Automation server attached to handle `h`.

Indicate the number of outputs to be returned by the function in a 1-by-1 `double` array, `numout`. The server returns output from the function in the cell array, `result`.

You can specify as many as 32 input arguments to be passed to the function. These arguments follow `numout` in the `Feval` argument list. There are four ways to pass an argument to the function being evaluated.

Passing Mechanism	Description
Pass the value itself	To pass any numeric or string value, specify the value in the `Feval` argument list: `a = h.Feval('sin', 1, -pi:0.01:pi);`

Passing Mechanism	Description

Pass a client variable	To pass an argument that is assigned to a variable in the client, specify the variable name alone:
	
	`x = -pi:0.01:pi;`
	`a = h.Feval('sin', 1, x);`

Reference a server variable	To reference a variable that is defined in the server, specify the variable name followed by an equals (=) sign:
	
	`h.PutWorkspaceData('x', 'base', -pi:0.01:pi);`
	`a = h.Feval('sin', 1, 'x=');`
	
	Note that the server variable is not reassigned.

Remarks

If you want output from `Feval` to be displayed at the client window, you must assign a returned value.

Server function names, like `Feval`, are case sensitive when using the first two syntaxes shown in the Syntax section.

There is no difference in the operation of the three syntaxes shown above for the MATLAB client.

Examples

Passing Arguments — MATLAB Client

This section contains a number of examples showing how to use `Feval` to execute MATLAB commands on a MATLAB Automation server.

- Concatenate two strings in the server by passing the input strings in a call to `strcat` through `Feval` (`strcat` deletes trailing spaces; use leading spaces):

```
h = actxserver('matlab.application');
a = h.Feval('strcat', 1, 'hello', ' world')
a =
    'hello world'
```

- Perform the same concatenation, passing a string and a local variable `clistr` that contains the second string:

```
clistr = ' world';
a = h.Feval('strcat', 1, 'hello', clistr)
a =
    'hello world'
```

- This next example is different in that the variable `srvstr` is defined in the server, not the client. Putting an equals sign after a variable name (e.g., `srvstr=`) indicates that it a server variable, and that MATLAB should not expect the variable to be defined on the client:

```
% Define the variable srvstr on the server.
h.PutCharArray('srvstr', 'base', ' world')

% Pass the name of the server variable using 'name=' syntax
a = h.Feval('strcat', 1, 'hello', 'srvstr=')
a =
    'hello world'
```

Visual Basic .NET Client

Here are the same examples shown above, but written for a Visual Basic .NET client. These examples return the same strings as shown above.

- Pass the two strings to the MATLAB function `strcat` on the server:

```
Dim Matlab As Object
Dim out As Object
Matlab = CreateObject("matlab.application")
out = Matlab.Feval("strcat", 1, "hello", " world")
```

- Define `clistr` locally and pass this variable:

```
Dim clistr As String
clistr = " world"
out = Matlab.Feval("strcat", 1, "hello", clistr)
```

- Pass the name of a variable defined on the server:

```
Matlab.PutCharArray("srvstr", "base", " world")
out = Matlab.Feval("strcat", 1, "hello", "srvstr=")
```

Feval Return Values — MATLAB Client. `Feval` returns data from the evaluated function in a cell array. The cell array has one row for every return value. You can control how many values are returned using the second input argument to `Feval`, as shown in this example.

The second argument in the following example specifies that `Feval` return three outputs from the `fileparts` function. As is the case here, you can request fewer than the maximum number of return values for a function (`fileparts` can return up to four):

```
a = h.Feval('fileparts', 3, 'd:\work\ConsoleApp.cpp')
a =
    'd:\work'
    'ConsoleApp'
    '.cpp'
```

Convert the returned values from the cell array `a` to char arrays:

```
a{:}
ans =
d:\work

ans =
ConsoleApp

ans =
.cpp
```

Feval Return Values — Visual Basic .NET Client

Here is the same example, but coded in Visual Basic. Define the argument returned by `Feval` as an `Object`.

```
Dim Matlab As Object
Dim out As Object
```

```
Matlab = CreateObject("matlab.application")
out = Matlab.Feval("fileparts", 3, "d:\work\ConsoleApp.cpp")
```

Purpose

Discrete Fourier transform

Syntax

```
Y = fft(X)
Y = fft(X,n)
Y = fft(X,[],dim)
Y = fft(X,n,dim)
```

Definition

The functions `X = fft(x)` and `x = ifft(X)` implement the transform and inverse transform pair given for vectors of length N by:

$$X(k) = \sum_{j=1}^{N} x(j)\omega_N^{(j-1)(k-1)}$$

$$x(j) = (1/N)\sum_{k=1}^{N} X(k)\omega_N^{-(j-1)(k-1)}$$

where

$$\omega_N = e^{(-2\pi i)/N}$$

is an Nth root of unity.

Description

`Y = fft(X)` returns the discrete Fourier transform (DFT) of vector `X`, computed with a fast Fourier transform (FFT) algorithm.

If `X` is a matrix, `fft` returns the Fourier transform of each column of the matrix.

If `X` is a multidimensional array, `fft` operates on the first nonsingleton dimension.

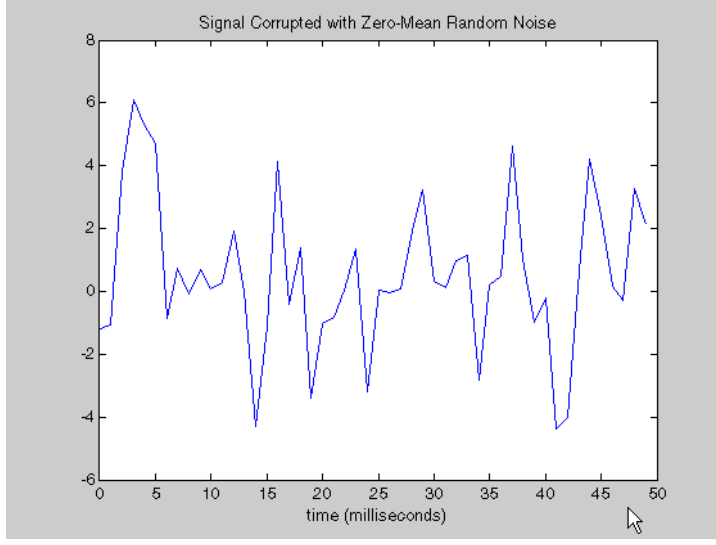
`Y = fft(X,n)` returns the `n`-point DFT. If the length of `X` is less than `n`, `X` is padded with trailing zeros to length `n`. If the length of `X` is greater than `n`, the sequence `X` is truncated. When `X` is a matrix, the length of the columns are adjusted in the same manner.

`Y = fft(X,[],dim)` and `Y = fft(X,n,dim)` applies the FFT operation across the dimension `dim`.

Examples

A common use of Fourier transforms is to find the frequency components of a signal buried in a noisy time domain signal. Consider data sampled at 1000 Hz. Form a signal containing a 50 Hz sinusoid of amplitude 0.7 and 120 Hz sinusoid of amplitude 1 and corrupt it with some zero-mean random noise:

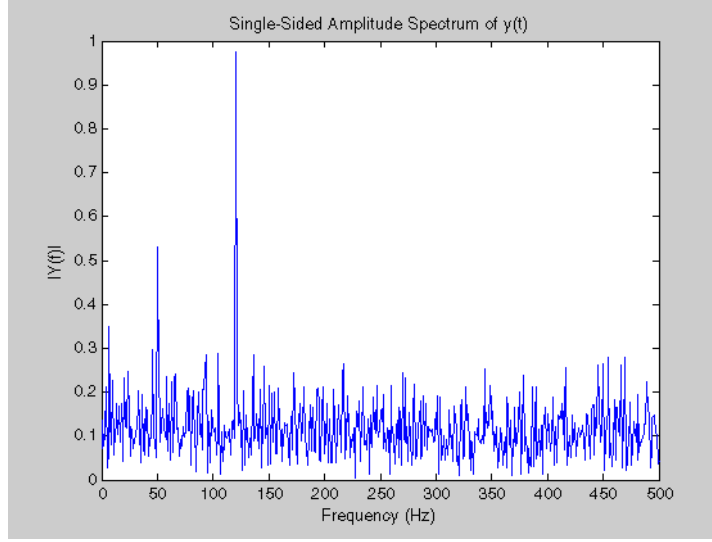
```
Fs = 1000;                    % Sampling frequency
T = 1/Fs;                     % Sample time
L = 1000;                     % Length of signal
t = (0:L-1)*T;                % Time vector
% Sum of a 50 Hz sinusoid and a 120 Hz sinusoid
x = 0.7*sin(2*pi*50*t) + sin(2*pi*120*t);
y = x + 2*randn(size(t));     % Sinusoids plus noise
plot(Fs*t(1:50),y(1:50))
title('Signal Corrupted with Zero-Mean Random Noise')
xlabel('time (milliseconds)')
```



It is difficult to identify the frequency components by looking at the original signal. Converting to the frequency domain, the discrete Fourier transform of the noisy signal y is found by taking the fast Fourier transform (FFT):

```
NFFT = 2^nextpow2(L); % Next power of 2 from length of y
Y = fft(y,NFFT)/L;
f = Fs/2*linspace(0,1,NFFT/2);

% Plot single-sided amplitude spectrum.
plot(f,2*abs(Y(1:NFFT/2)))
title('Single-Sided Amplitude Spectrum of y(t)')
xlabel('Frequency (Hz)')
ylabel('|Y(f)|')
```



The main reason the amplitudes are not exactly at 0.7 and 1 is because of the noise. Several executions of this code (including recomputation of y) will produce different approximations to 0.7 and 1. The other reason is that you have a finite length signal. Increasing L from 1000 to

10000 in the example above will produce much better approximations on average.

Algorithm

The FFT functions (`fft`, `fft2`, `fftn`, `ifft`, `ifft2`, `ifftn`) are based on a library called FFTW [3],[4]. To compute an N-point DFT when N is composite (that is, when $N = N_1 N_2$), the FFTW library decomposes the problem using the Cooley-Tukey algorithm [1], which first computes N_1 transforms of size N_2, and then computes N_2 transforms of size N_1. The decomposition is applied recursively to both the N_1- and N_2-point DFTs until the problem can be solved using one of several machine-generated fixed-size "codelets." The codelets in turn use several algorithms in combination, including a variation of Cooley-Tukey [5], a prime factor algorithm [6], and a split-radix algorithm [2]. The particular factorization of N is chosen heuristically.

When N is a prime number, the FFTW library first decomposes an N-point problem into three $(N-1)$-point problems using Rader's algorithm [7]. It then uses the Cooley-Tukey decomposition described above to compute the $(N-1)$-point DFTs.

For most N, real-input DFTs require roughly half the computation time of complex-input DFTs. However, when N has large prime factors, there is little or no speed difference.

The execution time for `fft` depends on the length of the transform. It is fastest for powers of two. It is almost as fast for lengths that have only small prime factors. It is typically several times slower for lengths that are prime or which have large prime factors.

Note You might be able to increase the speed of `fft` using the utility function `fftw`, which controls how MATLAB optimizes the algorithm used to compute an FFT of a particular size and dimension.

Data Type Support

`fft` supports inputs of data types `double` and `single`. If you call `fft` with the syntax `y = fft(X, ...)`, the output `y` has the same data type as the input `X`.

Purpose

2-D discrete Fourier transform

Syntax

```
Y = fft2(X)
Y = fft2(X,m,n)
```

Description

`Y = fft2(X)` returns the two-dimensional discrete Fourier transform (DFT) of `X`, computed with a fast Fourier transform (FFT) algorithm. The result `Y` is the same size as `X`.

`Y = fft2(X,m,n)` truncates `X`, or pads `X` with zeros to create an `m`-by-`n` array before doing the transform. The result is `m`-by-`n`.

Algorithm

`fft2(X)` can be simply computed as

```
fft(fft(X).').'
```

This computes the one-dimensional DFT of each column `X`, then of each row of the result. The execution time for `fft` depends on the length of the transform. It is fastest for powers of two. It is almost as fast for lengths that have only small prime factors. It is typically several times slower for lengths that are prime or which have large prime factors.

Note You might be able to increase the speed of `fft2` using the utility function `fftw`, which controls how MATLAB optimizes the algorithm used to compute an FFT of a particular size and dimension.

Data Type Support

`fft2` supports inputs of data types `double` and `single`. If you call `fft2` with the syntax `y = fft2(X, ...)`, the output `y` has the same data type as the input `X`.

`fft`, `fftn`, `fftw`, `fftshift`, `ifft2`

Purpose

N-D discrete Fourier transform

Syntax

```
Y = fftn(X)
Y = fftn(X,siz)
```

Description

`Y = fftn(X)` returns the discrete Fourier transform (DFT) of `X`, computed with a multidimensional fast Fourier transform (FFT) algorithm. The result `Y` is the same size as `X`.

`Y = fftn(X,siz)` pads `X` with zeros, or truncates `X`, to create a multidimensional array of size `siz` before performing the transform. The size of the result `Y` is `siz`.

Algorithm

`fftn(X)` is equivalent to

```
Y = X;
for p = 1:length(size(X))
    Y = fft(Y,[],p);
end
```

This computes in-place the one-dimensional fast Fourier transform along each dimension of `X`. The execution time for `fft` depends on the length of the transform. It is fastest for powers of two. It is almost as fast for lengths that have only small prime factors. It is typically several times slower for lengths that are prime or which have large prime factors.

Note You might be able to increase the speed of `fftn` using the utility function `fftw`, which controls how MATLAB optimizes the algorithm used to compute an FFT of a particular size and dimension.

Data Type Support

`fftn` supports inputs of data types `double` and `single`. If you call `fftn` with the syntax `y = fftn(X, ...)`, the output `y` has the same data type as the input `X`.

See Also fft, fft2, fftn, fftw, ifftn

Purpose

Shift zero-frequency component to center of spectrum

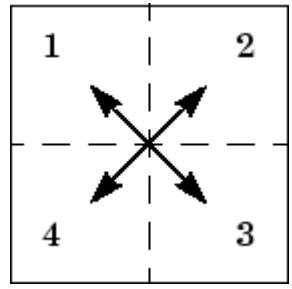
Syntax

```
Y = fftshift(X)
Y = fftshift(X,dim)
```

Description

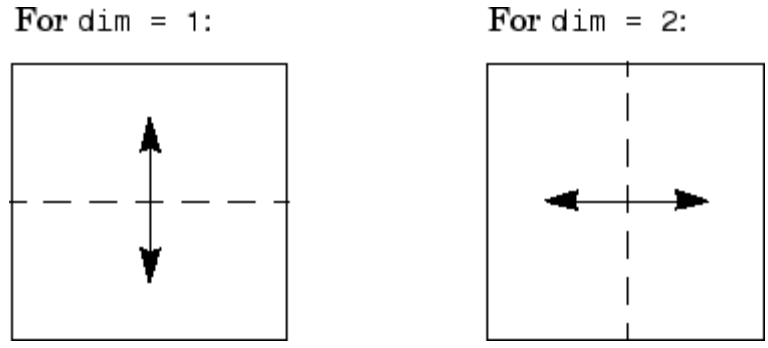
`Y = fftshift(X)` rearranges the outputs of `fft`, `fft2`, and `fftn` by moving the zero-frequency component to the center of the array. It is useful for visualizing a Fourier transform with the zero-frequency component in the middle of the spectrum.

For vectors, `fftshift(X)` swaps the left and right halves of `X`. For matrices, `fftshift(X)` swaps the first quadrant with the third and the second quadrant with the fourth.



For higher-dimensional arrays, `fftshift(X)` swaps “half-spaces” of `X` along each dimension.

`Y = fftshift(X,dim)` applies the `fftshift` operation along the dimension `dim`.



Note `ifftshift` will undo the results of `fftshift`. If the matrix `X` contains an odd number of elements, `ifftshift(fftshift(X))` must be done to obtain the original `X`. Simply performing `fftshift(X)` twice will not produce `X`.

Examples

For any matrix `X`

```
Y = fft2(X)
```

has `Y(1,1) = sum(sum(X))`; the zero-frequency component of the signal is in the upper-left corner of the two-dimensional FFT. For

```
Z = fftshift(Y)
```

this zero-frequency component is near the center of the matrix.

`circshift`, `fft`, `fft2`, `fftn`, `ifftshift`

Purpose

Interface to FFTW library run-time algorithm tuning control

Syntax

```
fftw('planner', method)
method = fftw('planner')
str = fftw('dwisdom')
str = fftw('swisdom')
fftw('dwisdom', str)
fftw('swisdom', str)
```

Description

`fftw` enables you to optimize the speed of the MATLAB FFT functions `fft`, `ifft`, `fft2`, `ifft2`, `fftn`, and `ifftn`. You can use `fftw` to set options for a tuning algorithm that experimentally determines the fastest algorithm for computing an FFT of a particular size and dimension at run time. MATLAB records the optimal algorithm in an internal data base and uses it to compute FFTs of the same size throughout the current session. The tuning algorithm is part of the FFTW library that MATLAB uses to compute FFTs.

`fftw('planner', method)` sets the method by which the tuning algorithm searches for a good FFT algorithm when the dimension of the FFT is not a power of 2. You can specify `method` to be one of the following. The default method is `estimate`:

- `'estimate'`
- `'measure'`
- `'patient'`
- `'exhaustive'`
- `'hybrid'`

When you call `fftw('planner', method)`, the next time you call one of the FFT functions, such as `fft`, the tuning algorithm uses the specified method to optimize the FFT computation. Because the tuning involves trying different algorithms, the first time you call an FFT function, it might run more slowly than if you did not call `fftw`. However,

subsequent calls to any of the FFT functions, for a problem of the same size, often run more quickly than they would without using `fftw`.

Note The FFT functions only use the optimal FFT algorithm during the current MATLAB session. “Reusing Optimal FFT Algorithms” on page 2-1118 explains how to reuse the optimal algorithm in a future MATLAB session.

If you set the method to `'estimate'`, the FFTW library does not use run-time tuning to select the algorithms. The resulting algorithms might not be optimal.

If you set the method to `'measure'`, the FFTW library experiments with many different algorithms to compute an FFT of a given size and chooses the fastest. Setting the method to `'patient'` or `'exhaustive'` has a similar result, but the library experiments with even more algorithms so that the tuning takes longer the first time you call an FFT function. However, subsequent calls to FFT functions are faster than with `'measure'`.

If you set `'planner'` to `'hybrid'`, MATLAB

- Sets method to `'measure'` method for FFT dimensions 8192 or smaller.
- Sets method to `'estimate'` for FFT dimensions greater than 8192.

`method = fftw('planner')` returns the current planner method.

`str = fftw('dwisdom')` returns the information in the FFTW library’s internal double-precision database as a string. The string can be saved and then later reused in a subsequent MATLAB session using the next syntax.

`str = fftw('swisdom')` returns the information in the FFTW library’s internal single-precision database as a string.

`fftw('dwisdom', str)` loads `fftw` wisdom represented by the string `str` into the FFTW library's internal double-precision wisdom database. `fftw('dwisdom','')` or `fftw('dwisdom',[])` clears the internal wisdom database.

`fftw('swisdom', str)` loads `fftw` wisdom represented by the string `str` into the FFTW library's internal single-precision wisdom database. `fftw('swisdom','')` or `fftw('swisdom',[])` clears the internal wisdom database.

Note on large powers of 2 For FFT dimensions that are powers of 2, between 2^{14} and 2^{22}, MATLAB uses special preloaded information in its internal database to optimize the FFT computation. No tuning is performed when the dimension of the FTT is a power of 2, unless you clear the database using the command `fftw('wisdom', [])`.

For more information about the FFTW library, see `http://www.fftw.org`.

Example

Comparison of Speed for Different Planner Methods

The following example illustrates the run times for different settings of `planner`. The example first creates some data and applies `fft` to it using the default method, `estimate`.

```
t=0:.001:5;
x = sin(2*pi*50*t)+sin(2*pi*120*t);
y = x + 2*randn(size(t));

tic; Y = fft(y,1458); toc
Elapsed time is 0.000400 seconds.
```

If you execute the commands

```
tic; Y = fft(y,1458); toc
```

a second time, MATLAB reports the elapsed time as essentially 0. To measure the elapsed time more accurately, you can execute the command `Y = fft(y,1458)` 1000 times in a loop.

```
tic; for k=1:1000
Y = fft(y,1458);
end; toc
Elapsed time is 0.098355 seconds.
```

This tells you that it takes approximately 1/1000 of a second to execute `fft(y, 1458)` a single time.

For comparison, set `planner` to `patient`. Since this `planner` explores possible algorithms more thoroughly than `hybrid`, the first time you run `fft`, it takes longer to compute the results.

```
fftw('planner','patient')
tic;Y = fft(y,1458);toc
Elapsed time is 0.000387 seconds.
```

However, the next time you call `fft`, it runs approximately 10 times faster than before you ran the method `patient`.

```
tic;for k=1:1000
Y=fft(y,1458);
end;toc
Elapsed time is 0.097793 seconds.
```

Reusing Optimal FFT Algorithms

In order to use the optimized FFT algorithm in a future MATLAB session, first save the “wisdom” using the command

```
str = fftw('wisdom')
```

You can save `str` for a future session using the command

```
save str
```

The next time you open MATLAB, load `str` using the command

```
load str
```

and then reload the “wisdom” into the FFTW database using the command

```
fftw('wisdom', str)
```

`fft`, `fft2`, `fftn`, `ifft`, `ifft2`, `ifftn`, `fftshift`.

fgetl

Purpose

Read line from file, discarding newline character

Syntax

```
tline = fgetl(fid)
```

Description

`tline = fgetl(fid)` returns the next line of the file associated with the file identifier `fid`. If `fgetl` encounters the end-of-file indicator, it returns `-1`. (See `fopen` for a complete description of `fid`.) `fgetl` is intended for use with files that contain newline characters.

MATLAB reads characters using the encoding scheme associated with the file. See `fopen` for more information.

The returned string `tline` does not include the line terminator(s) with the text line. To obtain the line terminators, use `fgets`.

Examples

The example reads every line of the M-file `fgetl.m`.

```
fid=fopen('fgetl.m');
while 1
    tline = fgetl(fid);
    if ~ischar(tline),   break,   end
    disp(tline)
end
fclose(fid);
```

See Also

`fgets`

Purpose

Read line of text from device and discard terminator

Syntax

```
tline = fgetl(obj)
[tline,count] = fgetl(obj)
[tline,count,msg] = fgetl(obj)
```

Arguments

`obj`	A serial port object.
`tline`	Text read from the instrument, excluding the terminator.
`count`	The number of values read, including the terminator.
`msg`	A message indicating if the read operation was unsuccessful.

Description

`tline = fgetl(obj)` reads one line of text from the device connected to `obj`, and returns the data to `tline`. The returned data does not include the terminator with the text line. To include the terminator, use `fgets`.

`[tline,count] = fgetl(obj)` returns the number of values read to `count`.

`[tline,count,msg] = fgetl(obj)` returns a warning message to `msg` if the read operation was unsuccessful.

Remarks

Before you can read text from the device, it must be connected to `obj` with the `fopen` function. A connected serial port object has a `Status` property value of `open`. An error is returned if you attempt to perform a read operation while `obj` is not connected to the device.

If `msg` is not included as an output argument and the read operation was not successful, then a warning message is returned to the command line.

The `ValuesReceived` property value is increased by the number of values read – including the terminator – each time `fgetl` is issued.

If you use the `help` command to display help for `fgetl`, then you need to supply the pathname shown below.

```
help serial/fgetl
```

Rules for Completing a Read Operation with fgetl

A read operation with `fgetl` blocks access to the MATLAB command line until:

- The terminator specified by the `Terminator` property is reached.
- The time specified by the `Timeout` property passes.
- The input buffer is filled.

Example

Create the serial port object `s`, connect `s` to a Tektronix TDS 210 oscilloscope, and write the `RS232?` command with the `fprintf` function. `RS232?` instructs the scope to return serial port communications settings.

```
s = serial('COM1');
fopen(s)
fprintf(s,'RS232?')
```

Because the default value for the `ReadAsyncMode` property is `continuous`, data is automatically returned to the input buffer.

```
s.BytesAvailable
ans =
    17
```

Use `fgetl` to read the data returned from the previous write operation, and discard the terminator.

```
settings = fgetl(s)
settings =
9600;0;0;NONE;LF
length(settings)

Functions

fgets, fopen

Properties

BytesAvailable, InputBufferSize, ReadAsyncMode, Status, Terminator, Timeout, ValuesReceived

fgets

Purpose

Read line from file, keeping newline character

Syntax

```
tline = fgets(fid)
tline = fgets(fid, nchar)
```

Description

`tline = fgets(fid)` returns the next line of the file associated with file identifier `fid`. If `fgets` encounters the end-of-file indicator, it returns `-1`. (See `fopen` for a complete description of `fid`.) `fgets` is intended for use with files that contain newline characters.

MATLAB reads characters using the encoding scheme associated with the file. See `fopen` for more information.

The returned string `tline` includes the line terminators associated with the text line. To obtain the string without the line terminators, use `fgetl`.

`tline = fgets(fid, nchar)` returns at most `nchar` characters of the next line. No additional characters are read after the line terminators or an end-of-file.

See Also

`fgetl`

Purpose

Read line of text from device and include terminator

Syntax

```
tline = fgets(obj)
[tline,count] = fgets(obj)
[tline,count,msg] = fgets(obj)
```

Arguments

`obj`	A serial port object.
`tline`	Text read from the instrument, including the terminator.
`count`	The number of bytes read, including the terminator.
`msg`	A message indicating if the read operation was unsuccessful.

Description

`tline = fgets(obj)` reads one line of text from the device connected to `obj`, and returns the data to `tline`. The returned data includes the terminator with the text line. To exclude the terminator, use `fgetl`.

`[tline,count] = fgets(obj)` returns the number of values read to `count`.

`[tline,count,msg] = fgets(obj)` returns a warning message to `msg` if the read operation was unsuccessful.

Remarks

Before you can read text from the device, it must be connected to `obj` with the `fopen`function. A connected serial port object has a `Status` property value of `open`. An error is returned if you attempt to perform a read operation while `obj` is not connected to the device.

If `msg` is not included as an output argument and the read operation was not successful, then a warning message is returned to the command line.

The `ValuesReceived` property value is increased by the number of values read – including the terminator – each time `fgets` is issued.

If you use the `help` command to display help for `fgets`, then you need to supply the pathname shown below.

```
help serial/fgets
```

Rules for Completing a Read Operation with fgets

A read operation with `fgets` blocks access to the MATLAB command line until:

- The terminator specified by the `Terminator` property is reached.
- The time specified by the `Timeout` property passes.
- The input buffer is filled.

Example

Create the serial port object `s`, connect `s` to a Tektronix TDS 210 oscilloscope, and write the `RS232?` command with the `fprintf` function. `RS232?` instructs the scope to return serial port communications settings.

```
s = serial('COM1');
fopen(s)
fprintf(s,'RS232?')
```

Because the default value for the `ReadAsyncMode` property is `continuous`, data is automatically returned to the input buffer.

```
s.BytesAvailable
ans =
    17
```

Use `fgets` to read the data returned from the previous write operation, and include the terminator.

```
settings = fgets(s)
settings =
9600;0;0;NONE;LF
length(settings)
ans =
    17
```

Disconnect s from the scope, and remove s from memory and the workspace.

```
fclose(s)
delete(s)
clear s
```

fieldnames

Purpose

Field names of structure, or public fields of object

Syntax

```
names = fieldnames(s)
names = fieldnames(obj)
names = fieldnames(obj, '-full')
```

Description

`names = fieldnames(s)` returns a cell array of strings containing the structure field names associated with the structure `s`.

`names = fieldnames(obj)` returns a cell array of strings containing the names of the public data fields associated with `obj`, which is a MATLAB, COM, or Java object.

`names = fieldnames(obj, '-full')` returns a cell array of strings containing the name, type, attributes, and inheritance of each field associated with `obj`, which is a MATLAB, COM, or Java object.

Examples

Given the structure

```
mystr(1,1).name = 'alice';
mystr(1,1).ID = 0;
mystr(2,1).name = 'gertrude';
mystr(2,1).ID = 1
```

the command `n = fieldnames(mystr)` yields

```
n =
    'name'
    'ID'
```

In another example, if `f` is an object of Java class `java.awt.Frame`, the command `fieldnames(f)` lists the properties of `f`.

```
f = java.awt.Frame;

fieldnames(f)
ans =
    'WIDTH'
```

```
'HEIGHT'
'PROPERTIES'
'SOMEBITS'
'FRAMEBITS'
'ALLBITS'
    .
    .
```

figure

Purpose

Create figure graphics object

Syntax

```
figure
figure('PropertyName',propertyvalue,...)
figure(h)
h = figure(...)
```

Description

`figure` creates figure graphics objects. Figure objects are the individual windows on the screen in which MATLAB displays graphical output.

`figure` creates a new figure object using default property values.

`figure('PropertyName',propertyvalue,...)` creates a new figure object using the values of the properties specified. MATLAB uses default values for any properties that you do not explicitly define as arguments.

`figure(h)` does one of two things, depending on whether or not a figure with handle `h` exists. If `h` is the handle to an existing figure, `figure(h)` makes the figure identified by `h` the current figure, makes it visible, and raises it above all other figures on the screen. The current figure is the target for graphics output. If `h` is not the handle to an existing figure, but is an integer, `figure(h)` creates a figure and assigns it the handle `h`. `figure(h)` where `h` is not the handle to a figure, and is not an integer, is an error.

`h = figure(...)` returns the handle to the figure object.

Remarks

To create a figure object, MATLAB creates a new window whose characteristics are controlled by default figure properties (both factory installed and user defined) and properties specified as arguments. See the properties section for a description of these properties.

You can specify properties as property name/property value pairs, structure arrays, and cell arrays (see the `set` and `get` reference pages for examples of how to specify these data types).

Use `set` to modify the properties of an existing figure or `get` to query the current values of figure properties.

The gcf command returns the handle to the current figure and is useful as an argument to the set and get commands.

Figures can be docked in the desktop. The Dockable property determines whether you can dock the figure.

Making a Figure Current

The current figure is the target for graphics output. There are two ways to make a figure h the current figure.

- Make the figure h current, visible, and displayed on top of other figures:

```
figure(h)
```

- Make the figure h current, but do not change its visibility or stacking with respect to other figures:

```
set(0,'CurrentFigure',h)
```

Examples

Specifying Figure Size and Screen Location

To create a figure window that is one quarter the size of your screen and is positioned in the upper left corner, use the root object's ScreenSize property to determine the size. ScreenSize is a four-element vector: [left, bottom, width, height]:

```
scrsz = get(0,'ScreenSize');
figure('Position',[1 scrsz(4)/2 scrsz(3)/2 scrsz(4)/2])
```

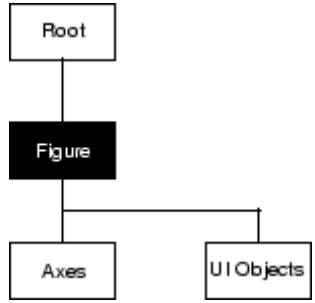
Specifying the Figure Window Title

You can add your own title to a figure by setting the Name property and you can turn off the figure number with the NumberTitle property:

```
figure('Name','Simulation Plot Window','NumberTitle','off')
```

See the Properties section for a description of all figure properties.

Object Hierarchy



Setting Default Properties

You can set default figure properties only on the root level.

```
set(0,'DefaultFigureProperty',PropertyValue...)
```

where *Property* is the name of the figure property and `PropertyValue` is the value you are specifying. Use `set` and `get` to access figure properties.

`Figure Properties` descriptions of all figure properties

See "Figure Properties" in the MATLAB Graphics User Guide for more information on figures.

Purpose

Figure properties

Modifying Properties

You can set and query graphics object properties in two ways:

- "The Property Editor" is an interactive tool that enables you to see and change object property values.
- The `set` and `get` commands enable you to set and query the values of properties.

To change the default values of properties, see "Setting Default Property Values".

Figure Property Descriptions

This section lists property names along with the type of values each accepts. Curly braces { } enclose default values.

`Alphamap`

m-by-1 matrix of alpha values

Figure alphamap. This property is an m-by-1 array of non-NaN alpha values. MATLAB accesses alpha values by their row number. For example, an index of 1 specifies the first alpha value, an index of 2 specifies the second alpha value, and so on. Alphamaps can be any length. The default alphamap contains 64 values that progress linearly from 0 to 1.

Alphamaps affect the rendering of surface, image, and patch objects, but do not affect other graphics objects.

`BeingDeleted`

`on | {off}` Read Only

This object is being deleted. The `BeingDeleted` property provides a mechanism that you can use to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object's delete function might call other functions that act on a number of different objects. These functions may not need to perform actions on objects that are going to be deleted, and therefore, can check the object's `BeingDeleted` property before acting.

`BusyAction`

`cancel | {queue}`

Callback function interruption. The `BusyAction` property enables you to control how MATLAB handles events that potentially interrupt executing callback functions. If there is a callback function executing, callback functions invoked subsequently always attempt to interrupt it. If the `Interruptible` property of the object whose callback is executing is set to `on` (the default), then interruption occurs at the next point where the event queue is processed. If the `Interruptible` property is `off`, the `BusyAction` property (of the object owning the executing callback) determines how MATLAB handles the event. The choices are

- `cancel` — Discard the event that attempted to execute a second callback function.
- `queue` — Queue the event that attempted to execute a second callback function until the current callback finishes.

`ButtonDownFcn`

functional handle, cell array containing function handle and additional arguments, or string (not recommended)

Button press callback function. A callback function that executes whenever you press a mouse button while the pointer is in the figure window, but not over a child object (i.e., uicontrol, uipanel, axes, or axes child). Define the `ButtonDownFcn` as a function handle. The function must define at least two input arguments (handle of figure associated with the mouse button press and an empty event structure)

See the figure's `SelectionType` property to determine whether modifier keys were also pressed.

See "Function Handle Callbacks" for information on how to use function handles to define the callback function.

Using the ButtonDownFcn

This example, creates a figure and defines a function handle callback for the `ButtonDownFcn` property. When the user **Ctrl-**clicks the figure, the callback creates a new figure having the same callback.

Click to view in editor — This link opens the MATLAB editor with the following example.

Click to run example — **Ctrl-**click the figure to create a new figure.

```
fh_cb = @newfig; % Create function handle for newfig function
figure('ButtonDownFcn',fh_cb);

function newfig(src,evnt)
   if strcmp(get(src,'SelectionType'),'alt')
      figure('ButtonDownFcn',fh_cb)
   else
      disp('Use control-click to create a new figure')
   end
end
```

`Children`

vector of handles

Children of the figure. A vector containing the handles of all axes, user-interface objects displayed within the figure. You can change the order of the handles and thereby change the stacking of the objects on the display.

When an object's HandleVisibility property is set to off, it is not listed in its parent's Children property. See HandleVisibility for more information.

Clipping
{on} | off

This property has no effect on figures.

CloseRequestFcn
functional handle, cell array containing function handle and additional arguments, or string (not recommended)

Function executed on figure close. This property defines a function that MATLAB executes whenever you issue the close command (either a close(figure_handle) or a close all), when you close a figure window from the computer's window manager menu, or when you quit MATLAB.

The CloseRequestFcn provides a mechanism to intervene in the closing of a figure. It allows you to, for example, display a dialog box to ask a user to confirm or cancel the close operation or to prevent users from closing a figure that contains a GUI.

The basic mechanism is

- A user issues the close command from the command line, by closing the window from the computer's window manager menu, or by quitting MATLAB.
- The close operation executes the function defined by the figure CloseRequestFcn. The default function is named closereq and is predefined as

```
if isempty(gcbf)
   if length(dbstack) == 1
      warning('MATLAB:closereq', ...
          'Calling closereq from the command line is now obsolet
   end
```

```
    close force
else
    delete(gcbf);
end
```

These statements unconditionally delete the current figure, destroying the window. `closereq` takes advantage of the fact that the `close` command makes all figures specified as arguments the current figure before calling the respective close request function.

Note that `closereq` honors the user's `ShowHiddenHandles` setting during figure deletion. This means that hidden figures are not deleted.

Redefining the CloseRequestFcn

Define the `CloseRequestFcn` as a function handle. For example,

```
set(gcf,'CloseRequestFcn',@my_closefcn)
```

Where `@my_closefcn` is a function handle referencing function `my_closefcn`.

Unless the close request function calls `delete` or `close`, MATLAB never closes the figure. (Note that you can always call `delete(`*`figure_handle`*`)` from the command line if you have created a window with a nondestructive close request function.)

A useful application of the close request function is to display a question dialog box asking the user to confirm the close operation. The following function illustrates how to do this.

Click to view in editor — This link opens the MATLAB editor with the following example.

Click to run example — **Ctrl-**click the figure to create a new figure.

```
function my_closereq(src,evnt)
```

```
% User-defined close request function
% to display a question dialog box
   selection = questdlg('Close This Figure?',...
      'Close Request Function',...
      'Yes','No','Yes');
   switch selection,
      case 'Yes',
         delete(gcf)
      case 'No'
      return
   end
end
```

Now create a figure using the yourCloseRequestFcn:

```
figure('CloseRequestFcn',@my_closereq)
```

To make this function your default close request function, set a default value on the root level.

```
set(0,'DefaultFigureCloseRequestFcn',@my_closereq)
```

MATLAB then uses this setting for the `CloseRequestFcn` of all subsequently created figures.

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

`Color`

`ColorSpec`

Background color. This property controls the figure window background color. You can specify a color using a three-element vector of RGB values or one of the MATLAB predefined names. See `ColorSpec` for more information.

`Colormap`

m-by-3 matrix of RGB values

Figure colormap. This property is an m-by-3 array of red, green, and blue (RGB) intensity values that define m individual colors. MATLAB accesses colors by their row number. For example, an index of 1 specifies the first RGB triplet, an index of 2 specifies the second RGB triplet, and so on.

Number of Colors Allowed

Colormaps can be any length (up to 256 only on MS-Windows), but must be three columns wide. The default figure colormap contains 64 predefined colors.

Objects That Use Colormaps

Colormaps affect the rendering of `surface`, image, and `patch` objects, but generally do not affect other graphics objects. See `colormap` and `ColorSpec` for more information.

`CreateFcn`

functional handle, cell array containing function handle and additional arguments, or string (not recommended)

Callback function executed during figure creation. This property defines a callback function that executes when MATLAB creates a figure object. You must define this property as a default value on the root level. For example, the statement

```
set(0,'DefaultFigureCreateFcn',@fig_create)
```

defines a default value on the root level that causes all figures created to execute the setup function `fig_create`, which is defined below:

```
function fig_create(src,evnt)
set(src,'Color',[.2 .1 .5],...
   'IntegerHandle','off',...
   'MenuBar','none',...
   'ToolBar','none')
```

```
end
```

MATLAB executes the create function after setting all properties for the figure. Setting this property on an existing figure object has no effect.

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

The handle of the object whose `CreateFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

`CurrentAxes`
handle of current axes

Target axes in this figure. MATLAB sets this property to the handle of the figure's current axes (i.e., the handle returned by the `gca` command when this figure is the current figure). In all figures for which axes children exist, there is always a current axes. The current axes does not have to be the topmost axes, and setting an axes to be the `CurrentAxes` does not restack it above all other axes.

You can make an axes current using the `axes` and `set` commands. For example, `axes(`*`axes_handle`*`)` and `set(gcf,'CurrentAxes',`*`axes_handle`*`)` both make the axes identified by the handle *`axes_handle`* the current axes. In addition, `axes(`*`axes_handle`*`)` restacks the axes above all other axes in the figure.

If a figure contains no axes, `get(gcf,'CurrentAxes')` returns the empty matrix. Note that the `gca` function actually creates an axes if one does not exist.

`CurrentCharacter`
single character

Last key pressed. MATLAB sets this property to the last key pressed in the figure window. `CurrentCharacter` is useful for obtaining user input.

`CurrentMenu`
(Obsolete)

This property produces a warning message when queried. It has been superseded by the root `CallbackObject` property.

`CurrentObject`
object handle

Handle of current object. MATLAB sets this property to the handle of the last object clicked on by the mouse. This object is the front-most object in the view. You can use this property to determine which object a user has selected. The function `gco` provides a convenient way to retrieve the `CurrentObject` of the `CurrentFigure`.

Note that the `HitTest` property controls whether an object can become the `CurrentObject`.

Hidden Handle Objects

Clicking on an object whose `HandleVisibility` property is set to `off` (such as axis labels and title) causes the `CurrentObject` property to be set to empty `[]`. To avoid returning an empty value when users click on hidden objects, set the hidden object's `HitTest` property to `off`.

Mouse Over

Note that cursor motion over objects does not update the `CurrentObject`; you must click on objects to update this property. See the `CurrentPoint` property for related information.

`CurrentPoint`

two-element vector: [*x*-coordinate, *y*-coordinate]

Location of last button click in this figure. MATLAB sets this property to the location of the pointer at the time of the most recent mouse button press. MATLAB updates this property whenever you press the mouse button while the pointer is in the figure window.

Note that if you select a point in the figure and then use the values returned by the `CurrentPoint` property to plot that point, there can be differences in the position due to round off errors.

CurrentPoint and Cursor Motion

In addition to the behavior described above, MATLAB updates `CurrentPoint` before executing callback routines defined for the figure `WindowButtonMotionFcn` and `WindowButtonUpFcn` properties. This enables you to query `CurrentPoint` from these callback routines. It behaves like this:

- If there is no callback routine defined for the `WindowButtonMotionFcn` or the `WindowButtonUpFcn`, then MATLAB updates the `CurrentPoint` only when the mouse button is pressed down within the figure window.
- If there is a callback routine defined for the `WindowButtonMotionFcn`, then MATLAB updates the `CurrentPoint` just before executing the callback. Note that the `WindowButtonMotionFcn` executes only within the figure window unless the mouse button is pressed down within the window and then held down while the pointer is moved around the screen. In this case, the routine executes (and the `CurrentPoint` is updated) anywhere on the screen until the mouse button is released.
- If there is a callback routine defined for the `WindowButtonUpFcn`, MATLAB updates the `CurrentPoint` just before executing

the callback. Note that the WindowButtonUpFcn executes only while the pointer is within the figure window unless the mouse button is pressed down initially within the window. In this case, releasing the button anywhere on the screen triggers callback execution, which is preceded by an update of the CurrentPoint.

The figure CurrentPoint is updated only when certain events occur, as previously described. In some situations, (such as when the WindowButtonMotionFcn takes a long time to execute and the pointer is moved very rapidly) the CurrentPoint may not reflect the actual location of the pointer, but rather the location at the time when the WindowButtonMotionFcn began execution.

The CurrentPoint is measured from the lower left corner of the figure window, in units determined by the Units property.

The root PointerLocation property contains the location of the pointer updated synchronously with pointer movement. However, the location is measured with respect to the screen, not a figure window.

See uicontrol for information on how this property is set when you click a uicontrol object.

DeleteFcn

functional handle, cell array containing function handle and additional arguments, or string (not recommended)

Delete figure callback function. A callback function that executes when the figure object is deleted (e.g., when you issue a delete or a close command). MATLAB executes the function before destroying the object's properties so these values are available to the callback routine.

See "Function Handle Callbacks" for information on how to use function handles to define the callback function.

The handle of the object whose `DeleteFcn` is being executed is accessible through the root `CallbackObject` property, which you can query using `gcbo`.

See also the figure `CloseRequestFcn` property

See "Function Handle Callbacks" for information on how to use function handles to define the callback function.

`DockControls`

{on} | off

Displays controls used to dock figure. This property determines whether the figure enables the **Desktop** menu item and the dock figure button in the titlebar that allow you to dock the figure into the MATLAB desktop.

By default, the figure docking controls are visible. If you set this property to `off`, the **Desktop** menu item that enables you to dock the figure is disabled and the figure dock button is not displayed.

See also the `WindowStyle` property for more information on docking figure.

`DoubleBuffer`

{on} | off

Flash-free rendering for simple animations. Double buffering is the process of drawing to an off-screen pixel buffer and then blitting the buffer contents to the screen once the drawing is complete. Double buffering generally produces flash-free rendering for simple animations (such as those involving lines, as opposed to objects containing large numbers of polygons). Use double buffering with the animated objects' `EraseMode` property set to `normal`. Use the `set` command to disable double buffering.

```
set(figure_handle,'DoubleBuffer','off')
```

Double buffering works only when the figure `Renderer` property is set to `painters`.

`FileName`
String

GUI FIG-filename. GUIDE stores the name of the FIG-file used to save the GUI layout in this property.

`FixedColors`
m-by-3 matrix of RGB values (read only)

Noncolormap colors. Fixed colors define all colors appearing in a figure window that are not obtained from the figure colormap. These colors include axis lines and labels, the colors of `line`, `text`, `uicontrol`, and `uimenu` objects, and any colors that you explicitly define, for example, with a statement like

```
set(gcf,'Color',[0.3,0.7,0.9])
```

Fixed color definitions reside in the system color table and do not appear in the figure colormap. For this reason, fixed colors can limit the number of simultaneously displayed colors if the number of fixed colors plus the number of entries in the figure colormap exceed your system's maximum number of colors.

(See the root `ScreenDepth` property for information on determining the total number of colors supported on your system. See the `MinColorMap` property for information on how MATLAB shares colors between applications.)

`HandleVisibility`
`{on} | callback | off`

Control access to object's handle by command-line users and GUIs. This property determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally drawing into or

deleting a figure that contains only user interface devices (such as a dialog box).

Handles are always visible when `HandleVisibility` is `on`.

Callback Visibility

Setting `HandleVisibility` to `callback` causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have complete access to object handles.

Visibility Off

Setting `HandleVisibility` to `off` makes handles invisible at all times. This may be necessary when a callback routine invokes a function that might potentially damage the GUI (such as evaluating a user-typed string), and so temporarily hides its own handles during the execution of that function.

Visibility and Handles Returned by Other Functions

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure`property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

Making All Handles Visible

You can set the root `ShowHiddenHandles` property to on to make all handles visible, regardless of their `HandleVisibility` settings (this does not affect the values of the `HandleVisibility` properties).

Validity of Hidden Handles

Handles that are hidden are still valid. If you know an object's handle, you can set and get its properties, and pass it to any function that operates on handles.

`HitTest`

`{on} | off`

Selectable by mouse click. `HitTest` determines if the figure can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the figure. If `HitTest` is `off`, clicking the figure sets the `CurrentObject` to the empty matrix.

`IntegerHandle`

`{on} | off`

Figure handle mode. Figure object handles are integers by default. When creating a new figure, MATLAB uses the lowest integer that is not used by an existing figure. If you delete a figure, its integer handle can be reused.

If you set this property to `off`, MATLAB assigns nonreusable real-number handles (e.g., 67.0001221) instead of integers. This feature is designed for dialog boxes where removing the handle from integer values reduces the likelihood of inadvertently drawing into the dialog box.

`Interruptible`

`{on} | off`

Callback routine interruption mode. The `Interruptible` property controls whether a figure callback function can be interrupted by subsequently invoked callbacks.

How callbacks are interrupted

MATLAB checks for queued events that can interrupt a callback function only when it encounters a call to `drawnow`, `figure`, `getframe`, or `pause` in the executing callback function. When one of these functions is executed, MATLAB processes all pending events, including executing all waiting callback functions. The interrupted callback then resumes execution.

What property callbacks are interruptible

Only callback functions defined for the `ButtonDownFcn`, `KeyPressFcn`, `KeyReleaseFcn`, `WindowButtonDownFcn`, `WindowButtonMotionFcn`, `WindowButtonUpFcn` , and `WindowScrollWheelFcn` are affected by the `Interruptible` property.

See the BusyAction property for related information.

`InvertHardcopy`

```
{on} | off
```

Change hardcopy to black objects on white background. This property affects only printed output. Printing a figure having a background color (`Color` property) that is not white results in poor contrast between graphics objects and the figure background and also consumes a lot of printer toner.

When `InvertHardCopy` is `on`, MATLAB eliminates this effect by changing the color of the figure and axes to white and the axis lines, tick marks, axis labels, etc., to black. `lines`, `text`, and the edges of `patches` and `surfaces` might be changed, depending on the `print` command options specified.

If you set `InvertHardCopy` to `off`, the printed output matches the colors displayed on the screen.

See `print` for more information on printing MATLAB figures.

`KeyPressFcn`
functional handle, cell array containing function handle and additional arguments, or string (not recommended)

Key press callback function. A callback function invoked by a key press that occurs while the figure window has focus. Define the `KeyPressFcn` as a function handle. The function must define at least two input arguments (handle of figure associated with key release and an event structure)

See "Function Handle Callbacks" for information on how to use function handles to define the callback function.

When there is no callback specified for this property (which is the default state), MATLAB passes any key presses to the command window. However, when you define a callback for this property, the figure retains focus with each key press and executes the specified callback with each key press.

KeyPressFcn Event Structure

When the callback is a function handle, MATLAB passes a structure to the callback function that contains the following fields.

Field	Contents
`Character`	The character displayed as a result of the key(s) pressed.

Field	Contents
`Modifier`	This field is a cell array that contains the names of one or more modifier keys that the user pressed (i.e., **control**, **alt**, **shift**). On Macintosh computers, MATLAB can also return **command**
`Key`	The key pressed (lower case label on key)

Some key combinations do not define a value for the `Character` field.

Using the KeyPressFcn

This example, creates a figure and defines a function handle callback for the `KeyPressFcn` property. When the "e" key is pressed, the callback exports the figure as an EPS file. When **Ctrl-t** is pressed, the callback exports the figure as a TIFF file.

```
function figure_keypress
   figure('KeyPressFcn',@printfig);

   function printfig(src,evnt)
      if evnt.Character == 'e'
         print ('-deps',['-f' num2str(src)])
      elseif length(evnt.Modifier) == 1 & strcmp(evnt.Modifier{:},'control') & evnt.Key == 't'
         print ('-dtiff','-r200',['-f' num2str(src)])
   end
end
```

`KeyReleaseFcn`

functional handle, or cell array containing function handle and additional arguments, string (not recommended)

Key release callback function. A callback function invoked by a key release that occurs while the figure window has focus. Define the `KeyReleaseFcn` as a function handle. The function must define at

least two input arguments (handle of figure associated with key release and an event structure)

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

KeyReleaseFcn Event Structure

When the callback is a function handle, MATLAB passes a structure as the second argument to the callback function that contains the following fields.

Field	Contents
`Character`	The character displayed as a result of the key(s) released.
`Modifier`	This field is a cell array that contains the names of one or more modifier keys that the user releases (i.e., **control**, **alt**, **shift**, or empty if no modifier keys were released). On Macintosh computers, MATLAB can also return **command**
`Key`	The lower case label on key that was released.

Some key combinations do not define a value for the `Character` field.

Properties Affected by the KeyReleaseFcn

When a callback is defined for the `KeyReleaseFcn` property, MATLAB updates the `CurrentCharacter`, `CurrentKey`, and `CurrentModifier` figure properties just before executing the callback.

Multiple Key Presses Events and a Single Key Release Event

Consider a figure having callbacks defined for both the `KeyPressFcn` and `KeyReleaseFcn`. In the case where a user presses multiple keys, one after another, MATLAB generates repeated `KeyPressFcn` events only for the last key pressed.

For example, suppose you press and hold down the **a** key, then press and hold down the **s** key. MATLAB generates repeated `KeyPressFcn` events for the **a** key until the **s** key is pressed, at which point MATLAB generates repeated `KeyPressFcn` events for the **s** key. If the **s** key is then released, a `KeyReleaseFcn` event is generated for the **s** key, but no new `KeyPressFcn` events are generated for the **a** key. When you then release the **a** key, the `KeyReleaseFcn` again executes.

The `KeyReleaseFcn` behavior is such that its callback is executed every time a key is released while the figure is in focus, regardless of what `KeyPressFcns` are generated.

Modifier Keys

When the user presses and releases a key and a modifier key, the modifier key is returned in the event structure `Modifier` field. If a modifier key is the only key pressed and released, it is not returned in the event structure of the `KeyReleaseFcn`, but is returned in the event structure of the `KeyPressFcn`.

Explore the Results

Click to view in editor — This link opens the MATLAB editor with the following example.

Click to run example — Press and release various key combinations while the figure has focus to see the data returned in the event structure.

The following code, creates a figure and defines a function handle callback for the `KeyReleaseFcn` property. The callback simply

displays the values returned by the event structure and enables you to explore the `KeyReleaseFcn` behavior when you release various key combinations.

```
function key_releaseFcn
   figure('KeyReleaseFcn',@cb)

   function cb(src,evnt)
      if ~isempty(evnt.Modifier)
         for ii = 1:length(evnt.Modifier)
            out = sprintf('Character: %c\nModifier: %s\nKey: %s\n',evnt.Character,evnt.Mod
            disp(out)
         end
      else
         out = sprintf('Character: %c\nModifier: %s\nKey: %s\n',evnt.Character,'No modifie
         disp(out)
      end
   end
end
```

`MenuBar`

`none | {figure}`

Enable-disable figure menu bar. This property enables you to display or hide the menu bar that MATLAB places at the top of a figure window. The default (`figure`) is to display the menu bar.

This property affects only built-in menus. Menus defined with the `uimenu` command are not affected by this property.

If you start MATLAB with the `nojvm` option, figures do not display the menu bar because most items require Java figures.

`MinColormap`

scalar (default = 64)

Minimum number of color table entries used. This property specifies the minimum number of system color table entries used

by MATLAB to store the colormap defined for the figure (see the `ColorMap` property). In certain situations, you may need to increase this value to ensure proper use of colors.

For example, suppose you are running color-intensive applications in addition to MATLAB and have defined a large figure colormap (e.g., 150 to 200 colors). MATLAB may select colors that are close but not exact from the existing colors in the system color table because there are not enough slots available to define all the colors you specified.

To ensure that MATLAB uses exactly the colors you define in the figure colormap, set `MinColorMap` equal to the length of the colormap.

```
set(gcf,'MinColormap',length(get(gcf,'ColorMap')))
```

Note that the larger the value of `MinColorMap`, the greater the likelihood that other windows (including other MATLAB figure windows) will be displayed in false colors.

`Name`

string

Figure window title. This property specifies the title displayed in the figure window. By default, `Name` is empty and the figure title is displayed as `Figure 1`, `Figure 2`, and so on. When you set this parameter to a string, the figure title becomes `Figure 1: <`*`string`*`>`. See the `NumberTitle` property.

`NextPlot`

`new | {add} | replace | replacechildren`

How to add next plot. `NextPlot` determines which figure MATLAB uses to display graphics output. If the value of the current figure is

- `new` — Create a new figure to display graphics (unless an existing parent is specified in the graphing function as a property/value pair).

- `add` — Use the current figure to display graphics (the default).
- `replace` — Reset all figure properties except `Position` to their defaults and delete all figure children before displaying graphics (equivalent to `clf reset`).
- `replacechildren` — Remove all child objects, but do not reset figure properties (equivalent to `clf`).

The `newplot` function provides an easy way to handle the `NextPlot` property. Also see the `NextPlot` axes property and "Controlling Graphics Output" for more information.

`NumberTitle`
`{on} | off` (GUIDE default `off`)

Figure window title number. This property determines whether the string `Figure No.  N` (where `N` is the figure number) is prefixed to the figure window title. See the `Name` property.

`PaperOrientation`
`{portrait} | landscape`

Horizontal or vertical paper orientation. This property determines how printed figures are oriented on the page. `portrait` orients the longest page dimension vertically; `landscape` orients the longest page dimension horizontally. See the `orient` command for more detail.

`PaperPosition`
four-element rect vector

Location on printed page. A rectangle that determines the location of the figure on the printed page. Specify this rectangle with a vector of the form

```
rect = [left, bottom, width, height]
```

where `left` specifies the distance from the left side of the paper to the left side of the rectangle and `bottom` specifies

the distance from the bottom of the page to the bottom of the rectangle. Together these distances define the lower left corner of the rectangle. `width` and `height` define the dimensions of the rectangle. The `PaperUnits` property specifies the units used to define this rectangle.

`PaperPositionMode`

`auto | {manual}`

WYSIWYG printing of figure. In `manual` mode, MATLAB honors the value specified by the `PaperPosition` property. In `auto` mode, MATLAB prints the figure the same size as it appears on the computer screen, centered on the page.

See the Pixels per Inch Solution for information on specifying a pixels per inch resolution setting for MATLAB figures. Doing so might be necessary to obtain a printed figure that is the same size as it is on screen.

`PaperSize`

`[width height]`

Paper size. This property contains the size of the current `PaperType`, measured in `PaperUnits`. See `PaperType` to select standard paper sizes.

`PaperType`

Select a value from the following table.

Selection of standard paper size. This property sets the `PaperSize` to one of the following standard sizes.

Property Value	Size (Width x Height)
`usletter (default)`	8.5-by-11 inches
`uslegal`	11-by-14 inches
`tabloid`	11-by-17 inches

Property Value	Size (Width x Height)
A0	841-by-1189mm
A1	594-by-841mm
A2	420-by-594mm
A3	297-by-420mm
A4	210-by-297mm
A5	148-by-210mm
B0	1029-by-1456mm
B1	728-by-1028mm
B2	514-by-728mm
B3	364-by-514mm
B4	257-by-364mm
B5	182-by-257mm
arch-A	9-by-12 inches
arch-B	12-by-18 inches
arch-C	18-by-24 inches
arch-D	24-by-36 inches
arch-E	36-by-48 inches
A	8.5-by-11 inches
B	11-by-17 inches
C	17-by-22 inches
D	22-by-34 inches
E	34-by-43 inches

Note that you may need to change the `PaperPosition` property in order to position the printed figure on the new paper size.

One solution is to use `normalized PaperUnits`, which enables MATLAB to automatically size the figure to occupy the same relative amount of the printed page, regardless of the paper size.

`PaperUnits`

```
normalized | {inches} | centimeters | points
```

Hardcopy measurement units. This property specifies the units used to define the `PaperPosition` and `PaperSize` properties. All units are measured from the lower left corner of the page. `normalized` units map the lower left corner of the page to (0, 0) and the upper right corner to (1.0, 1.0). `inches`, `centimeters`, and `points` are absolute units (one point equals 1/72 of an inch).

If you change the value of `PaperUnits`, it is good practice to return it to its default value after completing your computation so as not to affect other functions that assume `PaperUnits` is set to the default value.

`Parent`

handle

Handle of figure's parent. The parent of a figure object is the root object. The handle to the root is always 0.

`Pointer`

```
crosshair | {arrow} | watch | topl |
topr | botl | botr | circle | cross |
fleur | left | right | top | bottom |
fullcrosshair | ibeam | custom
```

Pointer symbol selection. This property determines the symbol used to indicate the pointer (cursor) position in the figure window. Setting `Pointer` to `custom` allows you to define your own pointer symbol. See the `PointerShapeCData` property and "Specifying the Figure Pointer" for more information.

`PointerShapeCData`
16-by-16 matrix

User-defined pointer. This property defines the pointer that is used when you set the `Pointer` property to `custom`. It is a 16-by-16 element matrix defining the 16-by-16 pixel pointer using the following values:

- `1` — Color pixel black.
- `2` — Color pixel white.
- `NaN` — Make pixel transparent (underlying screen shows through).

Element (1,1) of the `PointerShapeCData` matrix corresponds to the upper left corner of the pointer. Setting the `Pointer` property to one of the predefined pointer symbols does not change the value of the `PointerShapeCData`. Computer systems supporting 32-by-32 pixel pointers fill only one quarter of the available pixmap.

`PointerShapeHotSpot`
two-element vector

Pointer active area. A two-element vector specifying the row and column indices in the `PointerShapeCData` matrix defining the pixel indicating the pointer location. The location is contained in the `CurrentPoint` property and the root object's `PointerLocation` property. The default value is element (1,1), which is the upper left corner.

`Position`
four-element vector

Figure position. This property specifies the size and location on the screen of the figure window. Specify the position rectangle with a four-element vector of the form:

```
rect = [left, bottom, width, height]
```

where `left` and `bottom` define the distance from the lower left corner of the screen to the lower left corner of the figure window. `width` and `height` define the dimensions of the window. See the `Units` property for information on the units used in this specification. The `left` and `bottom` elements can be negative on systems that have more than one monitor.

Position of Docked Figures

If the figure is docked in the MATLAB desktop, then the `Position` property is specified with respect to the figure group container instead of the screen.

Moving and Resizing Figures

You can use the `get` function to obtain this property and determine the position of the figure and you can use the `set` function to resize and move the figure to a new location. You cannot set the figure `Position` when it is docked.

Note that on MS-Windows systems, figure windows cannot be less than 104 pixels wide, regardless of the value of the `Position` property.

`Renderer`

```
painters | zbuffer | OpenGL
```

Rendering method used for screen and printing This property enables you to select the method used to render MATLAB graphics. The choices are

- `painters` — The original rendering method used by MATLAB is faster when the figure contains only simple or small graphics objects.
- `zbuffer` — MATLAB draws graphics objects faster and more accurately because objects are colored on a per-pixel basis and MATLAB renders only those pixels that are visible in the scene

(thus eliminating front-to-back sorting errors). Note that this method can consume a lot of system memory if MATLAB is displaying a complex scene.

- `OpenGL` — OpenGL is a renderer that is available on many computer systems. This renderer is generally faster than painters or zbuffer and in some cases enables MATLAB to access graphics hardware that is available on some systems.

Hardware vs. Software OpenGL Implementations

There are two kinds of OpenGL implementations — hardware and software.

The hardware implementation makes use of special graphics hardware to increase performance and is therefore significantly faster than the software version. Many computers have this special hardware available as an option or may come with this hardware right out of the box.

Software implementations of OpenGL are much like the ZBuffer renderer that is available on MATLAB Version 5.0 and later; however, OpenGL generally provides superior performance to ZBuffer.

OpenGL Availability

OpenGL is available on all computers that run MATLAB. MATLAB automatically finds hardware accelerated versions of OpenGl if such versions are available. If the hardware accelerated version is not available, then MATLAB uses the software version (except on Macintosh systems, which do not support software OpenGL).

The following software versions are available:

- On UNIX systems, MATLAB uses the software version of OpenGL that is included in the MATLAB distribution.

- On MS-Windows, OpenGL is available as part of the operating system. If you experience problems with OpenGL, contact your graphics driver vendor to obtain the latest qualified version of OpenGL.
- On Macintosh systems. software OpenGL is not available.

MATLAB issues a warning if it cannot find a usable OpenGL library.

Selecting Hardware Accelerated or Software OpenGL

MATLAB enables you to switch between hardware accelerated and software OpenGL. However, MS-Windows and Unix systems behave differently:

- On MS-Windows systems, you can toggle between software and hardware versions any time during the MATLAB session.
- On UNIX systems, you must set the OpenGL version before MATLAB initializes OpenGL. Therefore, you cannot issue the `opengl info` command or create graphs before you call `opengl software`. To re-enable hardware accelerated OpenGL, you must restart MATLAB.
- On Macintosh systems. software OpenGL is not available.

If you do not want to use hardware OpenGL, but do want to use object transparency, you can issue the following command.

```
opengl software
```

This command forces MATLAB to use software OpenGL. Software OpenGL is useful if your hardware accelerated version of OpenGL does not function correctly and you want to use image, patch, or surface transparency, which requires the OpenGL renderer. To reenable hardware OpenGL, use the command

```
opengl hardware
```

on MS-Windows systems or restart MATLAB on UNIX systems.

By default, MATLAB uses hardware accelerated OpenGL.

See the `opengl` reference page for additional information

Determining What Version You Are Using

To determine the version and vendor of the OpenGL library that MATLAB is using on your system, type the following command at the MATLAB prompt:

```
opengl info
```

The returned information contains a line that indicates if MATLAB is using software (`Software = true`) or hardware accelerated (`Software = false`) OpenGL.

This command also returns a string of extensions to the OpenGL specification that are available with the particular library MATLAB is using. This information is helpful to The MathWorks, so please include this information if you need to report bugs.

Note that issuing the `opengl info` command causes MATLAB to initialize OpenGL.

OpenGL vs. Other MATLAB Renderers

There are some differences between drawings created with OpenGL and those created with the other renderers. The OpenGL specific differences include

- OpenGL does not do colormap interpolation. If you create a surface or patch using indexed color and interpolated face or edge coloring, OpenGL interpolates the colors through the RGB color cube instead of through the colormap.

- OpenGL does not support the `phong` value for the `FaceLighting` and `EdgeLighting` properties of `surfaces` and `patches`.
- OpenGL does not support logarithmic-scale axes.
- OpenGL and Zbuffer renderers display objects sorted in front to back order, as seen on the monitor, and lines always draw in front of faces when at the same location on the plane of the monitor. Painters sorts by child order (order specified).

If You Are Having Problems

Consult the OpenGL Technical Note if you are having problems using OpenGL. This technical note contains a wealth of information on MATLAB renderers.

`RendererMode`

```
{auto} | manual
```

Automatic or user selection of renderer. This property enables you to specify whether MATLAB should choose the `Renderer` based on the contents of the figure window, or whether the `Renderer` should remain unchanged.

When the `RendererMode` property is set to `auto`, MATLAB selects the rendering method for printing as well as for screen display based on the size and complexity of the graphics objects in the figure.

For printing, MATLAB switches to `zbuffer` at a greater scene complexity than for screen rendering because printing from a Z-buffered figure can be considerably slower than one using the `painters` rendering method, and can result in large PostScript files. However, the output does always match what is on the screen. The same holds true for OpenGL: the output is the same as that produced by the ZBuffer renderer — a bitmap with a resolution determined by the `print` command's `-r` option.

Criteria for Autoselection of OpenGL Renderer

When the `RendererMode` property is set to `auto`, MATLAB uses the following criteria to determine whether to select the OpenGL renderer:

If the `opengl` autoselection mode is `autoselect`, MATLAB selects OpenGL if

- The host computer has OpenGL installed and is in True Color mode (OpenGL does not fully support 8-bit color mode).
- The figure contains no logarithmic axes (logarithmic axes are not supported in OpenGL).
- MATLAB would select `zbuffer` based on figure contents.
- Patch objects' faces have no more than three vertices (some OpenGL implementations of patch tessellation are unstable).
- The figure contains less than 10 uicontrols (OpenGL clipping around uicontrols is slow).
- No line objects use markers (drawing markers is slow).
- Phong lighting is not specified (OpenGL does not support Phong lighting; if you specify Phong lighting, MATLAB uses the ZBuffer renderer).

  Or

- Figure objects use transparency (OpenGL is the only MATLAB renderer that supports transparency).

When the `RendererMode` property is set to `manual`, MATLAB does not change the `Renderer`, regardless of changes to the figure contents.

`Resize`

`{on} | off`

Window resize mode. This property determines if you can resize the figure window with the mouse. `on` means you can resize the window, `off` means you cannot. When `Resize` is `off`, the figure window does not display any resizing controls (such as boxes at the corners), to indicate that it cannot be resized.

`ResizeFcn`

functional handle, cell array containing function handle and additional arguments, or string (not recommended)

Window resize callback function. MATLAB executes the specified callback function whenever you resize the figure window and also when the figure is created. You can query the figure's `Position` property to determine the new size and position of the figure. During execution of the callback routine, the handle to the figure being resized is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

You can use `ResizeFcn` to maintain a GUI layout that is not directly supported by the MATLAB `Position/Units` paradigm.

For example, consider a GUI layout that maintains an object at a constant height in pixels and attached to the top of the figure, but always matches the width of the figure. The following `ResizeFcn` accomplishes this; it keeps the `uicontrol` whose `Tag` is `'StatusBar'` 20 pixels high, as wide as the figure, and attached to the top of the figure. Note the use of the `Tag` property to retrieve the uicontrol handle, and the `gcbo` function to retrieve the figure handle. Also note the defensive programming regarding figure `Units`, which the callback requires to be in pixels in order to work correctly, but which the callback also restores to their previous value afterwards.

```
u = findobj('Tag','StatusBar');
fig = gcbo;
old_units = get(fig,'Units');
set(fig,'Units','pixels');
figpos = get(fig,'Position');
```

```
upos = [0, figpos(4) - 20, figpos(3), 20];
set(u,'Position',upos);
set(fig,'Units',old_units);
```

You can change the figure `Position` from within the `ResizeFcn` callback; however, the `ResizeFcn` is not called again as a result.

Note that the `print` command can cause the `ResizeFcn` to be called if the `PaperPositionMode` property is set to `manual` and you have defined a resize function. If you do not want your resize function called by `print`, set the `PaperPositionMode` to `auto`.

See “Introduction” for an example of how to implement a resize function for a GUI.

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

`Selected`

`on | off`

Is object selected? This property indicates whether the figure is selected. You can, for example, define the `ButtonDownFcn` to set this property, allowing users to select the object with the mouse.

`SelectionHighlight`

`{on} | off`

figures do not indicate selection.

`SelectionType`

`{normal} | extend | alt | open`

Mouse selection type. MATLAB maintains this property to provide information about the last mouse button press that occurred within the figure window. This information indicates the type of selection made. Selection types are actions that are generally associated with particular responses from the user interface

software (e.g., single-clicking a graphics object places it in move or resize mode; double-clicking a filename opens it, etc.).

The physical action required to make these selections varies on different platforms. However, all selection types exist on all platforms.

Selection Type	MS-Windows	X-Windows
`Normal`	Click left mouse button.	Click left mouse button.
`Extend`	**Shift** - click left mouse button or click both left and right mouse buttons.	**Shift** - click left mouse button or click middle mouse button.
`Alternate`	**Control** - click left mouse button or click right mouse button.	**Control** - click left mouse button or click right mouse button.
`Open`	Double-click any mouse button.	Double-click any mouse button.

Note that the `ListBox` style of `uicontrols` sets the figure `SelectionType` property to `normal` to indicate a single mouse click or to `open` to indicate a double mouse click. See `uicontrol` for information on how this property is set when you click a uicontrol object.

`Tag`

string

User-specified object label. The `Tag` property provides a means to identify graphics objects with a user-specified label. This is particularly useful when you are constructing interactive graphics programs that would otherwise need to define object handles as

global variables or pass them as arguments between callback routines.

For example, suppose you want to direct all graphics output from an M-file to a particular figure, regardless of user actions that may have changed the current figure. To do this, identify the figure with a `Tag`.

```
figure('Tag','Plotting Figure')
```

Then make that figure the current figure before drawing by searching for the `Tag` with `findobj`.

```
figure(findobj('Tag','Plotting Figure'))
```

`Toolbar`

`none | {auto} | figure`

Control display of figure toolbar. The `Toolbar` property enables you to control whether MATLAB displays the default figure toolbar on figures. There are three possible values:

- `none` — do not display the figure toolbar
- `auto` — display the figure toolbar, but remove it if a uicontrol is added to the figure
- `figure` — display the figure toolbar

Note that this property affects only the figure toolbar; other toolbars (e.g., the Camera Toolbar or Plot Edit Toolbar) are not affected. Selecting **Figure Toolbar** from the figure **View** menu sets this property to `figure`.

If you start MATLAB with the `nojvm` option, figures do not display the toolbar because most tool require Java figures.

`Type`

`string (read only)`

Object class. This property identifies the kind of graphics object. For figures, `Type` is always the string `'figure'`.

`UIContextMenu`
handle of a uicontextmenu object

Associate a context menu with the figure. Assign this property the handle of a uicontextmenu object created in the figure. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the figure.

`Units`

```
{pixels} | normalized | inches |
centimeters | points | characters
```

Units of measurement. This property specifies the units MATLAB uses to interpret size and location data. All units are measured from the lower left corner of the window.

- `normalized` units map the lower left corner of the figure window to (0,0) and the upper right corner to (1.0,1.0).
- `inches`, `centimeters`, and `points` are absolute units (one point equals 1/72 of an inch).
- The size of a `pixel` depends on screen resolution.
- `characters` units are defined by characters from the default system font; the width of one character is the width of the letter x, the height of one character is the distance between the baselines of two lines of text.

This property affects the `CurrentPoint` and `Position` properties. If you change the value of `Units`, it is good practice to return it to its default value after completing your computation so as not to affect other functions that assume `Units` is set to the default value.

When specifying the units as property/value pairs during object creation, you must set the `Units` property before specifying the properties that you want to use these units.

`UserData`
matrix

User-specified data. You can specify `UserData` as any matrix you want to associate with the figure object. The object does not use this data, but you can access it using the `set` and `get` commands.

`Visible`
`{on} | off`

Object visibility. The `Visible` property determines whether an object is displayed on the screen. If the `Visible` property of a figure is `off`, the entire figure window is invisible.

A note about using the window button properties
Your window button callback functions might need to update the display by calling `drawnow` or `pause`, which causes MATLAB to process all events in the queue. Processing the event queue can cause your window button callback functions to be reentered. For example, a `drawnow` in the `WindowButtonDownFcn` might result in the `WindowButtonDownFcn` being called again before the first call has finished. You should design your code to handle reentrancy and you should not depend on global variables that might change state during reentrance.

You can use the `Interruptible` and `BusyAction` figure properties to control how events interact.

`WindowButtonDownFcn`
functional handle, cell array containing function handle and additional arguments, or string (not recommended)

Button press callback function. Use this property to define a callback that MATLAB executes whenever you press a mouse

button while the pointer is in the figure window. See the `WindowButtonMotionFcn` property for an example.

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

`WindowButtonMotionFcn`
functional handle, cell array containing function handle and additional arguments, or string (not recommended)

Mouse motion callback function. Use this property to define a callback that MATLAB executes whenever you move the pointer within the figure window. Define the `WindowButtonMotionFcn` as a function handle. The function must define at least two input arguments (handle of figure associated with key release and an event structure).

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

Example using all window button properties

Click to view in editor — This example enables you to use mouse motion to draw lines. It uses all three window button functions.

Click to run example — Click the left mouse button in the axes and move the cursor, left-click to define the line end point, right-click to end drawing mode.

Note On some computer systems, the `WindowButtonMotionFcn` is executed when a figure is created even though there has been no mouse motion within the figure.

`WindowButtonUpFcn`

functional handle, cell array containing function handle and additional arguments, or string (not recommended)

Button release callback function. Use this property to define a callback that MATLAB executes whenever you release a mouse button. Define the `WindowButtonUpFcn` as a function handle. The function must define at least two input arguments (handle of figure associated with key release and an event structure)

The button up event is associated with the figure window in which the preceding button down event occurred. Therefore, the pointer need not be in the figure window when you release the button to generate the button up event.

If the callback routines defined by `WindowButtonDownFcn` or `WindowButtonMotionFcn` contain `drawnow` commands or call other functions that contain `drawnow` commands and the `Interruptible` property is set to `off`, the `WindowButtonUpFcn` might not be called. You can prevent this problem by setting `Interruptible` to `on`.

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

`WindowScrollWheelFcn`

string, functional handle, or cell array containing function handle and additional arguments

Respond to mouse scroll wheel. Use this property to define a callback that MATLAB executes when the mouse wheel is scrolled while the figure has focus. MATLAB executes the callback with each single mouse wheel click.

Note that it is possible for another object to capture the event from MATLAB. For example, if the figure contains Java or ActiveX control objects that are listening for mouse scroll wheel

events, then these objects can consume the events and prevent the `WindowScrollWheelFcn` from executing.

There is no default callback defined for this property.

WindowScrollWheelFcn Event Structure

When the callback is a function handle, MATLAB passes a structure to the callback function that contains the following fields.

Field	Contents
`VerticalScrollCount`	A positive or negative integer that indicates the number of scroll wheel clicks. Positive values indicate clicks of the wheel scrolled in the down direction. Negative values indicate clicks of the wheel scrolled in the up direction.
`VerticalScrollAmount`	The current system setting for the number of lines that are scrolled for each click of the scroll wheel. If the mouse property setting for scrolling is set to `One screen at a time`, VerticalScrollAmount returns a value of 1.

Effects On Other Properties

- `CurrentObject` property — mouse scrolling does not update this figure property
- `CurrentPoint` property — if there is no callback defined for the `WindowScrollWheelFcn` property, then MATLAB does not update the `CurrentPoint` property as the scroll wheel is turned. However, if there is a callback defined for the `WindowScrollWheelFcn` property, then MATLAB updates the `CurrentPoint` property just before executing the callback. This enables you to determine the point at which the mouse scrolling occurred.
- `HitTest` property — the `WindowScrollWheelFcn` callback executes regardless of the setting of the figure `HitTest` property.
- `SelectionType` property — the `WindowScrollWheelFcn` callback has no effect on this property.

Values Returned by VerticalScrollCount

When a user moves the mouse scroll wheel by one click, MATLAB increments the count by +/- 1, depending on the direction of the scroll (scroll down being positive). When MATLAB calls the `WindowScrollWheelFcn` callback, the counter is reset. In most cases, this means that the absolute value of the returned value is 1. However, if the `WindowScrollWheelFcn` callback takes a long enough time to return and/or the user spins the scroll wheel very fast, then the returned value can have an absolute value greater than one.

The actual value returned by `VerticalScrollCount` is the algebraic sum of all scroll wheel clicks that occurred since last processed. This enables your callback to respond correctly to the user's action.

Example

Click to view in editor — This example creates a graph of a function and enables you to use the mouse scroll wheel to change the range over which a mathematical function is evaluated and update the graph to reflect the new limits as you turn the scroll wheel.

Click to run example — Mouse over the figure and scroll your mouse wheel.

Related Information

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

`WindowStyle`

`{normal} | modal | docked`

Normal, modal, or dockable window behavior. When `WindowStyle` is set to `modal`:

- The figure window traps all keyboard and mouse events over all MATLAB windows as long as they are visible.
- Windows belonging to applications other than MATLAB are unaffected.
- Modal figures remain stacked above all normal figures and the MATLAB command window.
- When multiple modal windows exist, the most recently created window keeps focus and stays above all other windows until it becomes invisible, or is returned to `WindowStyle normal` , or is deleted. At that time, focus reverts to the window that last had focus.

Use modal figures to create dialog boxes that force the user to respond without being able to interact with other windows. Typing **Control C** while the figure has focus causes all figures

with `WindowStyle modal` to revert to `WindowStyle normal` , allowing you to type at the command line.

Invisible Modal Figures

Figures with `WindowStyle modal` and `Visible off` do not behave modally until they are made visible, so it is acceptable to hide a `modal` window instead of destroying it when you want to reuse it.

Changing Modes

You can change the `WindowStyle` of a figure at any time, including when the figure is visible and contains children. However, on some systems this may cause the figure to flash or disappear and reappear, depending on the windowing system's implementation of normal and modal windows. For best visual results, you should set `WindowStyle` at creation time or when the figure is invisible.

Window Decorations on Modal Figures

Modal figures do not display `uimenu` children, built-in menus, or toolbars but it is not an error to create uimenus in a modal figure or to change `WindowStyle` to `modal` on a figure with uimenu children. The uimenu objects exist and their handles are retained by the figure. If you reset the figure's `WindowStyle` to `normal`, the uimenus are displayed.

Docked WindowStyle

When `WindowStyle` is set to `docked`, the figure is docked in the desktop or a document window. When you issue the following command,

```
set(figure_handle,'WindowStyle','docked')
```

MATLAB docks the figure identified by *`figure_handle`* and sets the `DockControls` property to `on`, if it was `off`.

Note that if `WindowStyle` is `docked`, you cannot set the `DockControls` property to `off`.

The value of the `WindowStyle` property is not changed by calling `reset` on a figure.

`WVisual`
identifier string (MS Windows only)

Specify pixel format for figure. MATLAB automatically selects a pixel format for figures based on your current display settings, the graphics hardware available on your system, and the graphical content of the figure.

Usually, MATLAB chooses the best pixel format to use in any given situation. However, in cases where graphics objects are not rendered correctly, you might be able select a different pixel format and improve results. See for more information.

Querying Available Pixel Formats on Window Systems

You can determine what pixel formats are available on your system for use with MATLAB using the following statement:

```
set(gcf,'WVisual')
```

MATLAB returns a list of the currently available pixel formats for the current figure. For example, the following are the first three entries from a typical list.

01 (RGB 16 bits(05 06 05 00) zdepth 24, Hardware Accelerated, Opengl, GDI, Window)

02 (RGB 16 bits(05 06 05 00) zdepth 24, Hardware Accelerated, Opengl, Double Buffered, Window)

03 (RGB 16 bits(05 06 05 00) zdepth 24, Hardware Accelerated, Opengl, Double Buffered, Window)

Use the number at the beginning of the string to specify which pixel format to use. For example,

```
set(gcf,'WVisual','02')
```

specifies the second pixel format in the list above. Note that pixel formats might differ on your system.

Understanding the WVisual String

The string returned by querying the `WVisual` property provide information on the pixel format. For example,

- `RGB 16 bits(05 06 05 00)` – indicates true color with 16-bit resolution (5 bits for red, 6 bits for green, 5 bits for blue, and 0 for alpha (transparency). MATLAB requires true color.
- `zdepth 24` – indicates 24-bit resolution for sorting object's front to back position on the screen. Selecting pixel formats with higher (24 or 32) zdepth might solve sorting problems.
- `Hardware Accelerated` – some graphics functions may be performed by hardware for increased speed. If there are incompatibilities between your particular graphic hardware and MATLAB, select a pixel format in which the term `Generic` appears instead of `Hardware Accelerated`.
- `Opengl` – supports OpenGL. See for more information.
- `GDI` – supports for Windows 2-D graphics interface.
- `Double Buffered` – support for double buffering with the OpenGL renderer. Note that the figure `DoubleBuffer` property applies only to the painters renderer.
- `Bitmap` – support for rendering into a bitmap (as opposed to drawing in the window)
- `Window` – support for rendering into a window

Pixel Formats and OpenGL

If you are experiencing problems using hardware OpenGL on your system, you can try using generic OpenGL, which is implemented in software. To do this, first instruct MATLAB to use the software version of OpenGL with the following statement.

```
opengl software
```

Then allow MATLAB to select best pixel format to use.

See the `Renderer` property for more information on how MATLAB uses OpenGL.

`WVisualMode`
`auto` | `manual` (MS Windows only)

Auto or manual selection of pixel format. `VisualMode` can take on two values — `auto` (the default) and `manual`. In `auto` mode, MATLAB selects the best pixel format to use based on your computer system and the graphical content of the figure. In `manual` mode, MATLAB does not change the visual from the one currently in use. Setting the `WVisual` property sets this property to `manual`.

`XDisplay`
display identifier (UNIX only)

Contains the display used for MATLAB. You can query this property to determine the name of the display that MATLAB is using. For example, if MATLAB is running on a system called `mycomputer`, querying `XDisplay` returns a string of the following form:

```
get(gcf,'XDisplay')
ans
mycomputer:0.0
```

Setting XDisplay on Motif

If your computer uses Motif-based figures, you can specify the display MATLAB uses for a figure by setting the value of the figure's `XDisplay` property. For example, to display the current figure on a system called `fred`, use the command

```
set(gcf,'XDisplay','fred:0.0')
```

`XVisual`
visual identifier (UNIX only)

Select visual used by MATLAB. You can select the visual used by MATLAB by setting the `XVisual` property to the desired visual ID. This can be useful if you want to test your application on an 8-bit or grayscale visual. To see what visuals are available on your system, use the UNIX `xdpyinfo` command. From MATLAB, type

```
!xdpyinfo
```

The information returned contains a line specifying the visual ID. For example,

```
visual id:    0x23
```

To use this visual with the current figure, set the `XVisual` property to the ID.

```
set(gcf,'XVisual','0x23')
```

To see which of the available visuals MATLAB can use, call `set` on the `XVisual` property:

```
set(gcf,'XVisual')
```

The following typical output shows the visual being used (in curly brackets) and other possible visuals. Note that MATLAB requires a TrueColor visual.

```
{ 0x23 (TrueColor, depth 24, RGB mask 0xff0000 0xff00 0x00ff) }
  0x24 (TrueColor, depth 24, RGB mask 0xff0000 0xff00 0x00ff)
```

```
  0x25 (TrueColor, depth 24, RGB mask 0xff0000 0xff00 0x00ff)
  0x26 (TrueColor, depth 24, RGB mask 0xff0000 0xff00 0x00ff)
  0x27 (TrueColor, depth 24, RGB mask 0xff0000 0xff00 0x00ff)
  0x28 (TrueColor, depth 24, RGB mask 0xff0000 0xff00 0x00ff)
  0x29 (TrueColor, depth 24, RGB mask 0xff0000 0xff00 0x00ff)
  0x2a (TrueColor, depth 24, RGB mask 0xff0000 0xff00 0x00ff)
```

You can also use the `glxinfo` Unix command to see what visuals are available for use with the OpenGL renderer. From MATLAB, type

```
!glxinfo
```

After providing information about the implementation of OpenGL on your system, `glxinfo` returns a table of visuals. The partial listing below shows typical output.

```
visual  x  bf lv rg d st colorbuffer ax dp st accumbuffer  ms  cav
 id dep cl sp sz l  ci b ro  r  g  b  a bf th cl  r  g  b  a ns b eat
-----------------------------------------------------------------
-
0x23 24 tc  0 24  0 r  y  .  8  8  8  8  0  0  0  0  0  0  0 0 None
0x24 24 tc  0 24  0 r  .  .  8  8  8  8  0  0  0  0  0  0  0 0 None
0x25 24 tc  0 24  0 r  y  .  8  8  8  8  0 24  8  0  0  0  0 0 None
0x26 24 tc  0 24  0 r  .  .  8  8  8  8  0 24  8  0  0  0  0 0 None
0x27 24 tc  0 24  0 r  y  .  8  8  8  8  0  0  0 16 16 16  0 0 Slow
```

The third column is the class of visual. `tc` means a true color visual. Note that some visuals may be labeled `Slow` under the caveat column. Such visuals should be avoided.

To determine which visual MATLAB will use by default with the OpenGL renderer, use the MATLAB `opengl info` command. The returned entry for the visual might look like the following.

```
Visual = 0x23 (TrueColor, depth 24, RGB mask 0xff0000 0xff00 0x00ff)
```

Experimenting with a different TrueColor visual may improve certain rendering problems.

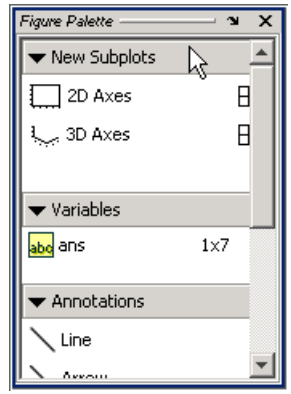
`XVisualMode`
`auto | manual`

Auto or manual selection of visual. `VisualMode` can take on two values — `auto` (the default) and `manual`. In `auto` mode, MATLAB selects the best visual to use based on the number of colors, availability of the OpenGL extension, etc. In `manual` mode, MATLAB does not change the visual from the one currently in use. Setting the `XVisual` property sets this property to `manual`.

figurepalette

Purpose

Show or hide figure palette



GUI Alternatives

Click the larger **Plotting Tools** icon  on the figure toolbar to collectively enable plotting tools, and the smaller icon  to collectively disable them. Open or close the **Figure Palette** tool from the figure's **View** menu. For details, see "The Figure Palette" in the MATLAB Graphics documentation.

Syntax

```
figurepalette('show')
figurepalette('hide')
figurepalette('toggle')
figurepalette(figure_handle,...)
```

Description

`figurepalette('show')` displays the palette on the current figure.

`figurepalette('hide')` hides the palette on the current figure.

`figurepalette('toggle')` or `figurepalette` toggles the visibility of the palette on the current figure.

`figurepalette(figure_handle,...)` shows or hides the palette on the figure specified by `figure_handle`.

See Also

plottools, plotbrowser, propertyeditor

fileattrib

Purpose

Set or get attributes of file or directory

Syntax

```
fileattrib
fileattrib('name')
fileattrib('name','attrib')
fileattrib('name','attrib','users')
fileattrib('name','attrib','users','s')
[status,message,messageid] =  fileattrib('name','attrib',
   'users','s')
```

Description

The `fileattrib` function is like the DOS `attrib` command or the UNIX `chmod` command.

`fileattrib` displays the attributes for the current directory. Values are as follows.

Value	Description
`0`	Attribute is off
`1`	Attribute is set (on)
`NaN`	Attribute does not apply

`fileattrib('name')` displays the attributes for `name`, where `name` is the absolute or relative pathname for a directory or file. Use the wildcard `*` at the end of `name` to view attributes for all matching files.

`fileattrib('name','attrib')` sets the attribute for `name`, where `name` is the absolute or relative pathname for a directory or file. Specify the `+` qualifier before the attribute to set it, and specify the `-` qualifier before the attribute to clear it. Use the wildcard `*` at the end of `name` to set attributes for all matching files. Values for *`attrib`* are as follows.

Value for attrib	Description
a	Archive (Windows only)
h	Hidden file (Windows only)
s	System file (Windows only)
w	Write access (Windows and UNIX)
x	Executable (UNIX only)

For example, `fileattrib('myfile.m','+w')` makes `myfile.m` a writable file.

`fileattrib('name','attrib','users')` sets the attribute for `name`, where `name` is the absolute or relative pathname for a directory or file, and defines which users are affected by *`attrib`*, where *`users`* is applicable only for UNIX systems. For more information about these attributes, see UNIX reference information for `chmod`. The default value for *`users`* is `u`. Values for *`users`* are

Value for users	Description
a	All users
g	Group of users
o	All other users
u	Current user

`fileattrib('name','attrib','users','s')` sets the attribute for `name`, where `name` is the absolute or relative pathname for a file or a directory and its contents, and defines which users are affected by *`attrib`*. Here the **s** specifies that *`attrib`* be applied to all contents of `name`, where `name` is a directory.

`[status,message,messageid] = fileattrib('name','attrib','users','s')` sets the attribute for `name`, returning the status, a message, and the

MATLAB error message ID (see `error` and `lasterror`). Here, `status` is `1` for success and is `0` for error. If `attrib`, *`users`*, and **`s`** are not specified, and `status` is `1`, `message` is a structure containing the file attributes and `messageid` is blank. If `status` is `0`, `messageid` contains the error. If you use a wildcard `*` at the end of `name`, `mess` will be a structure.

Examples

Get Attributes of File

To view the attributes of `myfile.m`, type

```
fileattrib('myfile.m')
```

MATLAB returns

```
             Name: 'd:/work/myfile.m'
          archive: 0
           system: 0
           hidden: 0
        directory: 0
         UserRead: 1
        UserWrite: 0
      UserExecute: 1
        GroupRead: NaN
       GroupWrite: NaN
     GroupExecute: NaN
        OtherRead: NaN
       OtherWrite: NaN
     OtherExecute: NaN
```

`UserWrite` is `0`, meaning `myfile.m` is read only. The `Group` and `Other` values are `NaN` because they do not apply to the current operating system, Windows.

Set File Attribute

To make `myfile.m` become writable, type

```
fileattrib('myfile.m','+w')
```

Running `fileattrib('myfile.m')` now shows `UserWrite` to be `1`.

Set Attributes for Specified Users

To make the directory `d:/work/results` be a read-only directory for all users, type

```
fileattrib('d:/work/results','-w','a')
```

The `-` preceding the write attribute, `w`, specifies that write status is removed.

Set Multiple Attributes for Directory and Its Contents

To make the directory `d:/work/results` and all its contents be read only and be hidden, on Windows, type

```
fileattrib('d:/work/results','+h-w','','s')
```

Because *`users`* is not applicable on Windows systems, its value is empty. Here, `s` applies the attribute to the contents of the specified directory.

Return Status and Structure of Attributes

To return the attributes for the directory `results` to a structure, type

```
[stat,mess]=fileattrib('results')
```

MATLAB returns

```
stat =
     1

mess =
            Name: 'd:\work\results'
         archive: 0
          system: 0
          hidden: 0
       directory: 1
        UserRead: 1
       UserWrite: 1
     UserExecute: 1
```

```
         GroupRead: NaN
        GroupWrite: NaN
      GroupExecute: NaN
         OtherRead: NaN
        OtherWrite: NaN
      OtherExecute: NaN
```

The operation was successful as indicated by the status, `stat`, being `1`. The structure `mess` contains the file attributes. Access the attribute values in the structure. For example, typing

```
mess.Name
```

returns the path for `results`

```
ans =
d:\work\results
```

Return Attributes with Wildcard for Name

Return the attributes for all files in the current directory whose names begin with `new`.

```
[stat,mess]=fileattrib('new*')
```

MATLAB returns

```
stat =
     1

mess =
1x3 struct array with fields:
    Name
    archive
    system
    hidden
    directory
    UserRead
    UserWrite
```

```
    UserExecute
    GroupRead
    GroupWrite
    GroupExecute
    OtherRead
    OtherWrite
    OtherExecute
```

The results indicate there are three matching files. To view the filenames, type

```
mess.Name
```

MATLAB returns

```
ans =
d:\work\results\newname.m

ans =
d:\work\results\newone.m

ans =
d:\work\results\newtest.m
```

To view just the first filename, type

```
mess(1).Name

ans =
d:\work\results\newname.m
```

`cd`, `copyfile`, `fileattrib`, `ls`, `mkdir`, `movefile`, `pwd`, `rmdir`

Purpose

Readable file formats

Description

This table shows the file formats that MATLAB is capable of reading.

File Format	Extension	File Content	Read Command	Returns
Text	MAT	Saved MATLAB workspace	`load`	Variables in the file
	CSV	Comma-separated numbers	`csvread`	Double array
	DLM	Delimited text	`dlmread`	Double array
	TAB	Tab-separated text	`dlmread`	Double array
Scientific Data	CDF	Data in Common Data Format	`cdfread`	Cell array of CDF records
	FITS	Flexible Image Transport System data	`fitsread`	Primary or extension table data
	HDF4	Data in Hierarchical Data Format, version 4	`hdfread`	HDF or HDF-EOS data set
	HDF5	Data in Hierarchical Data Format, version 5	`hdf5read`	HDF5 data set
Spreadsheet	XLS	Excel worksheet	`xlsread`	Double or cell array
	WK1	Lotus 123 worksheet	`wk1read`	Double or cell array

File Format	Extension	File Content	Read Command	Returns
Image	TIFF	TIFF image	`imread`	True color, grayscale, or indexed image(s)
	PNG	PNG image	`imread`	True color, grayscale, or indexed image
	HDF4	HDF4 image	`imread`	True color, grayscale, or indexed image(s)
	BMP	BMP image	`imread`	True color or indexed image
	JPEG	JPEG image	`imread`	True color or grayscale image
	GIF	GIF image	`imread`	Indexed image
	PCX	PCX image	`imread`	Indexed image
	XWD	XWD image	`imread`	Indexed image
	CUR	Cursor image	`imread`	Indexed image
	ICO	Icon image	`imread`	Indexed image
Audio file	AU	NeXT/SUN sound	`auread`	Sound data and sample rate
	WAV	Microsoft WAVE sound	`wavread`	Sound data and sample rate
Movie	AVI	Audio/video	`aviread`	MATLAB movie

See Also `fscanf`, `fread`, `textread`, `importdata`

Purpose

Character to separate file name and internal function name

Syntax

```
M = filemarker
```

Description

`M = filemarker` returns the character that separates a file and a within-file function name.

Examples

On Windows, for example, `filemarker` returns the '>' character:

```
filemarker
ans =
   >
```

You can use the following command on any platform to get the help text for subfunction `pdeodes` defined in M-file `pdepe.m`:

```
helptext = help(['pdepe' filemarker 'pdeodes'])

helptext =
 PDEODES  Assemble the difference equations and
    evaluate the time derivative for the ODE system.
```

See Also

`filesep`

fileparts

Purpose

Parts of file name and path

Syntax

```
[pathstr, name, ext, versn] = fileparts(filename)
```

Description

`[pathstr, name, ext, versn] = fileparts(filename)` returns the path, filename, extension, and version for the specified file. `filename` is a string enclosed in single quotes. The returned `ext` field contains a dot (`.`) before the file extension.

The `fileparts` function is platform dependent.

You can reconstruct the file from the parts using

```
fullfile(pathstr,[name ext versn])
```

Examples

Return the pieces of a file specification string to the separate string outputs `pathstr`, `name`, `ext`, and `versn`. The full file specification is

```
file = '\home\user4\matlab\classpath.txt';
```

Note that the character used to separate the segments of a pathname is dependent on the operating system you are currently running on. In this example, it is the backslash (`\`) character which is used as a separator on Windows systems. You can use the `filesep` function as shown below to insert the correct separator character:

```
sep = filesep;
file = ['' sep 'home' sep 'user4' sep 'matlab' sep ...
        'classpath.txt' ''];
```

Now use `fileparts` to return the path, filename, user name, and file version, if there is one:

```
[pathstr, name, ext, versn] = fileparts(file)

pathstr =
   \home\user4\matlab
```

```
name =
   classpath

ext =
   .txt

versn =
     ''
```

See Also

fullfile

filehandle

Purpose

Construct file handle object

Syntax

```
output = filehandle(arglist)
```

Description

`output = filehandle(arglist)` this file is a place-holder for now.

Example

See Also

`dialog`, `errordlg`, `helpdlg`, `listdlg`, `msgbox`, `questdlg`, `warndlg`

`figure`, `uiwait`, `uiresume`

"Predefined Dialog Boxes" on page 1-104 for related functions

Purpose

Directory separator for current platform

Syntax

```
f = filesep
```

Description

`f = filesep` returns the platform-specific file separator character. The file separator is the character that separates individual directory names in a path string.

Examples

On the PC,

```
iofun_dir = ['toolbox' filesep 'matlab' filesep 'iofun']

iofun_dir =

toolbox\matlab\iofun
```

On a UNIX system,

```
iodir = ['toolbox' filesep 'matlab' filesep 'iofun']

iodir =

toolbox/matlab/iofun
```

`fullfile`, `fileparts`, `pathsep`

fill

Purpose

Filled 2-D polygons

Syntax

```
fill(X,Y,C)
fill(X,Y,ColorSpec)
fill(X1,Y1,C1,X2,Y2,C2,...)
fill(...,'PropertyName',PropertyValue)
h = fill(...)
```

Description

The `fill` function creates colored polygons.

`fill(X,Y,C)` creates filled polygons from the data in `X` and `Y` with vertex color specified by `C`. `C` is a vector or matrix used as an index into the colormap. If `C` is a row vector, `length(C)` must equal `size(X,2)` and `size(Y,2)`; if `C` is a column vector, `length(C)` must equal `size(X,1)` and `size(Y,1)`. If necessary, `fill` closes the polygon by connecting the last vertex to the first.

`fill(X,Y,ColorSpec)` fills two-dimensional polygons specified by `X` and `Y` with the color specified by `ColorSpec`.

`fill(X1,Y1,C1,X2,Y2,C2,...)` specifies multiple two-dimensional filled areas.

`fill(...,'PropertyName',PropertyValue)` allows you to specify property names and values for a patch graphics object.

`h = fill(...)` returns a vector of handles to patch graphics objects, one handle per patch object.

Remarks

If `X` or `Y` is a matrix, and the other is a column vector with the same number of elements as rows in the matrix, `fill` replicates the column vector argument to produce a matrix of the required size. `fill` forms a vertex from corresponding elements in `X` and `Y` and creates one polygon from the data in each column.

The type of color shading depends on how you specify color in the argument list. If you specify color using `ColorSpec`, `fill` generates flat-shaded polygons by setting the patch object's `FaceColor` property to the corresponding RGB triple.

If you specify color using `C`, `fill` scales the elements of `C` by the values specified by the axes property `CLim`. After scaling `C`, `C` indexes the current colormap.

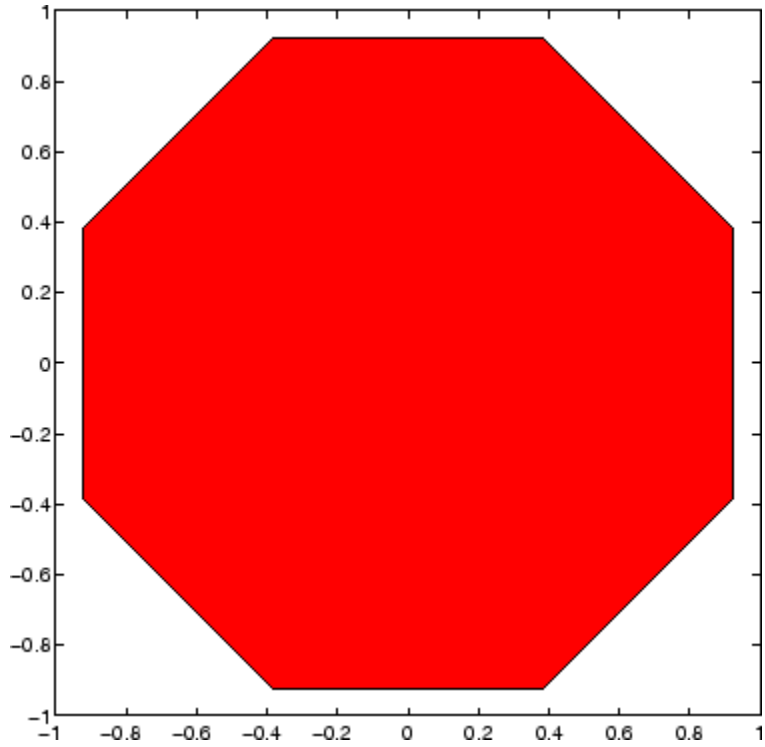
If `C` is a row vector, `fill` generates flat-shaded polygons where each element determines the color of the polygon defined by the respective column of the `X` and `Y` matrices. Each patch object's `FaceColor` property is set to `'flat'`. Each row element becomes the `CData` property value for the `n`th patch object, where *n* is the corresponding column in `X` or `Y`.

If `C` is a column vector or a matrix, `fill` uses a linear interpolation of the vertex colors to generate polygons with interpolated colors. It sets the patch graphics object `FaceColor` property to `'interp'` and the elements in one column become the `CData` property value for the respective patch object. If `C` is a column vector, `fill` replicates the column vector to produce the required sized matrix.

Examples

Create a red octagon.

```
t = (1/16:1/8:1)'*2*pi;
x = sin(t);
y = cos(t);
fill(x,y,'r')
axis square
```



See Also

`axis`, `caxis`, `colormap`, `ColorSpec`, `fill3`, `patch`

“Polygons and Surfaces” on page 1-90 for related functions

Purpose

Filled 3-D polygons

Syntax

```
fill3(X,Y,Z,C)
fill3(X,Y,Z,ColorSpec)
fill3(X1,Y1,Z1,C1,X2,Y2,Z2,C2,...)
fill3(...,'PropertyName',PropertyValue)
h = fill3(...)
```

Description

The `fill3` function creates flat-shaded and Gouraud-shaded polygons.

`fill3(X,Y,Z,C)` fills three-dimensional polygons. `X`, `Y`, and `Z` triplets specify the polygon vertices. If `X`, `Y`, or `Z` is a matrix, `fill3` creates *n* polygons, where *n* is the number of columns in the matrix. `fill3` closes the polygons by connecting the last vertex to the first when necessary.

`C` specifies color, where `C` is a vector or matrix of indices into the current colormap. If `C` is a row vector, `length(C)` must equal `size(X,2)` and `size(Y,2)`; if `C` is a column vector, `length(C)` must equal `size(X,1)` and `size(Y,1)`.

`fill3(X,Y,Z,ColorSpec)` fills three-dimensional polygons defined by `X`, `Y`, and `Z` with color specified by `ColorSpec`.

`fill3(X1,Y1,Z1,C1,X2,Y2,Z2,C2,...)` specifies multiple filled three-dimensional areas.

`fill3(...,'PropertyName',PropertyValue)` allows you to set values for specific patch properties.

`h = fill3(...)` returns a vector of handles to patch graphics objects, one handle per patch.

Algorithm

If `X`, `Y`, and `Z` are matrices of the same size, `fill3` forms a vertex from the corresponding elements of `X`, `Y`, and `Z` (all from the same matrix location), and creates one polygon from the data in each column.

If X, Y, or Z is a matrix, fill3 replicates any column vector argument to produce matrices of the required size.

If you specify color using ColorSpec, fill3 generates flat-shaded polygons and sets the patch object FaceColor property to an RGB triple.

If you specify color using C, fill3 scales the elements of C by the axes property CLim, which specifies the color axis scaling parameters, before indexing the current colormap.

If C is a row vector, fill3 generates flat-shaded polygons and sets the FaceColor property of the patch objects to 'flat'. Each element becomes the CData property value for the respective patch object.

If C is a column vector or a matrix, fill3 generates polygons with interpolated colors and sets the patch object FaceColor property to 'interp'. fill3 uses a linear interpolation of the vertex colormap indices when generating polygons with interpolated colors. The elements in one column become the CData property value for the respective patch object. If C is a column vector, fill3 replicates the column vector to produce the required sized matrix.

Examples

Create four triangles with interpolated colors.

```
X = [0 1 1 2;1 1 2 2;0 0 1 1];
Y = [1 1 1 1;1 0 1 0;0 0 0 0];
Z = [1 1 1 1;1 0 1 0;0 0 0 0];
C = [0.5000 1.0000 1.0000 0.5000;
     1.0000 0.5000 0.5000 0.1667;
     0.3330 0.3330 0.5000 0.5000];
fill3(X,Y,Z,C)
```

"Polygons and Surfaces" on page 1-90 for related functions

Purpose

1-D digital filter

Syntax

```
y = filter(b,a,X)
[y,zf] = filter(b,a,X)
[y,zf] = filter(b,a,X,zi)
y = filter(b,a,X,zi,dim)
[...] = filter(b,a,X,[],dim)
```

Description

The `filter` function filters a data sequence using a digital filter which works for both real and complex inputs. The filter is a *direct form II transposed* implementation of the standard difference equation (see "Algorithm").

`y = filter(b,a,X)` filters the data in vector `X` with the filter described by numerator coefficient vector `b` and denominator coefficient vector `a`. If `a(1)` is not equal to `1`, `filter` normalizes the filter coefficients by `a(1)`. If `a(1)` equals `0`, `filter` returns an error.

If `X` is a matrix, `filter` operates on the columns of `X`. If `X` is a multidimensional array, `filter` operates on the first nonsingleton dimension.

`[y,zf] = filter(b,a,X)` returns the final conditions, `zf`, of the filter delays. If `X` is a row or column vector, output `zf` is a column vector of `max(length(a),length(b))-1`. If `X` is a matrix, `zf` is an array of such vectors, one for each column of `X`, and similarly for multidimensional arrays.

`[y,zf] = filter(b,a,X,zi)` accepts initial conditions, `zi`, and returns the final conditions, `zf`, of the filter delays. Input `zi` is a vector of length `max(length(a),length(b))-1`, or an array with the leading dimension of size `max(length(a),length(b))-1` and with remaining dimensions matching those of `X`.

`y = filter(b,a,X,zi,dim)` and `[...]  = filter(b,a,X,[],dim)` operate across the dimension `dim`.

Example

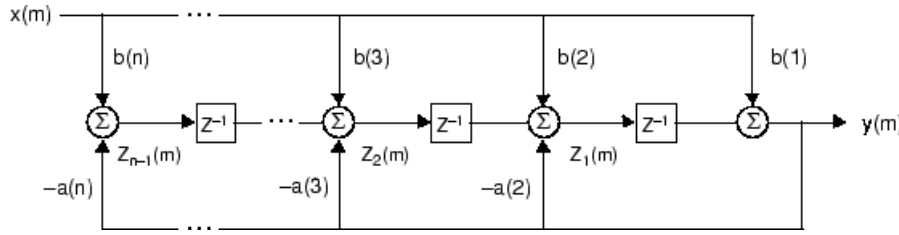
You can use `filter` to find a running average without using a `for` loop. This example finds the running average of a 16-element vector, using a window size of 5.

```
data = [1:0.2:4]';
windowSize = 5;
filter(ones(1,windowSize)/windowSize,1,data)

ans =
    0.2000
    0.4400
    0.7200
    1.0400
    1.4000
    1.6000
    1.8000
    2.0000
    2.2000
    2.4000
    2.6000
    2.8000
    3.0000
    3.2000
    3.4000
    3.6000
```

Algorithm

The `filter` function is implemented as a direct form II transposed structure,



or

```
y(n) = b(1)*x(n) + b(2)*x(n-1) + ... + b(nb+1)*x(n-nb)
                 - a(2)*y(n-1) - ... - a(na+1)*y(n-na)
```

where `n-1` is the filter order, which handles both FIR and IIR filters [1], `na` is the feedback filter order, and `nb` is the feedforward filter order.

The operation of `filter` at sample m is given by the time domain difference equations

$$
\begin{aligned}
y(m) &= b(1)x(m) + z_1(m-1) \\
z_1(m) &= b(2)x(m) + z_2(m-1) - a(2)y(m) \\
\vdots &= \quad \vdots \qquad\qquad \vdots \\
z_{n-2}(m) &= b(n-1)x(m) + z_{n-1}(m-1) - a(n-1)y(m) \\
z_{n-1}(m) &= b(n)x(m) - a(n)y(m)
\end{aligned}
$$

The input-output description of this filtering operation in the z-transform domain is a rational transfer function,

$$
Y(z) = \frac{b(1) + b(2)z^{-1} + \ldots + b(nb+1)z^{-nb}}{1 + a(2)z^{-1} + \ldots + a(na+1)z^{-na}} X(z)
$$

See Also

`filter2`

`filtfilt`, `filtic` in the Signal Processing Toolbox

References

[1] Oppenheim, A. V. and R.W. Schafer. *Discrete-Time Signal Processing*, Englewood Cliffs, NJ: Prentice-Hall, 1989, pp. 311-312.

Purpose

Shape frequency content of time series

Syntax

```
ts2 = filter(ts1,b,a)
ts2 = filter(ts1,b,a,Index)
```

Description

`ts2 = filter(ts1,b,a)` applies the transfer function filter $b(z^{-1})/a(z^{-1})$ to the data in the `timeseries` object `ts1`.

`b` and `a` are the coefficient arrays of the transfer function numerator and denominator, respectively.

`ts2 = filter(ts1,b,a,Index)` uses the optional `Index` integer array to specify the columns or rows to filter. When `ts.IsTimeFirst` is `true`, `Index` specifies one or more data columns. When `ts.IsTimeFirst` is `false`, Index specifies one or more data rows.

Remarks

The time-series data must be uniformly sampled to use this filter.

The following function

```
y = filter(b,a,x)
```

creates filtered data `y` by processing the data in vector `x` with the filter described by vectors `a` and `b`.

The `filter` function is a general tapped delay-line filter, described by the difference equation

$$a(1)y(n) = b(1)x(n) + b(2)x(n-1) + \ldots + b(nb)x(n-nb+1) - a(2)y(n-1) - \ldots - a(N_a)y(n-N_b+1)$$

Here, n is the index of the current sample, N_a is the order of the polynomial described by vector `a`, and N_b is the order of the polynomial described by vector `b`. The output $y(n)$ is a linear combination of current and previous inputs, $x(n)$ $x(n\text{-}1)$..., and previous outputs, $y(n\text{-}1)$ $y(n\text{-}2)$... .

You use the discrete filter to shape the data by applying a transfer function to the input signal.

Depending on your objectives, the transfer function you choose might alter both the amplitude and the phase of the variations in the data at different frequencies to produce either a smoother or a rougher output.

In digital signal processing (DSP), it is customary to write transfer functions as rational expressions in z^{-1} and to order the numerator and denominator terms in ascending powers of z^{-1}.

Taking the z-transform of the difference equation

$$\begin{aligned} a(1)y(n) = \; & b(1)x(n) + b(2)x(n-1) + \ldots + b(nb)x(n-nb+1) \\ & - a(2)y(n-1) - \ldots - a(na)y(n-na+1) \end{aligned}$$

results in the transfer function

$$Y(z) = H(z^{-1})X(z) = \frac{b(1) + b(2)z^{-1} + \ldots + b(nb)z^{-nb+1}}{a(1) + a(2)z^{-1} + \ldots + a(na)z^{-na+1}}X(z)$$

where $Y(z)$ is the z-transform of the filtered output $y(n)$. The coefficients b and a are unchanged by the z-transform.

Examples

Consider the following transfer function:

$$H(z^{-1}) = \frac{b(z^{-1})}{a(z^{-1})} = \frac{2 + 3z^{-1}}{1 + 0.2z^{-1}}$$

You will apply this transfer function to the data in `count.dat`.

1. Load the matrix `count` into the workspace.

```
load count.dat;
```

2. Create a time-series object based on this matrix.

```
count1=timeseries(count(:,1),[1:24]);
```

3 Enter the coefficients of the denominator ordered in ascending powers of z^{-1} to represent $1 + 0.2z^{-1}$.

```
a = [1 0.2];
```

4 Enter the coefficients of the numerator to represent $2 + 3z^{-1}$.

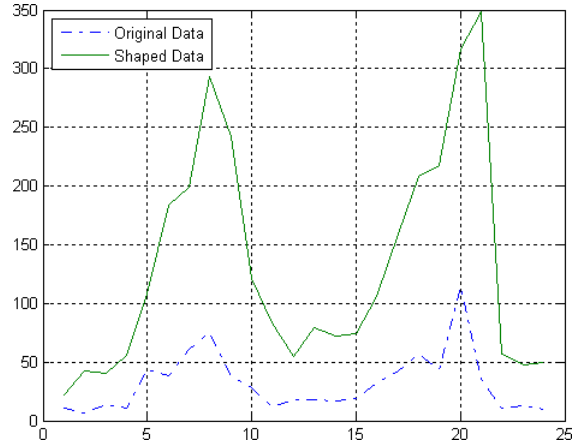
```
b = [2 3];
```

5 Call the filter function.

```
filter_count = filter(count1,b,a)
```

6 Compare the original data and the shaped data with an overlaid plot of the two curves:

```
plot(count1,'-.'), grid on, hold on
plot(filter_count,'-')
legend('Original Data','Shaped Data',2)
```



See Also

`idealfilter (timeseries)`, `timeseries`, `tsprops`

Purpose

2-D digital filter

Syntax

```
Y = filter2(h,X)
Y = filter2(h,X,shape)
```

Description

`Y = filter2(h,X)` filters the data in `X` with the two-dimensional FIR filter in the matrix `h`. It computes the result, `Y`, using two-dimensional correlation, and returns the central part of the correlation that is the same size as `X`.

`Y = filter2(h,X,shape)` returns the part of `Y` specified by the `shape` parameter. *`shape`* is a string with one of these values:

`'full'`	Returns the full two-dimensional correlation. In this case, `Y` is larger than `X`.
`'same'`	(default) Returns the central part of the correlation. In this case, `Y` is the same size as `X`.
`'valid'`	Returns only those parts of the correlation that are computed without zero-padded edges. In this case, `Y` is smaller than `X`.

Remarks

Two-dimensional correlation is equivalent to two-dimensional convolution with the filter matrix rotated 180 degrees. See the Algorithm section for more information about how `filter2` performs linear filtering.

Algorithm

Given a matrix `X` and a two-dimensional FIR filter `h`, `filter2` rotates your filter matrix 180 degrees to create a convolution kernel. It then calls `conv2`, the two-dimensional convolution function, to implement the filtering operation.

`filter2` uses `conv2` to compute the full two-dimensional convolution of the FIR filter with the input matrix. By default, `filter2` then extracts the central part of the convolution that is the same size as the input

matrix, and returns this as the result. If the `shape` parameter specifies an alternate part of the convolution for the result, `filter2` returns the appropriate part.

`conv2`, `filter`

find

Purpose

Find indices and values of nonzero elements

Syntax

```
ind = find(X)
ind = find(X, k)
ind = find(X, k, 'first')
ind = find(X, k, 'last')
[row,col] = find(X, ...)
[row,col,v] = find(X, ...)
```

Description

`ind = find(X)` locates all nonzero elements of array `X`, and returns the linear indices of those elements in vector `ind`. If `X` is a row vector, then `ind` is a row vector; otherwise, `ind` is a column vector. If `X` contains no nonzero elements or is an empty array, then `ind` is an empty array.

`ind = find(X, k)` or `ind = find(X, k, 'first')` returns at most the first `k` indices corresponding to the nonzero entries of `X`. `k` must be a positive integer, but it can be of any numeric data type.

`ind = find(X, k, 'last')` returns at most the last `k` indices corresponding to the nonzero entries of `X`.

`[row,col] = find(X, ...)` returns the row and column indices of the nonzero entries in the matrix `X`. This syntax is especially useful when working with sparse matrices. If `X` is an N-dimensional array with N > 2, `col` contains linear indices for the columns. For example, for a 5-by-7-by-3 array `X` with a nonzero element at `X(4,2,3)`, `find` returns 4 in `row` and 16 in `col`. That is, (7 columns in page 1) + (7 columns in page 2) + (2 columns in page 3) = 16.

`[row,col,v] = find(X, ...)` returns a column or row vector `v` of the nonzero entries in `X`, as well as row and column indices. If `X` is a logical expression, then `v` is a logical array. Output `v` contains the non-zero elements of the logical array obtained by evaluating the expression `X`. For example,

```
A= magic(4)
A =
    16     2     3    13
     5    11    10     8
```

```
     9     7     6    12
     4    14    15     1

[r,c,v]= find(A>10);

r', c', v'
ans =
     1     2     4     4     1     3
ans =
     1     2     2     3     4     4
ans =
     1     1     1     1     1     1
```

Here the returned vector `v` is a logical array that contains the nonzero elements of `N` where

```
N=(A>10)
```

Examples

Example 1

```
X = [1 0 4 -3 0 0 0 8 6];
indices = find(X)
```

returns linear indices for the nonzero entries of `X`.

```
indices =
     1     3     4     8     9
```

Example 2

You can use a logical expression to define `X`. For example,

```
find(X > 2)
```

returns linear indices corresponding to the entries of `X` that are greater than 2.

```
ans =
     3     8     9
```

Example 3

The following `find` command

```
X = [3 2 0; -5 0 7; 0 0 1];
[r,c,v] = find(X)
```

returns a vector of row indices of the nonzero entries of `X`

```
r =
     1
     2
     1
     2
     3
```

a vector of column indices of the nonzero entries of `X`

```
c =
     1
     1
     2
     3
     3
```

and a vector containing the nonzero entries of `X`.

```
v =
     3
    -5
     2
     7
     1
```

Example 4

The expression

```
[r,c,v] = find(X>2)
```

returns a vector of row indices of the nonzero entries of `X`

```
r =
     1
     2
```

a vector of column indices of the nonzero entries of `X`

```
c =
     1
     3
```

and a logical array that contains the non zero elements of `N` where `N=(X>2)`.

```
v =
     1
     1
```

Recall that when you use `find` on a logical expression, the output vector `v` does not contain the nonzero entries of the input array. Instead, it contains the nonzero values returned after evaluating the logical expression.

Example 5

Some operations on a vector

```
x = [11  0  33  0  55]';

find(x)
ans =
     1
     3
     5

find(x == 0)
ans =
     2
```

```
     4

find(0 < x & x < 10*pi)
ans =
     1
```

Example 6

For the matrix

```
M = magic(3)
M =
     8     1     6
     3     5     7
     4     9     2

find(M > 3, 4)
```

returns the indices of the first four entries of `M` that are greater than 3.

```
ans =
     1
     3
     5
     6
```

Example 7

If `X` is a vector of all zeros, `find(X)` returns an empty matrix. For example,

```
indices = find([0;0;0])
indices =
   Empty matrix: 0-by-1
```

See Also

`nonzeros`, `sparse`, `colon`, logical operators (elementwise and short-circuit), relational operators, `ind2sub`

Purpose

Find all graphics objects

Syntax

```
object_handles = findall(handle_list)
object_handles = findall(handle_list,'property','value',...)
```

Description

`object_handles = findall(handle_list)` returns the handles, including hidden handles, of all objects in the hierarchy under the objects identified in `handle_list`.

`object_handles = findall(handle_list,'property','value',...)` returns the handles of all objects in the hierarchy under the objects identified in `handle_list` that have the specified properties set to the specified values.

Remarks

`findall` is similar to `findobj`, except that it finds objects even if their `HandleVisibility` is set to `off`.

Examples

```
plot(1:10)
xlabel xlab
a = findall(gcf)
b = findobj(gcf)
c = findall(b,'Type','text') % return the xlabel handle twice
d = findobj(b,'Type','text') % can't find the xlabel handle
```

See Also

`allchild`, `findobj`

findfigs

Purpose

Find visible offscreen figures

Syntax

```
findfigs
```

Description

`findfigs` finds all visible figure windows whose display area is off the screen and positions them on the screen.

A window appears to MATLAB to be offscreen when its display area (the area not covered by the window's title bar, menu bar, and toolbar) does not appear on the screen.

This function is useful when you are bringing an application from a larger monitor to a smaller one (or one with lower resolution). Windows visible on the larger monitor may appear offscreen on a smaller monitor. Using `findfigs` ensures that all windows appear on the screen.

See Also

"Finding and Identifying Graphics Objects" on page 1-93 for related functions.

Purpose

Locate graphics objects with specific properties

Syntax

```
h = findobj
h = findobj('PropertyName',PropertyValue,...)
h =
findobj('PropertyName',PropertyValue,'-logicaloperator',
   PropertyName',PropertyValue,...)
h = findobj('-regexp','PropertyName','regexp',...)
h = findobj('-property','PropertyName')
h = findobj(objhandles,...)
h = findobj(objhandles,'-depth',d,...)
h = findobj(objhandles,'flat','PropertyName',PropertyValue,
   ...)
```

Description

`findobj` locates graphics objects and returns their handles. You can limit the search to objects with particular property values and along specific branches of the hierarchy.

`h = findobj` returns the handles of the root object and all its descendants.

`h = findobj('PropertyName',PropertyValue,...)` returns the handles of all graphics objects having the property *`PropertyName`*, set to the value `PropertyValue`. You can specify more than one property/value pair, in which case, `findobj` returns only those objects having all specified values.

`h = findobj('PropertyName',PropertyValue,'-logicaloperator', PropertyName',PropertyValue,...)` applies the logical operator to the property value matching. Possible values for *`-logicaloperator`* are:

- `-and`
- `-or`
- `-xor`
- `-not`

See the Examples section for examples of how to use these operators. See “Logical Operators” for an explanation of logical operators.

`h = findobj('-regexp','PropertyName','regexp',...)` matches objects using regular expressions as if the value of the property `PropertyName` was passed to the `regexp` function as

```
regexp(PropertyValue,'regexp')
```

If a match occurs, `findobj` returns the object's handle. See the `regexp` function for information on how MATLAB uses regular expressions.

`h = findobj('-property','PropertyName')` finds all objects having the specified property.

`h = findobj(objhandles,...)` restricts the search to objects listed in `objhandles` and their descendants.

`h = findobj(objhandles,'-depth',d,...)` specified the depth of the search. The depth argument `d` controls how many levels under the handles in `objhandles` are traversed. Specifying `d` as `inf` to get the default behavior of all levels. Specify `d` as `0` to get the same behavior as using the `flat` argument.

`h = findobj(objhandles,'flat','PropertyName',PropertyValue,...)` restricts the search to those objects listed in `objhandles` and does not search descendants.

Remarks

`findobj` returns an error if a handle refers to a nonexistent graphics object.

`findobj` correctly matches any legal property value. For example,

```
findobj('Color','r')
```

finds all objects having a `Color` property set to `red`, `r`, or `[1 0 0]`.

When a graphics object is a descendant of more than one object identified in `objhandles`, MATLAB searches the object each time

findobj encounters its handle. Therefore, implicit references to a graphics object can result in its handle being returned multiple times.

Examples

Find all line objects in the current axes:

```
h = findobj(gca,'Type','line')
```

Find all objects having a Label set to 'foo' and a String set to 'bar':

```
h = findobj('Label','foo','-and','String','bar');
```

Find all objects whose String is not 'foo' and is not 'bar':

```
h = findobj('-not','String','foo','-not','String','bar');
```

Find all objects having a String set to 'foo' and a Tag set to 'button one' and whose Color is not 'red' or 'blue':

```
h = findobj('String','foo','-and','Tag','button one',...
 '-and','-not',{'Color','red','-or','Color','blue'})
```

Find all objects for which you have assigned a value to the Tag property (that is, the value is not the empty string ''):

```
h = findobj('-regexp','Tag','[^'']')
```

Find all children of the current figure that have their BackgroundColor property set to a certain shade of gray ([.7 .7 .7]). Note that this statement also searches the current figure for the matching property value pair.

```
h = findobj(gcf,'-depth',1,'BackgroundColor',[.7 .7 .7])
```

copyobj, gcf, gca, gcbo, gco, get, regexp, set

See "Example — Using Logical Operators and Regular Expression" for more examples.

"Finding and Identifying Graphics Objects" on page 1-93 for related functions

findstr

Purpose

Find string within another, longer string

Syntax

```
k = findstr(str1, str2)
```

Description

`k = findstr(str1, str2)` searches the longer of the two input strings for any occurrences of the shorter string, returning the starting index of each such occurrence in the double array `k`. If no occurrences are found, then `findstr` returns the empty array, `[]`.

The search performed by `findstr` is case sensitive. Any leading and trailing blanks in either input string are explicitly included in the comparison.

Unlike the `strfind` function, the order of the input arguments to `findstr` is not important. This can be useful if you are not certain which of the two input strings is the longer one.

Examples

```
s = 'Find the starting indices of the shorter string.';

findstr(s, 'the')
ans =
     6    30

findstr('the', s)
ans =
     6    30
```

See Also

`strfind`, `strmatch`, `strtok`, `strcmp`, `strncmp`, `strcmpi`, `strncmpi`, `regexp`, `regexpi`, `regexprep`

Purpose

MATLAB termination M-file

Description

When MATLAB quits, it runs a script called `finish.m`, if the script exists and is on the MATLAB search path or in the current directory. This is a file you create yourself that instructs MATLAB to perform any final tasks just prior to terminating. For example, you might want to save the data in your workspace to a MAT-file before MATLAB exits.

`finish.m` is invoked whenever you do one of the following:

- Click the Close box  in the MATLAB desktop on Windows or the UNIX equivalent
- Select **Exit MATLAB** from the desktop **File** menu
- Type `quit` or `exit` at the Command Window prompt

Remarks

When using Handle Graphics in `finish.m`, use `uiwait`, `waitfor`, or `drawnow` so that figures are visible. See the reference pages for these functions for more information.

Examples

Two sample `finish.m` files are provided with MATLAB in *`matlabroot`*`/toolbox/local`. Use them to help you create your own `finish.m`, or rename one of the files to `finish.m` and add it to the path to use it:

- `finishsav.m` — Saves the workspace to a MAT-file when MATLAB quits.
- `finishdlg.m` — Displays a dialog allowing you to cancel quitting and saves the workspace. See also the MATLAB general preference for confirmation dialogs for quitting.

See Also

`quit`, `exit`, `startup`

"Quitting MATLAB" in the MATLAB Desktop Tools and Development Environment documentation

Purpose

Information about FITS file

Syntax

```
info = fitsinfo(filename)
```

Description

`info = fitsinfo(filename)` returns the structure, `info`, with fields that contain information about the contents of a Flexible Image Transport System (FITS) file. `filename` is a string enclosed in single quotes that specifies the name of the FITS file.

The `info` structure contains the following fields, listed in the order they appear in the structure. In addition, the info structure can also contain information about any number of optional file components, called *extensions* in FITS terminology. For more information, see "FITS File Extensions" on page 2-1227.

Field Name	Description	Return Type
`Filename`	Name of the file	String
`FileModDate`	File modification date	String
`FileSize`	Size of the file in bytes	Double
`Contents`	List of extensions in the file in the order that they occur	Cell array of strings
`PrimaryData`	Information about the primary data in the FITS file	Structure array

PrimaryData

The `PrimaryData` field is a structure that describes the primary data in the file. The following table lists the fields in the order they appear in the structure.

Field Name	Description	Return Type
`DataType`	Precision of the data	String
`Size`	Array containing the size of each dimension	Double array

Field Name	Description	Return Type
`DataSize`	Size of the primary data in bytes	Double
`MissingDataValue`	Value used to represent undefined data	Double
`Intercept`	Value, used with `Slope`, to calculate actual pixel values from the array pixel values, using the equation: `actual_value = Slope*array_value + Intercept`	Double
`Slope`	Value, used with `Intercept`, to calculate actual pixel values from the array pixel values, using the equation: `actual_value = Slope*array_value + Intercept`	Double
`Offset`	Number of bytes from beginning of the file to the location of the first data value	Double
`Keywords`	A number-of-keywords-by-3 cell array containing keywords, values, and comments of the header in each column	Cell array of strings

FITS File Extensions

A FITS file can also include optional extensions. If the file contains any of these extensions, the `info` structure can contain these additional fields.

- AsciiTable — Numeric information in tabular format, stored as ASCII characters

- BinaryTable — Numeric information in tabular format, stored in binary representation
- Image — A multidimensional array of pixels
- Unknown — Nonstandard extension

AsciiTable Extension

The `AsciiTable` structure contains the following fields, listed in the order they appear in the structure.

Field Name	Description	Return Type
`Rows`	Number of rows in the table	Double
`RowSize`	Number of characters in each row	Double
`NFields`	Number of fields in each row	Double array
`FieldFormat`	A 1-by-`NFields` cell containing formats in which each field is encoded. The formats are FORTRAN-77 format codes.	Cell array of strings
`FieldPrecision`	A 1-by-`NFields` cell containing precision of the data in each field	Cell array of strings
`FieldWidth`	A 1-by-`NFields` array containing the number of characters in each field	Double array
`FieldPos`	A 1-by-`NFields` array of numbers representing the starting column for each field	Double array
`DataSize`	Size of the data in the table in bytes	Double
`MissingDataValue`	A 1-by-`NFields` array of numbers used to represent undefined data in each field	Cell array of strings

Field Name	Description	Return Type
`Intercept`	A 1-by-`NFields` array of numbers used along with `Slope` to calculate actual data values from the array data values using the equation: `actual_value = Slope*array_value+Intercept`	Double array
`Slope`	A 1-by-`NFields` array of numbers used with `Intercept` to calculate true data values from the array data values using the equation: `actual_value = Slope*array_value+Intercept`	Double array
`Offset`	Number of bytes from beginning of the file to the location of the first data value in the table	Double
`Keywords`	A number-of-keywords-by-3 cell array containing all the Keywords, Values and Comments in the ASCII table header	Cell array of strings

BinaryTable Extension

The `BinaryTable` structure contains the following fields, listed in the order they appear in the structure.

Field Name	Description	Return Type
`Rows`	Number of rows in the table	Double
`RowSize`	Number of bytes in each row	Double
`NFields`	Number of fields in each row	Double

Field Name	Description	Return Type
`FieldFormat`	A 1-by-`NFields` cell array containing the data type of the data in each field. The data type is represented by a FITS binary table format code.	Cell array of strings
`FieldPrecision`	A 1-by-`NFields` cell containing precision of the data in each field	Cell array of strings
`FieldSize`	A 1-by-`NFields` array, where each element contains the number of values in the Nth field	Double array
`DataSize`	Size of the data in the Binary Table, in bytes. Includes any data past the main table.	Double
`MissingDataValue`	An 1-by-`NFields` array of numbers used to represent undefined data in each field	Cell array of double
`Intercept`	A 1-by-`NFields` array of numbers used along with Slope to calculate actual data values from the array data values using the equation: `actual_value = slope*array_value+Intercept`	Double array
`Slope`	A 1-by-`NFields` array of numbers used with Intercept to calculate true data values from the array data values using the equation: `actual_value = Slope*array_value+Intercept`	Double array

Field Name	Description	Return Type
`Offset`	Number of bytes from beginning of the file to the location of the first data value	Double
`ExtensionSize`	Size of any data past the main table, in bytes	Double
`ExtensionOffset`	Number of bytes from the beginning of the file to any data past the main table	Double
`Keywords`	A number-of-keywords-by-3 cell array containing all the Keywords, values, and comments in the Binary Table header	Cell array of strings

Image Extension

The `Image` structure contains the following fields, listed in the order they appear in the structure.

Field Name	Description	Return Type
`DataType`	Precision of the data	String
`Size`	Array containing sizes of each dimension	Double array
`DataSize`	Size of the data in the Image extension in bytes	Double
`Offset`	Number of bytes from the beginning of the file to the first data value	Double
`MissingDataValue`	Value used to represent undefined data	Double

Field Name	Description	Return Type
`Intercept`	Value, used with `Slope`, to calculate actual pixel values from the array pixel values, using the equation: `actual_value = Slope*array_value+Intercept`	Double
`Slope`	Value, used with `Intercept`, to calculate actual pixel values from the array pixel values, using the equation: `actual_value = Slope*array_value + Intercept`	Double
`Keywords`	A number-of-keywords-by-3 cell array containing all the Keywords, values, and comments in the Binary Table header	Cell array of strings

Unknown Structure

The `Unknown` structure contains the following fields, listed in the order they appear in the structure.

Field Name	Description	Return Type
`DataType`	Precision of the data	String
`Size`	Sizes of each dimension	Double array
`DataSize`	Size of the data in nonstandard extensions, in bytes	Double
`Offset`	Number of bytes from beginning of the file to the first data value	Double

Field Name	Description	Return Type
`MissingDataValue`	Representation of undefined data	Double
`Intercept`	Value, used with `Slope`, to calculate actual data values from the array data values, using the equation: `actual_value = Slope*array_value+Intercept`	Double
`Slope`	Value, used with `Intercept`, to calculate actual data values from the array data values, using the equation: `actual_value = Slope*array_value+Intercept`	Double
`Keywords`	A number-of-keywords-by-3 cell array containing all the Keywords, values, and comments in the Binary Table header	Cell array of strings

Example

Use `fitsinfo` to obtain information about the FITS file `tst0012.fits`. In addition to its primary data, the file also contains an example of the extensions `BinaryTable`, `Unknown`, `Image`, and `AsciiTable`.

```
S = fitsinfo('tst0012.fits');
S =
          Filename: [1x71 char]
       FileModDate: '12-Mar-2001 18:37:46'
          FileSize: 109440
          Contents: {'Primary' 'Binary Table' 'Unknown'
'Image' 'ASCII Table'}
       PrimaryData: [1x1 struct]
       BinaryTable: [1x1 struct]
```

```
           Unknown: [1x1 struct]
             Image: [1x1 struct]
        AsciiTable: [1x1 struct]
```

The `PrimaryData` field describes the data in the file. For example, the `Size` field indicates the data is a 102-by-109 matrix.

```
S.PrimaryData
          DataType: 'single'
              Size: [102 109]
          DataSize: 44472
 MissingDataValue: []
         Intercept: 0
             Slope: 1
            Offset: 2880
          Keywords: {25x3 cell}
```

The `AsciiTable` field describes the `AsciiTable` extension. For example, using the `FieldWidth` and `FieldPos` fields you can determine the length and location of each field within a row.

```
S.AsciiTable
ans =
              Rows: 53
           RowSize: 59
           NFields: 8
       FieldFormat: {'A9' 'F6.2' 'I3' 'E10.4' 'D20.15' 'A5' 'A1' 'I4'}
    FieldPrecision: {1x8 cell}
        FieldWidth: [9 6.2000 3 10.4000 20.1500 5 1 4]
          FieldPos: [1 11 18 22 33 54 54 55]
          DataSize: 3127
 MissingDataValue: {'*' '---.--' '  *' [] '*' '*' '*' ''}
         Intercept: [0 0 -70.2000 0 0 0 0 0]
             Slope: [1 1 2.1000 1 1 1 1 1]
            Offset: 103680
          Keywords: {65x3 cell}
```

See Also

`fitsread`

Purpose

Read data from FITS file

Syntax

```
data = fitsread(filename)
data = fitsread(filename, extname)
data = fitsread(filename, extname, index)
data = fitsread(filename, 'raw')
```

Description

`data = fitsread(filename)` reads the primary data of the Flexible Image Transport System (FITS) file specified by `filename`. Undefined data values are replaced by `NaN`. Numeric data are scaled by the slope and intercept values and are always returned in double precision. The `filename` argument is a string enclosed in single quotes.

`data = fitsread(filename, extname)` reads data from a FITS file according to the data array or extension specified in `extname`. You can specify only one `extname`. The valid choices for `extname` are shown in the following table.

Data Arrays or Extensions

extname	Description
'primary'	Read data from the primary data array.
'table'	Read data from the ASCII Table extension.
'bintable'	Read data from the Binary Table extension.
'image'	Read data from the Image extension.
'unknown'	Read data from the Unknown extension.

`data = fitsread(filename, extname, index)` is the same as the above syntax, except that if there is more than one of the specified extension type `extname` in the file, then only the one at the specified `index` is read.

`data = fitsread(filename, 'raw')` reads the primary or extension data of the FITS file, but, unlike the above syntaxes, does not replace

undefined data values with `NaN` and does not scale the data. The `data` returned has the same class as the data stored in the file.

Example

Read FITS file `tst0012.fits` into a 109-by-102 matrix called `data`.

```
data = fitsread('tst0012.fits');

whos data
  Name       Size            Bytes  Class

  data     109x102           88944  double array
```

Here is the beginning of the data read from the file.

```
data(1:5,1:6)
ans =
   135.200  134.9436  134.1752  132.8980  131.1165  128.8378
   137.568  134.9436  134.1752  132.8989  131.1167  126.3343
  135.9946  134.9437  134.1752  132.8989  131.1185  128.1711
  134.0093  134.9440  134.1749  132.8983  131.1201  126.3349
  131.5855  134.9439  134.1749  132.8989  131.1204  126.3356
```

Read only the Binary Table extension from the file.

```
data = fitsread('tst0012.fits', 'bintable')

data =
  Columns 1 through 4
    {11x1 cell}  [11x1 int16]  [11x3 uint8]  [11x2 double]
  Columns 5 through 9
    [11x3 cell]  {11x1 cell}  [11x1 int8]  {11x1 cell}  [11x3 int32]
  Columns 10 through 13
    [11x2 int32]  [11x2 single]  [11x1 double]  [11x1 uint8]
```

See Also

`fitsinfo`

Purpose

Round toward zero

Syntax

```
B = fix(A)
```

Description

`B = fix(A)` rounds the elements of `A` toward zero, resulting in an array of integers. For complex `A`, the imaginary and real parts are rounded independently.

Examples

```
a = [-1.9, -0.2, 3.4, 5.6, 7.0, 2.4+3.6i]

a =
  Columns 1 through 4
  -1.9000        -0.2000        3.4000        5.6000

  Columns 5 through 6
   7.0000        2.4000 + 3.6000i

fix(a)

ans =
  Columns 1 through 4
  -1.0000        0             3.0000        5.0000

  Columns 5 through 6
   7.0000        2.0000 + 3.0000i
```

See Also

`ceil`, `floor`, `round`

flipdim

Purpose

Flip array along specified dimension

Syntax

```
B = flipdim(A,dim)
```

Description

`B = flipdim(A,dim)` returns `A` with dimension `dim` flipped.

When the value of `dim` is `1`, the array is flipped row-wise down. When `dim` is `2`, the array is flipped columnwise left to right. `flipdim(A,1)` is the same as `flipud(A)`, and `flipdim(A,2)` is the same as `fliplr(A)`.

Examples

`flipdim(A,1)` where

```
A =

     1     4
     2     5
     3     6
```

produces

```
     3     6
     2     5
     1     4
```

See Also

`fliplr`, `flipud`, `permute`, `rot90`

Purpose

Flip matrix left to right

Syntax

```
B = fliplr(A)
```

Description

`B = fliplr(A)` returns `A` with columns flipped in the left-right direction, that is, about a vertical axis.

If `A` is a row vector, then `fliplr(A)` returns a vector of the same length with the order of its elements reversed. If `A` is a column vector, then `fliplr(A)` simply returns `A`.

Examples

If `A` is the 3-by-2 matrix,

```
A =
     1     4
     2     5
     3     6
```

`then fliplr(A)` produces

```
     4     1
     5     2
     6     3
```

If `A` is a row vector,

```
A =
     1     3     5     7     9
```

then `fliplr(A)` produces

```
     9     7     5     3     1
```

Limitations

The array being operated on cannot have more than two dimensions. This limitation exists because the axis upon which to flip a multidimensional array would be undefined.

See Also

`flipdim`, `flipud`, `rot90`

flipud

Purpose

Flip matrix up to down

Syntax

```
B = flipud(A)
```

Description

`B = flipud(A)` returns `A` with rows flipped in the up-down direction, that is, about a horizontal axis.

If `A` is a column vector, then `flipud(A)` returns a vector of the same length with the order of its elements reversed. If `A` is a row vector, then `flipud(A)` simply returns `A`.

Examples

If `A` is the 3-by-2 matrix,

```
A =
     1     4
     2     5
     3     6
```

`then flipud(A)` produces

```
     3     6
     2     5
     1     4
```

If `A` is a column vector,

```
A =
     3
     5
     7
```

then `flipud(A)` produces

```
A =
     7
     5
     3
```

Limitations

The array being operated on cannot have more than two dimensions. This limitation exists because the axis upon which to flip a multidimensional array would be undefined.

See Also

`flipdim`, `fliplr`, `rot90`

floor

Purpose

Round toward minus infinity

Syntax

```
B = floor(A)
```

Description

`B = floor(A)` rounds the elements of `A` to the nearest integers less than or equal to `A`. For complex `A`, the imaginary and real parts are rounded independently.

Examples

```
a = [-1.9, -0.2, 3.4, 5.6, 7.0, 2.4+3.6i]

a =
  Columns 1 through 4
  -1.9000            -0.2000             3.4000             5.6000

  Columns 5 through 6
   7.0000             2.4000 + 3.6000i

floor(a)

ans =
  Columns 1 through 4
  -2.0000            -1.0000             3.0000             5.0000

  Columns 5 through 6
   7.0000             2.0000 + 3.0000i
```

See Also

`ceil`, `fix`, `round`

Purpose

Count floating-point operations

Description

This is an obsolete function. With the incorporation of LAPACK in MATLAB version 6, counting floating-point operations is no longer practical.

flow

Purpose

Simple function of three variables

Syntax

```
v = flow
v = flow(n)
v = flow(x,y,z)
[x,y,z,v] = flow(...)
```

Description

`flow`, a function of three variables, generates fluid-flow data that is useful for demonstrating `slice`, `interp3`, and other functions that visualize scalar volume data.

`v = flow` produces a 50-by-25-by-25 array.

`v = flow(n)` produces a 2`n`-by-`n`-by-`n` array.

`v = flow(x,y,z)` evaluates the speed profile at the points `x`, `y`, and `z`.

`[x,y,z,v] = flow(...)` returns the coordinates as well as the volume data.

See Also

`slice`, `interp3`

"Volume Visualization" on page 1-102 for related functions

See "Example — Slicing Fluid Flow Data" for an example that uses `flow`.

Purpose

Find minimum of single-variable function on fixed interval

Syntax

```
x = fminbnd(fun,x1,x2)
x = fminbnd(fun,x1,x2,options)
[x,fval] = fminbnd(...)
[x,fval,exitflag] = fminbnd(...)
[x,fval,exitflag,output] = fminbnd(...)
```

Description

`fminbnd` finds the minimum of a function of one variable within a fixed interval.

`x = fminbnd(fun,x1,x2)` returns a value `x` that is a local minimizer of the function that is described in `fun` in the interval `x1 < x < x2`. `fun` is a function handle. See "Function Handles" in the MATLAB Programming documentation for more information.

"Parameterizing Functions Called by Function Functions" in the MATLAB Mathematics documentation, explains how to pass additional parameters to your objective function `fun`.

`x = fminbnd(fun,x1,x2,options)` minimizes with the optimization parameters specified in the structure `options`. You can define these parameters using the `optimset` function. `fminbnd` uses these `options` structure fields:

`Display`	Level of display. `'off'` displays no output; `'iter'` displays output at each iteration; `'final'` displays just the final output; `'notify'` (default) displays output only if the function does not converge.
`FunValCheck`	Check whether objective function values are valid. `'on'` displays an error when the objective function returns a value that is `complex` or `NaN`. `'off'` displays no error.
`MaxFunEvals`	Maximum number of function evaluations allowed.
`MaxIter`	Maximum number of iterations allowed.

`OutputFcn`	User-defined function that is called at each iteration. See "Output Function" in the Optimization Toolbox for more information.
`PlotFcns`	User-defined plot function that is called at each iteration. See "Plot Functions" in the Optimization Toolbox for more information.
`TolX`	Termination tolerance on `x`.

`[x,fval] = fminbnd(...)` returns the value of the objective function computed in `fun` at `x`.

`[x,fval,exitflag] = fminbnd(...)` returns a value `exitflag` that describes the exit condition of `fminbnd`:

`1`	`fminbnd` converged to a solution `x` based on `options.TolX`.
`0`	Maximum number of function evaluations or iterations was reached.
`-1`	Algorithm was terminated by the output function.
`-2`	Bounds are inconsistent (`x1 > x2`).

`[x,fval,exitflag,output] = fminbnd(...)` returns a structure `output` that contains information about the optimization:

`output.algorithm`	Algorithm used
`output.funcCount`	Number of function evaluations
`output.iterations`	Number of iterations
`output.message`	Exit message

Arguments

`fun` is the function to be minimized. `fun` accepts a scalar `x` and returns a scalar `f`, the objective function evaluated at `x`. The function `fun` can be specified as a function handle for an M-file function

```
x = fminbnd(@myfun,x1,x2);
```

where `myfun.m` is an M-file function such as

```
function f = myfun(x)
f = ...         % Compute function value at x.
```

or as a function handle for an anonymous function:

```
x = fminbnd(@(x) sin(x*x),x1,x2);
```

Other arguments are described in the syntax descriptions above.

Examples

`x = fminbnd(@cos,3,4)` computes π to a few decimal places and gives a message on termination.

```
[x,fval,exitflag] = ...
   fminbnd(@cos,3,4,optimset('TolX',1e-12,'Display','off'))
```

computes π to about 12 decimal places, suppresses output, returns the function value at `x`, and returns an `exitflag` of 1.

The argument `fun` can also be a function handle for an anonymous function. For example, to find the minimum of the function $f(x) = x^3 - 2x - 5$ on the interval `(0,2)`, create an anonymous function `f`

```
f = @(x)x.^3-2*x-5;
```

Then invoke `fminbnd` with

```
x = fminbnd(f, 0, 2)
```

The result is

```
x =
    0.8165
```

The value of the function at the minimum is

```
y = f(x)

y =
    -6.0887
```

If `fun` is parameterized, you can use anonymous functions to capture the problem-dependent parameters. For example, suppose you want to minimize the objective function `myfun` defined by the following M-file function.

```
function f = myfun(x,a)
f = (x - a)^2;
```

Note that `myfun` has an extra parameter `a`, so you cannot pass it directly to `fminbind`. To optimize for a specific value of `a`, such as `a = 1.5`.

1. Assign the value to `a`.

   ```
   a = 1.5; % define parameter first
   ```

2. Call `fminbnd` with a one-argument anonymous function that captures that value of `a` and calls `myfun` with two arguments:

   ```
   x = fminbnd(@(x) myfun(x,a),0,1)
   ```

Algorithm

`fminbnd` is an M-file. The algorithm is based on golden section search and parabolic interpolation. Unless the left endpoint x_1 is very close to the right endpoint x_2, `fminbnd` never evaluates `fun` at the endpoints, so `fun` need only be defined for x in the interval $x_1 < x < x_2$. If the minimum actually occurs at x_1 or x_2, `fminbnd` returns an interior point at a distance of no more than `2*TolX` from x_1 or x_2, where `TolX` is the termination tolerance. See [1] or [2] for details about the algorithm.

Limitations

The function to be minimized must be continuous. `fminbnd` may only give local solutions.

`fminbnd` often exhibits slow convergence when the solution is on a boundary of the interval.

`fminbnd` only handles real variables.

[2] Brent, Richard. P., *Algorithms for Minimization without Derivatives*, Prentice-Hall, Englewood Cliffs, New Jersey, 1973

Purpose

Find minimum of unconstrained multivariable function using derivative-free method

Syntax

```
x = fminsearch(fun,x0)
x = fminsearch(fun,x0,options)
[x,fval] = fminsearch(...)
[x,fval,exitflag] = fminsearch(...)
[x,fval,exitflag,output] = fminsearch(...)
```

Description

`fminsearch` finds the minimum of a scalar function of several variables, starting at an initial estimate. This is generally referred to as *unconstrained nonlinear optimization*.

`x = fminsearch(fun,x0)` starts at the point `x0` and finds a local minimum `x` of the function described in `fun`. `x0` can be a scalar, vector, or matrix. `fun` is a function handle. See "Function Handles" in the MATLAB Programming documentation for more information.

"Parameterizing Functions Called by Function Functions" in the MATLAB Mathematics documentation, explains how to pass additional parameters to your objective function `fun`. See also "Example 2" on page 2-1351 and "Example 3" on page 2-1351 below.

`x = fminsearch(fun,x0,options)` minimizes with the optimization parameters specified in the structure `options`. You can define these parameters using the `optimset` function. `fminsearch` uses these `options` structure fields:

`Display`	Level of display. `'off'` displays no output; `'iter'` displays output at each iteration; `'final'` displays just the final output; `'notify'` (default) displays output only if the function does not converge.
`FunValCheck`	Check whether objective function values are valid. `'on'` displays an error when the objective function returns a value that is `complex`, `Inf` or `NaN`. `'off'` (the default) displays no error.
`MaxFunEvals`	Maximum number of function evaluations allowed

`MaxIter`	Maximum number of iterations allowed
`OutputFcn`	User-defined function that is called at each iteration. See "Output Function" in the Optimization Toolbox for more information.
`PlotFcns`	User-defined plot function that is called at each iteration. See "Plot Functions" in the Optimization Toolbox for more information.
`TolFun`	Termination tolerance on the function value
`TolX`	Termination tolerance on `x`

`[x,fval] = fminsearch(...)` returns in `fval` the value of the objective function `fun` at the solution `x`.

`[x,fval,exitflag] = fminsearch(...)` returns a value `exitflag` that describes the exit condition of `fminsearch`:

`1`	`fminsearch` converged to a solution `x`.
`0`	Maximum number of function evaluations or iterations was reached.
`-1`	Algorithm was terminated by the output function.

`[x,fval,exitflag,output] = fminsearch(...)` returns a structure `output` that contains information about the optimization:

`output.algorithm`	Algorithm used
`output.funcCount`	Number of function evaluations
`output.iterations`	Number of iterations
`output.message`	Exit message

Arguments

`fun` is the function to be minimized. It accepts an input `x` and returns a scalar `f`, the objective function evaluated at `x`. The function `fun` can be specified as a function handle for an M-file function

```
x = fminsearch(@myfun, x0)
```

where `myfun` is an M-file function such as

```
function f = myfun(x)
f = ...            % Compute function value at x
```

or as a function handle for an anonymous function, such as

```
x = fminsearch(@(x)sin(x^2), x0);
```

Other arguments are described in the syntax descriptions above.

Examples

Example 1

A classic test example for multidimensional minimization is the Rosenbrock banana function

$$f(x) = 100(x_2 - x_1^2)^2 + (1 - x_1)^2$$

The minimum is at `(1,1)` and has the value `0`. The traditional starting point is `(-1.2,1)`. The anonymous function shown here defines the function and returns a function handle called `banana`:

```
banana = @(x)100*(x(2)-x(1)^2)^2+(1-x(1))^2;
```

Pass the function handle to `fminsearch`:

```
[x,fval] = fminsearch(banana,[-1.2, 1])
```

This produces

```
x =

    1.0000    1.0000

fval =

    8.1777e-010
```

This indicates that the minimizer was found to at least four decimal places with a value near zero.

Example 2

If `fun` is parameterized, you can use anonymous functions to capture the problem-dependent parameters. For example, suppose you want to minimize the objective function `myfun` defined by the following M-file function.

```
function f = myfun(x,a)
f = x(1)^2 + a*x(2)^2;
```

Note that `myfun` has an extra parameter `a`, so you cannot pass it directly to `fminsearch`. To optimize for a specific value of `a`, such as `a = 1.5`.

1. Assign the value to `a`.

   ```
   a = 1.5; % define parameter first
   ```

2. Call `fminsearch` with a one-argument anonymous function that captures that value of `a` and calls `myfun` with two arguments:

   ```
   x = fminsearch(@(x) myfun(x,a),[0,1])
   ```

Example 3

You can modify the first example by adding a parameter a to the second term of the banana function:

$$f(x) = 100(x_2 - x_1^2)^2 + (a - x_1)^2$$

This changes the location of the minimum to the point `[a,a^2]`. To minimize this function for a specific value of `a`, for example `a = sqrt(2)`, create a one-argument anonymous function that captures the value of `a`.

```
a = sqrt(2);
banana = @(x)100*(x(2)-x(1)^2)^2+(a-x(1))^2;
```

Then the statement

```
[x,fval] = fminsearch(banana, [-1.2, 1], ...
   optimset('TolX',1e-8));
```

seeks the minimum `[sqrt(2), 2]` to an accuracy higher than the default on `x`.

Algorithm

fminsearch uses the simplex search method of [1]. This is a direct search method that does not use numerical or analytic gradients.

If `n` is the length of `x`, a simplex in `n`-dimensional space is characterized by the `n+1` distinct vectors that are its vertices. In two-space, a simplex is a triangle; in three-space, it is a pyramid. At each step of the search, a new point in or near the current simplex is generated. The function value at the new point is compared with the function's values at the vertices of the simplex and, usually, one of the vertices is replaced by the new point, giving a new simplex. This step is repeated until the diameter of the simplex is less than the specified tolerance.

Limitations

`fminsearch` can often handle discontinuity, particularly if it does not occur near the solution. fminsearch may only give local solutions.

`fminsearch` only minimizes over the real numbers, that is, x must only consist of real numbers and $f(x)$ must only return real numbers. When x has complex variables, they must be split into real and imaginary parts.

References

[1] Lagarias, J.C., J. A. Reeds, M. H. Wright, and P. E. Wright, "Convergence Properties of the Nelder-Mead Simplex Method in Low Dimensions," *SIAM Journal of Optimization*, Vol. 9 Number 1, pp. 112-147, 1998.

Purpose

Open file, or obtain information about open files

Syntax

```
fid = fopen(filename)
fid = fopen(filename, permission)
fid = fopen(filename, permission_tmode)
[fid, message] = fopen(filename, permission)
[fid, message] = fopen(filename, permission, machineformat)
[fid, message] = fopen(filename, permission, machineformat,
   encoding)
fids = fopen('all')
[filename, permission, machineformat, encoding] = fopen(fid)
```

Description

`fid = fopen(filename)` opens the file `filename` for read access. (On Windows systems, `fopen` opens files for binary read access.) The `filename` argument is a string enclosed in single quotes. It can be a `MATLABPATH` relative partial pathname if the file is opened for reading only. A relative path is always searched for first with respect to the current directory. If it is not found, and reading only is specified or implied, then `fopen` does an additional search of the `MATLABPATH`.

`fid` is a scalar MATLAB integer, called a file identifier. You use the `fid` as the first argument to other file input/output routines. If `fopen` cannot open the file, it returns `-1`. Two file identifiers are automatically available and need not be opened. They are `fid=1` (standard output) and `fid=2` (standard error).

`fid = fopen(filename, permission)` opens the file `filename` in the specified `permission`. The `permission` argument can be any of the following:

Permission Specifiers

Permission	Description
'r'	Open file for reading (default).
'w'	Open file, or create new file, for writing; discard existing contents, if any.

Permission Specifiers (Continued)

Permission	Description
'a'	Open file, or create new file, for writing; append data to the end of the file.
'r+'	Open file for reading and writing.
'w+'	Open file, or create new file, for reading and writing; discard existing contents, if any.
'a+'	Open file, or create new file, for reading and writing; append data to the end of the file.
'A'	Append without automatic flushing; used with tape drives.
'W'	Write without automatic flushing; used with tape drives.

Note If the file is opened in update mode (`'+'`), an input command like `fread`, `fscanf`, `fgets`, or `fgetl` cannot be immediately followed by an output command like `fwrite` or `fprintf` without an intervening `fseek` or `frewind`. The reverse is also true: that is, an output command like `fwrite` or `fprintf` cannot be immediately followed by an input command like `fread`, `fscanf`, `fgets`, or `fgetl` without an intervening `fseek` or `frewind`.

`fid = fopen(filename, permission_tmode)` on Windows systems, opens the file in text mode instead of binary mode (the default). The `permission_tmode` argument consists of any of the specifiers shown in the Permission Specifiers on page 2-1255 table above, followed by the letter `t`, for example `'rt'` or `'wt+`. On UNIX, text and binary mode are the same.

Binary and Text Modes

Mode	Behavior
Binary	No characters are given special treatment.
Text	On a read operation, whenever MATLAB encounters a carriage return followed by a newline character, it removes the carriage return from the input. On a write or append operation, MATLAB inserts a carriage return before any newline character.

`[fid, message] = fopen(filename, permission)` opens a file as above. If it cannot open the file, `fid` equals `-1` and `message` contains a system-dependent error message. If `fopen` successfully opens a file, the value of `message` is empty.

`[fid, message] = fopen(filename, permission, machineformat)` opens the file with the specified `permission` and treats data read using `fread` or data written using `fwrite` as having a format given by `machineformat`. `machineformat` is one of the following strings:

Full Precision Support

`'ieee be'` or `'b'`	IEEE floating point with big-endian byte ordering
`'ieee le'` or `'l'`	IEEE floating point with little-endian byte ordering
`'ieee-be.l64'` or `'s'`	IEEE floating point with big-endian byte ordering and 64-bit long data type
`'ieee-le.l64'` or `'a'`	IEEE floating point with little-endian byte ordering and 64-bit long data type
`'native'` or `'n'`	Numeric format of the machine on which MATLAB is running (the default)

Full Precision Support (Continued)

'vaxd' or 'd'	VAX D floating point and VAX ordering
'vaxg' or 'g'	VAX G floating point and VAX ordering

Limited Precision Support: (double or equivalent)

'cray' or 'c'	Cray floating point with big-endian byte ordering

`[fid, message] = fopen(filename, permission, machineformat, encoding)` opens the specified file using the specified `permission` and `machineformat`. `encoding` is a string that specifies the character encoding scheme associated with the file. It must be the empty string (`''`) or a name or alias for an encoding scheme. Some examples are `'UTF-8'`, `'latin1'`, `'US-ASCII'`, and `'Shift_JIS'`. For common names and aliases, see the Web site `http://www.iana.org/assignments/character-sets`. If `encoding` is unspecified or is the empty string (`''`), MATLAB's default encoding scheme is used.

`fids = fopen('all')` returns a row vector containing the file identifiers of all open files, not including `1` and `2` (standard output and standard error). The number of elements in the vector is equal to the number of open files.

`[filename, permission, machineformat, encoding] = fopen(fid)` returns the `filename`, `permission`, `machineformat`, and `encoding` values used by MATLAB when it opened the file associated with identifier `fid`. MATLAB does not determine these output values by reading information from the opened file. For any of these parameters that were not specified when the file was opened, MATLAB returns its default value. The `encoding` string is a standard character encoding scheme name that may not be the same as the `encoding` argument used in the call to `fopen` that opened the file. An invalid `fid` returns empty strings for all output arguments.

The 'W' and 'A' modes do not automatically perform a flush of the current output buffer after output operations.

Examples

The example uses fopen to open a file and then passes the fid returned by fopen to other file I/O functions to read data from the file and then close the file.

```
fid = fopen('fgetl.m');
while 1
    tline = fgetl(fid);
    if ~ischar(tline),   break,   end
    disp(tline)
end
fclose(fid);
```

See Also

fclose, ferror, fprintf, fread, fscanf, fseek, ftell, fwrite

fopen (serial)

Purpose

Connect serial port object to device

Syntax

```
fopen(obj)
```

Arguments

`obj`	A serial port object or an array of serial port objects.

Description

`fopen(obj)` connects `obj` to the device.

Remarks

Before you can perform a read or write operation, `obj` must be connected to the device with the `fopen` function. When `obj` is connected to the device:

- Data remaining in the input buffer or the output buffer is flushed.
- The `Status` property is set to `open`.
- The `BytesAvailable`, `ValuesReceived`, `ValuesSent`, and `BytesToOutput` properties are set to 0.

An error is returned if you attempt to perform a read or write operation while `obj` is not connected to the device. You can connect only one serial port object to a given device.

Some properties are read-only while the serial port object is open (connected), and must be configured before using `fopen`. Examples include `InputBufferSize` and `OutputBufferSize`. Refer to the property reference pages to determine which properties have this constraint.

The values for some properties are verified only after `obj` is connected to the device. If any of these properties are incorrectly configured, then an error is returned when `fopen` is issued and `obj` is not connected to the device. Properties of this type include `BaudRate`, and are associated with device settings.

If you use the `help` command to display help for `fopen`, then you need to supply the pathname shown below.

```
help serial/fopen
```

Example

This example creates the serial port object `s`, connects `s` to the device using `fopen`, writes and reads text data, and then disconnects `s` from the device.

```
s = serial('COM1');
fopen(s)
fprintf(s,'*IDN?')
idn = fscanf(s);
fclose(s)
```

See Also

Functions

`fclose`

Properties

`BytesAvailable`, `BytesToOutput`, `Status`, `ValuesReceived`, `ValuesSent`

Purpose

Execute block of code specified number of times

Syntax

```
for x=initval:endval, statements, end
for x=initval:stepval:endval, statements, end
```

Description

`for x=initval:endval, statements, end` repeatedly executes one or more MATLAB *`statements`* in a loop. Loop counter variable `x` is initialized to value `initval` at the start of the first pass through the loop, and automatically increments by 1 each time through the loop. The program makes repeated passes through *`statements`* until either `x` has incremented to the value *`endval`*, or MATLAB encounters a `break`, or `return` instruction, thus forcing an immediately exit of the loop. If MATLAB encounters a `continue` statement in the loop code, it immediately exits the current pass at the location of the `continue` statement, skipping any remaining code in that pass, and begins another pass at the start of the loop *`statements`* with the value of the loop counter incremented by 1.

The values `initval` and `endval` must be real numbers or arrays of real numbers, or can also be calls to functions that return the same. The value assigned to `x` is often used in the code within the loop, however it is recommended that you do not assign to `x` in the loop code.

`for x=initval:stepval:endval, statements, end` is the same as the above syntax, except that loop counter `x` is incremented (or decremented when *`stepval`* is negative) by the value *`stepval`* on each iteration through the loop. The value `stepval` must be a real number or can also be a call to a function that returns a real number.

The general format is

```
for variable = initval:endval
    statement
    ...
    statement
end
```

The scope of the `for` statement is always terminated with a matching `end`.

See "Program Control Statements" in the MATLAB Programming documentation for more information on controlling the flow of your program code.

Remarks

It is recommended that you do not assign to the loop control variable while in the body of a loop. If you do assign to a variable that has the same name as the loop control variable (see `k` in the example below), then the value of that variable alternates between the value assigned by the `for` statement at the start of each loop iteration and the value explicitly assigned to it in the loop code:

```
for k=1:2
   disp(sprintf('   At the start of the loop, k = %d', k))
   k = 10;
   disp(sprintf('   Following the assignment, k = %d\n', k))
end

   At the start of the loop, k = 1
   Following the assignment, k = 10

   At the start of the loop, k = 2
   Following the assignment, k = 10
```

Examples

Assume `k` has already been assigned a value. Create the Hilbert matrix, using `zeros` to preallocate the matrix to conserve memory:

```
a = zeros(k,k)  % Preallocate matrix
for m = 1:k
    for n = 1:k
        a(m,n) = 1/(m+n -1);
    end
end
```

Step `s` with increments of `-0.1`:

```
for s = 1.0: -0.1: 0.0,..., end
```

Step `s` with values `1`, `5`, `8`, and `17`:

```
for s = [1,5,8,17], ..., end
```

Successively set `e` to the unit `n`-vectors:

```
for e = eye(n), ..., end
```

The line

```
for V = A, ..., end
```

has the same effect as

```
for k = 1:n, V = A(:,k); ..., end
```

except `k` is also set here.

See Also

`end`, `while`, `break`, `continue`, `return`, `if`, `switch`, `colon`

Purpose

Set display format for output

Graphical Interface

As an alternative to `format`, use preferences. Select **Preferences** from the **File** menu in the MATLAB desktop and use **Command Window** preferences.

Syntax

```
format
format type
format('type')
```

Description

Use the `format` function to control the output format of numeric values displayed in the Command Window.

Note The `format` function affects only how numbers are displayed, not how MATLAB computes or saves them.

`format` by itself, changes the output format to the default appropriate for the class of the variable currently being used. For floating-point variables, for example, the default is `format short` (i.e., 5-digit scaled, fixed-point values).

`format type` changes the format to the specified *`type`*. The tables shown below list the allowable values for *`type`*.

`format('type')` is the function form of the syntax.

The tables below show the allowable values for *`type`*, and provides an example for each type using `pi`.

Use these format types to switch between different output display formats for floating-point variables.

Type	Result
`short`	Scaled fixed point format, with 4 digits after the decimal point. For example, `3.1416`
`long`	Scaled fixed point format with 14 to 15 digits after the decimal point for double; and 7 digits after the decimal point for single. For example, `3.14159265358979`
`short e`	Floating point format, with 4 digits after the decimal point. For example, `3.1416e+000`
`long e`	Floating point format, with 14 to 15 digits after the decimal point for double; and 7 digits after the decimal point for single. For example, `3.141592653589793e+000`
`short g`	Best of fixed or floating point, with 4 digits after the decimal point. For example, `3.1416`
`long g`	Best of fixed or floating point, with 14 to 15 digits after the decimal point for double; and 7 digits after the decimal point for single. For example, `3.14159265358979`
`short eng`	Engineering format that has 4 digits after the decimal point, and a power that is a multiple of three. For example, `3.1416e+000`
`long eng`	Engineering format that has exactly 16 significant digits and a power that is a multiple of three. For example, `3.14159265358979e+000`

Use these format types to switch between different output display formats for all numeric variables.

Value for type	Result
`+`	+, -, blank
`bank`	Fixed dollars and cents. For example, `3.14`

Value for type	Result
`hex`	Hexadecimal (hexadecimal representation of a binary double-precision number). For example, `400921fb54442d18`
`rat`	Ratio of small integers. For example, `355/113`

Use these format types to affect the spacing in the display of all variables.

Value for type	Result	Example
`compact`	Suppresses excess line feeds to show more output in a single screen. Contrast with `loose`.	`theta = pi/2 theta = 1.5708`
`loose`	Adds linefeeds to make output more readable. Contrast with `compact`.	`theta = pi/2 theta = 1.5708`

Remarks

Computations on floating-point variables, namely `single` or `double`, are done in appropriate floating-point precision, no matter how those variables are displayed. Computations on integer variables are done natively in integer.

MATLAB always displays integer variables to the appropriate number of digits for the class. For example, MATLAB uses three digits to display numbers of type `int8` (i.e., -128:127). Setting `format` to `short` or `long` does not affect the display of integer variables.

The specified format applies only to the current MATLAB session. To maintain a format across sessions, use MATLAB preferences.

To see which `type` is currently in use, type

```
get(0,'Format')
```

To see if `compact` or `loose` formatting is currently selected, type

```
get(0,'FormatSpacing').
```

Examples

Example 1

Change the format to `long` by typing

```
format long
```

View the result for the value of `pi` by typing

```
pi
ans =
   3.14159265358979
```

View the current format by typing

```
get(0,'format')
ans =
   long
```

Set the format to `short e` by typing

```
format short e
```

or use the function form of the syntax

```
format('short','e')
```

Example 2

When the format is set to `short`, both `pi` and `single(pi)` display as 5-digit values:

```
format short

pi
ans =
    3.1416

single(pi)
ans =
    3.1416
```

Now set format to `long`, and `pi` displays a 15-digit value while `single(pi)` display an 8-digit value:

```
format long

pi
ans =
    3.14159265358979

single(pi)
ans =
    3.1415927
```

Example 3

Set the format to its default, and display the maximum values for integers and real numbers in MATLAB:

```
format

intmax('uint64')
ans =
   18446744073709551615

realmax
ans =
  1.7977e+308
```

Now change the format to hexadecimal, and display these same values:

```
format hex

intmax('uint64')
ans =
   ffffffffffffffff

realmax
ans =
   7fefffffffffffff
```

The hexadecimal display corresponds to the internal representation of the value. It is not the same as the hexadecimal notation in the C programming language.

Example 4

This example illustrates the `short eng` and `long eng` formats. The value assigned to variable `A` increases by a multiple of 10 each time through the `for` loop.

```
A = 5.123456789;

for k=1:10
   disp(A)
   A = A * 10;
end
```

The values displayed for `A` are shown here. The power of 10 is always a multiple of 3. The value itself is expressed in 5 or more digits for the `short eng` format, and in exactly 15 digits for `long eng`:

```
   format short eng                format long eng

     5.1235e+000                  5.12345678900000e+000
    51.2346e+000                 51.2345678900000e+000
   512.3457e+000                512.345678900000e+000
     5.1235e+003                  5.12345678900000e+003
    51.2346e+003                 51.2345678900000e+003
   512.3457e+003                512.345678900000e+003
     5.1235e+006                  5.12345678900000e+006
    51.2346e+006                 51.2345678900000e+006
   512.3457e+006                512.345678900000e+006
     5.1235e+009                  5.12345678900000e+009
```

Algorithms

If the largest element of a matrix is larger than 10^3 or smaller than 10^{-3}, MATLAB applies a common scale factor for the short and long formats. The function `format +` displays +, -, and blank characters for positive, negative, and zero elements. `format hex` displays the hexadecimal

representation of a binary double-precision number. `format rat` uses a continued fraction algorithm to approximate floating-point values by ratios of small integers. See `rat.m` for the complete code.

Purpose

Plot function between specified limits

Syntax

```
fplot(fun,limits)
fplot(fun,limits,LineSpec)
fplot(fun,limits,tol)
fplot(fun,limits,tol,LineSpec)
fplot(fun,limits,n)
fplot(fun,lims,...)
fplot(axes_handle,...)
[X,Y] = fplot(fun,limits,...)
```

Description

`fplot` plots a function between specified limits. The function must be of the form $y = f(x)$, where x is a vector whose range specifies the limits, and `y` is a vector the same size as `x` and contains the function's value at the points in x (see the first example). If the function returns more than one value for a given x, then y is a matrix whose columns contain each component of $f(x)$ (see the second example).

`fplot(fun,limits)` plots `fun` between the limits specified by `limits`. `limits` is a vector specifying the x-axis limits (`[xmin xmax]`), or the x- and y-axes limits, (`[xmin xmax ymin ymax]`).

`fun` must be

- The name of an M-file function
- A string with variable `x` that may be passed to `eval`, such as `'sin(x)'`, `'diric(x,10)'`, or `'[sin(x),cos(x)]'`
- A function handle for an M-file function or an anonymous function (see "Function Handles" and "Anonymous Functions" for more information)

The function $f(x)$ must return a row vector for each element of vector x. For example, if $f(x)$ returns `[f1(x),f2(x),f3(x)]` then for input `[x1;x2]` the function should return the matrix

```
f1(x1) f2(x1) f3(x1)
f1(x2) f2(x2) f3(x2)
```

`fplot(fun,limits,LineSpec)` plots `fun` using the line specification `LineSpec`.

`fplot(fun,limits,tol)` plots `fun` using the relative error tolerance `tol` (the default is `2e-3`, i.e., 0.2 percent accuracy).

`fplot(fun,limits,tol,LineSpec)` plots `fun` using the relative error tolerance `tol` and a line specification that determines line type, marker symbol, and color. See `LineSpec` for more information.

`fplot(fun,limits,n)` with `n >= 1` plots the function with a minimum of `n+1` points. The default `n` is `1`. The maximum step size is restricted to be `(1/n)*(xmax-xmin)`.

`fplot(fun,lims,...)` accepts combinations of the optional arguments `tol`, `n`, and `LineSpec`, in any order.

`fplot(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`[X,Y] = fplot(fun,limits,...)` returns the abscissas and ordinates for `fun` in `X` and `Y`. No plot is drawn on the screen; however, you can plot the function using `plot(X,Y)`.

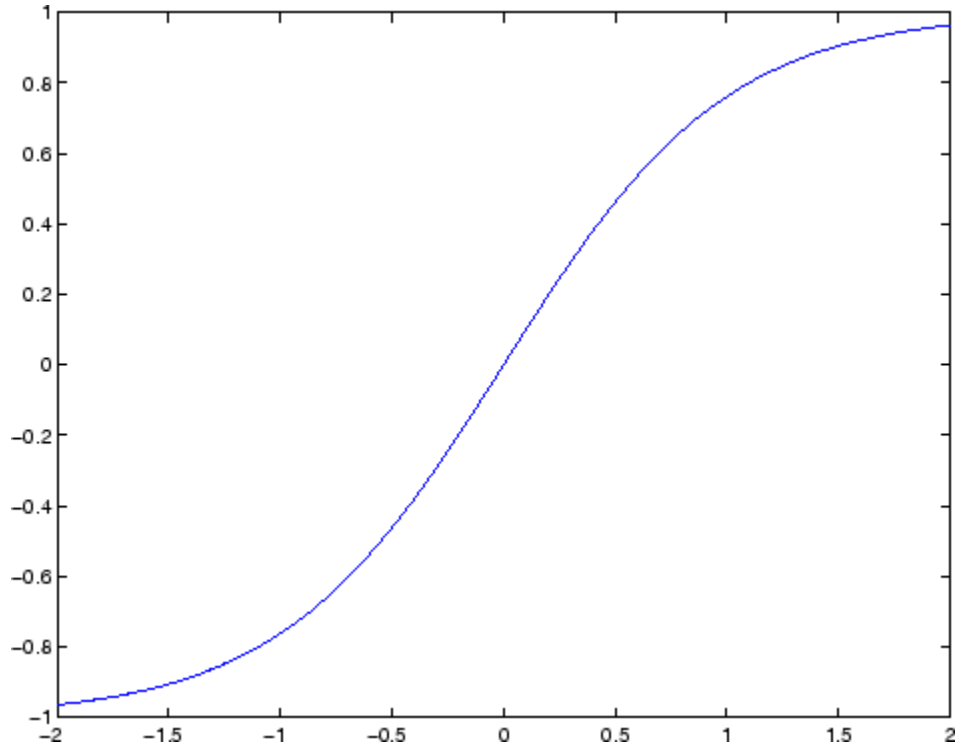
Remarks

`fplot` uses adaptive step control to produce a representative graph, concentrating its evaluation in regions where the function's rate of change is the greatest.

Examples

Plot the hyperbolic tangent function from -2 to 2:

```
fnch = @tanh;
fplot(fnch,[-2 2])
```



Create an M-file, `myfun`, that returns a two-column matrix:

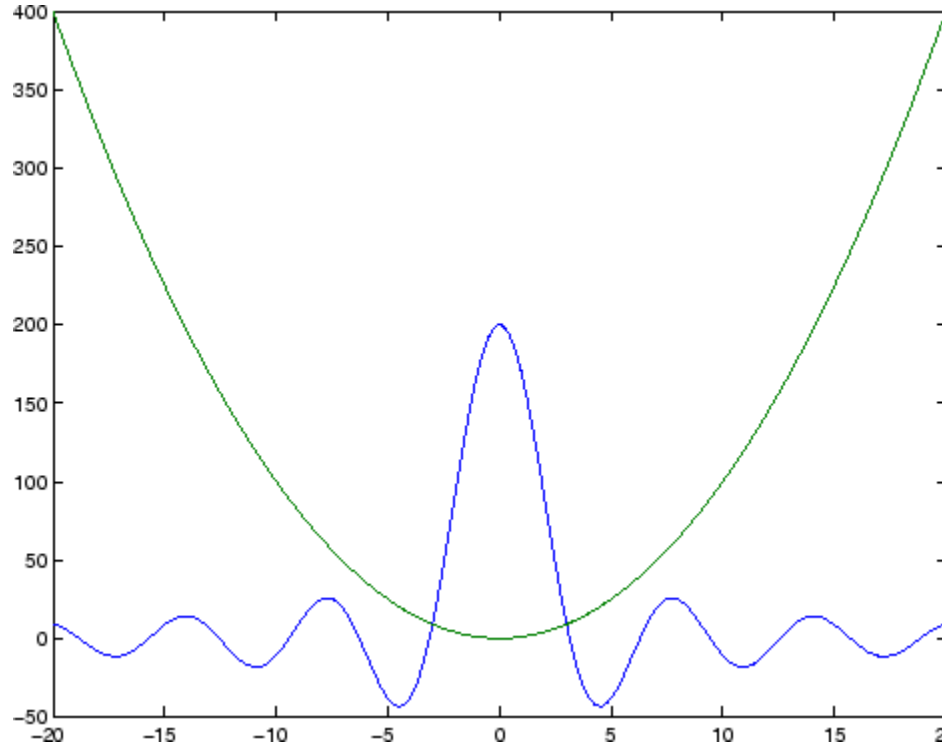
```
function Y = myfun(x)
Y(:,1) = 200*sin(x(:))./x(:);
Y(:,2) = x(:).^2;
```

Create a function handle pointing to `myfun`:

```
fh = @myfun;
```

Plot the function with the statement

```
fplot(fh,[-20 20])
```



Additional Example

This example passes function handles to `fplot`, one created from a MATLAB function and the other created from an anonymous function.

```
hmp = @humps;
subplot(2,1,1);fplot(hmp,[0 1])
sn = @(x) sin(1./x);
subplot(2,1,2);fplot(sn,[.01 .1])
```

Purpose

Write formatted data to file

Syntax

```
count = fprintf(fid, format, A, ...)
```

Description

`count = fprintf(fid, format, A, ...)` formats the data in the real part of matrix `A` (and in any additional matrix arguments) under control of the specified `format` string, and writes it to the file associated with file identifier `fid`. `fprintf` returns a count of the number of bytes written.

Argument `fid` is an integer file identifier obtained from `fopen`. (It can also be `1` for standard output (the screen) or `2` for standard error. See `fopen` for more information.) Omitting `fid` causes output to appear on the screen.

See "Formatting Strings" in the MATLAB Programming documentation for more detailed information on using string formatting commands.

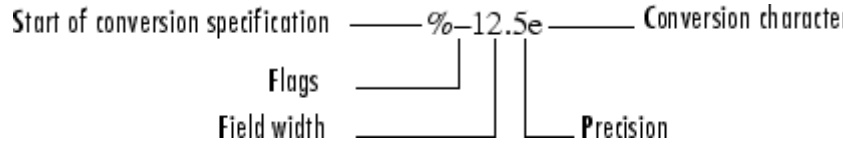
Format String

The `format` argument is a string containing ordinary characters and/or C language conversion specifications. A conversion specification controls the notation, alignment, significant digits, field width, and other aspects of output format. The format string can contain escape characters to represent nonprinting characters such as newline characters and tabs.

Conversion specifications begin with the `%` character and contain these optional and required elements:

- Flags (optional)
- Width and precision fields (optional)
- A subtype specifier (optional)
- Conversion character (required)

You specify these elements in the following order:



Flags

You can control the alignment of the output using any of these optional flags.

Character	Description	Example
Minus sign ( )	Left-justifies the converted argument in its field	`%-5.2d`
Plus sign (+)	Always prints a sign character (+ or)	`%+5.2d`
Space character	Inserts a space before the value	`% 5.2d`
Zero (0)	Pads with zeros rather than spaces	`%05.2d`

Field Width and Precision Specifications

You can control the width and precision of the output by including these options in the format string.

Character	Description	Example
Field width	A digit string specifying the minimum number of digits to be printed	`%6f`
Precision	A digit string including a period (.) specifying the number of digits to be printed to the right of the decimal point	`%6.2f`

Conversion Characters

Conversion characters specify the notation of the output.

Specifier	Description
%c	Single character
%d	Decimal notation (signed)
%e	Exponential notation (using a lowercase e as in 3.1415e+00)
%E	Exponential notation (using an uppercase E as in 3.1415E+00)
%f	Fixed-point notation
%g	The more compact of %e or %f, as defined in [2]. Insignificant zeros do not print.
%G	Same as %g, but using an uppercase E
%i	Decimal notation (signed)
%o	Octal notation (unsigned)
%s	String of characters
%u	Decimal notation (unsigned)
%x	Hexadecimal notation (using lowercase letters a–f)
%X	Hexadecimal notation (using uppercase letters A–F)

Conversion characters %o, %u, %x, and %X support subtype specifiers. See Remarks for more information.

Escape Characters

This table lists the escape character sequences you use to specify nonprinting characters in a format specification.

Character	Description
\b	Backspace
\f	Form feed
\n	New line

Character	Description
`\r`	Carriage return
`\t`	Horizontal tab
`\\`	Backslash
`\'' or ''` (two single quotes)	Single quotation mark
`%%`	Percent character

Remarks

When writing text to a file on Windows, it is recommended that you open the file in write-text mode (e.g., `fopen(file_id, 'wt')`). This ensures that lines in the file are terminated in such a way as to be compatible with all applications that might use the file.

MATLAB writes characters using the encoding scheme associated with the file. See `fopen` for more information.

The `fprintf` function behaves like its ANSI C language namesake with these exceptions and extensions:

- If you use `fprintf` to convert a MATLAB double into an integer, and the double contains a value that cannot be represented as an integer (for example, it contains a fraction), MATLAB ignores the specified conversion and outputs the value in exponential format. To successfully perform this conversion, use the `fix`, `floor`, `ceil`, or `round` function to change the value in the double into a value that can be represented as an integer before passing it to `sprintf`.
- The following nonstandard subtype specifiers are supported for the conversion characters `%o`, `%u`, `%x`, and `%X`.

`b` The underlying C data type is a double rather than an unsigned integer. For example, to print a double-precision value in hexadecimal, use a format like `'%bx'`.

`t` The underlying C data type is a float rather than an unsigned integer.

For example, to print a double value in hexadecimal, use the format `'%bx'`.

- The `fprintf` function is vectorized for nonscalar arguments. The function recycles the format string through the elements of `A` (columnwise) until all the elements are used up. The function then continues in a similar manner through any additional matrix arguments.

Note `fprintf` displays negative zero (`-0`) differently on some platforms, as shown in the following table.

	Conversion Character		
Platform	**%e or %E**	**%f**	**%g or %G**
PC	0.000000e+000	0.000000	0
Others	-0.000000e+00	-0.000000	-0

Examples

Example 1

Create a text file called `exp.txt` containing a short table of the exponential function. (On Windows platforms, it is recommended that you use `fopen` with the mode set to `'wt'` to open a text file for writing.)

```
x = 0:.1:1;
y = [x; exp(x)];
fid = fopen('exp.txt', 'wt');
fprintf(fid, '%6.2f %12.8f\n', y);
```

```
fclose(fid)
```

Now examine the contents of `exp.txt`:

```
type exp.txt
   0.00    1.00000000
   0.10    1.10517092
       ...
   1.00    2.71828183
```

Example 2

The command

```
fprintf( ...
  'A unit circle has circumference %g radians.\n', 2*pi)
```

displays a line on the screen:

```
A unit circle has circumference 6.283186 radians.
```

Example 3

To insert a single quotation mark in a string, use two single quotation marks together. For example,

```
fprintf(1,'It''s Friday.\n')
```

displays on the screen

```
It's Friday.
```

Example 4

Use `fprintf` to display a hyperlink on the screen. For example,

```
site = '"http://www.mathworks.com"';
title = 'The MathWorks Web Site';
fprintf(['<a href = ' site '>' title '</a>'])
```

creates the hyperlink

```
The Mathworks Web Site
```

in the Command Window. Click on this link to display The MathWorks home page in a MATLAB Web browser.

Example 5

The commands

```
B = [8.8  7.7; 8800  7700]
fprintf(1, 'X is %6.2f meters or %8.3f mm\n', 9.9, 9900, B)
```

display the lines

```
X is 9.90 meters or 9900.000 mm
X is 8.80 meters or 8800.000 mm
X is 7.70 meters or 7700.000 mm
```

Example 6

Explicitly convert MATLAB double-precision variables to integer values for use with an integer conversion specifier. For instance, to convert signed 32-bit data to hexadecimal format,

```
a = [6 10 14 44];
fprintf('%9X\n', a + (a<0)*2^32)
        6
        A
        E
       2C
```

[2] ANSI specification X3.159-1989: “Programming Language C,” ANSI, 1430 Broadway, New York, NY 10018.

Purpose

Write text to device

Syntax

```
fprintf(obj,'cmd')
fprintf(obj,'format','cmd')
fprintf(obj,'cmd','mode')
fprintf(obj,'format','cmd','mode')
```

Arguments

`obj`	A serial port object.
`'cmd'`	The string written to the device.
`'format'`	C language conversion specification.
`'mode'`	Specifies whether data is written synchronously or asynchronously.

Description

`fprintf(obj,'cmd')` writes the string `cmd` to the device connected to `obj`. The default format is `%s\n`. The write operation is synchronous and blocks the command line until execution is complete.

`fprintf(obj,'format','cmd')` writes the string using the format specified by *`format`*. *`format`* is a C language conversion specification. Conversion specifications involve the `%` character and the conversion characters d, i, o, u, x, X, f, e, E, g, G, c, and s. Refer to the `sprintf` file I/O format specifications or a C manual for more information.

`fprintf(obj,'cmd','mode')` writes the string with command line access specified by *`mode`*. If *`mode`* is `sync`, `cmd` is written synchronously and the command line is blocked. If *`mode`* is `async`, `cmd` is written asynchronously and the command line is not blocked. If *`mode`* is not specified, the write operation is synchronous.

`fprintf(obj,'format','cmd','mode')` writes the string using the specified format. If *`mode`* is `sync`, `cmd` is written synchronously. If *`mode`* is `async`, `cmd` is written asynchronously.

Remarks

Before you can write text to the device, it must be connected to `obj` with the `fclose` function. A connected serial port object has a `Status`

property value of `open`. An error is returned if you attempt to perform a write operation while `obj` is not connected to the device.

The `ValuesSent` property value is increased by the number of values written each time `fprintf` is issued.

An error occurs if the output buffer cannot hold all the data to be written. You can specify the size of the output buffer with the `OutputBufferSize` property.

If you use the `help` command to display help for `fprintf`, then you need to supply the pathname shown below.

```
help serial/fprintf
```

Synchronous Versus Asynchronous Write Operations

By default, text is written to the device synchronously and the command line is blocked until the operation completes. You can perform an asynchronous write by configuring the *`mode`* input argument to be `async`. For asynchronous writes:

- The `BytesToOutput` property value is continuously updated to reflect the number of bytes in the output buffer.
- The M-file callback function specified for the `OutputEmptyFcn` property is executed when the output buffer is empty.

You can determine whether an asynchronous write operation is in progress with the `TransferStatus` property.

Synchronous and asynchronous write operations are discussed in more detail in Controlling Access to the MATLAB Command Line.

Rules for Completing a Write Operation with fprintf

A synchronous or asynchronous write operation using `fprintf` completes when:

- The specified data is written.

- The time specified by the Timeout property passes.

Additionally, you can stop an asynchronous write operation with the stopasync function.

Rules for Writing the Terminator

All occurrences of \n in cmd are replaced with the Terminator property value. Therefore, when using the default format %s\n, all commands written to the device will end with this property value. The terminator required by your device will be described in its documentation.

Example

Create the serial port object s, connect s to a Tektronix TDS 210 oscilloscope, and write the RS232? command with the fprintf function. RS232? instructs the scope to return serial port communications settings.

```
s = serial('COM1');
fopen(s)
fprintf(s,'RS232?')
```

Because the default format for fprintf is %s\n, the terminator specified by the Terminator property was automatically written. However, in some cases you might want to suppress writing the terminator. To do so, you must explicitly specify a format for the data that does not include the terminator, or configure the terminator to empty.

```
fprintf(s,'%s','RS232?')
```

frame2im

Purpose

Convert movie frame to indexed image

Syntax

```
[X,Map] = frame2im(F)
```

Description

`[X,Map] = frame2im(F)` converts the single movie frame `F` into the indexed image `X` and associated colormap `Map`. The functions `getframe` and `im2frame` create a movie frame. If the frame contains true-color data, then `Map` is empty.

See Also

`getframe`, `im2frame`, `movie`

"Bit-Mapped Images" on page 1-92 for related functions

Purpose

Edit print frames for Simulink and Stateflow block diagrams

Syntax

```
frameedit
frameedit filename
```

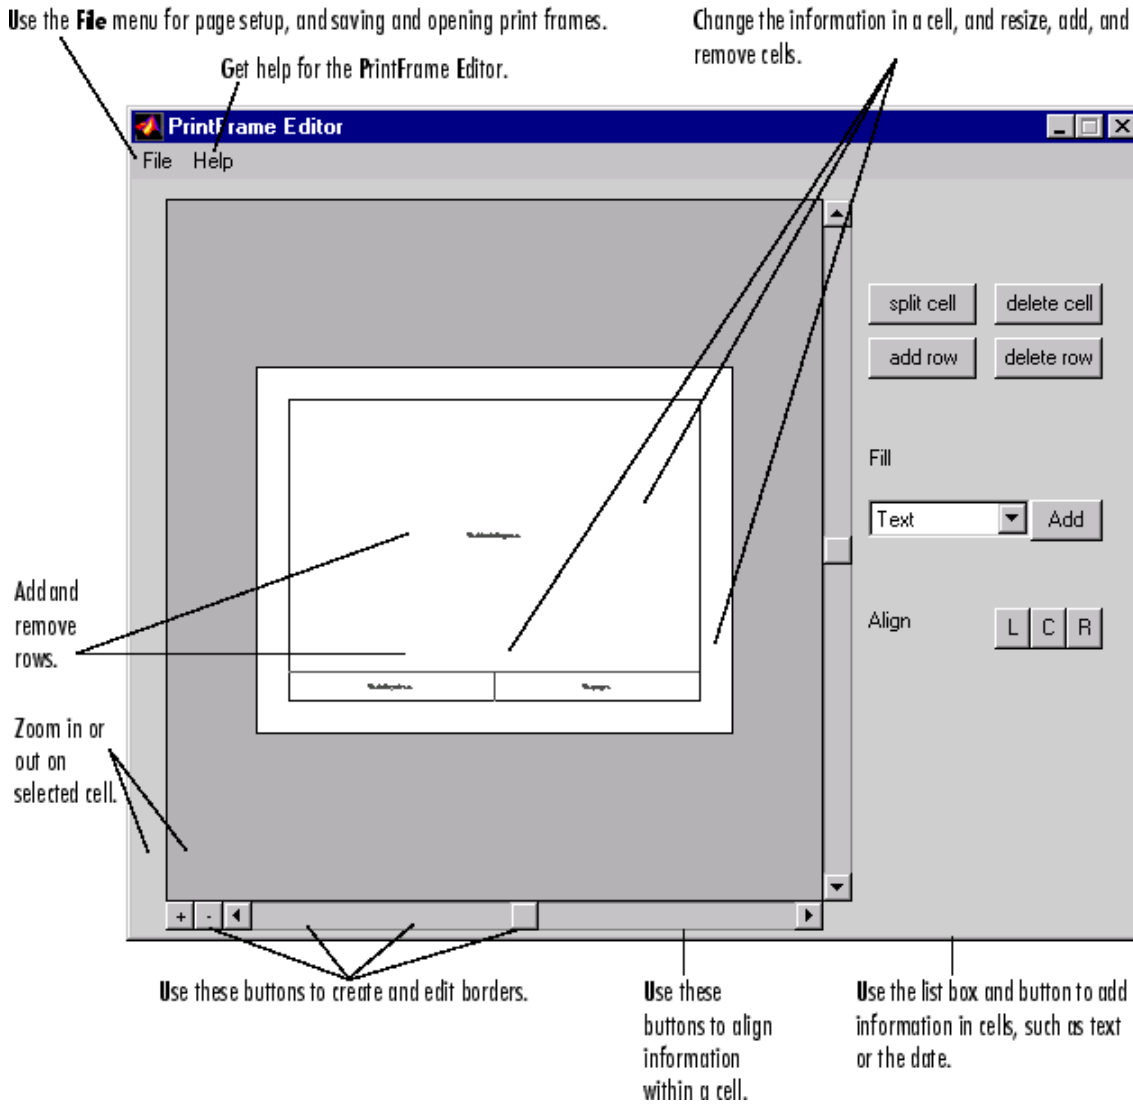
Description

`frameedit` starts the PrintFrame Editor, a graphical user interface you use to create borders for Simulink and Stateflow block diagrams. With no argument, `frameedit` opens the **PrintFrame Editor** window with a new file.

`frameedit filename` opens the **PrintFrame Editor** window with the specified filename, where `filename` is a figure file (`.fig`) previously created and saved using `frameedit`.

Remarks

This illustrates the main features of the PrintFrame Editor.



Closing the PrintFrame Editor

To close the **PrintFrame Editor** window, click the close box in the upper right corner, or select **Close** from the **File** menu.

Printing Simulink Block Diagrams with Print Frames

Select **Print** from the Simulink **File** menu. Check the **Frame** box and supply the filename for the print frame you want to use. Click **OK** in the **Print** dialog box.

Getting Help for the PrintFrame Editor

For further instructions on using the PrintFrame Editor, select **PrintFrame Editor Help** from the **Help** menu in the PrintFrame Editor.

fread

Purpose

Read binary data from file

Syntax

```
A = fread(fid)
A = fread(fid, count)
A = fread(fid, count, precision)
A = fread(fid, count, precision, skip)
A = fread(fid, count, precision, skip, machineformat)
[A, count] = fread(...)
```

Description

`A = fread(fid)` reads data in binary format from the file specified by `fid` into matrix `A`. Open the file using `fopen` before calling `fread`. The `fid` argument is the integer file identifier obtained from the `fopen` operation. MATLAB reads the file from beginning to end, and then positions the file pointer at the end of the file (see `feof` for details).

Note `fread` is intended primarily for binary data. When reading text files, use the `fgetl` function.

`A = fread(fid, count)` reads the number of elements specified by count. At the end of the `fread`, MATLAB sets the file pointer to the next byte to be read. A subsequent fread will begin at the location of the file pointer. See “Specifying the Number of Elements” on page 2-1293, below.

Note In the following syntaxes, the `count` and `skip` arguments are optional. For example, `fread(fid, precision)` is a valid syntax.

`A = fread(fid, count, precision)` reads the file according to the data format specified by the string `precision`. This argument commonly contains a data type specifier such as `int` or `float`, followed by an integer giving the size in bits. See “Specifying precision” on page 2-1293 and “Specifying Output Format” on page 2-1295, below.

`A = fread(fid, count, precision, skip)` includes an optional `skip` argument that specifies the number of bytes to skip after each `precision` value is read. If `precision` specifies a bit format like `'bitN'` or `'ubitN'`, the `skip` argument is interpreted as the number of bits to skip. See “Specifying a Skip Value” on page 2-1296, below.

`A = fread(fid, count, precision, skip, machineformat)` treats the data read as having a format given by `machineformat`. You can obtain the `machineformat` argument from the output of the `fopen` function. See `fopen` for possible values for `machineformat`.

`[A, count] = fread(...)` returns the data read from the file in `A`, and the number of elements successfully read in `count`.

Specifying the Number of Elements

Valid options for count are

`n`	Reads `n` elements into a column vector.
`inf`	Reads to the end of the file, resulting in a column vector containing the same number of elements as are in the file. If using `inf` results in an "out of memory" error, specify a numeric count value.
`[m,n]`	Reads enough elements to fill an `m`-by-`n` matrix, filling in elements in column order, padding with zeros if the file is too small to fill the matrix. `n` can be specified as `inf`, but `m` cannot.

Specifying precision

Any of the strings in the following table, either the MATLAB version or their C or Fortran equivalent, can be used for `precision`. If `precision` is not specified, MATLAB uses the default, which is `'uint8'`.

MATLAB	C or Fortran	Interpretation
’schar’	’signed char’	Signed integer; 8 bits
’uchar’	’unsigned char’	Unsigned integer; 8 bits

MATLAB	C or Fortran	Interpretation
'int8'	'integer*1'	Integer; 8 bits
'int16'	'integer*2'	Integer; 16 bits
'int32'	'integer*4'	Integer; 32 bits
'int64'	'integer*8'	Integer; 64 bits
'uint8'	'integer*1'	Unsigned integer; 8 bits
'uint16'	'integer*2'	Unsigned integer; 16 bits
'uint32'	'integer*4'	Unsigned integer; 32 bits
'uint64'	'integer*8'	Unsigned integer; 64 bits
'float32'	'real*4'	Floating-point; 32 bits
'float64'	'real*8'	Floating-point; 64 bits
'double'	'real*8'	Floating-point; 64 bits

The following platform-dependent formats are also supported, but they are not guaranteed to be the same size on all platforms.

MATLAB	C or Fortran	Interpretation
'char'	'char*1'	Character
'short'	'short'	Integer; 16 bits
'int'	'int'	Integer; 32 bits
'long'	'long'	Integer; 32 or 64 bits
'ushort'	'unsigned short'	Unsigned integer; 16 bits
'uint'	'unsigned int'	Unsigned integer; 32 bits
'ulong'	'unsigned long'	Unsigned integer; 32 or 64 bits
'float'	'float'	Floating-point; 32 bits

Note If the format is `'char'` or `'char*1'`, MATLAB reads characters using the encoding scheme associated with the file. See `fopen` for more information.

The following formats map to an input stream of bits rather than bytes.

MATLAB	C or Fortran	Interpretation
'bitN'	-	Signed integer; N bits ($1 \le N \le 64$)
'ubitN'	-	Unsigned integer; N bits ($1 \le N \le 64$)

Specifying Output Format

By default, numeric and character values are returned in class `double` arrays. To return these values stored in classes other than `double`, create your `format` argument by first specifying your source format, then following it with the characters "=>," and finally specifying your destination format. You are not required to use the exact name of a MATLAB class type for destination. (See `class` for details). `fread` translates the name to the most appropriate MATLAB class type. If the source and destination formats are the same, the following shorthand notation can be used.

```
*source
```

which means

```
source=>source
```

For example, `'*uint16'` is the same as `'uint16=>uint16'`.

Note You can also use the `*source` notation with an input stream that is specified as a number of bits (e.g., `bit4` or `ubit18`). MATLAB translates this into an output type that is a signed or unsigned integer (depending on the input type), and that is large enough to hold all of the bits in the source format. For example, `*ubit18` does not translate to `ubit18=>ubit18`, but instead to `ubit18=>uint32`.

This table shows some example precision format strings.

`'uint8=>uint8'`	Read in unsigned 8-bit integers and save them in an unsigned 8-bit integer array.
`'*uint8'`	Shorthand version of the above.
`'bit4=>int8'`	Read in signed 4-bit integers packed in bytes and save them in a signed 8-bit array. Each 4-bit integer becomes an 8-bit integer.
`'double=>real*4'`	Read in doubles, convert, and save as a 32-bit floating-point array.

Specifying a Skip Value

When `skip` is used, the `precision` string can contain a positive integer repetition factor of the form `'N*'`, which prefixes the source format specification, such as `'40*uchar'`.

Note Do not confuse the asterisk (*) used in the repetition factor with the asterisk used as precision format shorthand. The format string `'40*uchar'` is equivalent to `'40*uchar=>double'`, not `'40*uchar=>uchar'`.

When `skip` is specified, `fread` reads in, at most, a repetition factor number of values (default is 1), skips the amount of input specified by the `skip` argument, reads in another block of values, again skips

input, and so on, until `count` number of values have been read. If a `skip` argument is not specified, the repetition factor is ignored. Use the repetition factor with the `skip` argument to extract data in noncontiguous fields from fixed-length records.

Remarks

If the input stream is bytes and `fread` reaches the end of file (see `feof`) in the middle of reading the number of bytes required for an element, the partial result is ignored. However, if the input stream is bits, then the partial result is returned as the last value. If an error occurs before reaching the end of file, only full elements read up to that point are used.

Examples

Example 1

The file `alphabet.txt` contains the 26 letters of the English alphabet, all capitalized. Open the file for read access with `fopen`, and read the first five elements into output `c`. Because a precision has not been specified, MATLAB uses the default precision of `uint8`, and the output is numeric:

```
fid = fopen('alphabet.txt', 'r');
c = fread(fid, 5)'
c =
    65    66    67    68    69
fclose(fid);
```

This time, specify that you want each element read as an unsigned 8-bit integer and output as a character. (Using a precision of `'char=>char'` or `'*char'` will produce the same result):

```
fid = fopen('alphabet.txt', 'r');
c = fread(fid, 5, 'uint8=>char')'
c =
    ABCDE
fclose(fid);
```

When you leave out the optional count argument, MATLAB reads the file to the end, `A` through `Z`:

```
fid = fopen('alphabet.txt', 'r');
c = fread(fid, '*char')'
c =
    ABCDEFGHIJKLMNOPQRSTUVWXYZ
fclose(fid);
```

The `fopen` function positions the file pointer at the start of the file. So the first `fread` in this example reads the first five elements in the file, and then repositions the file pointer at the beginning of the next element. For this reason, the next `fread` picks up where the previous `fread` left off, at the character `F`.

```
fid = fopen('alphabet.txt', 'r');
c1 = fread(fid, 5, '*char');
c2 = fread(fid, 8, '*char');
c3 = fread(fid, 5, '*char');
fclose(fid);

sprintf('%c', c1, ' * ', c2, ' * ', c3)
ans =
   ABCDE * FGHIJKLM * NOPQR
```

Skip two elements between each read by specifying a `skip` argument of 2:

```
fid = fopen('alphabet.txt', 'r');
c = fread(fid, '*char', 2);    % Skip 2 bytes per read
fclose(fid);

sprintf('%c', c)
ans =
   ADGJMPSVY
```

Example 2

This command displays the complete M-file containing this `fread` help entry:

```
type fread.m
```

To simulate this command using `fread`, enter the following:

```
fid = fopen('fread.m', 'r');
F = fread(fid, '*char')';
fclose(fid);
```

In the example, the `fread` command assumes the default size, `'inf'`, and precision `'*char'` (the same as `'char=>char'`). `fread` reads the entire file. To display the result as readable text, the column vector is transposed to a row vector.

Example 3

As another example,

```
s = fread(fid, 120, '40*uchar=>uchar', 8);
```

reads in 120 bytes in blocks of 40, each separated by 8 bytes. Note that the class type of `s` is `'uint8'` since it is the appropriate class corresponding to the destination format `'uchar'`. Also, since 40 evenly divides 120, the last block read is a full block, which means that a final skip is done before the command is finished. If the last block read is not a full block, then `fread` does not finish with a skip.

See `fopen` for information about reading big and little-endian files.

Example 4

Invoke the `fopen` function with just an `fid` input argument to obtain the machine format for the file. You can see that this file was written in IEEE floating point with little-endian byte ordering (`'ieee-le'`) format:

```
fid = fopen('A1.dat', 'r');

[fname, mode, mformat] = fopen(fid);
mformat
mformat =
   ieee-le
```

Use the MATLAB format function (not related to the machine format type) to have MATLAB display output using hexadecimal:

```
format hex
```

Now use the `machineformat` input with `fread` to read the data from the file using the same format:

```
x = fread(fid, 6, 'uint64', 'ieee-le')
x =
   4260800000002000
   0000000000000000
   4282000000180000
   0000000000000000
   42ca5e0000258000
   42f0000464d45200
fclose(fid);
```

Change the machine format to IEEE floating point with big-endian byte ordering (`'ieee-be'`) and verify that you get different results:

```
fid = fopen('A1.dat', 'r');
x = fread(fid, 6, 'uint64', 'ieee-be')
x =
   4370000008400000
   0000000000000000
   4308000200100000
   0000000000000000
   4352c0002f0d0000
   43c022a6a3000000
fclose(fid);
```

Example 5

This example reads some Japanese text from a file that uses the Shift-JIS character encoding scheme. It creates a string of Unicode characters, `str`, and displays the string. Note that the computer must be configured to display Japanese (e.g., a Japanese Windows machine) for the output of `disp(str)` to be correct.

```
fid = fopen('japanese.txt', 'r', 'n', 'Shift_JIS');
str = fread(fid, '*char')';
```

```
fclose(fid);
disp(str);
```

fgetl, fscanf, fwrite, fprintf, fopen, fclose, fseek, ftell, feof

fread (serial)

Purpose

Read binary data from device

Syntax

```
A = fread(obj)
A = fread(obj,size,'precision')
[A,count] = fread(...)
[A,count,msg] = fread(...)
```

Arguments

`obj`	A serial port object.
`size`	The number of values to read.
`'precision'`	The number of bits read for each value, and the interpretation of the bits as character, integer, or floating-point values.
`A`	Binary data returned from the device.
`count`	The number of values read.
`msg`	A message indicating if the read operation was unsuccessful.

Description

`A = fread(obj)` and A = fread(obj,size) read binary data from the device connected to `obj`, and returns the data to `A`. The maximum number of values to read is specified by `size`. If `size` is not specified, the maximum number of values to read is determined by the object's `InputBufferSize` property. Valid options for `size` are:

`n`	Read at most `n` values into a column vector.
`[m,n]`	Read at most m-by-n values filling an m–by–n matrix in column order.

`size` cannot be `inf`, and an error is returned if the specified number of values cannot be stored in the input buffer. You specify the size, in bytes, of the input buffer with the `InputBufferSize` property. A value is defined as a byte multiplied by the *`precision`* (see below).

`A = fread(obj,size,'precision')` reads binary data with precision specified by *`precision`*.

`precision` controls the number of bits read for each value and the interpretation of those bits as integer, floating-point, or character values. If *`precision`* is not specified, `uchar` (an 8-bit unsigned character) is used. By default, numeric values are returned in double-precision arrays. The supported values for *`precision`* are listed below in Remarks.

`[A,count] = fread(...)` returns the number of values read to `count`.

`[A,count,msg] = fread(...)` returns a warning message to `msg` if the read operation was unsuccessful.

Remarks

Before you can read data from the device, it must be connected to `obj` with the `fopen` function. A connected serial port object has a `Status` property value of `open`. An error is returned if you attempt to perform a read operation while `obj` is not connected to the device.

If `msg` is not included as an output argument and the read operation was not successful, then a warning message is returned to the command line.

The `ValuesReceived` property value is increased by the number of values read, each time `fread` is issued.

If you use the `help` command to display help for `fread`, then you need to supply the pathname shown below.

```
help serial/fread
```

Rules for Completing a Binary Read Operation

A read operation with `fread` blocks access to the MATLAB command line until:

- The specified number of values are read.
- The time specified by the `Timeout` property passes.

Note The `Terminator` property is not used for binary read operations.

Supported Precisions

The supported values for *`precision`* are listed below.

Data Type	Precision	Interpretation
Character	`uchar`	8-bit unsigned character
	`schar`	8-bit signed character
	`char`	8-bit signed or unsigned character
Integer	`int8`	8-bit integer
	`int16`	16-bit integer
	`int32`	32-bit integer
	`uint8`	8-bit unsigned integer
	`uint16`	16-bit unsigned integer
	`uint32`	32-bit unsigned integer
	`short`	16-bit integer
	`int`	32-bit integer
	`long`	32- or 64-bit integer
	`ushort`	16-bit unsigned integer
	`uint`	32-bit unsigned integer
	`ulong`	32- or 64-bit unsigned integer

Data Type	Precision	Interpretation
Floating-point	`single`	32-bit floating point
	`float32`	32-bit floating point
	`float`	32-bit floating point
	`double`	64-bit floating point
	`float64`	64-bit floating point

Properties

`BytesAvailable`, `BytesAvailableFcn`, `InputBufferSize`, `Status`, `Terminator`, `ValuesReceived`

freqspace

Purpose

Frequency spacing for frequency response

Syntax

```
[f1,f2] = freqspace(n)
[f1,f2] = freqspace([m n])
[x1,y1] = freqspace(...,'meshgrid')
f = freqspace(N)
f = freqspace(N,'whole')
```

Description

`freqspace` returns the implied frequency range for equally spaced frequency responses. `freqspace` is useful when creating desired frequency responses for various one- and two-dimensional applications.

`[f1,f2] = freqspace(n)` returns the two-dimensional frequency vectors `f1` and `f2` for an `n`-by-`n` matrix.

For `n` odd, both `f1` and `f2` are `[-n+1:2:n-1]/n`.

For `n` even, both `f1` and `f2` are `[-n:2:n-2]/n`.

`[f1,f2] = freqspace([m n])` returns the two-dimensional frequency vectors `f1` and `f2` for an `m`-by-`n` matrix.

`[x1,y1] = freqspace(...,'meshgrid')` is equivalent to

```
[f1,f2] = freqspace(...);
[x1,y1] = meshgrid(f1,f2);
```

`f = freqspace(N)` returns the one-dimensional frequency vector `f` assuming `N` evenly spaced points around the unit circle. For `N` even or odd, `f` is `(0:2/N:1)`. For `N` even, `freqspace` therefore returns `(N+2)/2` points. For `N` odd, it returns `(N+1)/2` points.

`f = freqspace(N,'whole')` returns `N` evenly spaced points around the whole unit circle. In this case, `f` is `0:2/N:2*(N-1)/N`.

See Also

`meshgrid`

Purpose

Move file position indicator to beginning of open file

Syntax

```
frewind(fid)
```

Description

`frewind(fid)` sets the file position indicator to the beginning of the file specified by `fid`, an integer file identifier obtained from `fopen`.

Remarks

Rewinding a `fid` associated with a tape device might not work even though `frewind` does not generate an error message.

See Also

`fclose`, `ferror`, `fopen`, `fprintf`, `fread`, `fscanf`, `fseek`, `ftell`, `fwrite`

fscanf

Purpose

Read formatted data from file

Syntax

```
A = fscanf(fid, format)
[A,count] = fscanf(fid, format, size)
```

Description

`A = fscanf(fid, format)` reads data from the file specified by `fid`, converts it according to the specified `format` string, and returns it in matrix `A`. Argument `fid` is an integer file identifier obtained from `fopen`. `format` is a string specifying the format of the data to be read. See "Remarks" for details.

`[A,count] = fscanf(fid, format, size)` reads the amount of data specified by `size`, converts it according to the specified `format` string, and returns it along with a `count` of values successfully read. `size` is an argument that determines how much data is read. Valid options are

`n`	Read at most `n` numbers, characters, or strings.
`inf`	Read to the end of the file.
`[m,n]`	Read at most `(m*n)` numbers, characters, or strings. Fill a matrix of at most `m` rows in column order. `n` can be `inf`, but `m` cannot.

Characteristics of the output matrix `A` depend on the values read from the file and on the `size` argument. If fscanf reads only numbers, and if `size` is not of the form `[m,n]`, matrix `A` is a column vector of numbers. If fscanf reads only characters or strings, and if `size` is not of the form `[m,n]`, matrix `A` is a row vector of characters. See the Remarks section for more information.

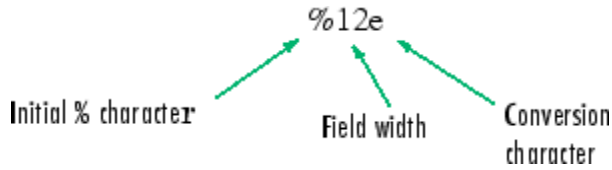
`fscanf` differs from its C language namesake `fscanf()` in an important respect — it is *vectorized* to return a matrix argument. The `format` string is cycled through the file until the first of these conditions occurs:

- The `format` string fails to match the data in the file
- The amount of data specified by `size` is read
- The end of the file is reached

Remarks

When MATLAB reads a specified file, it attempts to match the data in the file to the `format` string. If a match occurs, the data is written into the output matrix. If a partial match occurs, only the matching data is written to the matrix, and the read operation stops.

The `format` string consists of ordinary characters and/or conversion specifications. Conversion specifications indicate the type of data to be matched and involve the character `%`, optional width fields, and conversion characters, organized as shown below.



Add one or more of these characters between the `%` and the conversion character:

An asterisk (`*`)	Skip over the matched value. If `%*d`, then the value that matches `d` is ignored and is not stored.
A digit string	Maximum field width. For example, `%10d`.
A letter	The size of the receiving object, for example, `h` for short, as in `%hd` for a short integer, or `l` for long, as in `%ld` for a long integer, or `%lg` for a double floating-point number.

Valid conversion characters are

`%c`	Sequence of characters; number specified by field width
`%d`	Base 10 integers
`%e`, `%f`, `%g`	Floating-point numbers
`%i`	Defaults to base 10 integers. Data starting with `0` is read as base 8. Data starting with `0x` or `0X` is read as base 16.

`%o`	Signed octal integer
`%s`	A series of non-white-space characters
`%u`	Signed decimal integer
`%x`	Signed hexadecimal integer
`[...]`	Sequence of characters (`scanlist`)

Format specifiers `%e`, `%f`, and `%g` accept the text `'inf'`, `'-inf'`, `'nan'`, and `'-nan'`. This text is not case sensitive. The `fscanf` function converts these to the numeric representation of `Inf`, `-Inf`, `NaN`, and `-NaN`.

Use `%c` to read space characters or `%s` to skip all white space. MATLAB skips over any ordinary characters that are used in the format specifier (see Example 2 below).

MATLAB reads characters using the encoding scheme associated with the file. See `fopen` for more information. If the format string contains ordinary characters, MATLAB matches each of those characters with a character read from the file after converting both to the MATLAB internal representation of characters.

For more information about format strings, refer to the `scanf()` and `fscanf()` routines in a C language reference manual.

Output Characteristics: Only Numeric Values Read

Format characters that cause `fscanf` to read numbers from the file are `%d`, `%e`, `%f`, `%g`, `%i`, `%o`, `%u`, and `%x`. When `fscanf` reads only numbers from the file, the elements of the output matrix `A` are numbers.

When there is no `size` argument or the `size` argument is `inf`, `fscanf` reads to the end of the file. The output matrix is a column vector with one element for each number read from the input.

When the `size` argument is a scalar `n`, fscanf reads at most `n` numbers from the file. The output matrix is a column vector with one element for each number read from the input.

When the `size` argument is a matrix `[m,n]`, `fscanf` reads at most `(m*n)` numbers from the file. The output matrix contains at most `m` rows and `n` columns. `fscanf` fills the output matrix in column order, using as many columns as it needs to contain all the numbers read from the input. Any unfilled elements in the final column contain zeros.

Output Characteristics: Only Character Values Read

The format characters that cause `fscanf` to read characters and strings from the file are `%c` and `%s`. When `fscanf` reads only characters and strings from the file, the elements of the output matrix `A` are characters. When fscanf reads a string from the input, the output matrix includes one element for each character in the string.

When there is no `size` argument or the `size` argument is `inf`, `fscanf` reads to the end of the file. The output matrix is a row vector with one element for each character read from the input.

When the `size` argument is a scalar `n`, `fscanf` reads at most `n` character or string values from the file. The output matrix is a row vector with one element for each character read from the input. When string values are read from the input, the output matrix can contain more than `n` columns.

When the `size` argument is a matrix `[m,n]`, `fscanf` reads at most `(m*n)` character or string values from the file. The output matrix contains at most `m` rows. `fscanf` fills the output matrix in column order, using as many columns as it needs to contain all the characters read from the input. When string values are read from the input, the output matrix can contain more than `n` columns. Any unfilled elements in the final column contain `char(0)`.

Output Characteristics: Both Numeric and Character Values Read

When `fscanf` reads a combination of numbers and either characters or strings from the file, the elements of the output matrix `A` are numbers. This is true even when a format specifier such as `'%*d %s'` tells MATLAB to ignore numbers in the input string and output only characters or strings. When `fscanf` reads a string from the input, the

output matrix includes one element for each character in the string. All characters are converted to their numeric equivalents in the output matrix.

When there is no `size` argument or the `size` argument is `inf`, `fscanf` reads to the end of the file. The output matrix is a column vector with one element for each character read from the input.

When the `size` argument is a scalar `n`, `fscanf` reads at most `n` number, character, or string values from the file. The output matrix contains at most `n` rows. `fscanf` fills the output matrix in column order, using as many columns as it needs to represent all the numbers and characters read from the input. When string values are read from the input, the output matrix can contain more than one column. Any unfilled elements in the final column contain zeros.

When the `size` argument is a matrix `[m,n]`, `fscanf` reads at most `(m*n)` number, character, or string values from the file. The output matrix contains at most `m` rows. `fscanf` fills the output matrix in column order, using as many columns as it needs to represent all the numbers and characters read from the input. When string values are read from the input, the output matrix can contain more than `n` columns. Any unfilled elements in the final column contain zeros.

Note This section applies only when `fscanf` actually reads a combination of numbers and either characters or strings from the file. Even if the format string has both format characters that would result in numbers (such as `%d`) and format characters that would result in characters or strings (such as `%s`), `fscanf` might actually read only numbers or only characters or strings. If `fscanf` reads only numbers, see "Output Characteristics: Only Numeric Values Read" on page 2-1310. If `fscanf` reads only characters or strings, see "Output Characteristics: Only Character Values Read" on page 2-1311.

Examples

Example 1

An example in `fprintf` generates a text file called `exp.txt` that looks like this:

```
0.00    1.00000000
0.10    1.10517092
...
1.00    2.71828183
```

Read this file back into a two-column MATLAB matrix:

```
fid = fopen('exp.txt', 'r');
a = fscanf(fid, '%g %g', [2 inf])    % It has two rows now.
a = a';
fclose(fid)
```

Example 2

Start with a file `temp.dat` that contains temperature readings:

```
78 F 72 F 64 F 66 F 49 F
```

Open the file using `fopen` and read it with `fscanf`. If you include ordinary characters (such as the degree (°) and Farrenheit (`F`) symbols used here) in the conversion string, `fscanf` skips over those characters when reading the string:

```
fid = fopen('temps.dat', 'r');

degrees = char(176)
degrees =

fscanf(fid, ['%d' degrees 'F'])
ans =
    78
    72
    64
    66
    49
```

See Also

fgetl, fgets, fread, fprintf, fscanf, input, sscanf, textread

Purpose

Read data from device, and format as text

Syntax

```
A = fscanf(obj)
A = fscanf(obj,'format')
A = fscanf(obj,'format',size)
[A,count] = fscanf(...)
[A,count,msg] = fscanf(...)
```

Arguments

`obj`	A serial port object.
`'format'`	C language conversion specification.
`size`	The number of values to read.
`A`	Data read from the device and formatted as text.
`count`	The number of values read.
`msg`	A message indicating if the read operation was unsuccessful.

Description

`A = fscanf(obj)` reads data from the device connected to `obj`, and returns it to `A`. The data is converted to text using the `%c` format.

`A = fscanf(obj,'format')` reads data and converts it according to *`format`*. *`format`* is a C language conversion specification. Conversion specifications involve the `%` character and the conversion characters d, i, o, u, x, X, f, e, E, g, G, c, and s. Refer to the `sscanf` file I/O format specifications or a C manual for more information.

`A = fscanf(obj,'format',size)` reads the number of values specified by `size`. Valid options for `size` are:

`n`	Read at most `n` values into a column vector.
`[m,n]`	Read at most m-by-n values filling an m–by–n matrix in column order.

size cannot be inf, and an error is returned if the specified number of values cannot be stored in the input buffer. If size is not of the form [m,n], and a character conversion is specified, then A is returned as a row vector. You specify the size, in bytes, of the input buffer with the InputBufferSize property. An ASCII value is one byte.

[A,count] = fscanf(...) returns the number of values read to count.

[A,count,msg] = fscanf(...) returns a warning message to msg if the read operation did not complete successfully.

Remarks

Before you can read data from the device, it must be connected to obj with the fopen function. A connected serial port object has a Status property value of open. An error is returned if you attempt to perform a read operation while obj is not connected to the device.

If msg is not included as an output argument and the read operation was not successful, then a warning message is returned to the command line.

The ValuesReceived property value is increased by the number of values read – including the terminator – each time fscanf is issued.

If you use the help command to display help for fscanf, then you need to supply the pathname shown below.

```
help serial/fscanf
```

Rules for Completing a Read Operation with fscanf

A read operation with fscanf blocks access to the MATLAB command line until:

- The terminator specified by the Terminator property is read.
- The time specified by the Timeout property passes.
- The number of values specified by size is read.
- The input buffer is filled (unless size is specified)

Example

Create the serial port object `s` and connect `s` to a Tektronix TDS 210 oscilloscope, which is displaying sine wave.

```
s = serial('COM1');
fopen(s)
```

Use the `fprintf` function to configure the scope to measure the peak-to-peak voltage of the sine wave, return the measurement type, and return the peak-to-peak voltage.

```
fprintf(s,'MEASUREMENT:IMMED:TYPE PK2PK')
fprintf(s,'MEASUREMENT:IMMED:TYPE?')
fprintf(s,'MEASUREMENT:IMMED:VALUE?')
```

Because the default value for the `ReadAsyncMode` property is `continuous`, data associated with the two query commands is automatically returned to the input buffer.

```
s.BytesAvailable
ans =
    21
```

Use `fscanf` to read the measurement type. The operation will complete when the first terminator is read.

```
meas = fscanf(s)
meas =
PK2PK
```

Use `fscanf` to read the peak-to-peak voltage as a floating-point number, and exclude the terminator.

```
pk2pk = fscanf(s,'%e',14)
pk2pk =
    2.0200
```

Disconnect `s` from the scope, and remove `s` from memory and the workspace.

```
fclose(s)
delete(s)
clear s
```

See Also

Functions

fgetl, fgets, fopen, fread, strread

Properties

BytesAvailable, BytesAvailableFcn, InputBufferSize, Status, Terminator, Timeout

Purpose

Set file position indicator

Syntax

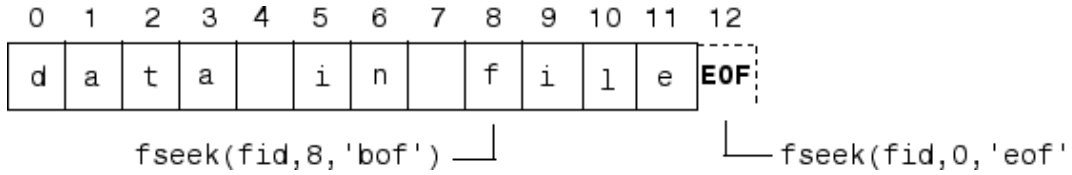
```
status = fseek(fid, offset, origin)
```

Description

`status = fseek(fid, offset, origin)` repositions the file position indicator in the file with the given `fid` to the byte with the specified `offset` relative to `origin`.

For a file having `n` bytes, the bytes are numbered from `0` to `n-1`. The position immediately following the last byte is the end-of-file, or `eof`, position. You would seek to the `eof` position if you wanted to add data to the end of a file.

This figure represents a file having 12 bytes, numbered 0 through 11. The first command shown seeks to the ninth byte of data in the file. The second command seeks just past the end of the file data, to the `eof` position.



`fseek` does not seek beyond the end of file `eof` position. If you attempt to seek beyond `eof`, MATLAB returns an error status.

Arguments

`fid`	An integer file identifier obtained from `fopen`	
`offset`	A value that is interpreted as follows,	
	`offset > 0`	Move position indicator `offset` bytes toward the end of the file.
	`offset = 0`	Do not change position.

	`offset < 0`	Move position indicator `offset` bytes toward the beginning of the file.
`origin`	A string whose legal values are	
	`'bof'`	`-1`: Beginning of file
	`'cof'`	`0`: Current position in file
	`'eof'`	`1`: End of file
`status`	A returned value that is `0` if the `fseek` operation is successful and `-1` if it fails. If an error occurs, use the function `ferror` to get more information.	

Examples

This example opens the file `test1.dat`, seeks to the 20th byte, reads fifty 32-bit unsigned integers into variable `A`, and closes the file. It then opens a second file, `test2.dat`, seeks to the end-of-file position, appends the data in `A` to the end of this file, and closes the file.

```
fid = fopen('test1.dat', 'r');
fseek(fid, 19, 'bof');
A = fread(fid, 50, 'uint32');
fclose(fid);

fid = fopen('test2.dat', 'r+');
fseek(fid, 0, 'eof');
fwrite(fid, A, 'uint32');
fclose(fid);
```

See Also

`fopen`, `fclose`, `ferror`, `fprintf`, `fread`, `fscanf`, `ftell`, `fwrite`

Purpose

File position indicator

Syntax

```
position = ftell(fid)
```

Description

`position = ftell(fid)` returns the location of the file position indicator for the file specified by `fid`, an integer file identifier obtained from `fopen`. The `position` is a nonnegative, zero-based integer specified in bytes from the beginning of the file. A returned value of `-1` for `position` indicates that the query was unsuccessful; use `ferror` to determine the nature of the error.

Remarks

`ftell` is likely to return an invalid `position` when *all* of the following are true. This is due to the way in which the Microsoft Windows C library currently handles its `ftell` and `fgetpos` commands:

- The file you are currently operating on is an ASCII text file.
- The file was written on a UNIX-based system, or uses the UNIX-style line terminator: a line feed (with no carriage return) at the end of each line of text. (This is the default output format for MATLAB functions `dlmwrite` and `csvwrite`.)
- You are reading the file on a Windows system.
- You opened the file with the `fopen` function with `mode` set to `'rt'`.
- The `ftell` command is directly preceded by an `fgets` or `fgetl` command.

Note that this does not affect the ability to accurately read from and write to this type of file from MATLAB.

`fclose`, `ferror`, `fopen`, `fprintf`, `fread`, `fscanf`, `fseek`, `fwrite`

Purpose

Connect to FTP server, creating FTP object

Syntax

```
f = ftp('host','username','password')
```

Description

`f = ftp('host','username','password')` connects to the FTP server, `host`, creating the FTP object, `f`. If a username and password are not required for an anonymous connection, only use the `host` argument. Specify an alternate port by separating it from `host` using a colon (:). After running `ftp`, perform file operation functions on the FTP object, `f`, using methods such as `cd` and others listed under "See Also." When you're finished using the server, run `close (ftp)` to close the connection.

FTP is not a secure protocol; others can see your username and password.

The `ftp` function is based on code from the Apache Jakarta Project.

Examples

Connect Without Username

Connect to `ftp.mathworks.com`, which does not require a username or password. Assign the resulting FTP object to `tmw`. You can access this FTP site to experiment with the FTP functions.

```
tmw=ftp('ftp.mathworks.com')
```

MATLAB returns

```
tmw =
 FTP Object
  host: ftp.mathworks.com
  user: anonymous
   dir: /
  mode: binary
```

Connect to Specified Port

To connect to port 34, type

```
tmw=ftp('ftp.mathworks.com:34')
```

Connect with Username

Connect to `ftp.testsite.com` and assign the resulting FTP object to `test`.

```
test=ftp('ftp.testsite.com','myname','mypassword')
```

MATLAB returns

```
test =
 FTP Object
  host: ftp.testsite.com
  user: myname
   dir: /
  mode: binary
  myname@ftp.testsite.com
  /
```

See Also

full

Purpose

Convert sparse matrix to full matrix

Syntax

```
A = full(S)
```

Description

`A = full(S)` converts a sparse matrix `S` to full storage organization. If `S` is a full matrix, it is left unchanged. If `A` is full, `issparse(A)` is `0`.

Remarks

Let `X` be an `m`-by-`n` matrix with `nz = nnz(X)` nonzero entries. Then `full(X)` requires space to store `m*n` real numbers while `sparse(X)` requires space to store `nz` real numbers and `(nz+n)` integers.

On most computers, a real number requires twice as much storage as an integer. On such computers, `sparse(X)` requires less storage than `full(X)` if the density, `nnz/prod(size(X))`, is less than one third. Operations on sparse matrices, however, require more execution time per element than those on full matrices, so density should be considerably less than two-thirds before sparse storage is used.

Examples

Here is an example of a sparse matrix with a density of about two-thirds. `sparse(S)` and `full(S)` require about the same number of bytes of storage.

```
S = sparse(+(rand(200,200) < 2/3));
A = full(S);
whos
Name    Size    Bytes     Class
  A    200X200 320000 double array
  S    200X200 318432 double array (sparse)
```

See Also

`issparse`, `sparse`

Purpose

Build full filename from parts

Syntax

```
f = fullfile(dir1, dir2, ..., filename)
```

Description

`f = fullfile(dir1, dir2, ..., filename)` builds a full file specification `f` from the directories and filename specified. Input arguments `dir1`, `dir2`, etc. and `filename` are each a string enclosed in single quotes. The output of the `fullfile` command is conceptually equivalent to

```
f = [dir1 filesep dir2 filesep ... filesep filename]
```

except that care is taken to handle the cases when the directories begin or end with a directory separator.

Examples

To create the full filename from a disk name, directories, and filename,

```
f = fullfile('C:', 'Applications', 'matlab', 'myfun.m')
f =
C:\Applications\matlab\myfun.m
```

The following examples both produce the same result on UNIX, but only the second one works on all platforms.

```
fullfile(matlabroot, 'toolbox/matlab/general/Contents.m')
fullfile(matlabroot, 'toolbox', 'matlab', 'general', ...
         'Contents.m')
```

See Also

`fileparts`, `filesep`, `path`, `pathsep`, `genpath`

Purpose

Construct function name string from function handle

Syntax

```
func2str(fhandle)
```

Description

`func2str(fhandle)` constructs a string `s` that holds the name of the function to which the function handle `fhandle` belongs.

When you need to perform a string operation, such as compare or display, on a function handle, you can use `func2str` to construct a string bearing the function name.

The `func2str` command does not operate on nonscalar function handles. Passing a nonscalar function handle to `func2str` results in an error.

Examples

Example 1

Convert a `sin` function handle to a string:

```
fhandle = @sin;

func2str(fhandle)
ans =
    sin
```

Example 2

The `catcherr` function shown here accepts function handle and data arguments and attempts to evaluate the function through its handle. If the function fails to execute, `catcherr` uses `sprintf` to display an error message giving the name of the failing function. The function name must be a string for `sprintf` to display it. The code derives the function name from the function handle using `func2str`:

```
function catcherr(func, data)
try
    ans = func(data);
    disp('Answer is:');
    ans
catch
```

```
        disp(sprintf('Error executing function ''%s''\n', ...
            func2str(func)))
    end
```

The first call to `catcherr` passes a handle to the `round` function and a valid data argument. This call succeeds and returns the expected answer. The second call passes the same function handle and an improper data type (a MATLAB structure). This time, `round` fails, causing `catcherr` to display an error message that includes the failing function name:

```
catcherr(@round, 5.432)
ans =
Answer is 5

xstruct.value = 5.432;
catcherr(@round, xstruct)
Error executing function "round"
```

See Also

`function_handle`, `str2func`, `functions`

function

Purpose

Declare M-file function

Syntax

```
function [out1, out2, ...] = funname(in1, in2, ...)
```

Description

`function [out1, out2, ...] = funname(in1, in2, ...)` defines function `funname` that accepts inputs `in1`, `in2`, etc. and returns outputs `out1`, `out2`, etc.

You add new functions to the MATLAB vocabulary by expressing them in terms of existing functions. The existing commands and functions that compose the new function reside in a text file called an *M-file*.

M-files can be either *scripts* or *functions*. Scripts are simply files containing a sequence of MATLAB statements. Functions make use of their own local variables and accept input arguments.

The name of an M-file begins with an alphabetic character and has a filename extension of `.m`. The M-file name, less its extension, is what MATLAB searches for when you try to use the script or function.

A line at the top of a function M-file contains the syntax definition. The name of a function, as defined in the first line of the M-file, should be the same as the name of the file without the `.m` extension.

The variables within the body of the function are all local variables.

A *subfunction*,visible only to the other functions in the same file, is created by defining a new function with the `function` keyword after the body of the preceding function or subfunction. Subfunctions are not visible outside the file where they are defined.

You can terminate any function with an `end` statement but, in most cases, this is optional. `end` statements are required only in M-files that employ one or more nested functions. Within such an M-file, *every* function (including primary, nested, private, and subfunctions) must be terminated with an `end` statement. You can terminate any function type with `end`, but doing so is not required unless the M-file contains a nested function.

Functions normally return when the end of the function is reached. Use a `return` statement to force an early return.

When MATLAB does not recognize a function by name, it searches for a file of the same name on disk. If the function is found, MATLAB compiles it into memory for subsequent use. The section "Determining Which Function Is Called" in the MATLAB Programming documentation explains how MATLAB interprets variable and function names that you enter, and also covers the precedence used in function dispatching.

When you call an M-file function from the command line or from within another M-file, MATLAB parses the function and stores it in memory. The parsed function remains in memory until cleared with the `clear` command or you `quit` MATLAB. The `pcode` command performs the parsing step and stores the result on the disk as a P-file to be loaded later.

Examples

Example 1

The existence of a file on disk called `stat.m` containing this code defines a new function called `stat` that calculates the mean and standard deviation of a vector:

```
function [mean,stdev] = stat(x)
n = length(x);
mean = sum(x)/n;
stdev = sqrt(sum((x-mean).^2/n));
```

Example 2

`avg` is a subfunction within the file `stat.m`:

```
function [mean,stdev] = stat(x)
n = length(x);
mean = avg(x,n);
stdev = sqrt(sum((x-avg(x,n)).^2)/n);

function mean = avg(x,n)
mean = sum(x)/n;
```

function_handle (@)

Purpose

Handle used in calling functions indirectly

Syntax

```
handle = @functionname
handle = @(arglist)anonymous_function
```

Description

`handle = @functionname` returns a handle to the specified MATLAB function.

A function handle is a MATLAB value that provides a means of calling a function indirectly. You can pass function handles in calls to other functions (often called *function functions*). You can also store function handles in data structures for later use (for example, as Handle Graphics callbacks). A function handle is one of the standard MATLAB data types.

At the time you create a function handle, the function you specify must be on the MATLAB path and in the current scope. This condition does not apply when you evaluate the function handle. You can, for example, execute a subfunction from a separate (out-of-scope) M-file using a function handle as long as the handle was created within the subfunction's M-file (in-scope).

`handle = @(arglist)anonymous_function` constructs an anonymous function and returns a `handle` to that function. The body of the function, to the right of the parentheses, is a single MATLAB statement or command. `arglist` is a comma-separated list of input arguments. Execute the function by calling it by means of the function handle, `handle`.

Remarks

The function handle is a standard MATLAB data type. As such, you can manipulate and operate on function handles in the same manner as on other MATLAB data types. This includes using function handles in structures and cell arrays:

```
S.a = @sin;  S.b = @cos;  S.c = @tan;
C = {@sin, @cos, @tan};
```

However, standard matrices or arrays of function handles are not supported:

```
A = [@sin, @cos, @tan];        % This is not supported
```

For nonoverloaded functions, subfunctions, and private functions, a function handle references just the one function specified in the `@functionname` syntax. When you evaluate an overloaded function by means of its handle, the arguments the handle is evaluated with determine the actual function that MATLAB dispatches to.

Use `isa(h, 'function_handle')` to see if variable `h` is a function handle.

Examples

Example 1 — Constructing a Handle to a Named Function

The following example creates a function handle for the `humps` function and assigns it to the variable `fhandle`.

```
fhandle = @humps;
```

Pass the handle to another function in the same way you would pass any argument. This example passes the function handle just created to `fminbnd`, which then minimizes over the interval `[0.3, 1]`.

```
x = fminbnd(fhandle, 0.3, 1)
x =
    0.6370
```

The `fminbnd` function evaluates the `@humps` function handle. A small portion of the `fminbnd` M-file is shown below. In line 1, the `funfcn` input parameter receives the function handle `@humps` that was passed in. The statement, in line 113, evaluates the handle.

```
1    function [xf,fval,exitflag,output] = ...
         fminbnd(funfcn,ax,bx,options,varargin)
             .
             .
             .
```

```
113  fx = funfcn(x,varargin{:});
```

Example 2 — Constructing a Handle to an Anonymous Function

The statement below creates an anonymous function that finds the square of a number. When you call this function, MATLAB assigns the value you pass in to variable `x`, and then uses `x` in the equation `x.^2`:

```
sqr = @(x) x.^2;
```

The `@` operator constructs a function handle for this function, and assigns the handle to the output variable `sqr`. As with any function handle, you execute the function associated with it by specifying the variable that contains the handle, followed by a comma-separated argument list in parentheses. The syntax is

```
fhandle(arg1, arg2, ..., argN)
```

To execute the `sqr` function defined above, type

```
a = sqr(5)
a =
   25
```

Because `sqr` is a function handle, you can pass it in an argument list to other functions. The code shown here passes the `sqr` anonymous function to the MATLAB `quad` function to compute its integral from zero to one:

```
quad(sqr, 0, 1)
ans =
   0.3333
```

See Also

`str2func`, `func2str`, `functions`, `isa`

Purpose

Information about function handle

Syntax

```
S = functions(funhandle)
```

Description

`S = functions(funhandle)` returns, in MATLAB structure `S`, the function name, type, filename, and other information for the function handle stored in the variable `funhandle`.

`functions` does not operate on nonscalar function handles. Passing a nonscalar function handle to `functions` results in an error.

Caution The `functions` function is provided for querying and debugging purposes. Because its behavior may change in subsequent releases, you should not rely upon it for programming purposes.

This table lists the standard fields of the return structure.

Field Name	Field Description
`function`	Function name
`type`	Function type (e.g., simple, overloaded)
`file`	The file to be executed when the function handle is evaluated with a nonoverloaded data type

Remarks

For handles to functions that overload one of the standard MATLAB data types, like `double` or `char`, the structure returned by `functions` contains an additional field named `methods`. The `methods` field is a substructure containing one field name for each MATLAB class that overloads the function. The value of each field is the path and name of the file that defines the method.

Examples

Example 1

To obtain information on a function handle for the `poly` function, type

```
f = functions(@poly)
f =
    function: 'poly'
        type: 'simple'
        file:  '$matlabroot\toolbox\matlab\polyfun\poly.m'
```

(The term `$matlabroot` used in this example stands for the file specification of the directory in which MATLAB software is installed for your system. Your output will display this file specification.)

Access individual fields of the returned structure using dot selection notation:

```
f.type
ans =
   simple
```

Example 2

The function `get_handles` returns function handles for a subfunction and private function in output arguments `s` and `p` respectively:

```
function [s, p] = get_handles
s = @mysubfun;
p = @myprivatefun;
%
function mysubfun
disp 'Executing subfunction mysubfun'
```

Call `get_handles` to obtain the two function handles, and then pass each to the `functions` function. MATLAB returns information in a structure having the fields `function`, `type`, `file`, and `parentage`. The `file` field contains the file specification for the subfunction or private function:

```
[fsub fprv] = get_handles;

functions(fsub)
ans =
```

```
     function: 'mysubfun'
         type: 'scopedfunction'
         file: 'c:\matlab\get_handles.m'
    parentage: {'mysubfun'  'get_handles'}

functions(fprv)
ans =
     function: 'myprivatefun'
         type: 'scopedfunction'
         file: 'c:\matlab\private\myprivatefun.m'
    parentage: {'myprivatefun'}
```

Example 3

In this example, the function `get_handles_nested.m` contains a nested function `nestfun`. This function has a single output which is a function handle to the nested function:

```
function handle = get_handles_nested(A)
nestfun(A);

   function y = nestfun(x)
   y = x + 1;
   end

handle = @nestfun;
end
```

Call this function to get the handle to the nested function. Use this handle as the input to `functions` to return the information shown here. Note that the `function` field of the return structure contains the names of the nested function and the function in which it is nested in the format. Also note that `functions` returns a `workspace` field containing the variables that are in context at the time you call this function by its handle:

```
fh = get_handles_nested(5);

fhinfo = functions(fh)
```

```
fhinfo =
     function: 'get_handles_nested/nestfun'
         type: 'nested'
         file: 'c:\matlab\get_handles_nested.m'
    workspace: [1x1 struct]

fhinfo.workspace
ans =
    handle: @get_handles_nested/nestfun
         A: 5
```

function_handle

Purpose

Evaluate general matrix function

Syntax

```
F = funm(A,fun)
F = funm(A, fun, options)
[F, exitflag] = funm(...)
[F, exitflag, output] = funm(...)
```

Description

`F = funm(A,fun)` evaluates the user-defined function `fun` at the square matrix argument `A`. `F = fun(x, k)` must accept a vector `x` and an integer `k`, and return a vector `f` of the same size of `x`, where `f(i)` is the `k`th derivative of the function `fun` evaluated at `x(i)`. The function represented by fun must have a Taylor series with an infinite radius of convergence, except for `fun = @log`, which is treated as a special case.

You can also use `funm` to evaluate the special functions listed in the following table at the matrix `A`.

Function	Syntax for Evaluating Function at Matrix A
exp	`funm(A, @exp)`
log	`funm(A, @log)`
sin	`funm(A, @sin)`
cos	`funm(A, @cos)`
sinh	`funm(A, @sinh)`
cosh	`funm(A, @cosh)`

For matrix square roots, use `sqrtm(A)` instead. For matrix exponentials, which of `expm(A)` or `funm(A, @exp)` is the more accurate depends on the matrix `A`.

"Parameterizing Functions Called by Function Functions", in the online MATLAB Mathematics documentation, explains how to provide additional parameters to the function `fun`, if necessary.

`F = funm(A, fun, options)` sets the algorithm's parameters to the values in the structure `options`. The following table lists the fields of `options`.

Field	Description	Values
`options.TolBlk`	Level of display	`'off'` (default), `'on'`, `'verbose'`
`options.TolTay`	Tolerance for blocking Schur form	Positive scalar. The default is `eps`.
`options.MaxTerms`	Maximum number of Tayor series terms	Positive integer. The default is `250`.
`options.MaxSqrt`	When computing a logarithm, maximum number of square roots computed in inverse scaling and squaring method.	Positive integer. The default is `100`.
`options.Ord`	Specifies the ordering of the Schur form `T`.	A vector of length `length(A)`. `options.Ord(i)` is the index of the block into which `T(i,i)` is placed. The default is `[]`.

`[F, exitflag] = funm(...)` returns a scalar `exitflag` that describes the exit condition of `funm`. `exitflag` can have the following values:

- `0` — The algorithm was successful.
- `1` — One or more Taylor series evaluations did not converge. However, the computed value of `F` might still be accurate.

`[F, exitflag, output] = funm(...)` returns a structure `output` with the following fields:

Field	Description
`output.terms`	Vector for which `output.terms(i)` is the number of Taylor series terms used when evaluating the ith block, or, in the case of the logarithm, the number of square roots.
`output.ind`	Cell array for which the `(i,j)` block of the reordered Schur factor `T` is `T(output.ind{i}, output.ind{j})`.
`output.ord`	Ordering of the Schur form, as passed to `ordschur`
`output.T`	Reordered Schur form

If the Schur form is diagonal then `output = struct('terms',ones(n,1),'ind',{1:n})`.

Examples

Example 1

The following command computes the matrix sine of the 3-by-3 magic matrix.

```
F=funm(magic(3), @sin)

F =

   -0.3850    1.0191    0.0162
    0.6179    0.2168   -0.1844
    0.4173   -0.5856    0.8185
```

Example 2

The statements

```
S = funm(X,@sin);
C = funm(X,@cos);
```

produce the same results to within roundoff error as

```
E = expm(i*X);
C = real(E);
S = imag(E);
```

In either case, the results satisfy `S*S+C*C = I`, where `I = eye(size(X))`.

Example 3

To compute the function `exp(x) + cos(x)` at `A` with one call to `funm`, use

```
F = funm(A,@fun_expcos)
```

where `fun_expcos` is the following M-file function.

```
function f = fun_expcos(x, k)
% Return kth derivative of exp + cos at X.
        g = mod(ceil(k/2),2);
        if mod(k,2)
           f = exp(x) + sin(x)*(-1)^g;
        else
           f = exp(x) + cos(x)*(-1)^g;
        end
```

Algorithm

The algorithm `funm` uses is described in [1].

Purpose

Write binary data to file

Syntax

```
count = fwrite(fid, A)
count = fwrite(fid, A, precision)
count = fwrite(fid, A, precision, skip)
count = fwrite(fid, A, precision, skip, machineformat)
```

Description

`count = fwrite(fid, A)` writes the elements of matrix `A` to the specified file. The data is written to the file in column order, and a `count` is kept of the number of elements written successfully.

`fid` is an integer file identifier obtained from `fopen`, or `1` for standard output or `2` for standard error.

`count = fwrite(fid, A, precision)` writes the elements of matrix `A` to the specified file, translating MATLAB values to the specified `precision`.

`precision` controls the form and size of the result. See `fread` for a list of allowed precisions. If `precision` is not specified, MATLAB uses the default, which is `'uint8'`. For `'bitN'` or `'ubitN'` precisions, `fwrite` sets all bits in `A` when the value is out of range. If the precision is `'char'` or `'char*1'`, MATLAB writes characters using the encoding scheme associated with the file. See `fopen` for more information.

`count = fwrite(fid, A, precision, skip)` includes an optional `skip` argument that specifies the number of bytes to skip before each `precision` value is written. With the `skip` argument present, `fwrite` skips and writes one value, skips and writes another value, etc., until all of `A` is written. If `precision` is a bit format like `'bitN'` or `'ubitN'`, `skip` is specified in bits. This is useful for inserting data into noncontiguous fields in fixed-length records.

`count = fwrite(fid, A, precision, skip, machineformat)` treats the data written as having a format given by `machineformat`. You can obtain the `machineformat` argument from the output of the `fopen` function. See `fopen` for possible values for `machineformat`.

Remarks

You cannot view or `type` the contents of the file you are writing with `fwrite` until you close the file with the `fclose` function.

Examples

Example 1

This example creates a 100-byte binary file containing the 25 elements of the 5-by-5 magic square, stored as 4-byte integers:

```
fid = fopen('magic5.bin', 'wb');
fwrite(fid, magic(5), 'integer*4')
```

Example 2

This example takes a string of Unicode characters, `str`, which contains Japanese text, and writes the string into a file using the Shift-JIS character encoding scheme:

```
fid = fopen('japanese_out.txt', 'w', 'n', 'Shift_JIS');
fwrite(fid, str, 'char');
fclose(fid);
```

See Also

`fclose`, `ferror`, `fopen`, `fprintf`, `fread`, `fscanf`, `fseek`, `ftell`

fwrite (serial)

Purpose

Write binary data to device

Syntax

```
fwrite(obj,A)
fwrite(obj,A,'precision')
fwrite(obj,A,'mode')
fwrite(obj,A,'precision','mode')
```

Arguments

`obj`	A serial port object.
`A`	The binary data written to the device.
`'precision'`	The number of bits written for each value, and the interpretation of the bits as character, integer, or floating-point values.
`'mode'`	Specifies whether data is written synchronously or asynchronously.

Description

`fwrite(obj,A)` writes the binary data `A` to the device connected to `obj`.

`fwrite(obj,A,'precision')` writes binary data with precision specified by *`precision`*.

`precision` controls the number of bits written for each value and the interpretation of those bits as integer, floating-point, or character values. If *`precision`* is not specified, `uchar` (an 8-bit unsigned character) is used. The supported values for *`precision`* are listed below in Remarks.

`fwrite(obj,A,'mode')` writes binary data with command line access specified by *`mode`*. If *`mode`* is `sync`, `A` is written synchronously and the command line is blocked. If *`mode`* is `async`, `A` is written asynchronously and the command line is not blocked. If *`mode`* is not specified, the write operation is synchronous.

`fwrite(obj,A,'precision','mode')` writes binary data with precision specified by *`precision`* and command line access specified by *`mode`*.

Remarks

Before you can write data to the device, it must be connected to `obj` with the `fopen` function. A connected serial port object has a `Status` property value of `open`. An error is returned if you attempt to perform a write operation while `obj` is not connected to the device.

The `ValuesSent` property value is increased by the number of values written each time `fwrite` is issued.

An error occurs if the output buffer cannot hold all the data to be written. You can specify the size of the output buffer with the `OutputBufferSize` property.

If you use the `help` command to display help for `fwrite`, then you need to supply the pathname shown below.

```
help serial/fwrite
```

Synchronous Versus Asynchronous Write Operations

By default, data is written to the device synchronously and the command line is blocked until the operation completes. You can perform an asynchronous write by configuring the *`mode`* input argument to be `async`. For asynchronous writes:

- The `BytesToOutput` property value is continuously updated to reflect the number of bytes in the output buffer.
- The M-file callback function specified for the `OutputEmptyFcn` property is executed when the output buffer is empty.

You can determine whether an asynchronous write operation is in progress with the `TransferStatus` property.

Synchronous and asynchronous write operations are discussed in more detail in Writing Data.

Rules for Completing a Write Operation with fwrite

A binary write operation using `fwrite` completes when:

- The specified data is written.

- The time specified by the `Timeout` property passes.

Note The `Terminator` property is not used with binary write operations.

Supported Precisions

The supported values for *`precision`* are listed below.

Data Type	Precision	Interpretation
Character	`uchar`	8-bit unsigned character
	`schar`	8-bit signed character
	`char`	8-bit signed or unsigned character
Integer	`int8`	8-bit integer
	`int16`	16-bit integer
	`int32`	32-bit integer
	`uint8`	8-bit unsigned integer
	`uint16`	16-bit unsigned integer
	`uint32`	32-bit unsigned integer
	`short`	16-bit integer
	`int`	32-bit integer
	`long`	32- or 64-bit integer
	`ushort`	16-bit unsigned integer
	`uint`	32-bit unsigned integer
	`ulong`	32- or 64-bit unsigned integer

Data Type	Precision	Interpretation
Floating-point	`single`	32-bit floating point
	`float32`	32-bit floating point
	`float`	32-bit floating point
	`double`	64-bit floating point
	`float64`	64-bit floating point

See Also

Functions

`fopen`, `fprintf`

Properties

`BytesToOutput`, `OutputBufferSize`, `OutputEmptyFcn`, `Status`, `Timeout`, `TransferStatus`, `ValuesSent`

Purpose

Find root of continuous function of one variable

Syntax

```
x = fzero(fun,x0)
x = fzero(fun,x0,options)
[x,fval] = fzero(...)
[x,fval,exitflag] = fzero(...)
[x,fval,exitflag,output] = fzero(...)
```

Description

`x = fzero(fun,x0)` tries to find a zero of `fun` near `x0`, if `x0` is a scalar. `fun` is a function handle. See "Function Handles" in the MATLAB Programming documentation for more information. The value `x` returned by `fzero` is near a point where `fun` changes sign, or `NaN` if the search fails. In this case, the search terminates when the search interval is expanded until an `Inf`, `NaN`, or complex value is found.

"Parameterizing Functions Called by Function Functions" in the MATLAB Mathematics documentation, explains how to pass additional parameters to your objective function `fun`. See also "Example 2" on page 2-1351 and "Example 3" on page 2-1351 below.

If `x0` is a vector of length two, `fzero` assumes `x0` is an interval where the sign of `fun(x0(1))` differs from the sign of `fun(x0(2))`. An error occurs if this is not true. Calling `fzero` with such an interval guarantees `fzero` will return a value near a point where `fun` changes sign.

`x = fzero(fun,x0,options)` minimizes with the optimization parameters specified in the structure `options`. You can define these parameters using the `optimset` function. `fzero` uses these `options` structure fields:

`Display`	Level of display. `'off'` displays no output; `'iter'` displays output at each iteration; `'final'` displays just the final output; `'notify'` (default) displays output only if the function does not converge.
FunValCheck	Check whether objective function values are valid. `'on'` displays an error when the objective function returns a value that is `complex` or `NaN`. `'off'` (the default) displays no error.
OutputFcn	User-defined function that is called at each iteration. See "Output Function" in the Optimization Toolbox for more information.
PlotFcns	User-defined plot function that is called at each iteration. See "Plot Functions" in the Optimization Toolbox for more information.
`TolX`	Termination tolerance on `x`

`[x,fval] = fzero(...)` returns the value of the objective function `fun` at the solution `x`.

`[x,fval,exitflag] = fzero(...)` returns a value `exitflag` that describes the exit condition of `fzero`:

- `1` Function converged to a solution `x`.
- `-1` Algorithm was terminated by the output function.
- `-3` `NaN` or `Inf` function value was encountered during search for an interval containing a sign change.
- `-4` Complex function value was encountered during search for an interval containing a sign change.
- `-5` `fzero` might have converged to a singular point.
- `-6` `fzero` can not detect a change in sign of the function.

`[x,fval,exitflag,output] = fzero(...)` returns a structure `output` that contains information about the optimization:

`output.algorithm`	Algorithm used
`output.funcCount`	Number of function evaluations
`output.intervaliterations`	Number of iterations taken to find an interval
`output.iterations`	Number of zero-finding iterations
`output.message`	Exit message

Note For the purposes of this command, zeros are considered to be points where the function actually crosses, not just touches, the *x*-axis.

Arguments

`fun` is the function whose zero is to be computed. It accepts a vector `x` and returns a scalar `f`, the objective function evaluated at `x`. The function `fun` can be specified as a function handle for an M-file function

```
x = fzero(@myfun,x0);
```

where `myfun` is an M-file function such as

```
function f = myfun(x)
f = ...            % Compute function value at x
```

or as a function handle for an anonymous function:

```
x = fzero(@(x)sin(x*x),x0);
```

Other arguments are described in the syntax descriptions above.

Examples

Example 1

Calculate π by finding the zero of the sine function near 3.

```
x = fzero(@sin,3)
x =
    3.1416
```

Example 2

To find the zero of cosine between 1 and 2

```
x = fzero(@cos,[1 2])
x =
    1.5708
```

Note that `cos(1)` and `cos(2)` differ in sign.

Example 3

To find a zero of the function $f(x) = x^3 - 2x - 5$

write an anonymous function `f`:

```
f = @(x)x.^3-2*x-5;
```

Then find the zero near 2:

```
z = fzero(f,2)
z =
    2.0946
```

Because this function is a polynomial, the statement `roots([1 0 -2 -5])` finds the same real zero, and a complex conjugate pair of zeros.

```
    2.0946
   -1.0473 + 1.1359i
   -1.0473 - 1.1359i
```

If `fun` is parameterized, you can use anonymous functions to capture the problem-dependent parameters. For example, suppose you want to minimize the objective function `myfun` defined by the following M-file function.

```
function f = myfun(x,a)
f = cos(a*x);
```

Note that `myfun` has an extra parameter `a`, so you cannot pass it directly to `fzero`. To optimize for a specific value of `a`, such as `a = 2`.

1. Assign the value to `a`.

```
a = 2; % define parameter first
```

2. Call `fzero` with a one-argument anonymous function that captures that value of `a` and calls `myfun` with two arguments:

```
x = fzero(@(x) myfun(x,a),0.1)
```

Algorithm

The `fzero` command is an M-file. The algorithm, which was originated by T. Dekker, uses a combination of bisection, secant, and inverse quadratic interpolation methods. An Algol 60 version, with some improvements, is given in [1]. A Fortran version, upon which the `fzero` M-file is based, is in [2].

Limitations

The `fzero` command finds a point where the function changes sign. If the function is *continuous*, this is also a point where the function has a value near zero. If the function is not continuous, `fzero` may return values that are discontinuous points instead of zeros. For example, `fzero(@tan,1)` returns `1.5708`, a discontinuous point in `tan`.

Furthermore, the `fzero` command defines a *zero* as a point where the function crosses the *x*-axis. Points where the function touches, but does not cross, the *x*-axis are not valid zeros. For example, `y = x.^2` is a parabola that touches the *x*-axis at 0. Because the function never crosses the *x*-axis, however, no zero is found. For functions with no valid zeros, `fzero` executes until `Inf`, `NaN`, or a complex value is detected.

Purpose

Test matrices

Syntax

```
[A,B,C,...] = gallery(matname,P1,P2,...)
[A,B,C,...] = gallery(matname,P1,P2,...,classname)
gallery(3)
gallery(5)
```

Description

`[A,B,C,...] = gallery(matname,P1,P2,...)` returns the test matrices specified by the quoted string `matname`. The `matname` input is the name of a matrix family selected from the table below. `P1,P2,...` are input parameters required by the individual matrix family. The number of optional parameters `P1,P2,...` used in the calling syntax varies from matrix to matrix. The exact calling syntaxes are detailed in the individual matrix descriptions below.

`[A,B,C,...] = gallery(matname,P1,P2,...,classname)` produces a matrix of class `classname`. The `classname` input is a quoted string that must be either `'single'` or `'double'`. If `classname` is not specified, then the class of the matrix is determined from those arguments among `P1,P2,...` that do not specify dimensions or select an option. If any of these arguments is of class `single` then the matrix is `single`; otherwise the matrix is `double`.

`gallery(3)` is a badly conditioned 3-by-3 matrix and `gallery(5)` is an interesting eigenvalue problem.

The gallery holds over fifty different test matrix functions useful for testing algorithms and other purposes.

Test Matrices			
binomial	cauchy	chebspec	chebvand
chow	circul	clement	compar
condex	cycol	dorr	dramadah
fiedler	forsythe	frank	gearmat

lehmer	leslie	lesp	lotkin
minij	moler	neumann	orthog
parter	pei	poisson	prolate
randcolu	randcorr	randhess	randjorth
rando	randsvd	redheff	riemann
ris	smoke	toeppd	tridiag
triw	wathen	wilk	

binomial — Multiple of involutory matrix

`A = gallery('binomial',n)` returns an `n`-by-`n` matrix,with integer entries such that `A^2 = 2^(n-1)*eye(n)`.

Thus, `B = A*2^((1-n)/2)` is involutory, that is, `B^2 = eye(n)`.

cauchy — Cauchy matrix

`C = gallery('cauchy',x,y)` returns an `n`-by-`n` matrix, `C(i,j) = 1/(x(i)+y(j))`. Arguments `x` and `y` are vectors of length `n`. If you pass in scalars for `x` and `y`, they are interpreted as vectors `1:x` and `1:y`.

`C = gallery('cauchy',x)` returns the same as above with `y = x`. That is, the command returns `C(i,j) = 1/(x(i)+x(j))`.

Explicit formulas are known for the inverse and determinant of a Cauchy matrix. The determinant `det(C)` is nonzero if `x` and `y` both have distinct elements. `C` is totally positive if `0 < x(1) <... < x(n)` and `0 < y(1) < ... < y(n)`.

chebspec — Chebyshev spectral differentiation matrix

`C = gallery('chebspec',n,switch)` returns a Chebyshev spectral differentiation matrix of order `n`. Argument `switch` is a variable that determines the character of the output matrix. By default, `switch = 0`.

For `switch = 0` ("no boundary conditions"), `C` is nilpotent (`C^n = 0`) and has the null vector `ones(n,1)`. The matrix `C` is similar to a Jordan block of size `n` with eigenvalue zero.

For `switch = 1`, `C` is nonsingular and well-conditioned, and its eigenvalues have negative real parts.

The eigenvector matrix of the Chebyshev spectral differentiation matrix is ill-conditioned.

chebvand — Vandermonde-like matrix for the Chebyshev polynomials

`C = gallery('chebvand',p)` produces the (primal) Chebyshev Vandermonde matrix based on the vector of points `p`, which define where the Chebyshev polynomial is calculated.

`C = gallery('chebvand',m,p)` where `m` is scalar, produces a rectangular version of the above, with `m` rows.

If `p` is a vector, then $C(i,j) = T_{i-1}(p(j))$ where T_{i-1} is the Chebyshev polynomial of degree i-1. If `p` is a scalar, then `p` equally spaced points on the interval `[0,1]` are used to calculate `C`.

chow — Singular Toeplitz lower Hessenberg matrix

`A = gallery('chow',n,alpha,delta)` returns `A` such that `A = H(alpha) + delta*eye(n)`, where $H_{i,j}(\alpha) = \alpha^{(i-j+1)}$ and argument `n` is the order of the Chow matrix. Default value for scalars `alpha` and `delta` are `1` and `0`, respectively.

`H(alpha)` has `p = floor(n/2)` eigenvalues that are equal to zero. The rest of the eigenvalues are equal to `4*alpha*cos(k*pi/(n+2))^2, k=1:n-p`.

circul — Circulant matrix

`C = gallery('circul',v)` returns the circulant matrix whose first row is the vector `v`.

A circulant matrix has the property that each row is obtained from the previous one by cyclically permuting the entries one step forward. It is a special Toeplitz matrix in which the diagonals "wrap around."

If `v` is a scalar, then `C = gallery('circul',1:v)`.

The eigensystem of `C` (`n`-by-`n`) is known explicitly: If `t` is an `n`th root of unity, then the inner product of `v` and $w = [1\ t\ t^2 \ldots t^{(n-1)}]$ is an eigenvalue of `C` and `w(n:-1:1)` is an eigenvector.

clement — Tridiagonal matrix with zero diagonal entries

`A = gallery('clement',n,sym)` returns an `n`-by-`n` tridiagonal matrix with zeros on its main diagonal and known eigenvalues. It is singular if order `n` is odd. About 64 percent of the entries of the inverse are zero. The eigenvalues include plus and minus the numbers `n-1`, `n-3`, `n-5`, `...`, as well as (for odd `n`) a final eigenvalue of `1` or `0`.

Argument `sym` determines whether the Clement matrix is symmetric. For `sym = 0` (the default) the matrix is nonsymmetric, while for `sym = 1`, it is symmetric.

compar — Comparison matrices

`A = gallery('compar',A,1)` returns `A` with each diagonal element replaced by its absolute value, and each off-diagonal element replaced by minus the absolute value of the largest element in absolute value in its row. However, if `A` is triangular `compar(A,1)` is too.

`gallery('compar',A)` is `diag(B) - tril(B,-1) - triu(B,1)`, where `B = abs(A)`. `compar(A)` is often denoted by M(A) in the literature.

`gallery('compar',A,0)` is the same as `gallery('compar',A)`.

condex — Counter-examples to matrix condition number estimators

`A = gallery('condex',n,k,theta)` returns a "counter-example" matrix to a condition estimator. It has order `n` and scalar parameter `theta` (default 100).

The matrix, its natural size, and the estimator to which it applies are specified by `k`:

`k = 1`	4-by-4	LINPACK
`k = 2`	3-by-3	LINPACK
`k = 3`	arbitrary	LINPACK (`rcond`) (independent of `theta`)
`k = 4`	`n >= 4`	LAPACK (RCOND) (default). It is the inverse of this matrix that is a counter-example.

If `n` is not equal to the natural size of the matrix, then the matrix is padded out with an identity matrix to order `n`.

cycol — Matrix whose columns repeat cyclically

`A = gallery('cycol',[m n],k)` returns an `m`-by-`n` matrix with cyclically repeating columns, where one "cycle" consists of `randn(m,k)`. Thus, the rank of matrix `A` cannot exceed `k`, and `k` must be a scalar.

Argument `k` defaults to `round(n/4)`, and need not evenly divide `n`.

`A = gallery('cycol',n,k)`, where `n` is a scalar, is the same as `gallery('cycol',[n n],k)`.

dorr — Diagonally dominant, ill-conditioned, tridiagonal matrix

`[c,d,e] = gallery('dorr',n,theta)` returns the vectors defining an `n`-by-`n`, row diagonally dominant, tridiagonal matrix that is ill-conditioned for small nonnegative values of `theta`. The default value of `theta` is `0.01`. The Dorr matrix itself is the same as `gallery('tridiag',c,d,e)`.

`A = gallery('dorr',n,theta)` returns the matrix itself, rather than the defining vectors.

dramadah — Matrix of zeros and ones whose inverse has large integer entries

`A = gallery('dramadah',n,k)` returns an `n`-by-`n` matrix of `0`'s and `1`'s for which `mu(A) = norm(inv(A),'fro')` is relatively large, although not necessarily maximal. An anti-Hadamard matrix `A` is a matrix with elements `0` or `1` for which `mu(A)` is maximal.

`n` and `k` must both be scalars. Argument `k` determines the character of the output matrix:

k = 1	Default. `A` is Toeplitz, with `abs(det(A)) = 1`, and `mu(A) > c(1.75)^n`, where `c` is a constant. The inverse of `A` has integer entries.
k = 2	`A` is upper triangular and Toeplitz. The inverse of `A` has integer entries.
k = 3	`A` has maximal determinant among lower Hessenberg (0,1) matrices. `det(A)` = the `n`th Fibonacci number. `A` is Toeplitz. The eigenvalues have an interesting distribution in the complex plane.

fiedler — Symmetric matrix

`A = gallery('fiedler',c)`, where `c` is a length `n` vector, returns the `n`-by-`n` symmetric matrix with elements `abs(n(i)-n(j))`. For scalar `c`, `A = gallery('fiedler',1:c)`.

Matrix `A` has a dominant positive eigenvalue and all the other eigenvalues are negative.

Explicit formulas for `inv(A)` and `det(A)` are given in [Todd, J., *Basic Numerical Mathematics*, Vol. 2: Numerical Algebra, Birkhauser, Basel, and Academic Press, New York, 1977, p. 159] and attributed to Fiedler. These indicate that `inv(A)` is tridiagonal except for nonzero `(1,n)` and `(n,1)` elements.

forsythe — Perturbed Jordan block

`A = gallery('forsythe',n,alpha,lambda)` returns the `n`-by-`n` matrix equal to the Jordan block with eigenvalue `lambda`, excepting that `A(n,1) = alpha`. The default values of scalars `alpha` and `lambda` are `sqrt(eps)` and `0`, respectively.

The characteristic polynomial of `A` is given by:

```
det(A-t*I) = (lambda-t)^N - alpha*(-1)^n.
```

frank — Matrix with ill-conditioned eigenvalues

`F = gallery('frank',n,k)` returns the Frank matrix of order `n`. It is upper Hessenberg with determinant `1`. If `k = 1`, the elements are reflected about the anti-diagonal `(1,n)` — `(n,1)`. The eigenvalues of `F` may be obtained in terms of the zeros of the Hermite polynomials. They are positive and occur in reciprocal pairs; thus if `n` is odd, `1` is an eigenvalue. `F` has `floor(n/2)` ill-conditioned eigenvalues — the smaller ones.

gcdmat — Greatest common divisor matrix

`A = gallery('gcdmat',n)` returns the `n`-by-`n` matrix with `(i,j)` entry `gcd(i,j)`. `Matrix` A is symmetric positive definite, and A.^r is symmetric positive semidefinite for all nonnegative `r`.

gearmat — Gear matrix

`A = gallery('gearmat',n,i,j)` returns the `n`-by-`n` matrix with ones on the sub- and super-diagonals, `sign(i)` in the `(1,abs(i))` position, `sign(j)` in the `(n,n+1-abs(j))` position, and zeros everywhere else. Arguments `i` and `j` default to `n` and `-n`, respectively.

Matrix `A` is singular, can have double and triple eigenvalues, and can be defective.

All eigenvalues are of the form `2*cos(a)` and the eigenvectors are of the form `[sin(w+a), sin(w+2*a), ..., sin(w+n*a)]`, where `a` and `w` are given in Gear, C. W., "A Simple Set of Test Matrices for Eigenvalue Programs," *Math. Comp.*, Vol. 23 (1969), pp. 119-125.

grcar — Toeplitz matrix with sensitive eigenvalues

`A = gallery('grcar',n,k)` returns an `n`-by-`n` Toeplitz matrix with `-1`s on the subdiagonal, `1`s on the diagonal, and `k` superdiagonals of `1`s. The default is `k = 3`. The eigenvalues are sensitive.

hanowa — Matrix whose eigenvalues lie on a vertical line in the complex plane

`A = gallery('hanowa',n,d)` returns an `n`-by-`n` block 2-by-2 matrix of the form:

```
[d*eye(m)   -diag(1:m)
diag(1:m)   d*eye(m)]
```

Argument `n` is an even integer `n=2*m`. Matrix `A` has complex eigenvalues of the form `d ± k*i`, for `1 <= k <= m`. The default value of `d` is `-1`.

house — Householder matrix

`[v,beta,s] = gallery('house',x,k)` takes `x`, an `n`-element column vector, and returns `V` and `beta` such that `H*x = s*e1`. In this expression, `e1` is the first column of `eye(n)`, `abs(s) = norm(x)`, and `H = eye(n) - beta*V*V'` is a Householder matrix.

`k` determines the sign of `s`:

`k = 0`	`sign(s) = -sign(x(1))` (default)
`k = 1`	`sign(s) = sign(x(1))`
`k = 2`	`sign(s) = 1` (`x` must be real)

If `x` is complex, then `sign(x) = x./abs(x)` when `x` is nonzero.

If `x = 0`, or if `x = alpha*e1` (`alpha >= 0`) and either `k = 1` or `k = 2`, then `V = 0`, `beta = 1`, and `s = x(1)`. In this case, `H` is the identity matrix, which is not strictly a Householder matrix.

`[v, beta] = gallery('house',x)` takes `x`, a scalar or `n`-element column vector, and returns `v` and `beta` such that `eye(n,n) -`

`beta*v*v'` is a Householder matrix. A Householder matrix `H` satisfies the relationship

```
H*x = -sign(x(1))*norm(x)*e1
```

where `e1` is the first column of `eye(n,n)`. Note that if `x` is complex, then `sign(x) exp(i*arg(x))` (which equals `x./abs(x)` when `x` is nonzero).

If `x = 0`, then `v = 0` and `beta = 1`.

invhess — Inverse of an upper Hessenberg matrix

`A = gallery('invhess',x,y)`, where `x` is a length `n` vector and `y` is a length `n-1` vector, returns the matrix whose lower triangle agrees with that of `ones(n,1)*x'` and whose strict upper triangle agrees with that of `[1 y]*ones(1,n)`.

The matrix is nonsingular if `x(1) ~= 0` and `x(i+1) ~= y(i)` for all `i`, and its inverse is an upper Hessenberg matrix. Argument `y` defaults to `-x(1:n-1)`.

If `x` is a scalar, `invhess(x)` is the same as `invhess(1:x)`.

invol — Involutory matrix

`A = gallery('invol',n)` returns an `n`-by-`n` involutory (`A*A = eye(n)`) and ill-conditioned matrix. It is a diagonally scaled version of `hilb(n)`.

`B = (eye(n)-A)/2` and `B = (eye(n)+A)/2` are idempotent (`B*B = B`).

ipjfact — Hankel matrix with factorial elements

`[A,d] = gallery('ipjfact',n,k)` returns `A`, an `n`-by-`n` Hankel matrix, and `d`, the determinant of `A`, which is known explicitly. If `k = 0` (the default), then the elements of `A` are `A(i,j) = (i+j)!` If `k = 1`, then the elements of `A` are `A(i,j) 1/(i+j)`.

Note that the inverse of `A` is also known explicitly.

jordbloc — Jordan block

`A = gallery('jordbloc',n,lambda)` returns the `n`-by-`n` Jordan block with eigenvalue `lambda`. The default value for `lambda` is `1`.

kahan — Upper trapezoidal matrix

`A = gallery('kahan',n,theta,pert)` returns an upper trapezoidal matrix that has interesting properties regarding estimation of condition and rank.

If `n` is a two-element vector, then `A` is `n(1)`-by-`n(2)`; otherwise, `A` is `n`-by-`n`. The useful range of `theta` is `0 < theta < pi`, with a default value of `1.2`.

To ensure that the QR factorization with column pivoting does not interchange columns in the presence of rounding errors, the diagonal is perturbed by `pert*eps*diag([n:-1:1])`. The default `pert` is `25`, which ensures no interchanges for `gallery('kahan',n)` up to at least `n = 90` in IEEE arithmetic.

kms — Kac-Murdock-Szego Toeplitz matrix

`A = gallery('kms',n,rho)` returns the `n`-by-`n` Kac-Murdock-Szego Toeplitz matrix such that `A(i,j) = rho^(abs(i-j))`, for real `rho`.

For complex `rho`, the same formula holds except that elements below the diagonal are conjugated. `rho` defaults to 0.5.

The KMS matrix `A` has these properties:

- An LDL' factorization with `L inv(gallery('triw',n,-rho,1))'`, and `D(i,i) (1-abs(rho)^2)*eye(n)`, except `D(1,1) = 1`.
- Positive definite if and only if `0 < abs(rho) < 1`.
- The inverse `inv(A)` is tridiagonal.

krylov — Krylov matrix

`B = gallery('krylov',A,x,j)` returns the Krylov matrix

```
[x, Ax, A^2x, ..., A^(j-1)x]
```

where `A` is an `n`-by-`n` matrix and `x` is a length `n` vector. The defaults are `x ones(n,1)`, and `j = n`.

`B = gallery('krylov',n)` is the same as `gallery('krylov',(randn(n))`.

lauchli — Rectangular matrix

`A = gallery('lauchli',n,mu)` returns the `(n+1)`-by-`n` matrix

```
[ones(1,n); mu*eye(n)]
```

The Lauchli matrix is a well-known example in least squares and other problems that indicates the dangers of forming `A'*A`. Argument `mu` defaults to `sqrt(eps)`.

lehmer — Symmetric positive definite matrix

`A = gallery('lehmer',n)` returns the symmetric positive definite `n`-by-`n` matrix such that `A(i,j) = i/j` for `j >= i`.

The Lehmer matrix `A` has these properties:

- `A` is totally nonnegative.
- The inverse `inv(A)` is tridiagonal and explicitly known.
- The order `n <= cond(A) <= 4*n*n`.

leslie —

`L = gallery('leslie',a,b)` is the `n`-by-`n` matrix from the Leslie population model with average birth numbers `a(1:n)` and survival rates `b(1:n-1)`. It is zero, apart from the first row (which contains the `a(i)`) and the first subdiagonal (which contains the `b(i)`). For a valid model, the `a(i)` are nonnegative and the `b(i)` are positive and bounded by 1, i.e., `0 < b(i) <= 1`.

`L = gallery('leslie',n)` generates the Leslie matrix with `a = ones(n,1)`, `b = ones(n-1,1)`.

lesp — Tridiagonal matrix with real, sensitive eigenvalues

`A = gallery('lesp',n)` returns an `n`-by-`n` matrix whose eigenvalues are real and smoothly distributed in the interval approximately `[-2*N-3.5, -4.5]`.

The sensitivities of the eigenvalues increase exponentially as the eigenvalues grow more negative. The matrix is similar to the symmetric tridiagonal matrix with the same diagonal entries and with off-diagonal entries 1, via a similarity transformation with `D = diag(1!,2!,...,n!)`.

lotkin — Lotkin matrix

`A = gallery('lotkin',n)` returns the Hilbert matrix with its first row altered to all ones. The Lotkin matrix `A` is nonsymmetric, ill-conditioned, and has many negative eigenvalues of small magnitude. Its inverse has integer entries and is known explicitly.

minij — Symmetric positive definite matrix

`A = gallery('minij',n)` returns the `n`-by-`n` symmetric positive definite matrix with `A(i,j) = min(i,j)`.

The `minij` matrix has these properties:

- The inverse `inv(A)` is tridiagonal and equal to `-1` times the second difference matrix, except its `(n,n)` element is `1`.
- Givens' matrix, `2*A-ones(size(A))`, has tridiagonal inverse and eigenvalues `0.5*sec((2*r-1)*pi/(4*n))^2`, where `r=1:n`.
- `(n+1)*ones(size(A))-A` has elements that are `max(i,j)` and a tridiagonal inverse.

moler — Symmetric positive definite matrix

`A = gallery('moler',n,alpha)` returns the symmetric positive definite `n`-by-`n` matrix `U'*U`, where `U = gallery('triw',n,alpha)`.

For the default `alpha = -1`, `A(i,j) = min(i,j)-2`, and `A(i,i) = i`. One of the eigenvalues of `A` is small.

neumann — Singular matrix from the discrete Neumann problem (sparse)

`C = gallery('neumann',n)` returns the sparse `n`-by-`n` singular, row diagonally dominant matrix resulting from discretizing the Neumann problem with the usual five-point operator on a regular mesh.

Argument `n` is a perfect square integer $n = m^2$ or a two-element vector. `C` is sparse and has a one-dimensional null space with null vector `ones(n,1)`.

orthog — Orthogonal and nearly orthogonal matrices

`Q = gallery('orthog',n,k)` returns the kth type of matrix of order `n`, where `k > 0` selects exactly orthogonal matrices, and `k < 0` selects diagonal scalings of orthogonal matrices. Available types are:

`k = 1` `Q(i,j) = sqrt(2/(n+1)) * sin(i*j*pi/(n+1))`

Symmetric eigenvector matrix for second difference matrix. This is the default.

`k = 2` `Q(i,j) = 2/(sqrt(2*n+1)) * sin(2*i*j*pi/(2*n+1))`

Symmetric.

`k = 3` `Q(r,s) = exp(2*pi*i*(r-1)*(s-1)/n) / sqrt(n)`

Unitary, the Fourier matrix. Q^4 is the identity. This is essentially the same matrix as `fft(eye(n))/sqrt(n)!`

`k = 4` Helmert matrix: a permutation of a lower Hessenberg matrix, whose first row is `ones(1:n)/sqrt(n)`.

`k = 5` `Q(i,j) = sin(2*pi*(i-1)*(j-1)/n) + cos(2*pi*(i-1)*(j-1)/n)`

Symmetric matrix arising in the Hartley transform.

`k = 6` `Q(i,j) = sqrt(2/n)*cos((i-1/2)*(j-1/2)*pi/n)`

Symmetric matrix arising as a discrete cosine transform.

`k = -1`	`Q(i,j) = cos((i-1)*(j-1)*pi/(n-1))` Chebyshev Vandermonde-like matrix, based on extrema of `T(n-1)`.
`k = -2`	`Q(i,j) = cos((i-1)*(j-1/2)*pi/n))` Chebyshev Vandermonde-like matrix, based on zeros of `T(n)`.

parter — Toeplitz matrix with singular values near pi

`C = gallery('parter',n)` returns the matrix `C` such that `C(i,j) = 1/(i-j+0.5)`.

`C` is a Cauchy matrix and a Toeplitz matrix. Most of the singular values of `C` are very close to `pi`.

pei — Pei matrix

`A = gallery('pei',n,alpha)`, where `alpha` is a scalar, returns the symmetric matrix `alpha*eye(n) + ones(n)`. The default for `alpha` is 1. The matrix is singular for `alpha` equal to either `0` or `-n`.

poisson — Block tridiagonal matrix from Poisson's equation (sparse)

`A = gallery('poisson',n)` returns the block tridiagonal (sparse) matrix of order `n^2` resulting from discretizing Poisson's equation with the 5-point operator on an `n`-by-`n` mesh.

prolate — Symmetric, ill-conditioned Toeplitz matrix

`A = gallery('prolate',n,w)` returns the `n`-by-`n` prolate matrix with parameter `w`. It is a symmetric Toeplitz matrix.

If `0 < w < 0.5` then `A` is positive definite

- The eigenvalues of `A` are distinct, lie in `(0,1)`, and tend to cluster around `0` and `1`.
- The default value of `w` is 0.25.

randcolu — Random matrix with normalized cols and specified singular values

`A = gallery('randcolu',n)` is a random `n`-by-`n` matrix with columns of unit 2-norm, with random singular values whose squares are from a uniform distribution.

`A'*A` is a correlation matrix of the form produced by `gallery('randcorr',n)`.

`gallery('randcolu',x)` where `x` is an `n`-vector (`n > 1`), produces a random `n`-by-`n` matrix having singular values given by the vector `x`. The vector `x` must have nonnegative elements whose sum of squares is `n`.

`gallery('randcolu',x,m)` where `m >= n`, produces an `m`-by-`n` matrix.

`gallery('randcolu',x,m,k)` provides a further option:

`k = 0`	`diag(x)` is initially subjected to a random two-sided orthogonal transformation, and then a sequence of Givens rotations is applied (default).
`k = 1`	The initial transformation is omitted. This is much faster, but the resulting matrix may have zero entries.

For more information, see:

[1] Davies, P. I. and N. J. Higham, "Numerically Stable Generation of Correlation Matrices and Their Factors," *BIT*, Vol. 40, 2000, pp. 640-651.

randcorr — Random correlation matrix with specified eigenvalues

`gallery('randcorr',n)` is a random `n`-by-`n` correlation matrix with random eigenvalues from a uniform distribution. A correlation matrix is a symmetric positive semidefinite matrix with `1`s on the diagonal (see `corrcoef`).

`gallery('randcorr',x)` produces a random correlation matrix having eigenvalues given by the vector `x`, where `length(x) > 1`. The vector `x` must have nonnegative elements summing to `length(x)`.

`gallery('randcorr',x,k)` provides a further option:

`k = 0`	The diagonal matrix of eigenvalues is initially subjected to a random orthogonal similarity transformation, and then a sequence of Givens rotations is applied (default).
`k = 1`	The initial transformation is omitted. This is much faster, but the resulting matrix may have some zero entries.

For more information, see:

[1] Bendel, R. B. and M. R. Mickey, "Population Correlation Matrices for Sampling Experiments," *Commun. Statist. Simulation Comput.*, B7, 1978, pp. 163-182.

[2] Davies, P. I. and N. J. Higham, "Numerically Stable Generation of Correlation Matrices and Their Factors," *BIT*, Vol. 40, 2000, pp. 640-651.

randhess — Random, orthogonal upper Hessenberg matrix

`H = gallery('randhess',n)` returns an `n`-by-`n` real, random, orthogonal upper Hessenberg matrix.

`H = gallery('randhess',x)` if `x` is an arbitrary, real, length `n` vector with `n > 1`, constructs `H` nonrandomly using the elements of `x` as parameters.

Matrix `H` is constructed via a product of `n-1` Givens rotations.

randjorth — Random J-orthogonal matrix

`A = gallery('randjorth', n)`, for a positive integer `n`, produces a random `n`-by-`n` J-orthogonal matrix `A`, where

- `J = blkdiag(eye(ceil(n/2)),-eye(floor(n/2)))`
- `cond(A) = sqrt(1/eps)`

J-orthogonality means that A'*J*A = J. Such matrices are sometimes called *hyperbolic*.

`A = gallery('randjorth', n, m)`, for positive integers `n` and `m`, produces a random (`n+m`)-by-(`n+m`) J-orthogonal matrix `A`, where

- `J = blkdiag(eye(n),-eye(m))`
- `cond(A) = sqrt(1/eps)`

`A = gallery('randjorth',n,m,c,symm,method)`

uses the following optional input arguments:

- `c` — Specifies `cond(A)` to be the scalar `c`.
- `symm` — Enforces symmetry if the scalar `symm` is nonzero.
- `method` — calls `qr` to perform the underlying orthogonal transformations if the scalar `method` is nonzero. A call to `qr` is much faster than the default method for large dimensions

rando — Random matrix composed of elements -1, 0 or 1

`A = gallery('rando',n,k)` returns a random `n`-by-`n` matrix with elements from one of the following discrete distributions:

`k = 1`	`A(i,j)` = 0 or 1 with equal probability (default).
`k = 2`	`A(i,j)` = -1 or 1 with equal probability.
`k = 3`	`A(i,j)` = -1, 0 or 1 with equal probability.

Argument `n` may be a two-element vector, in which case the matrix is `n(1)`-by-`n(2)`.

randsvd — Random matrix with preassigned singular values

`A = gallery('randsvd',n,kappa,mode,kl,ku)` returns a banded (multidiagonal) random matrix of order `n` with `cond(A) = kappa` and singular values from the distribution mode. If `n` is a two-element vector, `A` is `n(1)`-by-`n(2)`.

Arguments `kl` and `ku` specify the number of lower and upper off-diagonals, respectively, in `A`. If they are omitted, a full matrix is produced. If only `kl` is present, `ku` defaults to `kl`.

Distribution `mode` can be:

`1`	One large singular value.
`2`	One small singular value.
`3`	Geometrically distributed singular values (default).
`4`	Arithmetically distributed singular values.
`5`	Random singular values with uniformly distributed logarithm.
`< 0`	If `mode` is `-1`, `-2`, `-3`, `-4`, or `-5`, then `randsvd` treats `mode` as `abs(mode)`, except that in the original matrix of singular values the order of the diagonal entries is reversed: small to large instead of large to small.

Condition number `kappa` defaults to `sqrt(1/eps)`. In the special case where `kappa < 0`, `A` is a random, full, symmetric, positive definite matrix with `cond(A) = -kappa` and eigenvalues distributed according to `mode`. Arguments `kl` and `ku`, if present, are ignored.

`A = gallery('randsvd',n,kappa,mode,kl,ku,method)` specifies how the computations are carried out. `method = 0` is the default, while `method = 1` uses an alternative method that is much faster for large dimensions, even though it uses more flops.

redheff — Redheffer's matrix of 1s and 0s

`A = gallery('redheff',n)` returns an `n`-by-`n` matrix of 0's and 1's defined by `A(i,j) = 1`, if `j = 1` or if `i` divides `j`, and `A(i,j) = 0` otherwise.

The Redheffer matrix has these properties:

- `(n-floor(log2(n)))-1` eigenvalues equal to `1`
- A real eigenvalue (the spectral radius) approximately `sqrt(n)`
- A negative eigenvalue approximately `-sqrt(n)`
- The remaining eigenvalues are provably “small.”
- The Riemann hypothesis is true if and only if $\det(A) = O(n^{\frac{1}{2}+\varepsilon})$ for every epsilon `> 0`.

Barrett and Jarvis conjecture that “the small eigenvalues all lie inside the unit circle `abs(Z) = 1`,” and a proof of this conjecture, together with a proof that some eigenvalue tends to zero as `n` tends to infinity, would yield a new proof of the prime number theorem.

riemann — Matrix associated with the Riemann hypothesis

`A = gallery('riemann',n)` returns an `n`-by-`n` matrix for which the Riemann hypothesis is true if and only if

$$\det(A) = O(n!n^{-\frac{1}{2}+\varepsilon})$$

for every $\varepsilon > 0$.

The Riemann matrix is defined by:

```
A = B(2:n+1,2:n+1)
```

where `B(i,j) = i-1` if `i` divides `j`, and `B(i,j) = -1` otherwise.

The Riemann matrix has these properties:

- Each eigenvalue `e(i)` satisfies `abs(e(i)) <= m-1/m`, where `m = n+1`.
- `i <= e(i) <= i+1` with at most `m-sqrt(m)` exceptions.
- All integers in the interval `(m/3, m/2]` are eigenvalues.

ris — Symmetric Hankel matrix

`A = gallery('ris',n)` returns a symmetric `n`-by-`n` Hankel matrix with elements

```
A(i,j) = 0.5/(n-i-j+1.5)
```

The eigenvalues of `A` cluster around $\pi/2$ and $-\pi/2$. This matrix was invented by F.N. Ris.

smoke — Complex matrix with a 'smoke ring' pseudospectrum

`A = gallery('smoke',n)` returns an `n`-by-`n` matrix with 1's on the superdiagonal, `1` in the `(n,1)` position, and powers of roots of unity along the diagonal.

`A = gallery('smoke',n,1)` returns the same except that element `A(n,1)` is zero.

The eigenvalues of `gallery('smoke',n,1)` are the `n`th roots of unity; those of `gallery('smoke',n)` are the `n`th roots of unity times `2^(1/n)`.

toeppd — Symmetric positive definite Toeplitz matrix

`A = gallery('toeppd',n,m,w,theta)` returns an `n`-by-`n` symmetric, positive semi-definite (SPD) Toeplitz matrix composed of the sum of `m` rank 2 (or, for certain `theta`, rank 1) SPD Toeplitz matrices. Specifically,

```
T = w(1)*T(theta(1)) + ... + w(m)*T(theta(m))
```

where `T(theta(k))` has `(i,j)` element `cos(2*pi*theta(k)*(i-j))`.

By default: `m = n`, `w = rand(m,1)`, and `theta = rand(m,1)`.

toeppen — Pentadiagonal Toeplitz matrix (sparse)

`P = gallery('toeppen',n,a,b,c,d,e)` returns the `n`-by-`n` sparse, pentadiagonal Toeplitz matrix with the diagonals: `P(3,1) = a`, `P(2,1) = b`, `P(1,1) = c`, `P(1,2) = d`, and `P(1,3) = e`, where `a`, `b`, `c`, `d`, and `e` are scalars.

By default, `(a,b,c,d,e) = (1,-10,0,10,1)`, yielding a matrix of Rutishauser. This matrix has eigenvalues lying approximately on the line segment `2*cos(2*t) + 20*i*sin(t)`.

tridiag — Tridiagonal matrix (sparse)

`A = gallery('tridiag',c,d,e)` returns the tridiagonal matrix with subdiagonal `c`, diagonal `d`, and superdiagonal `e`. Vectors `c` and `e` must have `length(d)-1`.

`A = gallery('tridiag',n,c,d,e)`, where `c`, `d`, and `e` are all scalars, yields the Toeplitz tridiagonal matrix of order `n` with subdiagonal elements `c`, diagonal elements `d`, and superdiagonal elements `e`. This matrix has eigenvalues

```
d + 2*sqrt(c*e)*cos(k*pi/(n+1))
```

where `k = 1:n`. (see [1].)

`A = gallery('tridiag',n)` is the same as `A = gallery('tridiag',n,-1,2,-1)`, which is a symmetric positive definite M-matrix (the negative of the second difference matrix).

triw — Upper triangular matrix discussed by Wilkinson and others

`A = gallery('triw',n,alpha,k)` returns the upper triangular matrix with ones on the diagonal and `alpha`s on the first `k >= 0` superdiagonals.

Order `n` may be a 2-element vector, in which case the matrix is `n(1)`-by-`n(2)` and upper trapezoidal.

Ostrowski ["On the Spectrum of a One-parametric Family of Matrices," *J. Reine Angew. Math.,* 1954] shows that

```
cond(gallery('triw',n,2)) = cot(pi/(4*n))^2,
```

and, for large `abs(alpha)`, `cond(gallery('triw',n,alpha))` is approximately `abs(alpha)^n*sin(pi/(4*n-2))`.

Adding `-2^(2-n)` to the `(n,1)` element makes `triw(n)` singular, as does adding `-2^(1-n)` to all the elements in the first column.

wathen — Finite element matrix (sparse, random entries)

`A = gallery('wathen',nx,ny)` returns a sparse, random, `n`-by-`n` finite element matrix where `n = 3*nx*ny + 2*nx + 2*ny + 1`.

Matrix `A` is precisely the "consistent mass matrix" for a regular `nx`-by-`ny` grid of 8-node (serendipity) elements in two dimensions. `A` is symmetric, positive definite for any (positive) values of the "density," `rho(nx,ny)`, which is chosen randomly in this routine.

`A = gallery('wathen',nx,ny,1)` returns a diagonally scaled matrix such that

```
0.25 <= eig(inv(D)*A) <= 4.5
```

where `D = diag(diag(A))` for any positive integers `nx` and `ny` and any densities `rho(nx,ny)`.

wilk — Various matrices devised or discussed by Wilkinson

`[A,b] = gallery('wilk',n)` returns a different matrix or linear system depending on the value of `n`.

`n = 3`	Upper triangular system `Ux=b` illustrating inaccurate solution.
`n = 4`	Lower triangular system `Lx=b`, ill-conditioned.
`n = 5`	`hilb(6)(1:5,2:6)*1.8144`. A symmetric positive definite matrix.
`n = 21`	`W21+`, a tridiagonal matrix. eigenvalue problem. For more detail, see [2].

Purpose

Gamma functions

Syntax

```
Y = gamma(A)
Y = gammainc(X,A)
Y = gammainc(X,A,tail)
Y = gammaln(A)
```

Definition

The gamma function is defined by the integral:

$$\Gamma(a) = \int_0^\infty e^{-t}\, t^{a-1} dt$$

The gamma function interpolates the `factorial` function. For integer `n`:

```
gamma(n+1) = n! = prod(1:n)
```

The incomplete gamma function is:

$$P(x,a) = \frac{1}{\Gamma(a)} \int_0^x e^{-t} t^{a-1} dt$$

For any `a>=0`, `gammainc(x,a)` approaches 1 as `x` approaches `infinity`. For small `x` and `a`, `gammainc(x,a)` is approximately equal to `x^a`, so `gammainc(0,0) = 1`.

Description

`Y = gamma(A)` returns the gamma function at the elements of `A`. `A` must be real.

`Y = gammainc(X,A)` returns the incomplete gamma function of corresponding elements of `X` and `A`. Arguments `X` and `A` must be real and the same size (or either can be scalar).

`Y = gammainc(X,A,tail)` specifies the tail of the incomplete gamma function when `X` is non-negative. The choices for `tail` are `'lower'` (the default) and `'upper'`. The upper incomplete gamma function is defined as

```
1 - gammainc(x,a)
```

Note When `X` is negative, `Y` can be inaccurate for `abs(X)>A+1`.

`Y = gammaln(A)` returns the logarithm of the `gamma` function, `gammaln(A) = log(gamma(A))`. The `gammaln` command avoids the underflow and overflow that may occur if it is computed directly using `log(gamma(A))`.

Algorithm

The computations of `gamma` and `gammaln` are based on algorithms outlined in [1]. Several different minimax rational approximations are used depending upon the value of `A`. Computation of the incomplete `gamma` function is based on the algorithm in [2].

Purpose

Current axes handle

Syntax

```
h = gca
```

Description

`h = gca` returns the handle to the current axes for the current figure. If no axes exists, MATLAB creates one and returns its handle. You can use the statement

```
get(gcf,'CurrentAxes')
```

if you do not want MATLAB to create an axes if one does not already exist.

Current Axes

The current axes is the target for graphics output when you create axes children. The current axes is typically the last axes used for plotting or the last axes clicked on by the mouse. Graphics commands such as `plot`, `text`, and `surf` draw their results in the current axes. Changing the current figure also changes the current axes.

`axes`, `cla`, `gcf`, `findobj`

figure `CurrentAxes` property

"Finding and Identifying Graphics Objects" on page 1-93 for related functions

gcbf

Purpose

Handle of figure containing object whose callback is executing

Syntax

```
fig = gcbf
```

Description

`fig = gcbf` returns the handle of the figure that contains the object whose callback is currently executing. This object can be the figure itself, in which case, `gcbf` returns the figure's handle.

When no callback is executing, `gcbf` returns the empty matrix, `[]`.

The value returned by `gcbf` is identical to the `figure` output argument returned by `gcbo`.

See Also

`gcbo`, `gco`, `gcf`, `gca`

Purpose

Handle of object whose callback is executing

Syntax

```
h = gcbo
[h,figure] = gcbo
```

Description

`h = gcbo` returns the handle of the graphics object whose callback is executing.

`[h,figure] = gcbo` returns the handle of the current callback object and the handle of the figure containing this object.

Remarks

MATLAB stores the handle of the object whose callback is executing in the root `CallbackObject` property. If a callback interrupts another callback, MATLAB replaces the `CallbackObject` value with the handle of the object whose callback is interrupting. When that callback completes, MATLAB restores the handle of the object whose callback was interrupted.

The root `CallbackObject` property is read only, so its value is always valid at any time during callback execution. The root `CurrentFigure` property, and the figure `CurrentAxes` and `CurrentObject` properties (returned by `gcf`, `gca`, and `gco`, respectively) are user settable, so they can change during the execution of a callback, especially if that callback is interrupted by another callback. Therefore, those functions are not reliable indicators of which object's callback is executing.

When you write callback routines for the `CreateFcn` and `DeleteFcn` of any object and the figure `ResizeFcn`, you must use `gcbo` since those callbacks do not update the root's `CurrentFigure` property, or the figure's `CurrentObject` or `CurrentAxes` properties; they only update the root's `CallbackObject` property.

When no callbacks are executing, `gcbo` returns `[]` (an empty matrix).

`gca`, `gcf`, `gco`, `rootobject`

"Finding and Identifying Graphics Objects" on page 1-93 for related functions.

Purpose

Greatest common divisor

Syntax

```
G = gcd(A,B)
[G,C,D] = gcd(A,B)
```

Description

`G = gcd(A,B)` returns an array containing the greatest common divisors of the corresponding elements of integer arrays `A` and `B`. By convention, `gcd(0,0)` returns a value of `0`; all other inputs return positive integers for `G`.

`[G,C,D] = gcd(A,B)` returns both the greatest common divisor array `G`, and the arrays `C` and `D`, which satisfy the equation: `A(i).*C(i) + B(i).*D(i) = G(i)`. These are useful for solving Diophantine equations and computing elementary Hermite transformations.

Examples

The first example involves elementary Hermite transformations.

For any two integers `a` and `b` there is a `2`-by-`2` matrix `E` with integer entries and determinant = `1` (a *unimodular* matrix) such that:

```
E * [a;b] = [g,0],
```

where `g` is the greatest common divisor of `a` and `b` as returned by the command `[g,c,d] = gcd(a,b)`.

The matrix `E` equals:

```
c       d
-b/g    a/g
```

In the case where `a = 2` and `b = 4`:

```
[g,c,d] = gcd(2,4)
g =
     2
c =
     1
d =
     0
```

So that

```
E =
     1     0
    -2     1
```

In the next example, we solve for x and y in the Diophantine equation 30x + 56y = 8.

```
[g,c,d] = gcd(30,56)
g =
     2
c =
    -13
d =
     7
```

By the definition, for scalars c and d:

```
30(-13) + 56(7) = 2,
```

Multiplying through by 8/2:

```
30(-13*4) + 56(7*4) = 8
```

Comparing this to the original equation, a solution can be read by inspection:

```
x = (-13*4) = -52; y = (7*4) = 28
```

gcf

Purpose

Current figure handle

Syntax

```
h = gcf
```

Description

`h = gcf` returns the handle of the current figure. The current figure is the figure window in which graphics commands such as `plot`, `title`, and `surf` draw their results. If no figure exists, MATLAB creates one and returns its handle. You can use the statement

```
get(0,'CurrentFigure')
```

if you do not want MATLAB to create a figure if one does not already exist.

See Also

`clf`, `figure`, `gca`

Root `CurrentFigure` property

"Finding and Identifying Graphics Objects" on page 1-93 for related functions

Purpose

Handle of current object

Syntax

```
h = gco
h = gco(figure_handle)
```

Description

`h = gco` *returns* the handle of the current object.

`h = gco(figure_handle)` returns the value of the current object for the figure specified by `figure_handle`.

Remarks

The current object is the last object clicked on, excluding `uimenus`. If the mouse click did not occur over a figure child object, the figure becomes the current object. MATLAB stores the handle of the current object in the figure's `CurrentObject` property.

The `CurrentObject` of the `CurrentFigure` does not always indicate the object whose callback is being executed. Interruptions of callbacks by other callbacks can change the `CurrentObject` or even the `CurrentFigure`. Some callbacks, such as `CreateFcn` and `DeleteFcn`, and uimenu `Callback`, intentionally do not update `CurrentFigure` or `CurrentObject`.

`gcbo` provides the only completely reliable way to retrieve the handle to the object whose callback is executing, at any point in the `callback` function, regardless of the type of callback or of any previous interruptions.

Examples

This statement returns the handle to the current object in figure window 2:

```
h = gco(2)
```

See Also

`gca`, `gcbo`, `gcf`

The `root` object description

"Finding and Identifying Graphics Objects" on page 1-93 for related functions

Purpose

Test for greater than or equal to

Syntax

```
A >= B
ge(A, B)
```

Description

`A >= B` compares each element of array `A` with the corresponding element of array `B`, and returns an array with elements set to logical 1 (`true`) where `A` is greater than or equal to `B`, or set to logical 0 (`false`) where `A` is less than `B`. Each input of the expression can be an array or a scalar value.

If both `A` and `B` are scalar (i.e., 1-by-1 matrices), then MATLAB returns a scalar value.

If both `A` and `B` are nonscalar arrays, then these arrays must have the same dimensions, and MATLAB returns an array of the same dimensions as `A` and `B`.

If one input is scalar and the other a nonscalar array, then the scalar input is treated as if it were an array having the same dimensions as the nonscalar input array. In other words, if input `A` is the number 100, and `B` is a 3-by-5 matrix, then `A` is treated as if it were a 3-by-5 matrix of elements, each set to 100. MATLAB returns an array of the same dimensions as the nonscalar input array.

`ge(A, B)` is called for the syntax `A >= B` when either `A` or `B` is an object.

Examples

Create two 6-by-6 matrices, `A` and `B`, and locate those elements of `A` that are greater than or equal to the corresponding elements of `B`:

```
A = magic(6);
B = repmat(3*magic(3), 2, 2);

A >= B
ans =
     1     0     0     1     1     1
     0     1     0     1     1     1
     1     0     0     1     1     1
     0     1     1     0     1     0
```

```
     1     0     1     1     0     0
     0     1     1     1     0     1
```

`gt`, `eq`, `le`, `lt`, `ne`, “Relational Operators”

genpath

Purpose

Generate path string

Syntax

```
genpath
genpath directory
p = genpath('directory')
```

Description

`genpath` returns a path string formed by recursively adding all the directories below `matlabroot/toolbox`.

`genpath directory` returns a path string formed by recursively adding all the directories below `directory`. This path string does not include directories named private or directories that begin with the character `@`.

`p = genpath('directory')` returns the path string to variable, `p`.

Examples

You generate a path that includes `matlabroot/toolbox/images` and all directories below that with the following command:

```
p = genpath(fullfile(matlabroot,'toolbox','images'))
```

```
p =

   matlabroot\toolbox\images;matlabroot\toolbox\images\
   images;matlabroot\toolbox\images\images\ja;
   matlabroot\toolbox\images\imdemos;matlabroot\
   toolbox\images\imdemos\ja;
```

You can also use `genpath` in conjunction with `addpath` to add subdirectories to the path from the command line. The following example adds the `/control` directory and its subdirectories to the current path.

```
%  Display the current path
path

                MATLABPATH

      K:\toolbox\matlab\general
      K:\toolbox\matlab\ops
```

```
      K:\toolbox\matlab\lang
      K:\toolbox\matlab\elmat
      K:\toolbox\matlab\elfun
                :
                :
                :

%  Use GENPATH to add /control and its subdirectories
addpath(genpath('K:/toolbox/control'))

%  Display the new path
path

             MATLABPATH

      K:\toolbox\control
      K:\toolbox\control\ctrlutil
      K:\toolbox\control\control
      K:\toolbox\control\ctrlguis
      K:\toolbox\control\ctrldemos
      K:\toolbox\matlab\general
      K:\toolbox\matlab\ops
      K:\toolbox\matlab\lang
      K:\toolbox\matlab\elmat
      K:\toolbox\matlab\elfun
                :
                :
                :
```

"Search Path" in the MATLAB Desktop Tools and Development Environment documentation

genvarname

Purpose

Construct valid variable name from string

Syntax

```
varname = genvarname(str)
varname = genvarname(str, exclusions)
```

Description

`varname = genvarname(str)` constructs a string `varname` that is similar to or the same as the `str` input, and can be used as a valid variable name. `str` can be a single character array or a cell array of strings. If `str` is a cell array of strings, `genvarname` returns a cell array of strings in `varname`. The strings in a cell array returned by `genvarname` are guaranteed to be different from each other.

`varname = genvarname(str, exclusions)` returns a valid variable name that is different from any name listed in the `exclusions` input. The `exclusions` input can be a single character array or a cell array of strings. Specify the function `who` in the `exclusions` character array to create a variable name that will be unique in the current MATLAB workapace (see “Example 4” on page 2-1392, below).

Note `genvarname` returns a string that can be used as a variable name. It does not create a variable in the MATLAB workspace. You cannot, therefore, assign a value to the output of `genvarname`.

Remarks

A valid MATLAB variable name is a character string of letters, digits, and underscores, such that the first character is a letter, and the length of the string is less than or equal to the value returned by the `namelengthmax` function. Any string that exceeds `namelengthmax` is truncated in the `varname` output. See “Example 6” on page 2-1393, below.

The variable name returned by `genvarname` is not guaranteed to be different from other variable names currently in the MATLAB workspace unless you use the `exclusions` input in the manner shown in “Example 4” on page 2-1392, below.

If you use genvarname to generate a field name for a structure, MATLAB does create a variable for the structure and field in the MATLAB workspace. See “Example 3” on page 2-1391, below.

If the str input contains any whitespace characters, genvarname removes then and capitalizes the next alphabetic character in str. If str contains any nonalphanumeric characters, genvarname translates these characters into their hexadecimal value.

Examples

Example 1

Create four similar variable name strings that do not conflict with each other:

```
v = genvarname({'A', 'A', 'A', 'A'})
v =
    'A'    'A1'    'A2'    'A3'
```

Example 2

Read a column header hdr from worksheet trial2 in Excel spreadsheet myproj_apr23:

```
[data hdr] = xlsread('myproj_apr23.xls', 'trial2');
```

Make a variable name from the text of the column header that will not conflict with other names:

```
v = genvarname(['Column ' hdr{1,3}]);
```

Assign data taken from the spreadsheet to the variable in the MATLAB workspace:

```
eval([v '= data(1:7, 3);']);
```

Example 3

Collect readings from an instrument once every minute over the period of an hour into different fields of a structure. genvarname not only generates unique fieldname strings, but also creates the structure and fields in the MATLAB workspace:

```
for k = 1:60
record.(genvarname(['reading' datestr(clock, 'HHMMSS')])) = takeReading;
pause(60)
end
```

After the program ends, display the recorded data from the workspace:

```
record
record =
    reading090446: 27.3960
    reading090546: 23.4890
    reading090646: 21.1140
    reading090746: 23.0730
    reading090846: 28.5650
          .
          .
          .
```

Example 4

Generate variable names that are unique in the MATLAB workspace by putting the output from the `who` function in the `exclusions` list.

```
for k = 1:5
   t = clock;
   pause(uint8(rand * 10));
   v = genvarname('time_elapsed', who);
   eval([v ' = etime(clock,t)'])
   end
```

As this code runs, you can see that the variables created by `genvarname` are unique in the workspace:

```
time_elapsed =
    5.0070
time_elapsed1 =
    2.0030
time_elapsed2 =
    7.0010
```

```
time_elapsed3 =
    8.0010
time_elapsed4 =
    3.0040
```

After the program completes, use the `who` function to view the workspace variables:

```
who

k           time_elapsed   time_elapsed2  time_elapsed4
t           time_elapsed1  time_elapsed3  v
```

Example 5

If you try to make a variable name from a MATLAB keyword, `genvarname` creates a variable name string that capitalizes the keyword and precedes it with the letter `x`:

```
v = genvarname('global')
v =
   xGlobal
```

Example 6

If you enter a string that is longer than the value returned by the `namelengthmax` function, `genvarname` truncates the resulting variable name string:

```
namelengthmax
ans =
    63

vstr = genvarname(sprintf('%s%s', ...
   'This name truncates because it contains ', ...
   'more than the maximum number of characters'))
vstr =
ThisNameTruncatesBecauseItContainsMoreThanTheMaximumNumberOfCha
```

`isvarname`, `iskeyword`, `isletter`, `namelengthmax`, `who`, `regexp`

Purpose

Query object properties

Syntax

```
get(h)
get(h,'PropertyName')
<m-by-n value cell array> = get(H,pn)
a = get(h)
a = get(0,'Factory')
a = get(0,'FactoryObjectTypePropertyName')
a = get(h,'Default')
a = get(h,'DefaultObjectTypePropertyName')
```

Description

`get(h)` returns all properties of the graphics object identified by the handle `h` and their current values.

`get(h,'PropertyName')` returns the value of the property `'PropertyName'` of the graphics object identified by `h`.

`<m-by-n value cell array> = get(H,pn)` returns n property values for m graphics objects in the m-by-n cell array, where `m = length(H)` and n is equal to the number of property names contained in `pn`.

`a = get(h)` returns a structure whose field names are the object's property names and whose values are the current values of the corresponding properties. `h` must be a scalar. If you do not specify an output argument, MATLAB displays the information on the screen.

`a = get(0,'Factory')` returns the factory-defined values of all user-settable properties. `a` is a structure array whose field names are the object property names and whose field values are the values of the corresponding properties. If you do not specify an output argument, MATLAB displays the information on the screen.

`a = get(0,'FactoryObjectTypePropertyName')` returns the factory-defined value of the named property for the specified object type. The argument *`FactoryObjectTypePropertyName`* is the word `Factory` concatenated with the object type (e.g., `Figure`) and the property name (e.g., `Color`).

`FactoryFigureColor` `a = get(h,'Default')` returns all default values currently defined on object `h`. `a` is a structure array whose field names

are the object property names and whose field values are the values of the corresponding properties. If you do not specify an output argument, MATLAB displays the information on the screen.

`a = get(h,'Default`*`ObjectTypePropertyName`*`')` returns the factory-defined value of the named property for the specified object type. The argument *`DefaultObjectTypePropertyName`* is the word `Default` concatenated with the object type (e.g., `Figure`) and the property name (e.g., `Color`).

```
DefaultFigureColor
```

Examples

You can obtain the default value of the `LineWidth` property for line graphics objects defined on the root level with the statement

```
get(0,'DefaultLineLineWidth')
ans =
  0.5000
```

To query a set of properties on all axes children, define a cell array of property names:

```
props = {'HandleVisibility', 'Interruptible';
  'SelectionHighlight', 'Type'};
output = get(get(gca,'Children'),props);
```

The variable `output` is a cell array of dimension `length(get(gca,'Children')`-by-4.

For example, type

```
patch;surface;text;line
output = get(get(gca,'Children'),props)
output =
 'on'    'on'    'on'    'line'
 'on'    'off'   'on'    'text'
 'on'    'on'    'on'    'surface'
 'on'    'on'    'on'    'patch'
```

See Also

`findobj`, `gca`, `gcf`, `gco`, `set`

Handle Graphics Properties

“Finding and Identifying Graphics Objects” on page 1-93 for related functions

Purpose

Get property value from interface, or display properties

Syntax

```
V = h.get
V = h.get('propertyname')
V = get(h, ...)
```

Description

`V = h.get` returns a list of all properties and their values for the object or interface, `h`.

If `V` is empty, either there are no properties in the object, or MATLAB cannot read the object's type library. Refer to the COM vendor's documentation. For Automation objects, if the vendor provides documentation for a specific property, use the `V = get(h, ...)` syntax to call it.

`V = h.get('propertyname')` returns the value of the property specified in the string, `propertyname`.

`V = get(h, ...)` is an alternate syntax for the same operation.

Remarks

The meaning and type of the return value is dependent upon the specific property being retrieved. The object's documentation should describe the specific meaning of the return value. MATLAB may convert the data type of the return value. See "Handling COM Data in MATLAB" in the External Interfaces documentation for a description of how MATLAB converts COM data types.

Examples

Create a COM server running Microsoft Excel:

```
e = actxserver ('Excel.Application');
```

Retrieve a single property value:

```
e.Path
ans =
   D:\Applications\MSOffice\Office
```

Retrieve a list of all properties for the `CommandBars` interface:

```
c = e.CommandBars.get
ans =
                Application: [1x1
Interface.excel.application.CommandBars.Application]
                    Creator: 1.4808e+009
              ActionControl: []
              ActiveMenuBar: [1x1
Interface.excel.application.CommandBars.ActiveMenuBar]
                      Count: 94
            DisplayTooltips: 1
      DisplayKeysInTooltips: 0
               LargeButtons: 0
         MenuAnimationStyle: 'msoMenuAnimationNone'
                     Parent: [1x1
Interface.excel.application.CommandBars.Parent]
              AdaptiveMenus: 0
               DisplayFonts: 1
```

See Also

set, inspect, isprop, addproperty, deleteproperty

Purpose

Memmapfile object properties

Syntax

```
s = get(obj)
val = get(obj, prop)
```

Description

`s = get(obj)` returns the values of all properties of the `memmapfile` object `obj` in structure array `s`. Each property retrieved from the object is represented by a field in the output structure. The name and contents of each field are the same as the name and value of the property it represents.

Note Although property names of a `memmapfile` object are not case sensitive, field names of the output structure returned by `get` (named the same as the properties they represent) are case sensitive.

`val = get(obj, prop)` returns the value(s) of one or more properties specified by `prop`. The `prop` input can be a quoted string or a cell array of quoted strings, each containing a property name. If the latter is true, `get` returns the property values in a cell array.

Examples

You can use the `get` method of the `memmapfile` class to return information on any or all of the object's properties. Specify one or more property names to get the values of specific properties.

This example returns the values of the `Offset`, `Repeat`, and `Format` properties for a `memmapfile` object. Start by constructing the object:

```
m = memmapfile('records.dat',                  ...
               'Offset', 2048,                 ...
               'Format', {                     ...
                  'int16'  [2 2] 'model';      ...
                  'uint32' [1 1] 'serialno';   ...
                  'single' [1 3] 'expenses'});
```

Use the `get` method to return the specified property values in a 1-by-3 cell array `m_props`:

```
m_props = get(m, {'Offset', 'Repeat', 'Format'})
m_props =
    [2048]    [Inf]    {3x3 cell}

m_props{3}
ans =
    'int16'     [1x2 double]    'model'
    'uint32'    [1x2 double]    'serialno'
    'single'    [1x2 double]    'expenses'
```

Another way to return the same information is to use the `objname.property` syntax:

```
m_props = {m.Offset, m.Repeat, m.Format}
m_props =
    [2048]    [Inf]    {3x3 cell}
```

To return the values for all properties with `get`, pass just the object name:

```
s = get(m)
    Filename: 'd:\matlab\mfiles\records.dat'
    Writable: 0
      Offset: 2048
      Format: {3x3 cell}
      Repeat: Inf
        Data: [753 1]
```

To see just the `Format` field of the returned structure, type

```
s.Format
ans =
    'int16'     [1x2 double]    'model'
    'uint32'    [1x2 double]    'serialno'
    'single'    [1x2 double]    'expenses'
```

See Also

`memmapfile`, `disp(memmapfile)`

get (serial)

Purpose

Serial port object properties

Syntax

```
get(obj)
out = get(obj)
out = get(obj,'PropertyName')
```

Arguments

`obj`	A serial port object or an array of serial port objects.
`'PropertyName'`	A property name or a cell array of property names.
`out`	A single property value, a structure of property values, or a cell array of property values.

Description

`get(obj)` returns all property names and their current values to the command line for `obj`.

`out = get(obj)` returns the structure `out` where each field name is the name of a property of `obj`, and each field contains the value of that property.

`out = get(obj,'PropertyName')` returns the value `out` of the property specified by *`PropertyName`* for `obj`. If *`PropertyName`* is replaced by a 1-by-n or n-by-1 cell array of strings containing property names, then `get` returns a 1-by-n cell array of values to `out`. If `obj` is an array of serial port objects, then `out` will be a m-by-n cell array of property values where m is equal to the length of `obj` and n is equal to the number of properties specified.

Remarks

Refer to Displaying Property Names and Property Values for a list of serial port object properties that you can return with `get`.

When you specify a property name, you can do so without regard to case, and you can make use of property name completion. For example, if `s` is a serial port object, then these commands are all valid.

```
out = get(s,'BaudRate');
```

```
out = get(s,'baudrate');
out = get(s,'BAUD');
```

If you use the `help` command to display help for `get`, then you need to supply the pathname shown below.

```
help serial/get
```

Example

This example illustrates some of the ways you can use `get` to return property values for the serial port object `s`.

```
s = serial('COM1');
out1 = get(s);
out2 = get(s,{'BaudRate','DataBits'});
get(s,'Parity')
ans =
none
```

See Also

Functions

`set`

get (timer)

Purpose

Timer object properties

Syntax

```
get(obj)
V = get(obj)
V = get(obj,'PropertyName')
```

Description

`get(obj)` displays all property names and their current values for the timer object `obj`. `obj` must be a single timer object.

`V = get(obj)` returns a structure, `V`, where each field name is the name of a property of `obj` and each field contains the value of that property. If `obj` is an M-by-1 vector of timer objects, V is an M-by-1 array of structures.

`V = get(obj,'PropertyName')` returns the value, `V`, of the timer object property specified in *`PropertyName`*.

If *`PropertyName`* is a 1-by-N or N-by-1 cell array of strings containing property names, `V` is a 1-by-N cell array of values. If `obj` is a vector of timer objects, `V` is an M-by-N cell array of property values where M is equal to the length of `obj` and N is equal to the number of properties specified.

Examples

```
t = timer;
get(t)
       AveragePeriod: NaN
            BusyMode: 'drop'
            ErrorFcn: ''
       ExecutionMode: 'singleShot'
       InstantPeriod: NaN
                Name: 'timer-1'
    ObjectVisibility: 'on'
              Period: 1
             Running: 'off'
          StartDelay: 1
            StartFcn: ''
             StopFcn: ''
                 Tag: ''
```

```
          TasksExecuted: 0
         TasksToExecute: Inf
                TimerFcn: ''
                    Type: 'timer'
                UserData: []
get(t, {'StartDelay','Period'})
ans =

    [0]    [1]
```

See Also

`timer`, `set(timer)`

get (timeseries)

Purpose

Query `timeseries` object property values

Syntax

```
value = get(ts,'PropertyName')
get(ts)
```

Description

`value = get(ts,'PropertyName')` returns the value of the specified property of the `timeseries` object. The following syntax is equivalent:

```
value = ts.PropertyName
```

`get(ts)` displays all properties and values of the time series `ts`.

See Also

`set (timeseries)`, `timeseries`, `tsprops`

Purpose

Query `tscollection` object property values

Syntax

```
value = get(tsc,'PropertyName')
```

Description

`value = get(tsc,'PropertyName')` returns the value of the specified property of the `tscollection` object tsc. The following syntax is equivalent:

```
value = tsc.PropertyName
```

`get(tsc)` displays all properties and values of the `tscollection` object tsc.

See Also

`set (tscollection)`, `tscollection`

getabstime (timeseries)

Purpose

Extract date-string time vector into cell array

Syntax

```
getabstime(ts)
```

Description

`getabstime(ts)` extracts the time vector from the `timeseries` object `ts` as a cell array of date strings. To define the time vector relative to a calendar date, set the `TimeInfo.StartDate` property of the `timeseries` object. When the `TimeInfo.StartDate` format is a valid `datestr` format, the output strings from `getabstime` have the same format.

Examples

The following example shows how to extract a time vector as a cell array of date strings from a `timeseries` object.

1. Create a `timeseries` object.

   ```
   ts = timeseries([3 6 8 0 10]);
   ```

   The default time vector for `ts` is [0 1 2 3 4], which starts at 0 and increases in 1-second increments. The length of the time vector is equal to the length of the data.

2. Set the `StartDate` property.

   ```
   ts.TimeInfo.StartDate = '10/27/2005 07:05:36';
   ```

3. Extract the time vector.

   ```
   getabstime(ts)

   ans =

       '27-Oct-2005 07:05:36'
       '27-Oct-2005 07:05:37'
       '27-Oct-2005 07:05:38'
       '27-Oct-2005 07:05:39'
       '27-Oct-2005 07:05:40'
   ```

4 Change the date-string format of the time vector.

```
ts.TimeInfo.Format = 'mm/dd/yy'
```

5 Extract the time vector with the new date-string format.

```
getabstime(ts)

ans =

    '10/27/05'
    '10/27/05'
    '10/27/05'
    '10/27/05'
    '10/27/05'
```

See Also

`setabstime (timeseries)`, `timeseries`, `tsprops`

getabstime (tscollection)

Purpose

Extract date-string time vector into cell array

Syntax

```
getabstime(tsc)
```

Description

`getabstime(tsc)` extracts the time vector from the `tscollection` object tsc as a cell array of date strings. To define the time vector relative to a calendar date, set the `TimeInfo.StartDate` property of the time-series collection. When the `TimeInfo.StartDate` format is a valid `datestr` format, the output strings from `getabstime` have the same format.

Examples

1 Create a `tscollection` object.

```
tsc = tscollection(timeseries([3 6 8 0 10]));
```

2 Set the `StartDate` property.

```
tsc.TimeInfo.StartDate = '10/27/2005 07:05:36';
```

3 Extract a vector of absolute time values.

```
getabstime(tsc)

ans =

    '27-Oct-2005 07:05:36'
    '27-Oct-2005 07:05:37'
    '27-Oct-2005 07:05:38'
    '27-Oct-2005 07:05:39'
    '27-Oct-2005 07:05:40'
```

4 Change the date-string format of the time vector.

```
tsc.TimeInfo.Format = 'mm/dd/yy';
```

5 Extract the time vector with the new date-string format.

```
getabstime(tsc)
```

```
ans =

    '10/27/05'
    '10/27/05'
    '10/27/05'
    '10/27/05'
    '10/27/05'
```

See Also

datestr, setabstime (tscollection), tscollection

getappdata

Purpose

Value of application-defined data

Syntax

```
value = getappdata(h,name)
values = getappdata(h)
```

Description

`value = getappdata(h,name)` gets the value of the application-defined data with the name specified by `name`, in the object with handle `h`. If the application-defined data does not exist, MATLAB returns an empty matrix in `value`.

`values = getappdata(h)` returns all application-defined data for the object with handle `h`.

See Also

`setappdata`, `rmappdata`, `isappdata`

Purpose

Get character array from server

Syntax

MATLAB Client

```
string = h.GetCharArray('varname', 'workspace')
string = GetCharArray(h, 'varname', 'workspace')
string = invoke(h, 'GetCharArray', 'varname', 'workspace')
```

Method Signature

```
HRESULT GetCharArray ([in] BSTR varName, [in] BSTR Workspace,
[out, retval] BSTR *mlString)
```

Visual Basic Client

```
GetCharArray(varname As String, workspace As String) As String
```

Description

`GetCharArray` gets the character array stored in the variable `varname` from the specified `workspace` of the server attached to handle `h` and returns it in `string`. The *`workspace`* argument can be either `base` or `global`.

Remarks

If you want output from `GetCharArray` to be displayed at the client window, you must specify an output variable (e.g., `string`).

Server function names, like `GetCharArray`, are case sensitive when using the first syntax shown.

There is no difference in the operation of the three syntaxes shown above for the MATLAB client.

Examples

Assign a string to variable `str` in the base workspace of the server using `PutCharArray`. Read it back in the client with `GetCharArray`.

MATLAB Client

```
h = actxserver('matlab.application');
h.PutCharArray('str', 'base', ...
   'He jests at scars that never felt a wound.');
S = h.GetCharArray('str', 'base')
S =
  He jests at scars that never felt a wound.
```

Visual Basic .NET Client

This example uses the Visual Basic `MsgBox` command to control flow between MATLAB and the Visual Basic Client.

```
Dim Matlab As Object
Dim S As String
Matlab = CreateObject("matlab.application")
MsgBox("In MATLAB, type" & vbCrLf _
    & "str='new string';")
```

Open the MATLAB window, then type

```
str='new string';
```

Click **Ok**.

```
Try
    S = Matlab.GetCharArray("str", "base")
    MsgBox("str = " & S)
Catch ex As Exception
    MsgBox("You did not set 'str' in MATLAB")
End Try
```

The Visual Basic `MsgBox` displays what you typed in MATLAB.

See Also

`PutCharArray`, `GetWorkspaceData`, `PutWorkspaceData`, `GetVariable`, `Execute`

Purpose

Size of data sample in `timeseries` object

Syntax

```
getdatasamplesize(ts)
```

Description

`getdatasamplesize(ts)` returns the size of each data sample in a `timeseries` object.

Remarks

A time-series *data sample* consists of one or more scalar values recorded at a specific time. The number of data samples in is the same as the length of the time vector.

Examples

The following example shows how to get the size of a data sample in a `timeseries` object.

1 Load a 24-by-3 data array.

```
load count.dat
```

2 Create a `timeseries` object with 24 time values.

```
count_ts = timeseries(count,[1:24],'Name','VehicleCount')
```

3 Get the size of the data sample for this `timeseries` object.

```
getdatasamplesize(count_ts)

ans =

     1     3
```

The size of each data sample in `count_ts` is 1-by-3, which means that each data sample is stored as a row with three values.

See Also

`addsample`, `size (timeseries)`, `tsprops`

getenv

Purpose

Environment variable

Syntax

```
getenv 'name'
N = getenv('name')
```

Description

`getenv 'name'` searches the underlying operating system's environment list for a string of the form `name=value`, where `name` is the input string. If found, MATLAB returns the string `value`. If the specified name cannot be found, an empty matrix is returned.

`N = getenv('name')` returns `value` to the variable `N`.

Examples

```
os = getenv('OS')

os =
Windows_NT
```

See Also

`setenv`, `computer`, `pwd`, `ver`, `path`

Purpose

Field of structure array

Syntax

```
f = getfield(s,'field')
f = getfield(s, {i,j}, 'field', {k})
```

Description

`f = getfield(s,'field')`, where `s` is a 1-by-1 structure, returns the contents of the specified field. This is equivalent to the syntax `f = s.field`.

If `s` is a structure having dimensions greater than 1-by-1, `getfield` returns the first of all output values requested in the call. That is, for structure array `s(m,n)`, `getfield` returns `f = s(1,1).field`.

`f = getfield(s, {i,j}, 'field', {k})` returns the contents of the specified field. This is equivalent to the syntax `f = s(i,j).field(k)`. All subscripts must be passed as cell arrays — that is, they must be enclosed in curly braces (similar to`{i,j}` and `{k}` above). Pass field references as strings.

Remarks

In many cases, you can use dynamic field names in place of the `getfield` and `setfield` functions. Dynamic field names express structure fields as variable expressions that MATLAB evaluates at run-time. See Solution 1-19QWG for information about using dynamic field names versus the `getfield` and `setfield` functions.

Examples

Given the structure

```
mystr(1,1).name = 'alice';
mystr(1,1).ID = 0;
mystr(2,1).name = 'gertrude';
mystr(2,1).ID = 1
```

Then the command `f = getfield(mystr, {2,1}, 'name')` yields

```
f =
   gertrude
```

To list the contents of all name (or other) fields, embed `getfield` in a loop.

```
for k = 1:2
    name{k} = getfield(mystr, {k,1}, 'name');
end
name

name =

    'alice'    'gertrude'
```

The following example starts out by creating a structure using the standard structure syntax. It then reads the fields of the structure, using `getfield` with variable and quoted field names and additional subscripting arguments.

```
class = 5;     student = 'John_Doe';
grades(class).John_Doe.Math(10,21:30) = ...
             [85, 89, 76, 93, 85, 91, 68, 84, 95, 73];
```

Use `getfield` to access the structure fields.

```
getfield(grades, {class}, student, 'Math', {10,21:30})

ans =
   85   89   76   93   85   91   68   84   95   73
```

`setfield`, `fieldnames`, `isfield`, `orderfields`, `rmfield`, "Using Dynamic Field Names"

Purpose

Capture movie frame

Syntax

```
getframe
F = getframe
F = getframe(h)
F = getframe(h,rect)
```

Description

`getframe` returns a movie frame. The frame is a snapshot (pixmap) of the current axes or figure.

`F = getframe` gets a frame from the current axes.

`F = getframe(h)` gets a frame from the figure or axes identified by handle `h`.

`F = getframe(h,rect)` specifies a rectangular area from which to copy the pixmap. `rect` is relative to the lower left corner of the figure or axes `h`, in pixel units. `rect` is a four-element vector in the form `[left bottom width height]`, where `width` and `height` define the dimensions of the rectangle.

`getframe` returns a movie frame, which is a structure having two fields:

- `cdata` — The image data stored as a matrix of `uint8` values. The dimensions of `F.cdata` are height-by-width-by-3.
- `colormap` — The colormap stored as an n-by-3 matrix of doubles. `F.colormap` is empty on true color systems.

To capture an image, use this approach:

```
F = getframe(gcf);
image(F.cdata)
colormap(F.colormap)
```

Remarks

`getframe` is usually used in a `for` loop to assemble an array of movie frames for playback using `movie`. For example,

```
for j = 1:n plotting commands
 F(j) = getframe;
```

```
end
movie(F)
```

If you are capturing frames of a plot that takes a long time to generate or are repeatedly calling `getframe` in a loop, make sure that your computer's screen saver does not activate and that your monitor does not turn off for the duration of the capture; otherwise one or more of the captured frames can contain graphics from your screen saver or nothing at all.

Note In situations where MATLAB is running on a virtual desktop that is not currently visible on your monitor, calls to `getframe` will complete, but will capture a region on your monitor that corresponds to the position occupied by the figure or axes on the hidden desktop. Therefore, make sure that the window to be captured by `getframe` exists on the currently active desktop.

Capture Regions

Note that `F = getframe` returns the contents of the current axes, exclusive of the axis labels, title, or tick labels. `F = getframe(gcf)` captures the entire interior of the current figure window. To capture the figure window menu, use the form `F = getframe(h,rect)` with a rectangle sized to include the menu.

Resolution of Captured Frames

The resolution of the framed image depends on the size of the axes in pixels when `getframe` is called. As the `getframe` command takes a snapshot of the screen, if the axes is small in size (e.g., because you have restricted the view to a window within the axes), `getframe` will capture fewer screen pixels, and the captured image might have poor resolution if enlarged for display.

Examples

Make the `peaks` function vibrate.

```
Z = peaks; surf(Z)
```

```
axis tight
set(gca,'nextplot','replacechildren');
for j = 1:20
    surf(sin(2*pi*j/20)*Z,Z)
    F(j) = getframe;
end
movie(F,20) % Play the movie twenty times
```

`frame2im`, `image`, `im2frame`, `movie`

"Bit-Mapped Images" on page 1-92 for related functions

GetFullMatrix

Purpose

Get matrix from server

Syntax

MATLAB Client

```
[xreal ximag] = h.GetFullMatrix('varname', 'workspace',
zreal, zimag)
[xreal ximag] = GetFullMatrix(h, 'varname', 'workspace',
zreal, zimag)
[xreal ximag] = invoke(h, 'GetFullMatrix', 'varname', 'workspace',
zreal, zimag)
```

Method Signature

```
GetFullMatrix([in] BSTR varname,
[in] BSTR workspace, [in, out] SAFEARRAY(double) *pr,
[in, out] SAFEARRAY(double) *pi)
```

Visual Basic Client

```
GetFullMatrix(varname As String, workspace As String,
[out] XReal As Double, [out] XImag As Double
```

Note `GetFullMatrix` works only with values of type `double`. Use `GetVariable` or `GetWorkspaceData` for other types.

Description

`GetFullMatrix` gets the matrix stored in the variable `varname` from the specified `workspace` of the server attached to handle `h` and returns the real part in `xreal` and the imaginary part in `ximag`. The *`workspace`* argument can be either `base` or `global`.

The `zreal` and `zimag` arguments are matrices of the same size as the real and imaginary matrices (`xreal` and `ximag`) being returned from the server. The `zreal` and `zimag` matrices are commonly set to zero (see example below).

Remarks

If you want output from `GetFullMatrix` to be displayed at the client window, you must specify one or both output variables (e.g., `xreal` and/or `ximag`).

Server function names, like `GetFullMatrix`, are case sensitive when using the first syntax shown.

There is no difference in the operation of the three syntaxes shown above for the MATLAB client.

For VBScript clients, use the `GetWorkspaceData` and `PutWorkspaceData` functions to pass numeric data to and from the MATLAB workspace. These functions use the `variant` data type instead of `safearray`, which is not supported by VBScript.

Examples

Assign a 5-by-5 real matrix to the variable `M` in the base workspace of the server, and then read it back with `GetFullMatrix`.

MATLAB Client

```
h = actxserver('matlab.application');
h.PutFullMatrix('M','base',rand(5),zeros(5));

MReal = h.GetFullMatrix('M','base',zeros(5),zeros(5))
MReal =
    0.9501    0.7621    0.6154    0.4057    0.0579
    0.2311    0.4565    0.7919    0.9355    0.3529
    0.6068    0.0185    0.9218    0.9169    0.8132
    0.4860    0.8214    0.7382    0.4103    0.0099
    0.8913    0.4447    0.1763    0.8936    0.1389
```

Visual Basic .NET Client

This example uses the Visual Basic `MsgBox` command to control flow between MATLAB and the Visual Basic Client.

```
Dim MatLab As Object
Dim Result As String
Dim XReal(4, 4) As Double
Dim XImag(4, 4) As Double
Dim i, j As Integer

MatLab = CreateObject("matlab.application")
Result = MatLab.Execute("M = rand(5);")
```

```
MsgBox("In MATLAB, type" & vbCrLf _
  & "M(3,4)")
```

Open the MATLAB window and type

```
M(3,4)
```

Click **Ok**.

```
MatLab.GetFullMatrix("M", "base", XReal, XImag)
i = 2   %0-based array
j = 3

MsgBox("XReal(" & i + 1 & "," & j + 1 & ")" & _
       " = " & XReal(i, j))
```

Click **Ok** to close and terminate MATLAB.

Purpose

Interpolation method for `timeseries` object

Syntax

```
getinterpmethod(ts)
```

Description

`getinterpmethod(ts)` returns the interpolation method as a string that is used by the `timeseries` object `ts`. Predefined interpolation methods are `'zoh'` (zero-order hold) and `'linear'` (linear interpolation). The method strings are case sensitive.

Examples

1 Create a `timeseries` object.

```
ts = timeseries(rand(5));
```

2 Get the interpolation method for this object.

```
getinterpmethod(ts)

ans =

     linear
```

See Also

`setinterpmethod`, `timeseries`, `tsprops`

getpixelposition

Purpose

Get component position in pixels

Syntax

```
position = getpixelposition(handle)
position = getpixelposition(handle,recursive)
```

Description

`position = getpixelposition(handle)` gets the position, in pixel units, of the component with handle `handle`. The `position` is returned as a four-element vector that specifies the location and size of the component: [distance from left, distance from bottom, width, height].

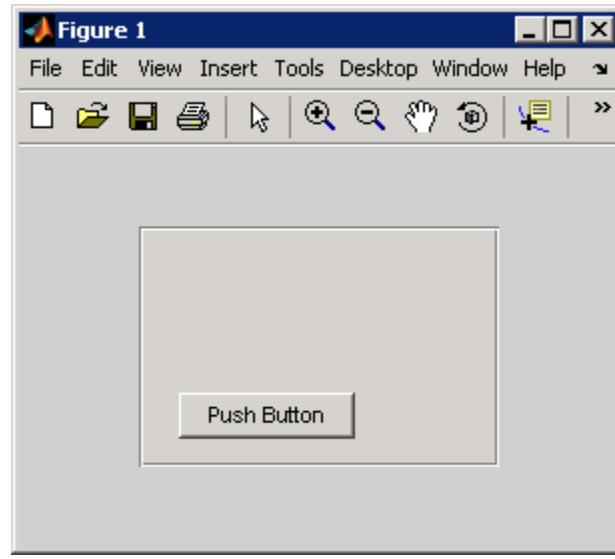
`position = getpixelposition(handle,recursive)` gets the position as above. If `recursive` is true, the returned position is relative to the parent figure of `handle`.

Example

This example creates a push button within a panel, and then retrieves its position, in pixels, relative to the panel.

```
f = figure('Position',[300 300 300 200]);
p = uipanel('Position',[.2 .2 .6 .6];
h1 = uicontrol(p,'Style','PushButton','Units','Normalized',...
               'String','Push Button','Position',[.1 .1 .5 .2]);
pos1 = getpixelposition(h1)

pos1 =
     18.6000  12.6000  88.0000  23.2000
```



The following statement retrieves the position of the push button, in pixels, relative to the figure.

```
pos1 = getpixelposition(h1,true)

pos1 =
      79.6000   53.6000   88.0000   23.2000
```

See Also

`setpixelposition`, `uicontrol`, `uipanel`

getpref

Purpose

Preference

Syntax

```
getpref('group','pref')
getpref('group','pref',default)
getpref('group',{'pref1','pref2',...'prefn'})
getpref('group',{'pref1',...'prefn'},{default1,...defaultn})
getpref('group')
getpref
```

Description

`getpref('group','pref')` returns the value for the preference specified by `group` and `pref`. It is an error to get a preference that does not exist.

`group` labels a related collection of preferences. You can choose any name that is a legal variable name, and is descriptive enough to be unique, e.g. `'ApplicationOnePrefs'`. The input argument `pref` identifies an individual preference in that group, and must be a legal variable name.

`getpref('group','pref',default)` returns the current value if the preference specified by `group` and `pref` exists. Otherwise creates the preference with the specified default value and returns that value.

`getpref('group',{'pref1','pref2',...'prefn'})` returns a cell array containing the values for the preferences specified by `group` and the cell array of preference names. The return value is the same size as the input cell array. It is an error if any of the preferences do not exist.

`getpref('group',{'pref1',...'prefn'},{default1,...defaultn})` returns a cell array with the current values of the preferences specified by `group` and the cell array of preference names. Any preference that does not exist is created with the specified default value and returned.

`getpref('group')` returns the names and values of all preferences in the `group` as a structure.

`getpref` returns all groups and preferences as a structure.

Note Preference values are persistent and maintain their values between MATLAB sessions. Where they are stored is system dependent.

Examples

Example 1

```
addpref('mytoolbox','version','1.0')
getpref('mytoolbox','version')

ans =
     1.0
```

Example 2

```
rmpref('mytoolbox','version')
getpref('mytoolbox','version','1.0');
getpref('mytoolbox','version')

ans =
     1.0
```

See Also

addpref, ispref, rmpref, setpref, uigetpref, uisetpref

getqualitydesc

Purpose

Data quality descriptions

Syntax

```
getqualitydesc(ts)
```

Description

`getqualitydesc(ts)` returns a cell array of data quality descriptions based on the `Quality` values you assigned to a `timeseries` object `ts`.

Examples

1 Create a `timeseries` object with `Data`, `Time`, and `Quality` values, respectively.

```
ts = timeseries([3; 4.2; 5; 6.1; 8], 1:5, [1; 0; 1; 0; 1]);
```

2 Set the `QualityInfo` property, consisting of `Code` and `Description`.

```
ts.QualityInfo.Code = [0 1];
ts.QualityInfo.Description = {'good' 'bad'};
```

3 Get the data quality description strings for `ts`.

```
getqualitydesc(ts)

ans =

    'bad'
    'good'
    'bad'
    'good'
    'bad'
```

See Also

`tsprops`

Purpose

Get error message for exception

Syntax

```
Report = getReport(ME)
```

Description

`Report = getReport(ME)` returns a formatted message string based on the current exception (represented by `MException` object `ME`) and that uses the same format as errors thrown by internal MATLAB code. The message string returned by `getReport` is the same as the error message displayed by MATLAB when it throws the exception.

Examples

Using the `surf` command without input arguments throws an exception. The `catch` function captures the exception in `MException` object `ME`. Use `getReport` to obtain the error text in the same format that MATLAB uses:

```
try
   surf
catch ME
   getReport(ME)
end

ans =
   ??? Error using ==> surf at 54
   Not enough input arguments.
```

See Also

`try`, `catch`, `error`, `assert`, `MException`, `disp(MException)`, `throw(MException)`, `rethrow(MException)`, `throwAsCaller(MException)`, `addCause(MException)`, `isequal(MException)`, `eq(MException)`, `ne(MException)`, `last(MException)`,

getsampleusingtime (timeseries)

Purpose

Extract data samples into new `timeseries` object

Syntax

```
ts2 = getsampleusingtime(ts1,Time)
ts2 = getsampleusingtime(ts1,StartTime,EndTime)
```

Description

`ts2 = getsampleusingtime(ts1,Time)` returns a new `timeseries` object `ts2` with a single sample corresponding to the time Time in ts1.

`ts2 = getsampleusingtime(ts1,StartTime,EndTime)` returns a new `timeseries` object `ts2` with samples between the times `StartTime` and `EndTime` in ts1.

Remarks

When the time vector in ts1 is numeric, `StartTime` and `EndTime` must also be numeric. When the times in ts1 are date strings and the `StartTime` and `EndTime` values are numeric, then the `StartTime` and `EndTime` values are treated as `datenum` values.

See Also

`timeseries`

Purpose

Extract data samples into new `tscollection` object

Syntax

```
tsc2 = getsampleusingtime(tsc1,Time)
tsc2 = getsampleusingtime(tsc1,StartTime,EndTime)
```

Description

`tsc2 = getsampleusingtime(tsc1,Time)` returns a new `tscollection` tsc2 with a single sample corresponding to Time in tsc1.

`tsc2 = getsampleusingtime(tsc1,StartTime,EndTime)` returns a new `tscollection` tsc2 with samples between the times StartTime and EndTime in tsc1.

Remarks

When the time vector in ts1 is numeric, `StartTime` and `EndTime` must also be numeric. When the times in ts1 are date strings and the `StartTime` and `EndTime` values are numeric, then the `StartTime` and `EndTime` values are treated as `datenum` values.

See Also

`tscollection`

gettimeseriesnames

Purpose

Cell array of names of `timeseries` objects in `tscollection` object

Syntax

```
names = gettimeseriesnames(tsc)
```

Description

`names = gettimeseriesnames(tsc)` returns `names` of `timeseries` objects in a `tscollection` object `tsc`. `names` is a cell array of strings.

Examples

1 Create `timeseries` objects `a` and `b`.

```
a = timeseries(rand(1000,1),'name','position');
b = timeseries(rand(1000,1),'name','response');
```

2 Create a `tscollection` object that includes these two time series.

```
tsc = tscollection({a,b});
```

3 Get the names of the `timeseries` objects in `tsc`.

```
names = gettimeseriesnames(tsc)

names =

    'position'    'response'
```

See Also

`timeseries`, `tscollection`, `tsprops`

Purpose

New `timeseries` object with samples occurring at or after event

Syntax

```
ts1 = gettsafteratevent(ts,event)
ts1 = gettsafteratevent(ts,event,n)
```

Description

`ts1 = gettsafteratevent(ts,event)` returns a new `timeseries` object ts1 with samples occurring at and after an event in ts, where event can be either a `tsdata.event` object or a string. When event is a `tsdata.event` object, the time defined by event is used. When event is a string, the first `tsdata.event` object in the `Events` property of the time series ts that matches the event name specifies the time.

`ts1 = gettsafteratevent(ts,event,n)` returns a new `timeseries` object ts1 with samples at and after an event in ts, where n is the number of the event occurrence with a matching event name.

Remarks

When the `timeseries` object `ts` contains date strings and `event` uses numeric time, the time selected by the `event` is treated as a date that is calculated relative to the `StartDate` property in `ts.TimeInfo`.

When `ts` uses numeric time and `event` uses calendar dates, the time selected by the `event` is treated as a numeric value that is not associated with a calendar date.

See Also

`gettsafterevent`, `gettsbeforeevent`, `gettsbetweenevents`, `tsdata.event`, `tsprops`

gettsafterevent

Purpose

New `timeseries` object with samples occurring after event

Syntax

```
ts1 = gettsafterevent(ts,event)
ts1 = ttsafterevent(ts,event,n)
```

Description

`ts1 = gettsafterevent(ts,event)` returns a new `timeseries` object ts1 with samples occurring after an event in ts, where event can be either a `tsdata.event` object or a string. When event is a `tsdata.event` object, the time defined by event is used. When event is a string, the first `tsdata.event` object in the `Events` property of `ts` that matches the event name specifies the time.

`ts1 = ttsafterevent(ts,event,n)` returns a new `timeseries` object `ts1` with samples occurring after an event in time series `ts`, where n is the number of the event occurrence with a matching event name.

Remarks

When the `timeseries` object `ts` contains date strings and `event` uses numeric time, the time selected by the `event` is treated as a date that is calculated relative to the `StartDate` property in `ts.TimeInfo`.

When `ts` uses numeric time and `event` uses calendar dates, the time selected by the `event` is treated as a numeric value that is not associated with a calendar date.

See Also

`gettsafteratevent`, `gettsbeforeevent`, `gettsbetweenevents`, `tsdata.event`, `tsprops`

Purpose

New `timeseries` object with samples occurring at event

Syntax

```
ts1 = gettsatevent(ts,event)
ts1 = gettsatevent(ts,event,n)
```

Description

`ts1 = gettsatevent(ts,event)` returns a new `timeseries` object `ts1` with samples occurring at an event in `ts`, where event can be either a `tsdata.event` object or a string. When event is a `tsdata.event` object, the time defined by event is used. When event is a string, the first `tsdata.event` object in the `Events` property of `ts` that matches the event name specifies the time.

`ts1 = gettsatevent(ts,event,n)` returns a new time series `ts1` with samples occurring at an event in time series `ts`, where n is the number of the event occurrence with a matching event name.

Remarks

When the `timeseries` object `ts` contains date strings and `event` uses numeric time, the time selected by the `event` is treated as a date that is calculated relative to the `StartDate` property in the `ts.TimeInfo`.

When `ts` uses numeric time and `event` uses calendar dates, the time selected by the `event` is treated as a numeric value that is not associated with a calendar date.

See Also

`gettsafterevent`, `gettsafteratevent`, `gettsbeforeevent`, `gettsbetweenevents`, `tsdata.event`, `tsprops`

gettsbeforeatevent

Purpose

New `timeseries` object with samples occurring before or at event

Syntax

```
ts1 = gettsbeforeatevent(ts,event)
ts1 = gettsbeforeatevent(ts,event,n)
```

Description

`ts1 = gettsbeforeatevent(ts,event)` returns a new `timeseries` object `ts1` with samples occurring at and before an event in `ts`, where event can be either a `tsdata.event` object or a string. When event is a `tsdata.event` object, the time defined by event is used. When event is a string, the first `tsdata.event` object in the `Events` property of `ts` that matches the event name specifies the time.

`ts1 = gettsbeforeatevent(ts,event,n)` returns a new `timeseries` object `ts1` with samples occurring at and before an event in time series `ts`, where n is the number of the event occurrence with a matching event name.

Remarks

When the `timeseries` object `ts` contains date strings and `event` uses numeric time, the time selected by the `event` is treated as a date that is calculated relative to the `StartDate` property in `ts.TimeInfo`.

When `ts` uses numeric time and `event` uses calendar dates, the time selected by the `event` is treated as a numeric value that is not associated with a calendar date.

See Also

`gettsafterevent`, `gettsbeforeevent`, `gettsbetweenevents`, `tsdata.event`, `tsprops`

Purpose

New `timeseries` object with samples occurring before event

Syntax

```
ts1 = gettsbeforeevent(ts,event)
ts1 = gettsbeforeevent(ts,event,n)
```

Description

`ts1 = gettsbeforeevent(ts,event)` returns a new `timeseries` object `ts1` with samples occurring before an event in `ts`, where event can be either a `tsdata.event` object or a string. When event is a `tsdata.event` object, the time defined by event is used. When event is a string, the first `tsdata.event` object in the `Events` property of `ts` that matches the event name specifies the time.

`ts1 = gettsbeforeevent(ts,event,n)` returns a new `timeseries` object `ts1` with samples occurring before an event in `ts`, where n is the number of the event occurrence with a matching event name.

Remarks

When the `timeseries` object `ts` contains date strings and `event` uses numeric time, the time selected by the `event` is treated as a date that is calculated relative to the `StartDate` property in `ts.TimeInfo`.

When `ts` uses numeric time and `event` uses calendar dates, the time selected by the `event` is treated as a numeric value that is not associated with a calendar date.

See Also

`gettsafterevent`, `gettsbeforeatevent`, `gettsbetweenevents`, `tsdata.event`, `tsprops`

gettsbetweenevents

Purpose

New `timeseries` object with samples occurring between events

Syntax

```
ts1 = gettsbetweenevents(ts,event1,event2)
ts1 = gettsbetweenevents(ts,event1,event2,n1,n2)
```

Description

`ts1 = gettsbetweenevents(ts,event1,event2)` returns a new `timeseries` object ts1 with samples occurring between events in `ts`, where `event1` and `event2` can be either a `tsdata.event` object or a string. When `event1` and `event2` are `tsdata.event` objects, the time defined by the events is used. When `event1` and `event2` are strings, the first `tsdata.event` object in the `Events` property of `ts` that matches the event names specifies the time.

`ts1 = gettsbetweenevents(ts,event1,event2,n1,n2)` returns a new `timeseries` object ts1 with samples occurring between events in `ts`, where `n1` and `n2` are the nth occurrences of the events with matching event names.

Remarks

When the `timeseries` object `ts` contains date strings and `event` uses numeric time, the time selected by the `event` is treated as a date that is calculated relative to the `StartDate` property in `ts.TimeInfo`.

When `ts` uses numeric time and `event` uses calendar dates, the time selected by the `event` is treated as a numeric value that is not associated with a calendar date.

See Also

`gettsafterevent`, `gettsbeforeevent`, `tsdata.event`, `tsprops`

Purpose

Get data from variable in server workspace

Syntax

MATLAB Client

```
D = h.GetVariable('varname', 'workspace')
D = GetVariable(h, 'varname', 'workspace')
D = invoke(h, 'GetVariable', 'varname', 'workspace')
```

Method Signature

```
HRESULT GetVariable([in] BSTR varname, [in] BSTR workspace,
[out, retval] VARIANT* pdata)
```

Visual Basic Client

```
GetVariable(varname As String, workspace As String) As Object
```

Description

`GetVariable` returns the data stored in the specified variable from the specified workspace of the server. Each syntax in the MATLAB Client section produce the same result. Note that the dot notation (`h.GetVariable`) is case sensitive.

`varname` from the specified `workspace` of the server that is attached to handle `h`. The *`workspace`* argument can be either `base` or `global`.

`varname` — the name of the variable whose data is returned

`workspace` — the workspace containing the variable can be either:

- `base` is the base workspace of the server
- `global` is the global workspace of the server (see `global` for more information about how to access variables in the global workspace).

Note `GetVariable` works on all MATLAB data types except sparse arrays, structures, and function handles.

Remarks

You can use `GetVariable` in place of `GetWorkspaceData`, `GetFullMatrix` and `GetCharArray` to get data stored in workspace variables when you

need a result returned explicitly (which might be required by some scripting languages).

Examples

This example assigns a cell array to the variable `C1` in the base workspace of the server, and then read it back with `GetVariable`, assigning it to a new variable `C2`.

MATLAB Client

```
h = actxserver('matlab.application');
h.PutWorkspaceData('C1', 'base', {25.72, 'hello', rand(4)});
C2 = h.GetVariable('C1','base')
C2 =
    [25.7200]    'hello'    [4x4 double]
```

Visual Basic .NET Client

```
Dim Matlab As Object
Dim Result As String
Dim C2 As Object
Matlab = CreateObject("matlab.application")
Result = Matlab.Execute("C1 = {25.72, 'hello', rand(4)};")
C2 = Matlab.GetVariable("C1", "base")
MsgBox("Second item in cell array: " & C2(0, 1))
```

The Visual Basic Client example creates a message box displaying the second element in the cell array, which is the string `hello`.

`GetWorkspaceData`, `PutWorkspaceData`, `GetFullMatrix`, `PutFullMatrix`, `GetCharArray`, `PutCharArray`, `Execute`

Purpose

Get data from server workspace

Syntax

MATLAB Client

```
D = h.GetWorkspaceData('varname', 'workspace')
D = GetWorkspaceData(h, 'varname', 'workspace')
D = invoke(h, 'GetWorkspaceData', 'varname', 'workspace')
```

Method Signature

```
HRESULT GetWorkspaceData([in] BSTR varname, [in] BSTR workspace,
[out] VARIANT* pdata)
```

Visual Basic Client

```
GetWorkspaceData(varname As String, workspace As String) As Object
```

Description

`GetWorkspaceData` gets the data stored in the variable `varname` from the specified `workspace` of the server attached to handle `h` and returns it in output argument `D`. The *`workspace`* argument can be either `base` or `global`.

Note `GetWorkspaceData` works on all MATLAB data types except sparse arrays, structures, and function handles.

Remarks

You can use `GetWorkspaceData` in place of `GetFullMatrix` and `GetCharArray` to get numeric and character array data respectively.

If you want output from `GetWorkspaceData` to be displayed at the client window, you must specify an output variable.

Server function names, like `GetWorkspaceData`, are case sensitive when using the first syntax shown.

There is no difference in the operation of the three syntaxes shown above for the MATLAB client.

The `GetWorkspaceData` and `PutWorkspaceData` functions pass numeric data as a `variant` data type. These functions are especially useful for

VBScript clients as VBScript does not support the `safearray` data type used by `GetFullMatrix` and `PutFullMatrix`.

Examples

Assign a cell array to variable `C1` in the base workspace of the server, and then read it back with `GetWorkspaceData`.

MATLAB Client

```
h = actxserver('matlab.application');
h.PutWorkspaceData('C1', 'base', ...
                   {25.72, 'hello', rand(4)});
C2 = h.GetWorkspaceData('C1', 'base')

C2 =
    [25.7200]    'hello'    [4x4 double]
```

Visual Basic .NET Client

This example uses the Visual Basic `MsgBox` command to control flow between MATLAB and the Visual Basic Client.

```
Dim Matlab, C2 As Object
Dim Result As String
Matlab = CreateObject("matlab.application")
Result = MatLab.Execute("C1 = {25.72, 'hello', rand(4)};")
MsgBox("In MATLAB, type" & vbCrLf & "C1")
Matlab.GetWorkspaceData("C1", "base", C2)
MsgBox("second value of C1 = " & C2(0, 1))
```

See Also

`PutWorkspaceData`, `GetFullMatrix`, `PutFullMatrix`, `GetCharArray`, `PutCharArray`, `GetVariable`, `Execute`

Purpose

Graphical input from mouse or cursor

Syntax

```
[x,y] = ginput(n)
[x,y] = ginput
[x,y,button] = ginput(...)
```

Description

`ginput` enables you to select points from the figure using the mouse for cursor positioning. The figure must have focus before `ginput` receives input.

`[x,y] = ginput(n)` enables you to select `n` points from the current axes and returns the *x*- and *y*-coordinates in the column vectors `x` and `y`, respectively. Press the **Return** key to terminate the input before entering `n` points.

`[x,y] = ginput` gathers an unlimited number of points until you press the **Return** key.

Note Clicking an axes makes that axes the current axes. Although you may set the current axes before calling `ginput`, whichever axes the user clicks becomes the current axes and `ginput` returns points relative to that axes. For example, if a user selects points from multiple axes, the results returned are relative to the different axes' coordinate systems.

`[x,y,button] = ginput(...)` returns the *x*-coordinates, the *y*-coordinates, and the button or key designation. `button` is a vector of integers indicating which mouse buttons you pressed (1 for left, 2 for middle, 3 for right), or ASCII numbers indicating which keys on the keyboard you pressed.

Examples

Pick 10 two-dimensional points from the figure window.

```
[x,y] = ginput(10)
```

Position the cursor with the mouse. Enter data points by pressing a mouse button or a key on the keyboard. To terminate input before entering 10 points, press the **Return** key.

Purpose

Declare global variables

Syntax

```
global X Y Z
```

Description

`global X Y Z` defines `X`, `Y`, and `Z` as global in scope.

Ordinarily, each MATLAB function, defined by an M-file, has its own local variables, which are separate from those of other functions, and from those of the base workspace. However, if several functions, and possibly the base workspace, all declare a particular name as global, they all share a single copy of that variable. Any assignment to that variable, in any function, is available to all the functions declaring it global.

If the global variable does not exist the first time you issue the `global` statement, it is initialized to the empty matrix.

If a variable with the same name as the global variable already exists in the current workspace, MATLAB issues a warning and changes the value of that variable to match the global.

Remarks

Use `clear global` *`variable`* to clear a global variable from the global workspace. Use `clear` *`variable`* to clear the global link from the current workspace without affecting the value of the global.

To use a global within a callback, declare the global, use it, then clear the global link from the workspace. This avoids declaring the global after it has been referenced. For example,

```
cbstr = sprintf('%s, %s, %s, %s, %s', ...
   'global MY_GLOBAL',                ...
   'MY_GLOBAL = 100',                 ...
   'disp(MY_GLOBAL)',                 ...
   'MY_GLOBAL = MY_GLOBAL+1',         ...
   'clear MY_GLOBAL');

uicontrol('style', 'pushbutton', 'CallBack', cbstr, ...
   'string', 'count')
```

There is no function form of the global command (i.e., you cannot use parentheses and quote the variable names).

Examples

Here is the code for the functions `tic` and `toc` (some comments abridged). These functions manipulate a stopwatch-like timer. The global variable `TICTOC` is shared by the two functions, but it is invisible in the base workspace or in any other functions that do not declare it.

```
function tic
%    TIC Start a stopwatch timer.
%        TIC; any stuff; TOC
%    prints the time required.
%    See also: TOC, CLOCK.
global TICTOC
TICTOC = clock;

function t = toc
%    TOC Read the stopwatch timer.
%    TOC prints the elapsed time since TIC was used.
%    t = TOC; saves elapsed time in t, does not print.
%    See also: TIC, ETIME.
global TICTOC
if nargout < 1
    elapsed_time = etime(clock, TICTOC)
else
    t = etime(clock, TICTOC);
end
```

See Also

`clear`, `isglobal`, `who`

Purpose

Generalized minimum residual method (with restarts)

Syntax

```
x = gmres(A,b)
gmres(A,b,restart)
gmres(A,b,restart,tol)
gmres(A,b,restart,tol,maxit)
gmres(A,b,restart,tol,maxit,M)
gmres(A,b,restart,tol,maxit,M1,M2)
gmres(A,b,restart,tol,maxit,M1,M2,x0)
[x,flag] = gmres(A,b,...)
[x,flag,relres] = gmres(A,b,...)
[x,flag,relres,iter] = gmres(A,b,...)
[x,flag,relres,iter,resvec] = gmres(A,b,...)
```

Description

`x = gmres(A,b)` attempts to solve the system of linear equations `A*x = b` for `x`. The `n`-by-`n` coefficient matrix `A` must be square and should be large and sparse. The column vector `b` must have length `n`. `A` can be a function handle `afun` such that `afun(x)` returns `A*x`. See "Function Handles" in the MATLAB Programming documentation for more information. For this syntax, `gmres` does not restart; the maximum number of iterations is `min(n,10)`.

"Parameterizing Functions Called by Function Functions", in the MATLAB Mathematics documentation, explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `gmres` converges, a message to that effect is displayed. If `gmres` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual `norm(b-A*x)/norm(b)` and the iteration number at which the method stopped or failed.

`gmres(A,b,restart)` restarts the method every `restart` inner iterations. The maximum number of outer iterations is `min(n/restart,10)`. The maximum number of total iterations is `restart*min(n/restart,10)`. If `restart` is `n` or `[]`, then `gmres` does not restart and the maximum number of total iterations is `min(n,10)`.

`gmres(A,b,restart,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `gmres` uses the default, `1e-6`.

`gmres(A,b,restart,tol,maxit)` specifies the maximum number of outer iterations, i.e., the total number of iterations does not exceed `restart*maxit`. If `maxit` is `[]` then `gmres` uses the default, `min(n/restart,10)`. If `restart` is `n` or `[]`, then the maximum number of total iterations is `maxit` (instead of `restart*maxit`).

`gmres(A,b,restart,tol,maxit,M)` and `gmres(A,b,restart,tol,maxit,M1,M2)` use preconditioner `M` or `M = M1*M2` and effectively solve the system `inv(M)*A*x = inv(M)*b` for `x`. If `M` is `[]` then `gmres` applies no preconditioner. `M` can be a function handle `mfun` such that `mfun(x)` returns `M\x`.

`gmres(A,b,restart,tol,maxit,M1,M2,x0)` specifies the first initial guess. If `x0` is `[]`, then `gmres` uses the default, an all-zero vector.

`[x,flag] = gmres(A,b,...)` also returns a convergence flag:

`flag = 0`	`gmres` converged to the desired tolerance `tol` within `maxit` outer iterations.
`flag = 1`	`gmres` iterated `maxit` times but did not converge.
`flag = 2`	Preconditioner `M` was ill-conditioned.
`flag = 3`	`gmres` stagnated. (Two consecutive iterates were the same.)

Whenever `flag` is not `0`, the solution `x` returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = gmres(A,b,...)` also returns the relative residual `norm(b-A*x)/norm(b)`. If `flag` is `0`, `relres <= tol`.

`[x,flag,relres,iter] = gmres(A,b,...)` also returns both the outer and inner iteration numbers at which `x` was computed, where `0 <= iter(1) <= maxit` and `0 <= iter(2) <= restart`.

`[x,flag,relres,iter,resvec] = gmres(A,b,...)` also returns a vector of the residual norms at each inner iteration, including `norm(b-A*x0)`.

Examples

Example 1

```
A = gallery('wilk',21);
b = sum(A,2);
tol = 1e-12;
maxit = 15;
M1 = diag([10:-1:1 1 1:10]);

x = gmres(A,b,10,tol,maxit,M1);
```

displays the following message:

```
gmres(10) converged at outer iteration 2 (inner iteration 9) to
a solution with relative residual 3.3e-013
```

Example 2

This example replaces the matrix `A` in Example 1 with a handle to a matrix-vector product function `afun`, and the preconditioner `M1` with a handle to a backsolve function `mfun`. The example is contained in an M-file `run_gmres` that

- Calls `gmres` with the function handle `@afun` as its first argument.
- Contains `afun` and `mfun` as nested functions, so that all variables in `run_gmres` are available to `afun` and `mfun`.

The following shows the code for `run_gmres`:

```
function x1 = run_gmres
n = 21;
A = gallery('wilk',n);
b = sum(A,2);
tol = 1e-12;  maxit = 15;
x1 = gmres(@afun,b,10,tol,maxit,@mfun);
```

```
    function y = afun(x)
        y = [0; x(1:n-1)] + ...
              [((n-1)/2:-1:0)'; (1:(n-1)/2)'].*x + ...
              [x(2:n); 0];
    end

    function y = mfun(r)
        y = r ./ [((n-1)/2:-1:1)'; 1; (1:(n-1)/2)'];
    end
end
```

When you enter

```
x1 = run_gmres;
```

MATLAB displays the message

```
gmres(10) converged at outer iteration 2 (inner iteration 9) to
a solution with relative residual 3.3e-013
```

Example 3

```
load west0479
A = west0479
b = sum(A,2)
[x,flag] = gmres(A,b,5)
```

`flag` is `1` because `gmres` does not converge to the default tolerance `1e-6` within the default 10 outer iterations.

```
[L1,U1] = luinc(A,1e-5);
[x1,flag1] = gmres(A,b,5,1e-6,5,L1,U1);
```

`flag1` is `2` because the upper triangular `U1` has a zero on its diagonal, and `gmres` fails in the first iteration when it tries to solve a system such as `U1*y = r` for `y` using backslash.

```
[L2,U2] = luinc(A,1e-6);
```

```
tol = 1e-15;
[x4,flag4,relres4,iter4,resvec4] = gmres(A,b,4,tol,5,L2,U2);
[x6,flag6,relres6,iter6,resvec6] = gmres(A,b,6,tol,3,L2,U2);
[x8,flag8,relres8,iter8,resvec8] = gmres(A,b,8,tol,3,L2,U2);
```

`flag4`, `flag6`, and `flag8` are all `0` because `gmres` converged when restarted at iterations 4, 6, and 8 while preconditioned by the incomplete LU factorization with a drop tolerance of `1e-6`. This is verified by the plots of outer iteration number against relative residual. A combined plot of all three clearly shows the restarting at iterations 4 and 6. The total number of iterations computed may be more for lower values of `restart`, but the number of length `n` vectors stored is fewer, and the amount of work done in the method decreases proportionally.

Purpose

Plot nodes and links representing adjacency matrix

Syntax

```
gplot(A,Coordinates)
gplot(A,Coordinates,LineSpec)
```

Description

The `gplot` function graphs a set of coordinates using an adjacency matrix.

`gplot(A,Coordinates)` plots a graph of the nodes defined in `Coordinates` according to the *n*-by-*n* adjacency matrix `A`, where *n* is the number of nodes. `Coordinates` is an *n*-by-2 matrix, where *n* is the number of nodes and each coordinate pair represents one node.

`gplot(A,Coordinates,LineSpec)` plots the nodes using the line type, marker symbol, and color specified by *`LineSpec`*.

Remarks

For two-dimensional data, `Coordinates(i,:) = [x(i) y(i)]` denotes node `i`, and `Coordinates(j,:) = [x(j)y(j)]` denotes node `j`. If node `i` and node `j` are connected, `A(i,j)` or `A(j,i)` is nonzero; otherwise, `A(i,j)` and `A(j,i)` are zero.

Examples

To draw half of a Bucky ball with asterisks at each node,

```
k = 1:30;
[B,XY] = bucky;
gplot(B(k,k),XY(k,:),'-*')
axis square
```

Purpose

MATLAB code from M-files published to HTML

Syntax

```
grabcode('name.html')
grabcode('urlname')
codeString = grabcode('name.html')
```

Description

`grabcode('name.html')` copies MATLAB code from the file `name.html` and pastes it into an untitled document in the Editor/Debugger. Use `grabcode` to get MATLAB code from demos or other published M-files when the M-file source code is not readily available. The file `name.html` was created by publishing `name.m`, an M-file containing cells. The MATLAB code from `name.m` is included at the end of `name.html` as HTML comments.

`grabcode('urlname')` copies MATLAB code from the `urlname` location and pastes it into an untitled document in the Editor/Debugger.

`codeString = grabcode('name.html')` get MATLAB code from the file `name.html` and assigns it the variable `codeString`.

Examples

Run

```
sineWaveString = grabcode('d:/mymfiles/sine_wave_.html')
```

and MATLAB displays

```
sineWaveString =

%% Simple Sine Wave Plot

%% Part One: Calculate Sine Wave
% Define the range |x|.
% Calculate the sine |y| over that range.
x = 0:.01:6*pi;
y = sin(x);

%% Part Two: Plot Sine Wave
% Graph the result.
```

```
plot(x,y)
```

Purpose

Numerical gradient

Syntax

```
FX = gradient(F)
[FX,FY] = gradient(F)
[FX,FY,FZ,...] = gradient(F)
[...] = gradient(F,h)
[...] = gradient(F,h1,h2,...)
```

Definition

The *gradient* of a function of two variables, $F(x, y)$, is defined as

$$\nabla F = \frac{\partial F}{\partial x}\hat{i} + \frac{\partial F}{\partial y}\hat{j}$$

and can be thought of as a collection of vectors pointing in the direction of increasing values of F. In MATLAB, numerical gradients (differences) can be computed for functions with any number of variables. For a function of N variables, $F(x, y, z, \ldots)$,

$$\nabla F = \frac{\partial F}{\partial x}\hat{i} + \frac{\partial F}{\partial y}\hat{j} + \frac{\partial F}{\partial z}\hat{k} + \ldots$$

Description

`FX = gradient(F)` where `F` is a vector returns the one-dimensional numerical gradient of `F`. `FX` corresponds to $\partial F/\partial x$, the differences in x (horizontal) direction.

`[FX,FY] = gradient(F)` where `F` is a matrix returns the x and y components of the two-dimensional numerical gradient. `FX` corresponds to $\partial F/\partial x$, the differences in x (horizontal) direction. `FY` corresponds to $\partial F/\partial y$, the differences in the y (vertical) direction. The spacing between points in each direction is assumed to be one.

`[FX,FY,FZ,...] = gradient(F)` where `F` has `N dimensions` returns the `N` components of the gradient of `F`. There are two ways to control the spacing between values in `F`:

- A single spacing value, `h`, specifies the spacing between points in every direction.

- `N` spacing values (`h1,h2,...`) specifies the spacing for each dimension of `F`. Scalar spacing parameters specify a constant spacing for each dimension. Vector parameters specify the coordinates of the values along corresponding dimensions of `F`. In this case, the length of the vector must match the size of the corresponding dimension.

Note The first output `FX` is always the gradient along the 2nd dimension of `F`, going across columns. The second output `FY` is always the gradient along the 1st dimension of `F`, going across rows. For the third output `FZ` and the outputs that follow, the Nth output is the gradient along the Nth dimension of `F`.

`[...] = gradient(F,h)` where `h` is a scalar uses `h` as the spacing between points in each direction.

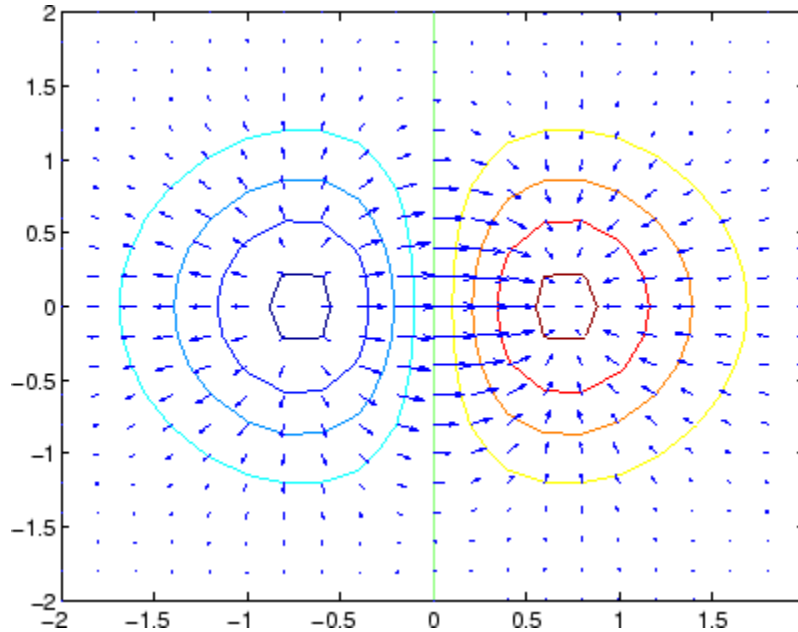
`[...] = gradient(F,h1,h2,...)` with `N` spacing parameters specifies the spacing for each dimension of `F`.

Examples

The statements

```
v = -2:0.2:2;
[x,y] = meshgrid(v);
z = x .* exp(-x.^2 - y.^2);
[px,py] = gradient(z,.2,.2);
contour(v,v,z), hold on, quiver(v,v,px,py), hold off
```

produce



Given,

```
F(:,:,1) = magic(3); F(:,:,2) = pascal(3);
gradient(F)
```

takes `dx = dy = dz = 1`.

```
[PX,PY,PZ] = gradient(F,0.2,0.1,0.2)
```

takes `dx = 0.2`, `dy = 0.1`, and `dz = 0.2`.

"Color Operations" on page 1-98 for related functions

Purpose

Grid lines for 2-D and 3-D plots

GUI Alternative

To control the presence and appearance of grid lines on a graph, use the Property Editor, one of the plotting tools  . For details, see The Property Editor in the MATLAB Graphics documentation.

Syntax

```
grid on
grid off
grid
grid(axes_handle,...)
grid minor
```

Description

The `grid` function turns the current axes' grid lines on and off.

`grid on` adds major grid lines to the current axes.

`grid off` removes major and minor grid lines from the current axes.

`grid` toggles the major grid visibility state.

`grid(axes_handle,...)` uses the axes specified by `axes_handle` instead of the current axes.

Algorithm

`grid` sets the `XGrid`, `YGrid`, and `ZGrid` properties of the axes.

`grid minor` sets the `XMinorGrid`, `YMinorGrid`, and `ZMinorGrid` properties of the axes.

You can set the grid lines for just one axis using the `set` command and the individual property. For example,

```
set(axes_handle,'XGrid','on')
```

turns on only *x*-axis grid lines.

You can set grid line width with the axes `LineWidth` property.

`box`, `axes`, `set`

The properties of axes objects

“Axes Operations” on page 1-96 for related functions

Purpose

Data gridding

Syntax

```
ZI = griddata(x,y,z,XI,YI)
[XI,YI,ZI] = griddata(x,y,z,XI,YI)
[...] = griddata(...,method)
[...] = griddata(...,method,options)
```

Description

`ZI = griddata(x,y,z,XI,YI)` fits a surface of the form `z = f(x,y)` to the data in the (usually) nonuniformly spaced vectors `(x,y,z)`. `griddata` interpolates this surface at the points specified by `(XI,YI)` to produce `ZI`. The surface always passes through the data points. `XI` and `YI` usually form a uniform grid (as produced by `meshgrid`).

`XI` can be a row vector, in which case it specifies a matrix with constant columns. Similarly, `YI` can be a column vector, and it specifies a matrix with constant rows.

`[XI,YI,ZI] = griddata(x,y,z,XI,YI)` returns the interpolated matrix `ZI` as above, and also returns the matrices `XI` and `YI` formed from row vector `XI` and column vector `yi`. These latter are the same as the matrices returned by `meshgrid`.

`[...] = griddata(...,method)` uses the specified interpolation method:

'linear'	Triangle-based linear interpolation (default)
'cubic'	Triangle-based cubic interpolation
'nearest'	Nearest neighbor interpolation
'v4'	MATLAB 4 `griddata` method

The `method` defines the type of surface fit to the data. The `'cubic'` and `'v4'` methods produce smooth surfaces while `'linear'` and `'nearest'` have discontinuities in the first and zero'th derivatives, respectively. All the methods except `'v4'` are based on a Delaunay triangulation of the data. If `method` is `[]`, then the default `'linear'` method is used.

`[...] = griddata(...,method,options)` specifies a cell array of strings `options` to be used in Qhull via `delaunayn`. If `options` is `[]`, the default `delaunayn` options are used. If `options` is `{''}`, no options are used, not even the default.

Occasionally, `griddata` might return points on or very near the convex hull of the data as `NaN`s. This is because roundoff in the computations sometimes makes it difficult to determine if a point near the boundary is in the convex hull.

Remarks

`XI` and `YI` can be matrices, in which case `griddata` returns the values for the corresponding points `(XI(i,j),YI(i,j))`. Alternatively, you can pass in the row and column vectors `xi` and `yi`, respectively. In this case, `griddata` interprets these vectors as if they were matrices produced by the command `meshgrid(xi,yi)`.

Examples

Sample a function at 100 random points between ±2.0:

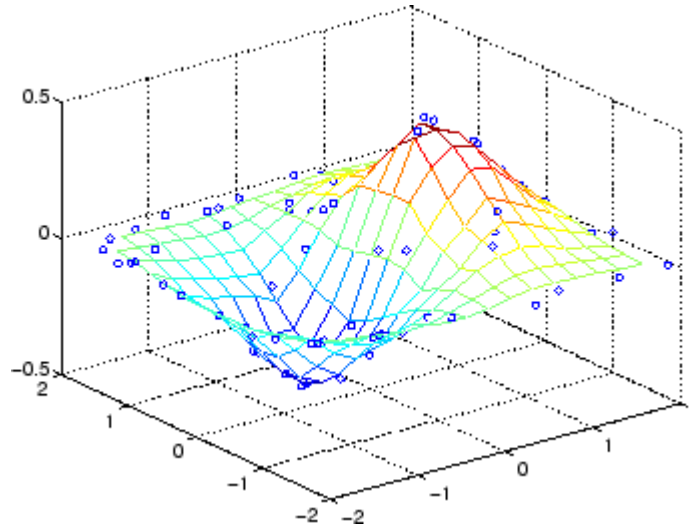
```
rand('seed',0)
x = rand(100,1)*4-2;  y = rand(100,1)*4-2;
z = x.*exp(-x.^2-y.^2);
```

`x`, `y`, and `z` are now vectors containing nonuniformly sampled data. Define a regular grid, and grid the data to it:

```
ti = -2:.25:2;
[XI,YI] = meshgrid(ti,ti);
ZI = griddata(x,y,z,XI,YI);
```

Plot the gridded data along with the nonuniform data points used to generate it:

```
mesh(XI,YI,ZI), hold
plot3(x,y,z,'o'), hold off
```



Algorithm

The `griddata(...,'v4')` command uses the method documented in [2]. The other `griddata` methods are based on a Delaunay triangulation of the data that uses Qhull [1]. For information about Qhull, see `http://www.qhull.org/`. For copyright information, see `http://www.qhull.org/COPYING.txt`.

```

Description

`w = griddata3(x,y,z,v,xi,yi,zi)` fits a hypersurface of the form $w = f(x, y, z)$ to the data in the (usually) nonuniformly spaced vectors (`x`, `y`, `z`, `v`). `griddata3` interpolates this hypersurface at the points specified by (`xi`,`yi`,`zi`) to produce `w`. `w` is the same size as `xi`, `yi`, and `zi`.

(`xi`,`yi`,`zi`) is usually a uniform grid (as produced by `meshgrid`) and is where `griddata3` gets its name.

`w = griddata3(x,y,z,v,xi,yi,zi,method)` defines the type of surface that is fit to the data, where `method` is either:

`'linear'`	Tesselation-based linear interpolation (default)
`'nearest'`	Nearest neighbor interpolation

If `method` is `[]`, the default `'linear'` method is used.

`w = griddata3(x,y,z,v,xi,yi,zi,method,options)` specifies a cell array of strings `options` to be used in Qhull via `delaunayn`.

If `options` is `[]`, the default options are used. If `options` is `{''}`, no options are used, not even the default.

Examples

Create vectors `x`, `y`, and `z` containing nonuniformly sampled data:

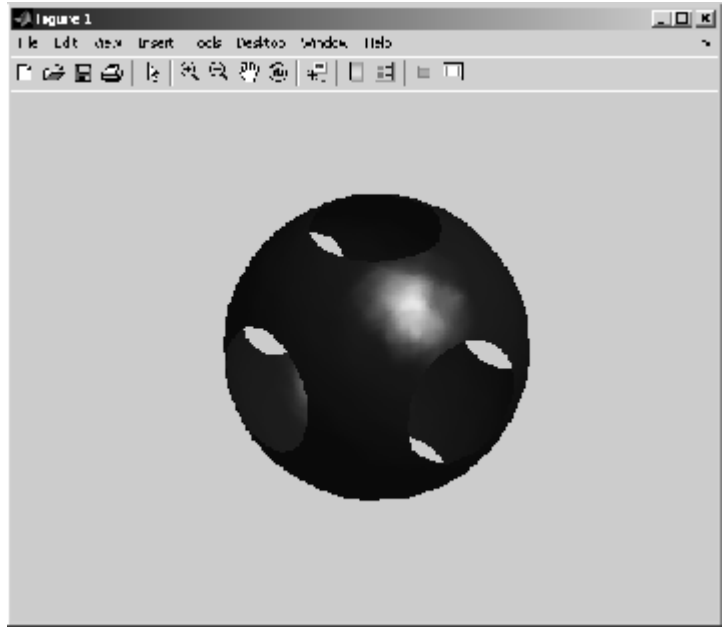
```
rand('state',0);
x = 2*rand(5000,1)-1;
y = 2*rand(5000,1)-1;
z = 2*rand(5000,1)-1;
v = x.^2 + y.^2 + z.^2;
```

Define a regular grid, and grid the data to it:

```
d = -0.8:0.05:0.8;
[xi,yi,zi] = meshgrid(d,d,d);
w = griddata3(x,y,z,v,xi,yi,zi);
```

Since it is difficult to visualize 4D data sets, use isosurface at 0.8:

```
p = patch(isosurface(xi,yi,zi,w,0.8));
isonormals(xi,yi,zi,w,p);
set(p,'FaceColor','blue','EdgeColor','none');
view(3), axis equal, axis off, camlight, lighting phong
```



Algorithm

The `griddata3` methods are based on a Delaunay triangulation of the data that uses Qhull [1]. For information about Qhull, see `http://www.qhull.org/`. For copyright information, see `http://www.qhull.org/COPYING.txt`.

griddatan

Purpose

Data gridding and hypersurface fitting (dimension >= 2)

Syntax

```
yi = griddatan(X,y,xi)
yi = griddatan(x,y,z,v,xi,yi,zi,method)
```

Description

`yi = griddatan(X,y,xi)` fits a hyper-surface of the form $y = f(X)$ to the data in the (usually) nonuniformly-spaced vectors (`X`, `y`). `griddatan` interpolates this hyper-surface at the points specified by `xi` to produce `yi`. `xi` can be nonuniform.

`X` is of dimension `m`-by-`n`, representing `m` points in n-dimensional space. `y` is of dimension `m`-by-`1`, representing `m` values of the hyper-surface f(`X`). `xi` is a vector of size `p`-by-`n`, representing `p` points in the n-dimensional space whose surface value is to be fitted. `yi` is a vector of length `p` approximating the values f(`xi`). The hypersurface always goes through the data points (`X`,`y`). `xi` is usually a uniform grid (as produced by `meshgrid`).

`yi = griddatan(x,y,z,v,xi,yi,zi,method)` defines the type of surface fit to the data, where `'method'` is one of:

'linear'	Tessellation-based linear interpolation (default)
'nearest'	Nearest neighbor interpolation

All the methods are based on a Delaunay tessellation of the data.

If `method` is `[]`, the default `'linear'` method is used.

`yi = griddatan(x,y,z,v,xi,yi,zi,method,options)` specifies a cell array of strings `options` to be used in Qhull via `delaunayn`.

If `options` is `[]`, the default options are used. If `options` is `{''}`, no options are used, not even the default.

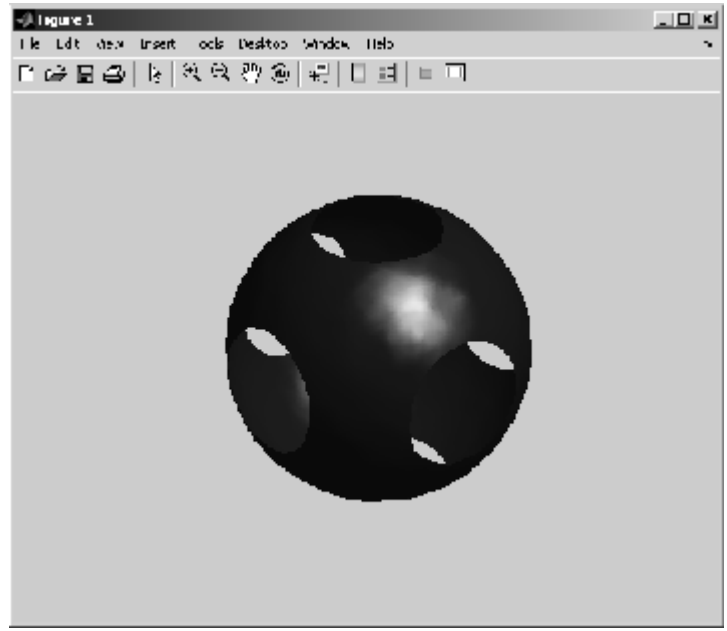
Examples

```
rand('state',0)
X = 2*rand(5000,3)-1;
Y = sum(X.^2,2);
d = -0.8:0.05:0.8;
```

```
[yO,xO,zO] = ndgrid(d,d,d);
XI = [xO(:) yO(:) zO(:)];
YI = griddatan(X,Y,XI);
```

Since it is difficult to visualize 4D data sets, use isosurface at 0.8:

```
YI = reshape(YI, size(xO));
p = patch(isosurface(xO,yO,zO,YI,0.8));
isonormals(xO,yO,zO,YI,p);
set(p,'FaceColor','blue','EdgeColor','none');
view(3), axis equal, axis off, camlight, lighting phong
```



Algorithm

The `griddatan` methods are based on a Delaunay triangulation of the data that uses Qhull [1]. For information about Qhull, see `http://www.qhull.org/`. For copyright information, see `http://www.qhull.org/COPYING.txt`.

Reference

[1] Barber, C. B., D.P. Dobkin, and H.T. Huhdanpaa, "The Quickhull Algorithm for Convex Hulls," ACM Transactions on Mathematical Software, Vol. 22, No. 4, Dec. 1996, p. 469-483. Available in PDF format at http://www.acm.org/pubs/citations/journals/toms/1996-22-4/p469-barber/.

Purpose

Generalized singular value decomposition

Syntax

```
[U,V,X,C,S] = gsvd(A,B)
sigma = gsvd(A,B)
```

Description

`[U,V,X,C,S] = gsvd(A,B)` returns unitary matrices `U` and `V`, a (usually) square matrix `X`, and nonnegative diagonal matrices `C` and `S` so that

```
A = U*C*X'
B = V*S*X'
C'*C + S'*S = I
```

`A` and `B` must have the same number of columns, but may have different numbers of rows. If `A` is `m`-by-`p` and `B` is `n`-by-`p`, then `U` is `m`-by-`m`, `V` is `n`-by-`n` and `X` is `p`-by-`q` where `q = min(m+n,p)`.

`sigma = gsvd(A,B)` returns the vector of generalized singular values, `sqrt(diag(C'*C)./diag(S'*S))`.

The nonzero elements of `S` are always on its main diagonal. If `m >= p` the nonzero elements of `C` are also on its main diagonal. But if `m < p`, the nonzero diagonal of `C` is `diag(C,p-m)`. This allows the diagonal elements to be ordered so that the generalized singular values are nondecreasing.

`gsvd(A,B,0)`, with three input arguments and either `m` or `n >= p`, produces the "economy-sized"decomposition where the resulting `U` and `V` have at most `p` columns, and `C` and `S` have at most `p` rows. The generalized singular values are `diag(C)./diag(S)`.

When `B` is square and nonsingular, the generalized singular values, `gsvd(A,B)`, are equal to the ordinary singular values, `svd(A/B)`, but they are sorted in the opposite order. Their reciprocals are `gsvd(B,A)`.

In this formulation of the `gsvd`, no assumptions are made about the individual ranks of `A` or `B`. The matrix `X` has full rank if and only if the matrix `[A;B]` has full rank. In fact, `svd(X)` and `cond(X)` are equal to `svd([A;B])` and `cond([A;B])`. Other formulations, eg. G. Golub and

C. Van Loan [1], require that `null(A)` and `null(B)` do not overlap and replace `X` by `inv(X)` or `inv(X')`.

Note, however, that when `null(A)` and `null(B)` do overlap, the nonzero elements of `C` and `S` are not uniquely determined.

Examples

Example 1

The matrices have at least as many rows as columns.

```
A = reshape(1:15,5,3)
B = magic(3)
A =
          1     6    11
          2     7    12
          3     8    13
          4     9    14
          5    10    15
B =
          8     1     6
          3     5     7
          4     9     2
```

The statement

```
[U,V,X,C,S] = gsvd(A,B)
```

produces a 5-by-5 orthogonal `U`, a 3-by-3 orthogonal `V`, a 3-by-3 nonsingular `X`,

```
X =
         2.8284   -9.3761   -6.9346
        -5.6569   -8.3071  -18.3301
         2.8284   -7.2381  -29.7256
```

and

```
C =
         0.0000         0         0
```

```
         0    0.3155         0
         0         0    0.9807
         0         0         0
         0         0         0
S =
    1.0000         0         0
         0    0.9489         0
         0         0    0.1957
```

Since `A` is rank deficient, the first diagonal element of `C` is zero.

The economy sized decomposition,

```
[U,V,X,C,S] = gsvd(A,B,0)
```

produces a 5-by-3 matrix `U` and a 3-by-3 matrix `C`.

```
U =
    0.5700   -0.6457   -0.4279
   -0.7455   -0.3296   -0.4375
   -0.1702   -0.0135   -0.4470
    0.2966    0.3026   -0.4566
    0.0490    0.6187   -0.4661

C =
    0.0000         0         0
         0    0.3155         0
         0         0    0.9807
```

The other three matrices, `V`, `X`, and `S` are the same as those obtained with the full decomposition.

The generalized singular values are the ratios of the diagonal elements of `C` and `S`.

```
sigma = gsvd(A,B)
sigma =
    0.0000
    0.3325
```

```
        5.0123
```

These values are a reordering of the ordinary singular values

```
svd(A/B)
ans =
        5.0123
        0.3325
        0.0000
```

Example 2

The matrices have at least as many columns as rows.

```
A = reshape(1:15,3,5)
B = magic(5)
A =

     1     4     7    10    13
     2     5     8    11    14
     3     6     9    12    15
B =
    17    24     1     8    15
    23     5     7    14    16
     4     6    13    20    22
    10    12    19    21     3
    11    18    25     2     9
```

The statement

```
[U,V,X,C,S] = gsvd(A,B)
```

produces a 3-by-3 orthogonal `U`, a 5-by-5 orthogonal `V`, a 5-by-5 nonsingular `X` and

```
C =
             0         0    0.0000         0         0
             0         0         0    0.0439         0
             0         0         0         0    0.7432
```

```
S =
        1.0000         0         0         0         0
             0    1.0000         0         0         0
             0         0    1.0000         0         0
             0         0         0    0.9990         0
             0         0         0         0    0.6690
```

In this situation, the nonzero diagonal of `C` is `diag(C,2)`. The generalized singular values include three zeros.

```
sigma = gsvd(A,B)
sigma =
             0
             0
        0.0000
        0.0439
        1.1109
```

Reversing the roles of `A` and `B` reciprocates these values, producing two infinities.

```
gsvd(B,A)
ans =
      1.0e+016 *

        0.0000
        0.0000
        4.4126
           Inf
           Inf
```

Algorithm

The generalized singular value decomposition uses the C-S decomposition described in [1], as well as the built-in `svd` and `qr` functions. The C-S decomposition is implemented in a subfunction in the `gsvd` M-file.

Diagnostics

The only warning or error message produced by `gsvd` itself occurs when the two input arguments do not have the same number of columns.

`qr`, `svd`

References

[1] Golub, Gene H. and Charles Van Loan, *Matrix Computations*, Third Edition, Johns Hopkins University Press, Baltimore, 1996

Purpose

Test for greater than

Syntax

```
A > B
gt(A, B)
```

Description

`A > B` compares each element of array `A` with the corresponding element of array `B`, and returns an array with elements set to logical 1 (`true`) where `A` is greater than `B`, or set to logical 0 (`false`) where `A` is less than or equal to `B`. Each input of the expression can be an array or a scalar value.

If both `A` and `B` are scalar (i.e., 1-by-1 matrices), then MATLAB returns a scalar value.

If both `A` and `B` are nonscalar arrays, then these arrays must have the same dimensions, and MATLAB returns an array of the same dimensions as `A` and `B`.

If one input is scalar and the other a nonscalar array, then the scalar input is treated as if it were an array having the same dimensions as the nonscalar input array. In other words, if input `A` is the number 100, and `B` is a 3-by-5 matrix, then `A` is treated as if it were a 3-by-5 matrix of elements, each set to 100. MATLAB returns an array of the same dimensions as the nonscalar input array.

`gt(A, B)` is called for the syntax `A>B` when either `A` or `B` is an object.

Examples

Create two 6-by-6 matrices, `A` and `B`, and locate those elements of `A` that are greater than the corresponding elements of `B`:

```
A = magic(6);
B = repmat(3*magic(3), 2, 2);

A > B
ans =
     1     0     0     1     1     1
     0     1     0     1     1     1
     1     0     0     1     0     1
     0     1     1     0     1     0
```

```
     1     0     1     1     0     0
     0     1     1     1     0     1
```

`lt`, `ge`, `le`, `ne`, `eq`, "Relational Operators"

Purpose

Mouse placement of text in 2-D view

Syntax

```
gtext('string')
gtext({'string1','string2','string3',...})
gtext({'string1';'string2';'string3';...})
h = gtext(...)
```

Description

`gtext` displays a text string in the current figure window after you select a location with the mouse.

`gtext('string')` waits for you to press a mouse button or keyboard key while the pointer is within a figure window. Pressing a mouse button or any key places `'string'` on the plot at the selected location.

`gtext({'string1','string2','string3',...})` places all strings with one click, each on a separate line.

`gtext({'string1';'string2';'string3';...})` places one string per click, in the sequence specified.

`h = gtext(...)` returns the handle to a text graphics object that is placed on the plot at the location you select.

Remarks

As you move the pointer into a figure window, the pointer becomes crosshairs to indicate that `gtext` is waiting for you to select a location. `gtext` uses the functions `ginput` and `text`.

Examples

Place a label on the current plot:

```
gtext('Note this divergence!')
```

See Also

`ginput`, `text`

"Annotating Plots" on page 1-87 for related functions

guidata

Purpose

Store or retrieve GUI data

Syntax

```
guidata(object_handle,data)
data = guidata(object_handle)
```

Description

`guidata(object_handle,data)` stores the variable `data` as GUI data. If `object_handle` is not a figure handle, then the object's parent figure is used. `data` can be any MATLAB variable, but is typically a structure, which enables you to add new fields as required.

`guidata` can manage only one variable at any time. Subsequent calls to `guidata(object_handle,data)` overwrite the previously created version of GUI `data`.

Note for GUIDE Users GUIDE uses `guidata` to store and maintain the `handles` structure. From a GUIDE-generated GUI M-file, do not use `guidata` to store any data other than `handles`. If you do, you may overwrite the `handles` structure and your GUI will not work. If you need to store other data with your GUI, you can add it to the `handles` structure. See GUI Data in the MATLAB documentation.

`data = guidata(object_handle)` returns previously stored data, or an empty matrix if nothing has been stored.

To change the data managed by `guidata`:

1. Get a copy of the data with the command `data = guidata(object_handle)`.
2. Make the desired changes to `data`.
3. Save the changed version of `data` with the command `guidata(object_handle,data)`.

`guidata` provides application developers with a convenient interface to a figure's application data:

- You do not need to create and maintain a hard-coded property name for the application data throughout your source code.
- You can access the data from within a subfunction callback routine using the component's handle (which is returned by `gcbo`), without needing to find the figure's handle.

If you are not using GUIDE, `guidata` is particularly useful in conjunction with `guihandles`, which creates a structure containing the handles of all the components in a GUI.

Examples

In this example, `guidata` is used to save a structure on a GUI figure's application data from within the initialization section of the application M-file. This structure is initially created by `guihandles` and then used to save additional data as well.

```
% create structure of handles
myhandles = guihandles(figure_handle);
% add some additional data
myhandles.numberOfErrors = 0;
% save the structure
guidata(figure_handle,myhandles)
```

You can recall the data from within a subfunction callback routine and then save the structure again:

```
% get the structure in the subfunction
myhandles = guidata(gcbo);
myhandles.numberOfErrors = myhandles.numberOfErrors + 1;
% save the changes to the structure
guidata(gcbo,myhandles)
```

`guide`, `guihandles`, `getappdata`, `setappdata`

guide

Purpose

Open GUI Layout Editor

Syntax

```
guide
guide('filename.fig')
guide('fullpath')
guide(HandleList)
```

Description

`guide` initiates the GUI design environment (GUIDE) tools that allow you to create or edit GUIs interactively.

`guide` opens the GUIDE Quick Start dialog where you can choose to open a previously created GUI or create a new one using one of the provided templates.

`guide('filename.fig')` opens the FIG-file named `filename.fig` for editing if it is on the MATLAB path.

`guide('fullpath')` opens the FIG-file at `fullpath` even if it is not on the MATLAB path.

`guide(HandleList)` opens the content of each of the figures in `HandleList` in a separate copy of the GUIDE design environment.

See Also

`inspect`

Creating GUIs

Purpose

Create structure of handles

Syntax

```
handles = guihandles(object_handle)
handles = guihandles
```

Description

`handles = guihandles(object_handle)` returns a structure containing the handles of the objects in a figure, using the value of their `Tag` properties as the fieldnames, with the following caveats:

- Objects are excluded if their `Tag` properties are empty, or are not legal variable names.
- If several objects have the same `Tag`, that field in the structure contains a vector of handles.
- Objects with hidden handles are included in the structure.

`handles = guihandles` returns a structure of handles for the current figure.

gunzip

Purpose

Uncompress GNU zip files

Syntax

```
gunzip(files)
gunzip(files,outputdir)
gunzip(url, ...)
filenames = gunzip(...)
```

Description

`gunzip(files)` uncompresses GNU zip files from the list of files specified in `files`. Directories recursively gunzip all of their content. The output files have the same name, excluding the extension `.gz`, and are written to the same directory as the input files.

`files` is a string or cell array of strings containing a list of files or directories. Individual files that are on the MATLAB path can be specified as partial pathnames. Otherwise an individual file can be specified relative to the current directory or with an absolute path. Directories must be specified relative to the current directory or with absolute paths. On UNIX systems, directories can also start with `~/` or `~username/`, which expands to the current user's home directory or the specified user's home directory, respectively. The wildcard character `*` can be used when specifying files or directories, except when relying on the MATLAB path to resolve a filename or partial pathname.

`gunzip(files,outputdir)` writes the gunzipped file into the directory `outputdir`. `outputdir` is created if it does not exist.

`gunzip(url, ...)` extracts the GNU zip contents from an Internet universal resource locator (URL). The URL must include the protocol type (e.g., `'http://'`). The URL is downloaded to the temp directory and deleted.

`filenames = gunzip(...)` gunzips the files and returns the relative pathnames of the gunzipped files in the string cell array `filenames`.

Examples

To gunzip all `.gz` files in the current directory,

```
gunzip('*.gz');
```

To gunzip Cleve Moler's "Numerical Computing with MATLAB" examples to the output directory `ncm`:

```
url ='http://www.mathworks.com/moler/ncm.tar.gz';
gunzip(url,'ncm')
untar('ncm/ncm.tar','ncm')
```

See Also

`gzip`, `tar`, `untar`, `unzip`, `zip`

gzip

Purpose

Compress files into GNU zip files

Syntax

```
gzip(files)
gzip(files,outputdir)
filenames = gzip(...)
```

Description

`gzip(files)` creates GNU zip files from the list of files specified in `files`. Directories recursively `gzip` all their contents. Each output gzipped file is written to the same directory as the input file and with the file extension `.gz`.

`files` is a string or cell array of strings containing a list of files or directories to `gzip`. Individual files that are on the MATLAB path can be specified as partial pathnames. Otherwise an individual file can be specified relative to the current directory or with an absolute path. Directories must be specified relative to the current directory or with absolute paths. On UNIX systems, directories can also start with `~/` or *`~username/`*, which expands to the current user's home directory or the specified user's home directory, respectively. The wildcard character `*` can be used when specifying files or directories, except when relying on the MATLAB path to resolve a filename or partial pathname.

`gzip(files,outputdir)` writes the gzipped files into the directory `outputdir`. `outputdir` is created if it does not exist.

`filenames = gzip(...)` gzips the files and returns the relative pathnames of all gzipped files in the string cell array `filenames`.

Example

To `gzip` all `.m` and `.mat` files in the current directory and store the results in the directory `archive`,

```
gzip({'*.m','*.mat'},'archive');
```

See Also

`gunzip`, `tar`, `untar`, `unzip`, `zip`

Purpose

Hadamard matrix

Syntax

```
H = hadamard(n)
```

Description

`H = hadamard(n)` returns the Hadamard matrix of order `n`.

Definition

Hadamard matrices are matrices of 1's and `-1`'s whose columns are orthogonal,

```
H'*H = n*I
```

where `[n n]=size(H)` and `I = eye(n,n)` ,.

They have applications in several different areas, including combinatorics, signal processing, and numerical analysis, [1], [2].

An `n`-by-`n` Hadamard matrix with `n > 2` exists only if `rem(n,4) = 0`. This function handles only the cases where `n`, `n/12`, or `n/20` is a power of 2.

Examples

The command `hadamard(4)` produces the 4-by-4 matrix:

```
   1     1     1     1
   1    -1     1    -1
   1     1    -1    -1
   1    -1    -1     1
```

hankel

Purpose

Hankel matrix

Syntax

```
H = hankel(c)
H = hankel(c,r)
```

Description

`H = hankel(c)` returns the square Hankel matrix whose first column is `c` and whose elements are zero below the first anti-diagonal.

`H = hankel(c,r)` returns a Hankel matrix whose first column is `c` and whose last row is `r`. If the last element of `c` differs from the first element of `r`, the last element of `c` prevails.

Definition

A Hankel matrix is a matrix that is symmetric and constant across the anti-diagonals, and has elements `h(i,j) = p(i+j-1)`, where vector `p = [c r(2:end)]` completely determines the Hankel matrix.

Examples

A Hankel matrix with anti-diagonal disagreement is

```
c = 1:3; r = 7:10;
h = hankel(c,r)
h =
     1     2     3     8
     2     3     8     9
     3     8     9    10

p = [1 2 3 8 9 10]
```

Purpose

Summary of MATLAB HDF4 capabilities

Description

MATLAB provides a set of low-level functions that enable you to access the HDF4 library developed by the National Center for Supercomputing Applications (NCSA). For information about HDF4, go to the HDF Web page at `http://www.hdfgroup.org`.

Note For information about MATLAB HDF5 capabilities, which is a completely separate, incompatible format, see `hdf5`.

The following table lists all the HDF4 application programming interfaces (APIs) supported by MATLAB with the name of the MATLAB function used to access the API. To use these functions, you must be familiar with the HDF library. For more information about using these MATLAB functions, see Working with Scientific Data Formats.

Application Programming Interface	Description	MATLAB Function
Annotations	Stores, manages, and retrieves text used to describe an HDF file or any of the data structures contained in the file.	`hdfan`
General Raster Images	Stores, manages, and retrieves raster images, their dimensions and palettes. It can also manipulate unattached palettes. Note: Use the MATLAB functions `imread` and `imwrite` with HDF raster image formats.	`hdfdf24`, `hdfdfr8`

Application Programming Interface	Description	MATLAB Function
HDF-EOS	Provides functions to read HDF-EOS grid (GD), point (PT), and swath (SW) data.	`hdfgd`, `hdfpt`, `hdfsw`
HDF Utilities	Provides functions to open and close HDF files and handle errors.	`hdfh`, `hdfhd`, `hdfhe`
MATLAB HDF Utilitie	Provides utility functions that help you work with HDF files in the MATLAB environment.	`hdfml`
Scientific Data	Stores, manages, and retrieves multidimensional arrays of character or numeric data, along with their dimensions and attributes.	`hdfsd`
V Groups	Creates and retrieves groups of other HDF data objects, such as raster images or V data.	`hdfv`
V Data	Stores, manages, and retrieves multivariate data stored as records in a table.	`hdfvf`, `hdfvh`, `hdfvs`

Purpose

Summary of MATLAB HDF5 capabilities

Description

MATLAB provides both high-level and low-level access to HDF5 files. The high-level access functions make it easy to read a data set from an HDF5 file or write a variable from the MATLAB workspace into an HDF5 file. The MATLAB low-level interface provides direct access to the more than 200 functions in the HDF5 library. MATLAB currently supports version HDF5-1.6.5 of the library.

Note For information about MATLAB HDF4 capabilities, which is a completely separate, incompatible format, see `hdf`.

The following sections provide an overview of both this high- and low-level access. To use these MATLAB functions, you must be familiar with HDF5 programming concepts and, when using the low-level functions, details about the functions in the library. To get this information, go to the HDF Web page at `http://www.hdfgroup.org`.

High-level Access

MATLAB includes three functions that provide high-level access to HDF5 files:

- `hdf5info`
- `hdf5read`
- `hdf5write`

Using these functions you can read data and metadata from an HDF5 file and write data from the MATLAB workspace to a file in HDF5 format. For more information about these functions, see their individual reference pages.

Low-level Access

MATLAB provides direct access to the over 200 functions in the HDF5 Library. Using these functions, you can read and write complex

datatypes, utilize HDF5 data subsetting capabilities, and take advantage of other features present in the HDF5 library.

The HDF5 library organizes the routines in the library into interfaces. MATLAB organizes the corresponding MATLAB functions into class directories that match these HDF5 library interfaces. For example, the MATLAB functions for the HDF5 Attribute Interface are in the @H5A class directory.

The following table lists all the HDF5 library interfaces in alphabetical order by name. The table includes the name of the associated MATLAB class directory.

HDF5 Library Interface	MATLAB Class Directory	Description
Attribute	`@H5A`	Manipulate metadata associated with data sets or groups
Dataset	`@H5D`	Manipulate multidimensional arrays of data elements, together with supporting metadata
Dataspace	`@H5S`	Define and work with data spaces, which describe the the dimensionality of a data set
Datatype	`@H5T`	Define the type of variable that is stored in a data set
Error	`@H5E`	Handle errors
File	`@H5F`	Access files
Filters and Compression	`@H5Z`	Create inline data filters and data compression
Group	`@H5G`	Organize objects in a file; analogous to a directory structure
Identifier	`@H5I`	Manipulate HDF5 object identifiers

HDF5 Library Interface	MATLAB Class Directory	Description
Library	`@H5`	General-purpose functions for use with the entire HDF5 library, such as initialization
MATLAB	`@H5ML`	MATLAB utility functions that are not part of the HDF5 library itself.
Property	`@H5P`	Manipulate object property lists
Reference	`@H5R`	Manipulate HDF5 references, which are like UNIX links or Windows shortcuts

In most cases, the syntax of the MATLAB function is identical to the syntax of the HDF5 library function. To get detailed information about the MATLAB syntax of an HDF5 library function, view the help for the individual MATLAB function, as follows:

```
help @H5F/open
```

To view a list of all the MATLAB HDF5 functions in a particular interface, type:

```
help imagesci/@H5F
```

`hdf`, `hdf5info`, `hdf5read`, `hdf5write`

hdf5info

Purpose

Information about HDF5 file

Syntax

```
fileinfo = hdf5info(filename)
fileinfo = hdf5info(...,'ReadAttributes',BOOL)
[...] = hdf5info(..., 'V71Dimensions', BOOL)
```

Description

`fileinfo = hdf5info(filename)` returns a structure `fileinfo` whose fields contain information about the contents of the HDF5 file `filename`. `filename` is a string that specifies the name of the HDF5 file.

`fileinfo = hdf5info(...,'ReadAttributes',BOOL)` specifies whether `hdf5info` returns the values of the attributes or just information describing the attributes. By default, `hdf5info` reads in attribute values (`BOOL = true`).

`[...] = hdf5info(..., 'V71Dimensions', BOOL)` specifies whether to report the dimensions of data sets and attributes as they were returned in previous versions of `hdf5info` (MATLAB 7.1 [R14SP3] and earlier). If `BOOL` is true, `hdf5info` swaps the first two dimensions of the data set. This behavior was intended to account for the difference in how HDF5 and MATLAB express array dimenions. HDF5 describes data set dimensions in row-major order; MATLAB stores data in column-major order. However, swapping these dimensions may not correctly reflect the intent of the data in the file and may invalidate metadata. When `BOOL` is false (the default), `hdf5info` returns data dimensions that correctly reflect the data ordering as it is written in the file—each dimension in the output variable matches the same dimension in the file.

Note If you use the `'V71Dimensions'` parameter and intend on passing the `fileinfo` structure returned to the `hdf5read` function, you should also specify the `'V71Dimensions'` parameters with `hdf5read`. If you do not, `hdf5read` uses the new behavior when reading the data set and certain metadata returned by `hdf5info` does not match the actual data returned by `hdf5read`.

Examples

```
fileinfo = hdf5info('example.h5')

fileinfo =

          Filename: 'example.h5'
        LibVersion: '1.4.5'
            Offset: 0
          FileSize: 8172
    GroupHierarchy: [1x1 struct]
```

To get more information about the contents of the HDF5 file, look at the `GroupHierarchy` field in the `fileinfo` structure returned by `hdf5info`.

```
toplevel = fileinfo.GroupHierarchy

toplevel =

      Filename: [1x64 char]
          Name: '/'
        Groups: [1x2 struct]
      Datasets: []
     Datatypes: []
         Links: []
    Attributes: [1x2 struct]
```

To probe further into the file hierarchy, keep examining the `Groups` field.

See also

`hdf5read`, `hdf5write`

hdf5read

Purpose

Read HDF5 file

Syntax

```
data = hdf5read(filename,datasetname)
attr = hdf5read(filename,attributename)
[data, attr] = hdf5read(...,'ReadAttributes',BOOL)
data = hdf5read(hinfo)
[...] = hdf5read(..., 'V71Dimensions', BOOL)
```

Description

`data = hdf5read(filename,datasetname)` reads all the data in the data set `datasetname` that is stored in the HDF5 file `filename` and returns it in the variable `data`. To determine the names of data sets in an HDF5 file, use the `hdf5info` function.

The return value, `data`, is a multidimensional array. `hdf5read` maps HDF5 data types to native MATLAB data types, whenever possible. If it cannot represent the data using MATLAB data types, `hdf5read` uses one of the HDF5 data type objects. For example, if an HDF5 file contains a data set made up of an enumerated data type, `hdf5read` uses the `hdf5.h5enum` object to represent the data in the MATLAB workspace. The `hdf5.h5enum` object has data members that store the enumerations (names), their corresponding values, and the enumerated data. For more information about the HDF5 data type objects, see the `hdf5` reference page.

`attr = hdf5read(filename,attributename)` reads all the metadata in the attribute `attributename`, stored in the HDF5 file `filename`, and returns it in the variable `attr`. To determine the names of attributes in an HDF5 file, use the `hdf5info` function.

`[data, attr] = hdf5read(...,'ReadAttributes',BOOL)` reads all the data, as well as all of the associated attribute information contained within that data set. By default, `BOOL` is false.

`data = hdf5read(hinfo)` reads all of the data in the data set specified in the structure `hinfo` and returns it in the variable `data`. The `hinfo` structure is extracted from the output returned by `hdf5info`, which specifies an HDF5 file and a specific data set.

`[...] = hdf5read(..., 'V71Dimensions', BOOL)` specifies whether to change the majority of data sets read from the file. If `BOOL` is true, `hdf5read` permutes the first two dimensions of the data set, as it did in previous releases (MATLAB 7.1 [R14SP3] and earlier). This behavior was intended to account for the difference in how HDF5 and MATLAB express array dimensions. HDF5 describes data set dimensions in row-major order; MATLAB stores data in column-major order. However, permuting these dimensions may not correctly reflect the intent of the data and may invalidate metadata. When `BOOL` is false (the default), the data dimensions correctly reflect the data ordering as it is written in the file — each dimension in the output variable matches the same dimension in the file.

Examples

Use `hdf5info` to get information about an HDF5 file and then use `hdf5read` to read a data set, using the information structure (`hinfo`) returned by `hdf5info` to specify the data set.

```
hinfo = hdf5info('example.h5');
dset = hdf5read(hinfo.GroupHierarchy.Groups(2).Datasets(1));
```

See Also

`hdf5`, `hdf5info`, `hdf5write`

Purpose

Write data to file in HDF5 format

Syntax

```
hdf5write(filename,location,dataset)
hdf5write(filename,details,dataset)
hdf5write(filename,details,attribute)
hdf5write(filename, details1, dataset1, details2, dataset2,
   ...)
hdf5write(filename,...,'WriteMode',mode,...)
hdf5write(..., 'V71Dimensions', BOOL)
```

Description

`hdf5write(filename,location,dataset)` writes the data `dataset` to the HDF5 file, `filename`. If `filename` does not exist, `hdf5write` creates it. If `filename` exists, `hdf5write` overwrites the existing file, by default, but you can also append data to an existing file using an optional syntax.

`location` defines where to write the data set in the file. HDF5 files are organized in a hierarchical structure similar to a UNIX directory structure. `location` is a string that resembles a UNIX path.

`hdf5write` maps the data in `dataset` to HDF5 data types according to rules outlined below.

`hdf5write(filename,details,dataset)` writes `dataset` to `filename` using the values in the `details` structure. For a data set, the `details` structure can contain the following fields.

Field Name	Description	Data Type
`Location`	Location of the data set in the file	Character array
`Name`	Name to attach to the data set	Character array

`hdf5write(filename,details,attribute)` writes the metadata `attribute` to `filename` using the values in the `details` structure. For an attribute, the `details` structure can contain following fields.

Field Name	Description	Data Type
`AttachedTo`	Location of the object this attribute modifies	Structure array
`AttachType`	Identifies what kind of object this attribute modifies; possible values are `'group'` and `'dataset'`	Character array
`Name`	Name to attach to the data set	Character array

`hdf5write(filename, details1, dataset1, details2, dataset2,...)` writes multiple data sets and associated attributes to `filename` in one operation. Each data set and attribute must have an associated `details` structure.

`hdf5write(filename,...,'WriteMode',mode,...)` specifies whether `hdf5write` overwrites the existing file (the default) or appends data sets and attributes to the file. Possible values for mode are `'overwrite'` and `'append'`.

`hdf5write(..., 'V71Dimensions', BOOL)` specifies whether to change the majority of data sets written to the file. If `BOOL` is true, `hdf5write` permutes the first two dimensions of the data set, as it did in previous releases (MATLAB 7.1 [R14SP3] and earlier). This behavior was intended to account for the difference in how HDF5 and MATLAB express array dimensions. HDF5 describes data set dimensions in row-major order; MATLAB stores data in column-major order. However, permuting these dimensions may not correctly reflect the intent of the data and may invalidate metadata. When `BOOL` is false (the default), the data written to the file correctly reflects the data ordering of the data sets — each dimension in the file's data sets matches the same dimension in the corresponding MATLAB variable.

Data Type Mappings

The following table lists how `hdf5write` maps the data type from the workspace into an HDF5 file. If the data in the workspace that is being written to the file is a MATLAB data type, `hdf5write` uses the following rules when translating MATLAB data into HDF5 data objects.

MATLAB Data Type	HDF5 Data Set or Attribute
Numeric	Corresponding HDF5 native data type. For example, if the workspace data type is `uint8`, the `hdf5write` function writes the data to the file as 8-bit integers. The size of the HDF5 dataspace is the same size as the MATLAB array.
String	Single, null-terminated string
Cell array of strings	Multiple, null-terminated strings, each the same length. Length is determined by the length of the longest string in the cell array. The size of the HDF5 dataspace is the same size as the cell array.
Cell array of numeric data	Numeric array, the same dimensions as the cell array. The elements of the array must all have the same size and type. The data type is determined by the first element in the cell array.
Structure array	HDF5 compound type. Individual fields in the structure employ the same data translation rules for individual data types. For example, a cell array of strings becomes a multiple, null-terminated strings.
HDF5 objects	If the data being written to the file is composed of HDF5 objects, `hdf5write` uses the same data type when writing to the file. For all HDF5 objects, except `HDF5.h5enum` objects, the dataspace has the same dimensions as the array of HDF5 objects passed to the function. For `HDF5.h5enum` objects, the size and dimensions of the data set in the HDF5 file is the same as the object's Data field.

Examples

Write a 5-by-5 data set of `uint8` values to the root group.

```
hdf5write('myfile.h5', '/dataset1', uint8(magic(5)))
```

Write a 2-by-2 string data set in a subgroup.

```
dataset = {'north', 'south'; 'east', 'west'};
hdf5write('myfile2.h5', '/group1/dataset1.1', dataset);
```

Write a data set and attribute to an existing group.

```
dset = single(rand(10,10));
dset_details.Location = '/group1/dataset1.2';
dset_details.Name = 'Random';

attr = 'Some random data';
attr_details.Name = 'Description';
attr_details.AttachedTo = '/group1/dataset1.2/Random';
attr_details.AttachType = 'dataset';

hdf5write('myfile2.h5', dset_details, dset, ...
           attr_details, attr, 'WriteMode', 'append');
```

Write a data set using objects.

```
dset = hdf5.h5array(magic(5));
hdf5write('myfile3.h5', '/g1/objects', dset);
```

See Also

hdf5, hdf5read, hdf5info

hdfinfo

Purpose

Information about HDF4 or HDF-EOS file

Syntax

```
S = hdfinfo(filename)
S = hdfinfo(filename,mode)
```

Description

`S = hdfinfo(filename)` returns a structure `S` whose fields contain information about the contents of an HDF4 or HDF-EOS file. `filename` is a string that specifies the name of the HDF4 file.

`S = hdfinfo(filename,mode)` reads the file as an HDF4 file, if `mode` is `'hdf'`, or as an HDF-EOS file, if `mode` is `'eos'`. If `mode` is `'eos'`, only HDF-EOS data objects are queried. To retrieve information on the entire contents of a file containing both HDF4 and HDF-EOS objects, `mode` must be `'hdf'`.

Note `hdfinfo` can be used on Version 4.x HDF files or Version 2.x HDF-EOS files. To get information about an HDF5 file, use `hdf5info`.

The set of fields in the returned structure `S` depends on the individual file. Fields that can be present in the `S` structure are shown in the following table.

Mode	Field Name	Description	Return Type
`HDF`	`Attributes`	Attributes of the data set	Structure array
	`Description`	Annotation description	Cell array
	`Filename`	Name of the file	String
	`Label`	Annotation label	Cell array
	`Raster8`	Description of 8-bit raster images	Structure array

Mode	Field Name	Description	Return Type
	`Raster24`	Description of 24-bit raster images	Structure array
	`SDS`	Description of scientific data sets	Structure array
	`Vdata`	Description of Vdata sets	Structure array
	`Vgroup`	Description of Vgroups	Structure array
`EOS`	`Filename`	Name of the file	String
	`Grid`	Grid data	Structure array
	`Point`	Point data	Structure array
	`Swath`	Swath data	Structure array

Those fields in the table above that contain structure arrays are further described in the tables shown below.

Fields Common to Returned Structure Arrays

Structure arrays returned by `hdfinfo` contain some common fields. These are shown in the table below. Not all structure arrays will contain all of these fields.

Field Name	Description	Data Type
`Attributes`	Data set attributes. Contains fields `Name` and `Value`.	Structure array
`Description`	Annotation description	Cell array
`Filename`	Name of the file	String
`Label`	Annotation label	Cell array

Field Name	Description	Data Type
`Name`	Name of the data set	String
`Rank`	Number of dimensions of the data set	Double
`Ref`	Data set reference number	Double
`Type`	Type of HDF or HDF-EOS object	String

Fields Specific to Certain Structures

Structure arrays returned by `hdfinfo` also contain fields that are unique to each structure. These are shown in the tables below.

Fields of the Attribute Structure

Field Name	Description	Data Type
`Name`	Attribute name	String
`Value`	Attribute value or description	Numeric or string

Fields of the Raster8 and Raster24 Structures

Field Name	Description	Data Type
`HasPalette`	`1` (`true`) if the image has an associated palette, otherwise `0` (`false`) (8-bit only)	Logical
`Height`	Height of the image, in pixels	Number
`Interlace`	Interlace mode of the image (24-bit only)	String

Fields of the Raster8 and Raster24 Structures (Continued)

Field Name	Description	Data Type
`Name`	Name of the image	String
`Width`	Width of the image, in pixels	Number

Fields of the SDS Structure

Field Name	Description	Data Type
`DataType`	Data precision	String
`Dims`	Dimensions of the data set. Contains fields `Name`, `DataType`, `Size`, `Scale`, and `Attributes`. `Scale` is an array of numbers to place along the dimension and demarcate intervals in the data set.	Structure array
`Index`	Index of the SDS	Number

Fields of the Vdata Structure

Field Name	Description	Data Type
`DataAttributes`	Attributes of the entire data set. Contains fields `Name` and `Value`.	Structure array
`Class`	Class name of the data set	String
`Fields`	Fields of the Vdata. Contains fields `Name` and `Attributes`.	Structure array

Fields of the Vdata Structure (Continued)

Field Name	Description	Data Type
`NumRecords`	Number of data set records	Double
`IsAttribute`	`1` (`true`) if Vdata is an attribute, otherwise `0` (`false`)	Logical

Fields of the Vgroup Structure

Field Name	Description	Data Type
`Class`	Class name of the data set	String
`Raster8`	Description of the 8-bit raster image	Structure array
`Raster24`	Description of the 24-bit raster image	Structure array
`SDS`	Description of the Scientific Data sets	Structure array
`Tag`	Tag of this Vgroup	Number
`Vdata`	Description of the Vdata sets	Structure array
`Vgroup`	Description of the Vgroups	Structure array

Fields of the Grid Structure

Field Name	Description	Data Type
`Columns`	Number of columns in the grid	Number

Fields of the Grid Structure (Continued)

Field Name	Description	Data Type
`DataFields`	Description of the data fields in each `Grid` field of the grid. Contains fields `Name`, `Rank`, `Dims`, `NumberType`, `FillValue`, and `TileDims`.	Structure array
`LowerRight`	Lower right corner location, in meters	Number
`Origin Code`	Origin code for the grid	Number
`PixRegCode`	Pixel registration code	Number
`Projection`	Projection code, zone code, sphere code, and projection parameters of the grid. Contains fields `ProjCode`, `ZoneCode`, `SphereCode`, and `ProjParam`.	Structure
`Rows`	Number of rows in the grid	Number
`UpperLeft`	Upper left corner location, in meters	Number

Fields of the Point Structure

Field Name	Description	Data Type
`Level`	Description of each level of the point. Contains fields `Name`, `NumRecords`, `FieldNames`, `DataType`, and `Index`.	Structure

Fields of the Swath Structure

Field Name	Description	Data Type
`DataFields`	Data fields in the swath. Contains fields `Name`, `Rank`, `Dims`, `NumberType`, and `FillValue`.	Structure array
`GeolocationFields`	Geolocation fields in the swath. Contains fields `Name`, `Rank`, `Dims`, `NumberType`, and `FillValue`.	Structure array
`IdxMapInfo`	Relationship between indexed elements of the geolocation mapping. Contains fields `Map` and `Size`.	Structure
`MapInfo`	Relationship between data and geolocation fields. Contains fields `Map`, `Offset`, and `Increment`.	Structure

Examples

To retrieve information about the file `example.hdf`,

```
fileinfo = hdfinfo('example.hdf')

fileinfo =
    Filename: 'example.hdf'
         SDS: [1x1 struct]
       Vdata: [1x1 struct]
```

And to retrieve information from this about the scientific data set in `example.hdf`,

```
sds_info = fileinfo.SDS
```

```
sds_info =
       Filename: 'example.hdf'
           Type: 'Scientific Data Set'
           Name: 'Example SDS'
           Rank: 2
       DataType: 'int16'
     Attributes: []
           Dims: [2x1 struct]
          Label: {}
    Description: {}
          Index: 0
```

See Also

hdfread, hdf

Purpose

Read data from HDF4 or HDF-EOS file

Syntax

```
data = hdfread(filename, datasetname)
data = hdfread(hinfo.fieldname)
data = hdfread(...,param1,value1,param2,value2,...)
[data,map] = hdfread(...)
```

Description

`data = hdfread(filename, datasetname)` returns all the data in the data set specified by `datasetname` from the HDF4 or HDF-EOS file specified by `filename`. To determine the name of a data set in an HDF4 file, use the `hdfinfo` function.

Note `hdfread` can be used on Version 4.x HDF files or Version 2.x HDF-EOS files. To read data from and HDF5 file, use `hdf5read`.

`data = hdfread(hinfo.fieldname)` returns all the data in the data set specified by `hinfo.fieldname`, where `hinfo` is the structure returned by the `hdfinfo` function and *`fieldname`* is the name of a field in the structure that relates to a particular type of data set. For example, to read an HDF scientific data set, specify the `SDS` field, as in `hinfo.SDS`. To read HDF V data, specify the `Vdata` field, as in `hinfo.Vdata`. `hdfread` can get the name of the HDF file from these structures.

`data = hdfread(...,param1,value1,param2,value2,...)` returns subsets of the data according to the specified parameter and value pairs. See the tables below to find the valid parameters and values for different types of data sets.

`[data,map] = hdfread(...)` returns the image `data` and the colormap `map` for an 8-bit raster image.

Subsetting Parameters

The following tables show the subsetting parameters that can be used with the `hdfread` function for certain types of HDF4 data. These data types are

- HDF Scientific Data (SD)
- HDF Vdata (V)
- HDF-EOS Grid Data
- HDF-EOS Point Data
- HDF-EOS Swath Data

Note the following:

- If a parameter requires multiple values, the values must be stored in a cell array. For example, the `'Index'` parameter requires three values: `start`, `stride`, and `edge`. Enclose these values in curly braces as a cell array.

  ```
  hdfread(dataset_name, 'Index', {start,stride,edge})
  ```

- All values that are indices are 1-based.

Subsetting Parameters for HDF Scientific Data (SD) Data Sets

When you are working with HDF SD files, `hdfread` supports the parameters listed in this table.

Parameter	Description
'Index'	Three-element cell array, {start,stride,edge}, specifying the location, range, and values to be read from the data set • start — A 1-based array specifying the position in the file to begin reading Default: 1, start at the first element of each dimension. The values specified must not exceed the size of any dimension of the data set. • stride — A 1-based array specifying the interval between the values to read Default: 1, read every element of the data set. • edge — A 1-based array specifying the length of each dimension to read Default: An array containing the lengths of the corresponding dimensions

For example, this code reads the data set Example SDS from the HDF file example.hdf. The 'Index' parameter specifies that hdfread start reading data at the beginning of each dimension, read until the end of each dimension, but only read every other data value in the first dimension.

```
hdfread('example.hdf','Example SDS', ...
                    'Index', {[], [2 1], []})
```

Subsetting Parameters for HDF Vdata Sets

When you are working with HDF Vdata files, hdfread supports these parameters.

Parameter	Description
'Fields'	Text string specifying the name of the data set field to be read from. When specifying multiple field names, use a comma-separated list.
'FirstRecord'	1-based number specifying the record from which to begin reading
'NumRecords'	Number specifying the total number of records to read

For example, this code reads the Vdata set `Example Vdata` from the HDF file `example.hdf`.

```
hdfread('example.hdf', 'Example Vdata', 'FirstRecord', 400,...
        'NumRecords', 50)
```

Subsetting Parameters for HDF-EOS Grid Data

When you are working with HDF-EOS grid data, `hdfread` supports three types of parameters:

- Required parameters
- Optional parameters
- Mutually exclusive parameters — You can only specify one of these parameters in a call to `hdfread`, and you cannot use these parameters in combination with any optional parameter.

Parameter	Description
Required Parameter	
'Fields'	String naming the data set field to be read. You can specify only one field name for a Grid data set.
Mutually Exclusive Optional Parameters	

Parameter	Description
'Index'	Three-element cell array, {start,stride,edge}, specifying the location, range, and values to be read from the data set start — An array specifying the position in the file to begin reading Default: 1, start at the first element of each dimension. The values must not exceed the size of any dimension of the data set. stride — An array specifying the interval between the values to read Default: 1, read every element of the data set. edge — An array specifying the length of each dimension to read Default: An array containing the lengths of the corresponding dimensions
'Interpolate'	Two-element cell array, {longitude,latitude}, specifying the longitude and latitude points that define a region for bilinear interpolation. Each element is an N-length vector specifying longitude and latitude coordinates.
'Pixels'	Two-element cell array, {longitude,latitude}, specifying the longitude and latitude coordinates that define a region. Each element is an N-length vector specifying longitude and latitude coordinates. This region is converted into pixel rows and columns with the origin in the upper left corner of the grid. Note: This is the pixel equivalent of reading a 'Box' region.
'Tile'	Vector specifying the coordinates of the tile to read, for HDF-EOS Grid files that support tiles
Optional Parameters	
'Box'	Two-element cell array, {longitude,latitude}, specifying the longitude and latitude coordinates that define a region. longitude and latitude are each two-element vectors specifying longitude and latitude coordinates.

Parameter	Description
`'Time'`	Two-element cell array, `[start stop]`, where `start` and `stop` are numbers that specify the start and end-point for a period of time
`'Vertical'`	Two-element cell array, `{dimension, range}` `dimension` — String specifying the name of the data set field to be read from. You can specify only one field name for a Grid data set. `range` — Two-element array specifying the minimum and maximum range for the subset. If `dimension` is a dimension name, then `range` specifies the range of elements to extract. If `dimension` is a field name, then `range` specifies the range of values to extract. `'Vertical'` subsetting can be used alone or in conjunction with `'Box'` or `'Time'`. To subset a region along multiple dimensions, vertical subsetting can be used up to eight times in one call to `hdfread`.

For example,

```
hdfread(grid_dataset, 'Fields', fieldname, ...
                'Vertical', {dimension, [min, max]})
```

Subsetting Parameters for HDF-EOS Point Data

When you are working with HDF-EOS Point data, `hdfread` has two required parameters and three optional parameters.

Parameter	Description
Required Parameters	
`'Fields'`	String naming the data set field to be read. For multiple field names, use a comma-separated list.
`'Level'`	1-based number specifying which level to read from in an HDF-EOS Point data set
Optional Parameters	

Parameter	Description
'Box'	Two-element cell array, {longitude,latitude}, specifying the longitude and latitude coordinates that define a region. longitude and latitude are each two-element vectors specifying longitude and latitude coordinates.
'RecordNumbers'	Vector specifying the record numbers to read
'Time'	Two-element cell array, [start stop], where start and stop are numbers that specify the start and endpoint for a period of time

For example,

```
hdfread(point_dataset, 'Fields', {field1, field2}, ...
         'Level', level, 'RecordNumbers', [1:50, 200:250])
```

Subsetting Parameters for HDF-EOS Swath Data

When you are working with HDF-EOS Swath data, hdfread supports three types of parameters:

- Required parameters
- Optional parameters
- Mutually exclusive

You can only use one of the mutually exclusive parameters in a call to hdfread, and you cannot use these parameters in combination with any optional parameter.

Parameter	Description
Required Parameter	
'Fields'	String naming the data set field to be read. You can specify only one field name for a Swath data set.
Mutually Exclusive Optional Parameters	

Parameter	Description
`'Index'`	Three-element cell array, `{start,stride,edge}`, specifying the location, range, and values to be read from the data set • `start` — An array specifying the position in the file to begin reading Default: `1`, start at the first element of each dimension. The values must not exceed the size of any dimension of the data set. • `stride` — An array specifying the interval between the values to read Default: `1`, read every element of the data set. • `edge` — An array specifying the length of each dimension to read Default: An array containing the lengths of the corresponding dimensions
`'Time'`	Three-element cell array, `{start, stop, mode}`, where `start` and `stop` specify the beginning and the endpoint for a period of time, and `mode` is a string defining the criterion for the inclusion of a cross track in a region. The cross track is within a region if any of these conditions is met: • Its midpoint is within the box (`mode='midpoint'`). • Either endpoint is within the box (`mode='endpoint'`). • Any point is within the box (`mode='anypoint'`).
Optional Parameters	

Parameter	Description
`'Box'`	Three-element cell array, `{longitude, latitude, mode}` specifying the longitude and latitude coordinates that define a region. `longitude` and `latitude` are two-element vectors that specify longitude and latitude coordinates. `mode` is a string defining the criterion for the inclusion of a cross track in a region. The cross track is within a region if any of these conditions is met: • Its midpoint is within the box (`mode='midpoint'`). • Either endpoint is within the box (`mode='endpoint'`). • Any point is within the box (`mode='anypoint'`).
`'ExtMode'`	String specifying whether geolocation fields and data fields must be in the same swath (`mode='internal'`), or can be in different swaths (`mode='external'`) Note: `mode` is only used when extracting a time period or a region.
`'Vertical'`	Two-element cell array, `{dimension, range}` • `dimension` is a string specifying either a dimension name or field name to subset the data by. • `range` is a two-element vector specifying the minimum and maximum range for the subset. If `dimension` is a dimension name, then `range` specifies the range of elements to extract. If `dimension` is a field name, then `range` specifies the range of values to extract. `'Vertical'` subsetting can be used alone or in conjunction with `'Box'` or `'Time'`. To subset a region along multiple dimensions, vertical subsetting can be used up to eight times in one call to `hdfread`.

For example,

```
hdfread('example.hdf', swath_dataset, 'Fields', fieldname, ...
```

```
'Time', {start, stop, 'midpoint'})
```

Examples

Example 1

Specify the name of the HDF file and the name of the data set. This example reads a data set named `'Example SDS'` from a sample HDF file.

```
data = hdfread('example.hdf', 'Example SDS')
```

Example 2

Use data returned by `hdfinfo` to specify the data set to read.

1. Call `hdfinfo` to retrieve information about the contents of the HDF file.

```
fileinfo = hdfinfo('example.hdf')
fileinfo =

    Filename: 'N:\toolbox\matlab\demos\example.hdf'
         SDS: [1x1 struct]
       Vdata: [1x1 struct]
```

2. Extract the structure containing information about the particular data set you want to import from the data returned by `hdfinfo`. The example uses the structure in the `SDS` field to retrieve a scientific data set.

```
sds_info = fileinfo.SDS
sds_info =

       Filename: 'N:\toolbox\matlab\demos\example.hdf'
           Type: 'Scientific Data Set'
           Name: 'Example SDS'
           Rank: 2
       DataType: 'int16'
     Attributes: []
           Dims: [2x1 struct]
          Label: {}
```

```
        Description: {}
              Index: 0
```

3 You can pass this structure to `hdfread` to import the data in the data set.

```
data = hdfread(sds_info)
```

Example 3

You can use the information returned by `hdfinfo` to check the size of the data set.

```
sds_info.Dims.Size
ans =
    16
ans =
     5
```

Using the `'index'` parameter with `hdfread`, you can read a subset of the data in the data set. This example specifies a starting index of `[3 3]`, an interval of 1 between values (`[]` meaning the default value of 1), and a length of 10 rows and 2 columns.

```
data = hdfread(sds_info, 'Index', {[3 3],[],[10 2]});

data(:,1)
ans =
     7
     8
     9
    10
    11
    12
    13
    14
    15
    16
```

```
data(:,2)
ans =
     8
     9
    10
    11
    12
    13
    14
    15
    16
    17
```

Example 4

This example uses the `Vdata` field from the information returned by `hdfinfo` to read two fields of the data, `Idx` and `Temp`.

```
info = hdfinfo('example.hdf');

data = hdfread(info.Vdata,...
   'Fields',{'Idx','Temp'})

data =
    [1x10 int16]
    [1x10 int16]

index = data{1,1};
temp = data{2,1};

temp(1:6)
ans =
     0    12     3     5    10    -1
```

See Also

`hdfinfo`, `hdf`

hdftool

Purpose

Browse and import data from HDF4 or HDF-EOS files

Syntax

```
hdftool
hdftool(filename)
h = hdftool(...)
```

Description

`hdftool` starts the HDF Import Tool, a graphical user interface used to browse the contents of HDF4 and HDF-EOS files and import data and subsets of data from these files. To open an HDF4 or HDF-EOS file, select **Open** from the **File** menu. You can open multiple files in the HDF Import Tool by selecting **Open** from the **File** menu.

`hdftool(filename)` opens the HDF4 or HDF-EOS file specified by `filename` in the HDF Import Tool.

`h = hdftool(...)` returns a handle `h` to the HDF Import Tool. To close the tool from the command line, use `close(h)`.

Example

```
hdftool('example.hdf');
```

`hdf`, `hdfinfo`, `hdfread`, `uiimport`

Purpose

Help for MATLAB functions in Command Window

GUI Alternatives

Use the Help browser **Contents** for a product to view **Functions — Alphabetical List** or **Functions — By Category**, or run `doc functionname` to view more extensive help for a function in the Help browser.

Syntax

```
help
help /
help functionname
help modelname.mdl
help toolboxname
help toolboxname/functionname
help classname.methodname
help classname
help syntax
t = help('topic')
```

Description

`help` lists all primary help topics in the Command Window. Each main help topic corresponds to a directory name on the MATLAB search path.

`help /` lists all operators and special characters, along with their descriptions.

`help functionname` displays M-file help, which is a brief description and the syntax for `functionname`, in the Command Window. The output includes a link to `doc functionname`, which displays the reference page in the Help browser, often providing additional information. Output also includes see also links, which display help in the Command Window for related functions. If `functionname` is overloaded, that is, appears in multiple directories on the search path, `help` displays the M-file help for the first `functionname` found on the search path, and displays a hyperlinked list of the overloaded functions and their directories. If `functionname` is also the name of a toolbox, `help` also displays a list of subdirectories and hyperlinked list of functions in the toolbox, as defined in the `Contents.m` file for the toolbox.

`help modelname.mdl` displays the complete description for the MDL-file `modelname` as defined in **Model Properties > Description**. If Simulink is installed, you do not need to specify the `.mdl` extension.

`help toolboxname` displays the `Contents.m` file for the specified directory named `toolboxname`, where `Contents.m` contains a list and corresponding description of M-files in `toolboxname` — see the Remarks topic, "Creating Contents Files for Your Own M-File Directories" on page 2-1530. It is not necessary to give the full pathname of the directory; the last component, or the last several components, are sufficient. If `toolboxname` is also a function name, help also displays the M-file help for the function `toolboxname`.

`help toolboxname/functionname` displays the M-file help for the `functionname` that resides in the `toolboxname` directory. Use this form to get direct help for an overloaded function.

`help classname.methodname` displays help for the method `methodname` of the fully qualified class `classname`. If you do not know the fully qualified class for the method, use `class(obj)`, where `methodname` is of the same class as the object `obj`.

`help classname` displays help for the fully qualified class `classname`.

`help` **`syntax`** displays M-file help describing the syntax used in MATLAB commands and functions.

`t = help('topic')` returns the help text for `topic` as a string, with each line separated by `/n`, where `topic` is any allowable argument for `help`.

Note M-file help displayed in the Command Window uses all uppercase characters for the function and variable names to make them stand out from the rest of the text. When typing function names, however, use lowercase characters. Some functions for interfacing to Java do use mixed case; the M-file help accurately reflects that and you should use mixed case when typing them. For example, the `javaObject` function uses mixed case.

Remarks

To prevent long descriptions from scrolling off the screen before you have time to read them, enter `more on`, and then enter the `help` statement.

Creating Online Help for Your Own M-Files

The MATLAB help system, like MATLAB itself, is highly extensible. You can write help descriptions for your own M-files and toolboxes using the same self-documenting method that MATLAB M-files and toolboxes use.

The `help` function lists all help topics by displaying the first line (the H1 line) of the contents files in each directory on the MATLAB search path. The contents files are the M-files named `Contents.m` within each directory.

Typing `helptopic` , where `topic` is a directory name, displays the comment lines in the `Contents.m` file located in that directory. If a contents file does not exist, `help` displays the H1 lines of all the files in the directory.

Typing `help topic`, where `topic` is a function name, displays help for the function by listing the first contiguous comment lines in the M-file `topic.m`.

Create self-documenting online help for your own M-files by entering text on one or more contiguous comment lines, beginning with the second line of the file (first line if it is a script). For example, the function `soundspeed.m` begins with

```
function c=soundspeed(s,t,p)
% soundspeed computes the speed of sound in water
% where c is the speed of sound in water in m/s

t = 0:.1:35;
```

When you execute `help soundspeed`, MATLAB displays

```
soundspeed computes the speed of sound in water
where c is the speed of sound in water in m/s
```

These lines are the first block of contiguous comment lines. After the first contiguous comment lines, enter an executable statement or blank line, which effectively ends the help section. Any later comments in the M-file do not appear when you type `help` for the function.

The first comment line in any M-file (the H1 line) is special. It should contain the function name and a brief description of the function. The `lookfor` function searches and displays this line, and `help` displays these lines in directories that do not contain a `Contents.m` file. For the `soundspeed` example, the H1 line is

```
% soundspeed computes speed of sound in water
```

Use the "Help Report" to help you create and manage M-file help for your own files.

Creating Contents Files for Your Own M-File Directories

A `Contents.m` file is provided for each M-file directory included with the MATLAB software. If you create directories in which to store your own M-files, it is a good practice to create `Contents.m` files for them, too. Use the "Contents Report" to help you create and maintain your own `Contents.m` files.

Examples

`help close` displays help for the `close` function.

`help database/close` displays help for the `close` function in Database Toolbox.

`help datafeed` displays help for Datafeed Toolbox.

`help database` lists the functions in Database Toolbox and displays help for the `database` function, because there are a function and a toolbox called `database`.

`help general` lists all functions in the directory *`matlabroot`*`/toolbox/matlab/general`. This illustrates how to specify a relative partial pathname rather than a full pathname.

`help f14_dap` displays the description of the Simulink `f14_dap.mdl` model file (Simulink must be installed.).

`t = help('close')` gets help for the function `close` and stores it as a string in `t`.

See Also

`class`, `doc`, `docsearch`, `helpbrowser`, `helpwin`, `lookfor`, `more`, `partialpath`, `path`, `what`, `which`, `whos`

helpbrowser

Purpose

Open Help browser to access all online documentation and demos

GUI Alternatives

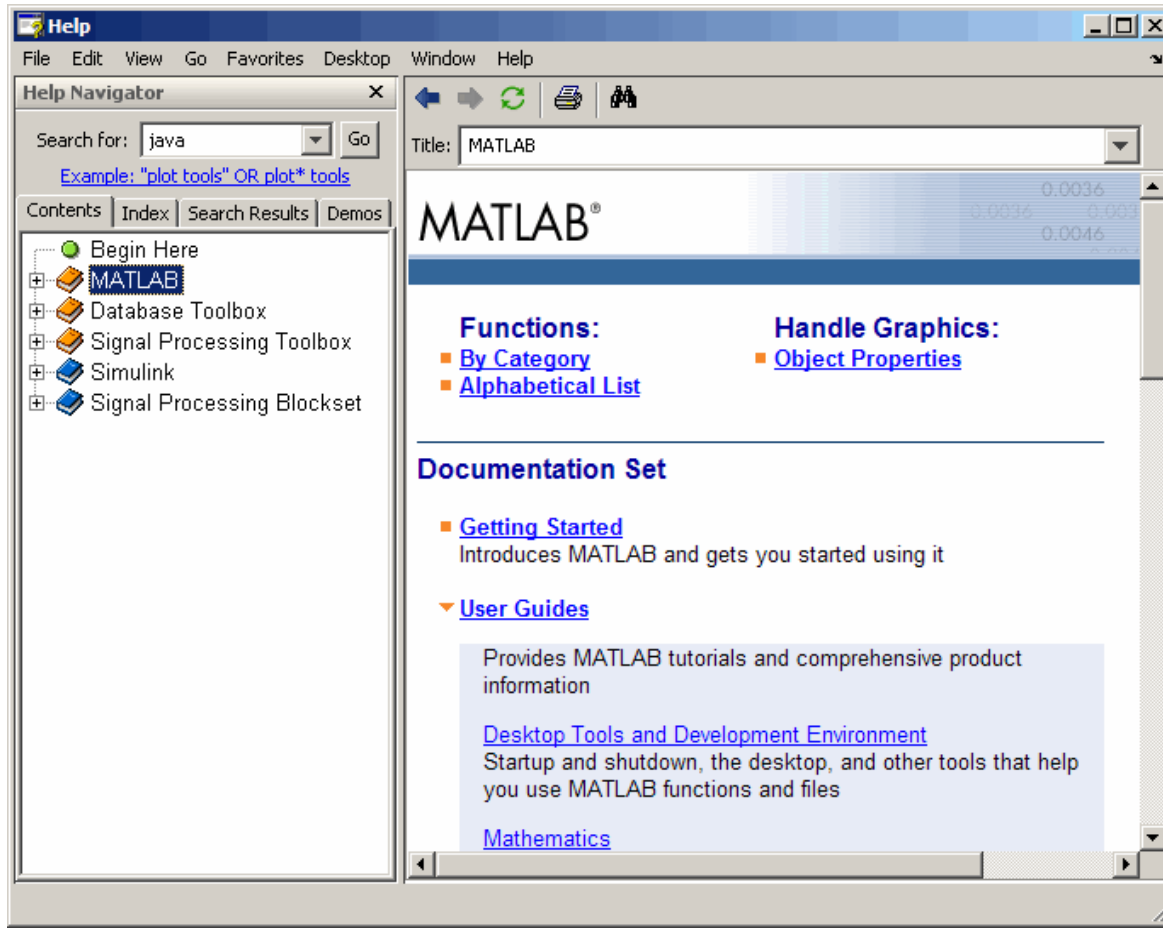
As an alternative to the `helpbrowser` function, select **Desktop > Help** or click the Help button  on the toolbar in the MATLAB desktop.

Syntax

```
helpbrowser
```

Description

`helpbrowser` displays the Help browser, providing direct access to a comprehensive library of online documentation, including reference pages and user guides. If the Help browser was previously opened in the current session, `helpbrowser` shows the last page viewed; otherwise it shows the **Begin Here** page. For details, see the "Help Browser Overview" topic in the MATLAB Desktop Tools and Development Environment documentation.



See Also

`builddocsearchdb`, `doc`, `docopt`, `docsearch`, `help`, `helpdesk`, `helpwin`, `lookfor`, `web`

helpdesk

Purpose

Open Help browser

Syntax

```
helpdesk
```

Description

`helpdesk` displays the Help browser and shows the “Begin Here” page. In previous releases, `helpdesk` displayed the Help Desk, which was the precursor to the Help browser. In a future release, the `helpdesk` function will be phased out — use the `doc` or `helpbrowser` function instead.

See Also

`doc`, `helpbrowser`

Purpose

Create and open help dialog box

Syntax

```
helpdlg
helpdlg('helpstring')
helpdlg('helpstring','dlgname')
h = helpdlg(...)
```

Description

`helpdlg` creates a nonmodal help dialog box or brings the named help dialog box to the front.

Note A nonmodal dialog box enables the user to interact with other windows before responding. For more information, see `WindowStyle` in the MATLAB Figure Properties.

`helpdlg` displays a dialog box named `'Help Dialog'` containing the string `'This is the default help string.'`

`helpdlg('helpstring')` displays a dialog box named `'Help Dialog'` containing the string specified by `'helpstring'`.

`helpdlg('helpstring','dlgname')` displays a dialog box named `'dlgname'` containing the string `'helpstring'`.

`h = helpdlg(...)` returns the handle of the dialog box.

Remarks

MATLAB wraps the text in `'helpstring'` to fit the width of the dialog box. The dialog box remains on your screen until you press the **OK** button or the **Enter** key. After either of these actions, the help dialog box disappears.

Examples

The statement

```
helpdlg('Choose 10 points from the figure','Point Selection');
```

displays this dialog box:

`figure`, `uiwait`, `uiresume`

“Predefined Dialog Boxes” on page 1-104 for related functions

Purpose

Provide access to M-file help for all functions

Syntax

```
helpwin
helpwin topic
```

Description

`helpwin` lists topics for groups of functions in the Help browser. It shows brief descriptions of the topics and provides links to display M-file help for the functions in the Help browser. You cannot follow links in the `helpwin` list of functions if MATLAB is busy (for example, running a program).

`helpwin topic` displays help information for the topic in the Help browser. If `topic` is a directory, it displays all functions in the directory. If `topic` is a function, `helpwin` displays M-file help for that function in the Help browser. From the page, you can access a list of directories (**Default Topics** link) as well as the reference page help for the function (**Go to online doc** link). You cannot follow links in the `helpwin` list of functions if MATLAB is busy (for example, running a program).

Examples

Typing

```
helpwin datafun
```

displays the functions in the `datafun` directory and a brief description of each.

Typing

```
helpwin fft
```

displays the M-file help for the `fft` function in the Help browser.

`doc`, `docopt`, `help`, `helpbrowser`, `lookfor`, `web`

hess

Purpose

Hessenberg form of matrix

Syntax

```
H = hess(A)
[P,H] = hess(A)
[AA,BB,Q,Z] = HESS(A,B)
```

Description

`H = hess(A)` finds `H`, the Hessenberg form of matrix `A`.

`[P,H] = hess(A)` produces a Hessenberg matrix `H` and a unitary matrix `P` so that `A = P*H*P'` and `P'*P = eye(size(A))` .

`[AA,BB,Q,Z] = HESS(A,B)` for square matrices `A` and `B`, produces an upper Hessenberg matrix `AA`, an upper triangular matrix `BB`, and unitary matrices `Q` and `Z` such that `Q*A*Z = AA` and `Q*B*Z = BB`.

Definition

A Hessenberg matrix is zero below the first subdiagonal. If the matrix is symmetric or Hermitian, the form is tridiagonal. This matrix has the same eigenvalues as the original, but less computation is needed to reveal them.

Examples

`H` is a 3-by-3 eigenvalue test matrix:

```
H =
   -149    -50   -154
    537    180    546
    -27     -9    -25
```

Its Hessenberg form introduces a single zero in the (3,1) position:

```
hess(H) =
   -149.0000    42.2037   -156.3165
   -537.6783   152.5511   -554.9272
           0     0.0728      2.4489
```

Algorithm

Inputs of Type Double

For inputs of type double, `hess` uses the following LAPACK routines to compute the Hessenberg form of a matrix:

Matrix A	Routine
Real symmetric	DSYTRD DSYTRD, DORGTR, (with output P)
Real nonsymmetric	DGEHRD DGEHRD, DORGHR (with output P)
Complex Hermitian	ZHETRD ZHETRD, ZUNGTR (with output P)
Complex non-Hermitian	ZGEHRD ZGEHRD, ZUNGHR (with output P)

Inputs of Type Single

For inputs of type `single`, `hess` uses the following LAPACK routines to compute the Hessenberg form of a matrix:

Matrix A	Routine
Real symmetric	SSYTRD SSYTRD, DORGTR, (with output P)
Real nonsymmetric	SGEHRD SGEHRD, SORGHR (with output P)
Complex Hermitian	CHETRD CHETRD, CUNGTR (with output P)
Complex non-Hermitian	CGEHRD CGEHRD, CUNGHR (with output P)

References

Anderson, E., Z. Bai, C. Bischof, S. Blackford, J. Demmel, J. Dongarra, J. Du Croz, A. Greenbaum, S. Hammarling,

A. McKenney, and D. Sorensen, *LAPACK User's Guide* (`http://www.netlib.org/lapack/lug/lapack_lug.html`), Third Edition, SIAM, Philadelphia, 1999.

Purpose

Convert hexadecimal number string to decimal number

Syntax

```
d = hex2dec('hex_value')
```

Description

`d = hex2dec('hex_value')` converts *`hex_value`* to its floating-point integer representation. The argument *`hex_value`* is a hexadecimal integer stored in a MATLAB string. The value of *`hex_value`* must be smaller than hexadecimal `10,000,000,000,000`.

If *`hex_value`* is a character array, each row is interpreted as a hexadecimal string.

Examples

```
hex2dec('3ff')

ans =

        1023
```

For a character array `S`,

```
S =
0FF
2DE
123
hex2dec(S)

ans =

255
734
291
```

See Also

`dec2hex`, `format`, `hex2num`, `sprintf`

hex2num

Purpose

Convert hexadecimal number string to double-precision number

Syntax

```
n = hex2num(S)
```

Description

`n = hex2num(S)`, where `S` is a 16 character string representing a hexadecimal number, returns the IEEE double-precision floating-point number `n` that it represents. Fewer than 16 characters are padded on the right with zeros. If `S` is a character array, each row is interpreted as a double-precision number.

`NaN`s, infinities and denorms are handled correctly.

Example

```
hex2num('400921fb54442d18')
```

returns `Pi`.

```
hex2num('bff')
```

returns

```
ans =

    -1
```

See Also

`num2hex`, `hex2dec`, `sprintf`, `format`

Purpose

Export figure

GUI Alternative

Use the **File —> Saveas** on the figure window menu to access the **Export Setup** GUI. Use **Edit —> Copy Figure** to copy the figure's contents to your system's clipboard. For details, see How to Print or Export in the MATLAB Graphics documentation.

Syntax

```
hgexport(h,filename)
hgexport(h,'-clipboard')
```

Description

`hgexport(h,filename)` writes figure `h` to the file `filename`.

`hgexport(h,'-clipboard')` writes figure `h` to the Windows clipboard.

The format in which the figure is exported is determined by which renderer you use. The Painters renderer generates a metafile. The ZBuffer and OpenGL renderers generate a bitmap.

See Also

`print`

hggroup

Purpose

Create hggroup object

Syntax

Description

An hggroup object can be the parent of any axes children except light objects, as well as other hggroup objects. You can use hggroup objects to form a group of objects that can be treated as a single object with respect to the following cases:

- Visible — Setting the hggroup object's `Visible` property also sets each child object's `Visible` property to the same value.
- Selectable — Setting each hggroup child object's `HitTest` property to `off` enables you to select all children by clicking any child object.
- Current object — Setting each hggroup child object's `HitTest` property to `off` enables the hggroup object to become the current object when any child object is picked. See the next section for an example.

Examples

This example defines a callback for the `ButtonDownFcn` property of an hggroup object. In order for the hggroup to receive the mouse button down event that executes the `ButtonDownFcn` callback, the `HitTest` properties of all the line objects must be set to `off`. The event is then passed up the hierarchy to the hggroup.

The following function creates a random set of lines that are parented to an hggroup object. The subfunction `set_lines` defines a callback that executes when the mouse button is pressed over any of the lines. The callback simply increases the widths of all the lines by 1 with each button press.

Note If you are using the MATLAB help browser, you can run this example or open it in the MATLAB editor.

```
function doc_hggroup
```

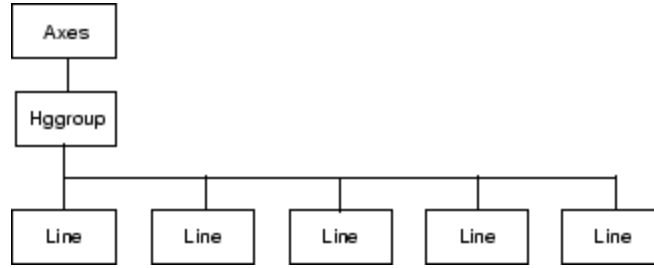
```
hg = hggroup('ButtonDownFcn',@set_lines);
hl  = line(randn(5),randn(5),'HitTest','off','Parent',hg);

function set_lines(cb,eventdata)
hl = get(cb,'Children');% cb is handle of hggroup object
lw = get(hl,'LineWidth');% get current line widths
set(hl,{'LineWidth'},num2cell([lw{:}]+1,[5,1])')
```

Note that selecting any one of the lines selects all the lines. (To select an object, enable plot edit mode by selecting **Plot Edit** from the **Tools** menu.)

Instance Diagram for This Example

The following diagram shows the object hierarchy created by this example.



Hggroup Properties

Setting Default Properties

You can set default hggroup properties on the axes, figure, and root levels.

```
set(0,'DefaultHggroup<i>Property</i>',PropertyValue...)
set(gcf,'DefaultHggroup<i>Property</i>',PropertyValue...)
set(gca,'DefaultHggroup<i>Property</i>',PropertyValue...)
```

where *`Property`* is the name of the `hggroup` property whose default value you want to set and `PropertyValue` is the value you are specifying. Use `set` and `get` to access the hggroup properties.

`Hggroup Properties` for property descriptions

Purpose

Hggroup properties

Modifying Properties

You can set and query graphics object properties using the `set` and `get` commands.

To change the default values of properties, see "Setting Default Property Values".

See "Group Objects" for general information on this type of object.

Hggroup Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

`Annotation`

`hg.Annotation` object Read Only

Control the display of hggroup objects in legends. The `Annotation` property enables you to specify whether this hggroup object is represented in a figure legend.

Querying the `Annotation` property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the hggroup object is displayed in a figure legend:

IconDisplayStyle Value	Purpose
`on`	Include the hggroup object in a legend as one entry, but not its children objects

IconDisplayStyle Value	Purpose
`off`	Do not include the hggroup or its children in a legend (default)
`children`	Include only the children of the hggroup as separate entries in the legend

Setting the `IconDisplayStyle` property

These commands set the `IconDisplayStyle` of a graphics object with handle `hobj` to `children`, which causes each child object to have an entry in the legend:

```
hAnnotation = get(hobj,'Annotation');
hLegendEntry = get(hAnnotation','LegendInformation');
set(hLegendEntry,'IconDisplayStyle','children')
```

Using the `IconDisplayStyle` property

See “Controlling Legends” for more information and examples.

`BeingDeleted`
`on | {off}` Read Only

This object is being deleted. The `BeingDeleted` property provides a mechanism that you can use to determine whether objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object’s delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the `delete` function executes, after which the object no longer exists.

For example, an object’s delete function might call other functions that act on a number of different objects. These functions might not need to perform actions on objects if the objects are going to be deleted, and therefore can check the object’s `BeingDeleted` property before acting.

`BusyAction`

`cancel | {queue}`

Callback routine interruption. The `BusyAction` property enables you to control how MATLAB handles events that potentially interrupt executing callbacks. If there is a callback function executing, callbacks invoked subsequently always attempt to interrupt it.

If the `Interruptible` property of the object whose callback is executing is set to `on` (the default), then interruption occurs at the next point where the event queue is processed. If the `Interruptible` property is `off`, the `BusyAction` property (of the object owning the executing callback) determines how MATLAB handles the event. The choices are

- `cancel` — Discard the event that attempted to execute a second callback routine.
- `queue` — Queue the event that attempted to execute a second callback routine until the current callback finishes.

`ButtonDownFcn`

functional handle, cell array containing function handle and additional arguments, or string (not recommended)

Button press callback function. A callback function that executes whenever you press a mouse button while the pointer is over the children of the hggroup object. Define the `ButtonDownFcn` as a function handle. The function must define at least two input arguments (handle of figure associated with the mouse button press and an empty event structure).

See “Function Handle Callbacks” for information on how to use function handles to define the callbacks.

`Children`

array of graphics object handles

Children of the hggroup object. An array containing the handles of all objects parented to the hggroup object (whether visible or not).

Note that if a child object's `HandleVisibility` property is set to `callback` or `off`, its handle does not appear in the hggroup `Children` property unless you set the Root `ShowHiddenHandles` property to `on`:

```
set(0,'ShowHiddenHandles','on')
```

`Clipping`
`{on} | off`

Clipping mode. MATLAB clips stairs plots to the axes plot box by default. If you set `Clipping` to `off`, lines might be displayed outside the axes plot box.

`CreateFcn`
functional handle, cell array containing function handle and additional arguments, or string (not recommended)

Callback executed during object creation. This property defines a callback function that executes when MATLAB creates an hggroup object. You must define this property as a default value for hggroup objects or in a call to the `hggroup` function to create a new hggroup object. For example, the statement

```
set(0,'DefaulthggroupCreateFcn',@myCreateFcn)
```

defines a default value on the root level that applies to every hggroup object created in that MATLAB session. Whenever you create an hggroup object, the function associated with the function handle `@myCreateFcn` executes.

MATLAB executes the callback after setting all the hggroup object's properties. Setting the `CreateFcn` property on an existing hggroup object has no effect.

The handle of the object whose `CreateFcn` is being executed is passed by MATLAB as the first argument to the callback function and is also accessible through the root `CallbackObject` property, which you can query using `gcbo`.

See Function Handle Callbacks for information on how to use function handles to define the callback function.

`DeleteFcn`

functional handle, cell array containing function handle and additional arguments, or string (not recommended)

Callback executed during object deletion. A callback function that executes when the hggroup object is deleted (e.g., this might happen when you issue a `delete` command on the hggroup object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object's properties so the callback routine can query these values.

The handle of the object whose `DeleteFcn` is being executed is passed by MATLAB as the first argument to the callback function and is accessible through the root `CallbackObject` property, which you can query using `gcbo`.

See "Function Handle Callbacks" for information on how to use function handles to define the callback function.

See the `BeingDeleted` property for related information.

`DisplayName`

string (default is empty string)

String used by legend for this hggroup object. The `legend` function uses the string defined by the `DisplayName` property to label this hggroup object in the legend.

- If you specify string arguments with the `legend` function, `DisplayName` is set to this hggroup object's corresponding string and that string is used for the legend.
- If `DisplayName` is empty, legend creates a string of the form, `['data' n]`, where *n* is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, `DisplayName` is set to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add programmatically a legend that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See "Controlling Legends" for more examples.

`EraseMode`

`{normal} | none | xor | background`

Erase mode. This property controls the technique MATLAB uses to draw and erase hggroup child objects. Alternative erase modes are useful for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to ensure that all objects are rendered correctly. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- `none` — Do not erase objects when they are moved or destroyed. While the objects are still visible on the screen after erasing

with `EraseMode` `none`, you cannot print these objects because MATLAB stores no information about their former locations.

- `xor` — Draw and erase the object by performing an exclusive OR (XOR) with each pixel index of the screen behind it. Erasing the object does not damage the color of the objects behind it. However, the color of the erased object depends on the color of the screen behind it and it is correctly colored only when it is over the axes background color (or the figure background color if the axes `Color` property is set to `none`). That is, it isn't erased correctly if there are objects behind it.
- `background` — Erase the graphics objects by redrawing them in the axes background color, (or the figure background color if the axes `Color` property is set to `none`). This damages other graphics objects that are behind the erased object, but the erased object is always properly colored.

Set the axes background color with the axes `Color` property. Set the figure background color with the figure `Color` property.

Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB may mathematically combine layers of colors (e.g., performing an XOR of a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the MATLAB `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

```
HandleVisibility
     {on} | callback | off
```

Control access to object's handle by command-line users and GUIs. This property determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally accessing the hggroup object.

- `on` — Handles are always visible when `HandleVisibility` is `on`.
- `callback` — Setting `HandleVisibility` to `callback` causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Setting `HandleVisibility` to `off` makes handles invisible at all times. This might be necessary when a callback invokes a function that might potentially damage the GUI (such as evaluating a user-typed string) and so temporarily hides its own handles during the execution of that function.

Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Properties Affected by Handle Visibility

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

Overriding Handle Visibility

You can set the root ShowHiddenHandles property to on to make all handles visible regardless of their HandleVisibility settings (this does not affect the values of the HandleVisibility properties). See also findall.

Handle Validity

Handles that are hidden are still valid. If you know an object's handle, you can set and get its properties, and pass it to any function that operates on handles.

HitTest

{on} | off

Pickable by mouse click. HitTest determines whether the hggroup object can become the current object (as returned by the gco command and the figure CurrentObject property) as a result of a mouse click on the hggroup child objects. Note that to pick the hggroup object, its children must have their HitTest property set to off.

If the hggroup object's HitTest is off, clicking it picks the object behind it.

Interruptible

{on} | off

Callback routine interruption mode. The Interruptible property controls whether an hggroup object callback can be interrupted by callbacks invoked subsequently.

Only callbacks defined for the ButtonDownFcn property are affected by the Interruptible property. MATLAB checks for events that can interrupt a callback only when it encounters a drawnow, figure, getframe, or pause command in the routine. See the BusyAction property for related information.

Setting `Interruptible` to `on` allows any graphics object's callback to interrupt callback routines originating from an hggroup property. Note that MATLAB does not save the state of variables or the display (e.g., the handle returned by the `gca` or `gcf` command) when an interruption occurs.

`Parent`
axes handle

Parent of hggroup object. This property contains the handle of the hggroup object's parent object. The parent of an hggroup object is the axes, hggroup, or hgtransform object that contains it.

See "Objects That Can Contain Other Objects" for more information on parenting graphics objects.

`Selected`
`on | {off}`

Is object selected? When you set this property to `on`, MATLAB displays selection handles at the corners and midpoints of hggroup child objects if the `SelectionHighlight` property is also `on` (the default).

`SelectionHighlight`
`{on} | off`

Objects are highlighted when selected. When the `Selected` property is `on`, MATLAB indicates the selected state by drawing selection handles on the hggroup child objects. When `SelectionHighlight` is `off`, MATLAB does not draw the handles.

`Tag`
string

User-specified object label. The `Tag` property provides a means to identify graphics objects with a user-specified label. This is particularly useful when you are constructing interactive graphics

programs that would otherwise need to define object handles as global variables or pass them as arguments between callbacks.

For example, you might create an hggroup object and set the `Tag` property:

```
t = hggroup('Tag','group1')
```

When you want to access the object, you can use `findobj` to find its handle. For example,

```
h = findobj('Tag','group1');
```

`Type`

string (read only)

Type of graphics object. This property contains a string that identifies the class of graphics object. For hggroup objects, `Type` is `'hggroup'`. The following statement finds all the hggroup objects in the current axes.

```
t = findobj(gca,'Type','hggroup');
```

`UIContextMenu`

handle of a uicontextmenu object

Associate a context menu with the hggroup object. Assign this property the handle of a uicontextmenu object created in the hggroup object's figure. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click the hggroup object.

`UserData`

array

User-specified data. This property can be any data you want to associate with the hggroup object (including cell arrays and structures). The hggroup object does not set values for this property, but you can access it using the `set` and `get` functions.

`Visible`

`{on} | off`

Visibility of hggroup object and its children. By default, hggroup object visibility is `on`. This means all children of the hggroup are visible unless the child object's `Visible` property is set to `off`. Setting an hggroup object's `Visible` property to `off` also makes its children invisible.

Purpose

Load Handle Graphics object hierarchy from file

GUI Alternative

Use the **File —> Open** on the figure window menu to access figure files with the **Open** dialog.

Syntax

```
h = hgload('filename')
[h,old_prop_values] = hgload(...,property_structure)
hgload(...,'all')
```

Description

`h = hgload('filename')` loads Handle Graphics objects and its children if any from the FIG-file specified by `filename` and returns handles to the top-level objects. If `filename` contains no extension, then MATLAB adds the `.fig` extension.

`[h,old_prop_values] = hgload(...,property_structure)` overrides the properties on the top-level objects stored in the FIG-file with the values in `property_structure`, and returns their previous values in `old_prop_values`.

`property_structure` must be a structure having field names that correspond to property names and values that are the new property values.

`old_prop_values` is a cell array equal in length to `h`, containing the old values of the overridden properties for each object. Each cell contains a structure having field names that are property names, each of which contains the original value of each property that has been changed. Any property specified in `property_structure` that is not a property of a top-level object in the FIG-file is not included in `old_prop_values`.

`hgload(...,'all')` overrides the default behavior, which does not reload nonserializable objects saved in the file. These objects include the default toolbars and default menus.

Nonserializable objects (such as the default toolbars and the default menus) are normally not reloaded because they are loaded from different files at figure creation time. This allows revisions of the default menus and toolbars to occur without affecting existing FIG-files.

Passing the string `all` to `hgload` ensures that any nonserializable objects contained in the file are also reloaded.

Note that, by default, `hgsave` excludes nonserializable objects from the FIG-file unless you use the `all` flag.

See Also

`hgsave`, `open`

"Figure Windows" on page 1-95 for related functions

Purpose

Save Handle Graphics object hierarchy to file

GUI Alternative

Use the **File —> Saveas** on the figure window menu to access the Export Setup GUI. For details, see How to Print or Export in the MATLAB Graphics documentation.

Syntax

```
hgsave('filename')
hgsave(h,'filename')
hgsave(...,'all')
hgsave(...,'-v6')
```

Description

`hgsave('filename')` saves the current figure to a file named `filename`.

`hgsave(h,'filename')` saves the objects identified by the array of handles `h` to a file named `filename`. If you do not specify an extension for `filename`, then MATLAB adds the extension `.fig`. If `h` is a vector, none of the handles in `h` may be ancestors or descendents of any other handles in `h`.

`hgsave(...,'all')` overrides the default behavior, which does not save nonserializable objects. Nonserializable objects include the default toolbars and default menus. This allows revisions of the default menus and toolbars to occur without affecting existing FIG-files and also reduces the size of FIG-files. Passing the string `all` to `hgsave` ensures that nonserializable objects are also saved.

Note: the default behavior of `hgload` is to ignore nonserializable objects in the file at load time. This behavior can be overwritten using the `all` argument with `hgload`.

`hgsave(...,'-v6')` saves the FIG-file in a format that can be loaded by versions prior to MATLAB 7.

Full Backward Compatibility

When creating a figure you want to save and use in a MATLAB version prior to MATLAB 7, use the `'v6'` option with the plotting function and the `'-v6'` option for `hgsave`. Check the reference page for the plotting function you are using for more information.

See “Plot Objects and Backward Compatibility” for more information.

See Also

`hgload`, `open`, `save`

“Figure Windows” on page 1-95 for related functions

Purpose

Create hgtransform graphics object

Syntax

```
h = hgtransform
h = hgtransform('PropertyName',propertyvalue,...)
```

Description

`h = hgtransform` creates an hgtransform object and returns its handle.

`h = hgtransform('PropertyName',propertyvalue,...)` creates an hgtransform object with the property value settings specified in the argument list.

Hgtransform objects can contain other objects and thereby enable you to treat the hgtransform and its children as a single entity with respect to visibility, size, orientation, etc. You can group objects together by parenting them to a single hgtransform object (i.e., setting the object's `Parent` property to the hgtransform object's handle). For example,

```
h = hgtransform;
surface('Parent',h,...)
```

The primary advantage of parenting objects to an hgtransform object is that it provides the ability to perform *transforms* (e.g., translation, scaling, rotation, etc.) on the child objects in unison.

The parent of an hgtransform object is either an axes object or another hgtransform.

Although you cannot see an hgtransform object, setting its `Visible` property to `off` makes all its children invisible as well.

Exceptions and Limitations

- An hgtransform object can be the parent of any number axes children objects belonging to the same axes, with the exception of light objects.
- hgtransform objects can never be the parent of axes objects and therefore can contain objects only from a single axes.
- hgtransform objects can be the parent of other hgtransform objects within the same axes.

- You cannot transform image objects because images are not true 3-D objects. Texture mapping the image data to a surface `CData` enables you to produce the effect of transforming an image in 3-D space.

Note Many plotting functions clear the axes (i.e., remove axes children) before drawing the graph. Clearing the axes also deletes any hgtransform objects in the axes.

More Information

- The references in the "See Also" on page 2-1568 section for information on types of transforms
- The "Examples" on page 2-1564 section provides examples that illustrate the use of transforms.

Examples

Transforming a Group of Objects

This example shows how to create a 3-D star with a group of surface objects parented to a single hgtransform object. The hgtransform object is then rotated about the *z*-axis while its size is scaled.

Note If you are using the MATLAB help browser, you can run this example or open it in the MATLAB editor.

---

1 Create an axes and adjust the view. Set the axes limits to prevent auto limit selection during scaling.

```
ax = axes('XLim',[-1.5 1.5],'YLim',[-1.5 1.5],...
 'ZLim',[-1.5 1.5]);
view(3); grid on; axis equal
```

2 Create the objects you want to parent to the hgtransform object.

```
[x y z] = cylinder([.2 0]);
```

```
h(1) = surface(x,y,z,'FaceColor','red');
h(2) = surface(x,y,-z,'FaceColor','green');
h(3) = surface(z,x,y,'FaceColor','blue');
h(4) = surface(-z,x,y,'FaceColor','cyan');
h(5) = surface(y,z,x,'FaceColor','magenta');
h(6) = surface(y,-z,x,'FaceColor','yellow');
```

3 Create an hgtransform object and parent the surface objects to it.

```
t = hgtransform('Parent',ax);
set(h,'Parent',t)
```

4 Select a renderer and show the objects.

```
set(gcf,'Renderer','opengl')
drawnow
```

5 Initialize the rotation and scaling matrix to the identity matrix (`eye`).

```
Rz = eye(4);
Sxy = Rz;
```

6 Form the *z*-axis rotation matrix and the scaling matrix. Rotate 360 degrees (2*pi radians) and scale by using the increasing values of r.

```
for r = 1:.1:2*pi
 % Z-axis rotation matrix
 Rz = makehgtform('zrotate',r);
 % Scaling matrix
 Sxy = makehgtform('scale',r/4);
 % Concatenate the transforms and
 % set the hgtransform Matrix property
    set(t,'Matrix',Rz*Sxy)
    drawnow
end
pause(1)
```

7 Reset to the original orientation and size using the identity matrix.

```
set(t,'Matrix',eye(4))
```

Transforming Objects Independently

This example creates two hgtransform objects to illustrate how each can be transformed independently within the same axes. One of the hgtransform objects has been moved (by translation) away from the origin.

Note If you are using the MATLAB help browser, you can run this example or open it in the MATLAB editor.

---

1. Create and set up the axes object that will be the parent of both hgtransform objects. Set the limits to accommodate the translated object.

```
ax = axes('XLim',[-2 1],'YLim',[-2 1],'ZLim',[-1 1]);
view(3); grid on; axis equal
```

2. Create the surface objects to group.

```
[x y z] = cylinder([.3 0]);
h(1) = surface(x,y,z,'FaceColor','red');
h(2) = surface(x,y,-z,'FaceColor','green');
h(3) = surface(z,x,y,'FaceColor','blue');
h(4) = surface(-z,x,y,'FaceColor','cyan');
h(5) = surface(y,z,x,'FaceColor','magenta');
h(6) = surface(y,-z,x,'FaceColor','yellow');
```

3. Create the hgtransform objects and parent them to the same axes.

```
t1 = hgtransform('Parent',ax);
t2 = hgtransform('Parent',ax);
```

4. Set the renderer to use OpenGL.

```
set(gcf,'Renderer','opengl')
```

5 Parent the surfaces to hgtransform `t1`, then copy the surface objects and parent the copies to hgtransform `t2`.

```
set(h,'Parent',t1)
h2 = copyobj(h,t2);
```

6 Translate the second hgtransform object away from the first hgtransform object and display the result.

```
Txy = makehgtform('translate',[-1.5 -1.5 0]);
set(t2,'Matrix',Txy)
drawnow
```

7 Rotate both hgtransform objects in opposite directions. Hgtransform `t2` has already been translated away from the origin, so to rotate it about its *z*-axis you must first translate it to its original position. You can do this with the identity matrix (`eye`).

```
% rotate 10 times (2pi radians = 1 rotation)
for r = 1:.1:20*pi
 % Form z-axis rotation matrix
 Rz = makehgtform('zrotate',r);
 % Set transforms for both hgtransform objects
 set(t1,'Matrix',Rz)
 set(t2,'Matrix',Txy*inv(Rz)*I)
 drawnow
end
```

Setting Default Properties

You can set default hgtransform properties on the axes, figure, and root levels:

```
set(0,'DefaultHgtransform*PropertyName*',propertyvalue,...)
set(gcf,'DefaultHgtransform*PropertyName*',propertyvalue,...)
set(gca,'DefaultHgtransform*PropertyName*',propertyvalue,...)
```

where *`PropertyName`* is the name of the hgtransform property and `propertyvalue` is the value you are specifying. Use `set` and `get` to access hgtransform properties.

"Group Objects" for more information and examples.

`Hgtransform Properties` for property descriptions

Purpose

Hgtransform properties

Modifying Properties

You can set and query graphics object properties using the `set` and `get` commands.

To change the default values of properties, see “Setting Default Property Values”.

See “Group Objects” for general information on this type of object.

Hgtransform Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

`Annotation`

`hg.Annotation` object Read Only

Control the display of hgtransform objects in legends. The `Annotation` property enables you to specify whether this hgtransform object is represented in a figure legend.

Querying the `Annotation` property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the hgtransform object is displayed in a figure legend:

IconDisplayStyle Value	Purpose
`on`	Include the hgtransform object in a legend as one entry, but not its children objects

IconDisplayStyle Value	Purpose
`off`	Do not include the hgtransform or its children in a legend (default)
`children`	Include only the children of the hgtransform as separate entries in the legend

Setting the `IconDisplayStyle` property

These commands set the `IconDisplayStyle` of a graphics object with handle `hobj` to `children`, which causes each child object to have an entry in the legend:

```
hAnnotation = get(hobj,'Annotation');
hLegendEntry = get(hAnnotation','LegendInformation');
set(hLegendEntry,'IconDisplayStyle','children')
```

Using the `IconDisplayStyle` property

See “Controlling Legends” for more information and examples.

`BeingDeleted`
`on | {off}` Read Only

This object is being deleted. The `BeingDeleted` property provides a mechanism that you can use to determine whether objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object's delete function might call other functions that act on a number of different objects. These functions might not need to perform actions on objects if the objects are going to be deleted, and therefore can check the object's `BeingDeleted` property before acting.

`BusyAction`

`cancel | {queue}`

Callback routine interruption. The `BusyAction` property enables you to control how MATLAB handles events that potentially interrupt executing callback functions. If there is a callback executing, callbacks invoked subsequently always attempt to interrupt it.

If the `Interruptible` property of the object whose callback is executing is set to `on` (the default), then interruption occurs at the next point where the event queue is processed. If the `Interruptible` property is `off`, the `BusyAction` property (of the object owning the executing callback) determines how MATLAB handles the event. The choices are

- `cancel` — Discard the event that attempted to execute a second callback routine.
- `queue` — Queue the event that attempted to execute a second callback routine until the current callback finishes.

`ButtonDownFcn`

functional handle, cell array containing function handle and additional arguments, or string (not recommended)

Button press callback function. A callback function that executes whenever you press a mouse button while the pointer is within the extent of the hgtransform object, but not over another graphics object. The extent of an hgtransform object is the smallest rectangle that encloses all the children. Note that you cannot execute the hgtransform object's button down function if it has no children.

Define the `ButtonDownFcn` as a function handle. The function must define at least two input arguments (handle of figure associated with the mouse button press and an empty event structure).

See “Function Handle Callbacks” for information on how to use function handles to define the callbacks.

`Children`
array of graphics object handles

Children of the hgtransform object. An array containing the handles of all graphics objects parented to the hgtransform object (whether visible or not).

The graphics objects that can be children of an hgtransform are images, lights, lines, patches, rectangles, surfaces, and text. You can change the order of the handles and thereby change the stacking of the objects on the display.

Note that if a child object's `HandleVisibility` property is set to `callback` or `off`, its handle does not show up in the hgtransform `Children` property unless you set the Root `ShowHiddenHandles` property to `on`.

`Clipping`
`{on} | off`

This property has no effect on hgtransform objects.

`CreateFcn`
functional handle, cell array containing function handle and additional arguments, or string (not recommended)

Callback executed during object creation. This property defines a callback function that executes when MATLAB creates an hgtransform object. You must define this property as a default value for hgtransform objects. For example, the statement

```
set(0,'DefaultHgtransformCreateFcn',@myCreateFcn)
```

defines a default value on the root level that applies to every hgtransform object created in a MATLAB session. Whenever you

create an hgtransform object, the function associated with the function handle `@myCreateFcn` executes.

MATLAB executes the callback after setting all the hgtransform object's properties. Setting the `CreateFcn` property on an existing hgtransform object has no effect.

The handle of the object whose `CreateFcn` is being executed is passed by MATLAB as the first argument to the callback function and is accessible through the root `CallbackObject` property, which you can query using `gcbo`.

See "Function Handle Callbacks" for information on how to use function handles to define the callback function.

`DeleteFcn`

functional handle, cell array containing function handle and additional arguments, or string (not recommended)

Callback executed during object deletion. A callback function that executes when the hgtransform object is deleted (e.g., this might happen when you issue a `delete` command on the hgtransform object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object's properties so the callback routine can query these values.

The handle of the object whose `DeleteFcn` is being executed is passed by MATLAB as the first argument to the callback function and is accessible through the root `CallbackObject` property, which can be queried using `gcbo`.

See "Function Handle Callbacks" for information on how to use function handles to define the callback function.

See the `BeingDeleted` property for related information.

`DisplayName`

string (default is empty string)

String used by legend for this hgtransform object. The `legend` function uses the string defined by the `DisplayName` property to label this hgtransform object in the legend.

- If you specify string arguments with the `legend` function, `DisplayName` is set to this hgtransform object's corresponding string and that string is used for the legend.
- If `DisplayName` is empty, legend creates a string of the form, `['data' n]`, where *n* is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, `DisplayName` is set to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add programmatically a legend that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See "Controlling Legends" for more examples.

`EraseMode`

`{normal} | none | xor | background`

Erase mode. This property controls the technique MATLAB uses to draw and erase hgtransform child objects (light objects have no erase mode). Alternative erase modes are useful for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to ensure that all objects are rendered correctly. This mode produces the most accurate picture, but is the slowest. The other modes are faster,

but do not perform a complete redraw and are therefore less accurate.

- `none` — Do not erase objects when they are moved or destroyed. While the objects are still visible on the screen after erasing with `EraseMode none`, you cannot print these objects because MATLAB stores no information about their former locations.
- `xor`— Draw and erase the object by performing an exclusive OR (XOR) with each pixel index of the screen behind it. Erasing the object does not damage the color of the objects behind it. However, the color of the erased object depends on the color of the screen behind it and it is correctly colored only when it is over the axes background color (or the figure background color if the axes `Color` property is set to `none`). That is, it isn't erased correctly if there are objects behind it.
- `background` — Erase the graphics objects by redrawing them in the axes background color, (or the figure background color if the axes `Color` property is set to `none`). This damages other graphics objects that are behind the erased object, but the erased object is always properly colored.

  Set the axes background color with the axes `Color` property. Set the figure background color with the figure `Color` property.

Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB can mathematically combine layers of colors (e.g., performing an XOR operation on a pixel color and the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the MATLAB `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

`HandleVisibility`
`{on} | callback | off`

Control access to object's handle by command-line users and GUIs. This property determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally accessing the hgtransform object.

- `on` — Handles are always visible when `HandleVisibility` is `on`.
- `callback` — Setting `HandleVisibility` to `callback` causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Setting `HandleVisibility` to `off` makes handles invisible at all times. This might be necessary when a callback invokes a function that might potentially damage the GUI (such as evaluating a user-typed string) and so temporarily hides its own handles during the execution of that function.

Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Properties Affected by Handle Visibility

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property,

figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

Overriding Handle Visibility

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings (this does not affect the values of the `HandleVisibility` properties). See also `findall`.

Handle Validity

Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

`HitTest`

```
{on} | off
```

Pickable by mouse click. `HitTest` determines whether the hgtransform object can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click within the limits of the hgtransform object. If `HitTest` is `off`, clicking the hgtransform picks the object behind it.

`Interruptible`

```
{on} | off
```

Callback routine interruption mode. The `Interruptible` property controls whether an hgtransform object callback can be interrupted by callbacks invoked subsequently. Only callbacks defined for the `ButtonDownFcn` property are affected by the `Interruptible` property. MATLAB checks for events that can interrupt a callback only when it encounters a `drawnow`, `figure`,

getframe, or pause command in the routine. See the BusyAction property for related information.

Setting Interruptible to on allows any graphics object's callback to interrupt callback routines originating from an hgtransform property. Note that MATLAB does not save the state of variables or the display (e.g., the handle returned by the gca or gcf command) when an interruption occurs.

Matrix
4-by-4 matrix

Transformation matrix applied to hgtransform object and its children. The hgtransform object applies the transformation matrix to all its children.

See "Group Objects" for more information and examples.

Parent
figure handle

Parent of hgtransform object. This property contains the handle of the hgtransform object's parent object. The parent of an hgtransform object is the axes, hggroup, or hgtransform object that contains it.

See "Objects That Can Contain Other Objects" for more information on parenting graphics objects.

Selected
on | {off}

Is object selected? When you set this property to on, MATLAB displays selection handles on all child objects of the hgtransform if the SelectionHighlight property is also on (the default).

SelectionHighlight
{on} | off

Objects are highlighted when selected. When the `Selected` property is `on`, MATLAB indicates the selected state by drawing selection handles on the objects parented to the hgtransform. When `SelectionHighlight` is `off`, MATLAB does not draw the handles.

`Tag`

string

User-specified object label. The `Tag` property provides a means to identify graphics objects with a user-specified label. This is particularly useful when you are constructing interactive graphics programs that would otherwise need to define object handles as global variables or pass them as arguments between callbacks.

For example, you might create an hgtransform object and set the `Tag` property:

```
t = hgtransform('Tag','subgroup1')
```

When you want to access the hgtransform object to add another object, you can use `findobj` to find the hgtransform object's handle. The following statement adds a line to `subgroup1` (assuming `x` and `y` are defined).

```
line('XData',x,'YData',y,'Parent',findobj('Tag','subgroup1'))
```

`Type`

string (read only)

Type of graphics object. This property contains a string that identifies the class of graphics object. For hgtransform objects, `Type` is set to '`hgtransform`'. The following statement finds all the hgtransform objects in the current axes.

```
t = findobj(gca,'Type','hgtransform');
```

`UIContextMenu`

handle of a uicontextmenu object

Associate a context menu with the hgtransform object. Assign this property the handle of a uicontextmenu object created in the hgtransform object's figure. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the extent of the hgtransform object.

`UserData`
array

User-specified data. This property can be any data you want to associate with the hgtransform object (including cell arrays and structures). The hgtransform object does not set values for this property, but you can access it using the `set` and `get` functions.

`Visible`
`{on} | off`

Visibility of hgtransform object and its children. By default, hgtransform object visibility is `on`. This means all children of the hgtransform are visible unless the child object's `Visible` property is set to `off`. Setting an hgtransform object's `Visible` property to `off` also makes its children invisible.

Purpose

Remove hidden lines from mesh plot

Syntax

```
hidden on
hidden off
hidden
```

Description

Hidden line removal draws only those lines that are not obscured by other objects in the field of view.

`hidden on` turns on hidden line removal for the current graph so lines in the back of a mesh are hidden by those in front. This is the default behavior.

`hidden off` turns off hidden line removal for the current graph.

`hidden` toggles the hidden line removal state.

Algorithm

`hidden on` sets the `FaceColor` property of a surface graphics object to the background `Color` of the axes (or of the figure if axes `Color` is `none`).

Examples

Set hidden line removal `off` and `on` while displaying the `peaks` function.

```
mesh(peaks)
hidden off
hidden on
```

`shading`, `mesh`

The surface properties `FaceColor` and `EdgeColor`

"Creating Surfaces and Meshes" on page 1-97 for related functions

hilb

Purpose

Hilbert matrix

Syntax

```
H = hilb(n)
```

Description

`H = hilb(n)` returns the Hilbert matrix of order `n`.

Definition

The Hilbert matrix is a notable example of a poorly conditioned matrix [1]. The elements of the Hilbert matrices are $H(i,j) = 1/(i+j-1)$.

Examples

Even the fourth-order Hilbert matrix shows signs of poor conditioning.

```
cond(hilb(4)) =
    1.5514e+04
```

Note See the M-file for a good example of efficient MATLAB programming where conventional `for` loops are replaced by vectorized statements.

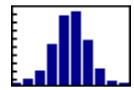
Purpose

Histogram plot



GUI Alternatives

To graph selected variables, use the Plot Selector  in the Workspace Browser, or use the Figure Palette Plot Catalog. Manipulate graphs in *plot edit* mode with the Property Editor. For details, see Plotting Tools — Interactive Plotting in the MATLAB Graphics documentation and Creating Graphics from the Workspace Browser in the MATLAB Desktop Tools documentation.

Syntax

```
n = hist(Y)
n = hist(Y,x)
n = hist(Y,nbins)
[n,xout] = hist(...)
hist(...)
hist(axes_handle,...)
```

Description

A histogram shows the distribution of data values.

`n = hist(Y)` bins the elements in vector `Y` into 10 equally spaced containers and returns the number of elements in each container as a row vector. If `Y` is an `m`-by-`p` matrix, `hist` treats the columns of `Y` as vectors and returns a 10-by-`p` matrix `n`. Each column of `n` contains the results for the corresponding column of `Y`. No elements of `Y` can be complex.

`n = hist(Y,x)` where `x` is a vector, returns the distribution of `Y` among `length(x)` bins with centers specified by `x`. For example, if `x` is a 5-element vector, `hist` distributes the elements of `Y` into five bins centered on the *x*-axis at the elements in `x`, none of which can be complex. Note: use `histc` if it is more natural to specify bin edges instead of centers.

`n = hist(Y,nbins)` where `nbins` is a scalar, uses `nbins` number of bins.

`[n,xout] = hist(...)` returns vectors `n` and `xout` containing the frequency counts and the bin locations. You can use `bar(xout,n)` to plot the histogram.

`hist(...)` without output arguments produces a histogram plot of the output described above. `hist` distributes the bins along the *x*-axis between the minimum and maximum values of `Y`.

`hist(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

Remarks

All elements in vector `Y` or in one column of matrix `Y` are grouped according to their numeric range. Each group is shown as one bin.

The histogram's *x*-axis reflects the range of values in `Y`. The histogram's *y*-axis shows the number of elements that fall within the groups; therefore, the *y*-axis ranges from `0` to the greatest number of elements deposited in any bin. The *x*-range of the leftmost and rightmost bins extends to include the entire data range in the case when the user-specified range does not cover the data range. If you want a plot in which this does not happen (that is, all bins have equal width), you can create a histogram-like display using the `bar` command.

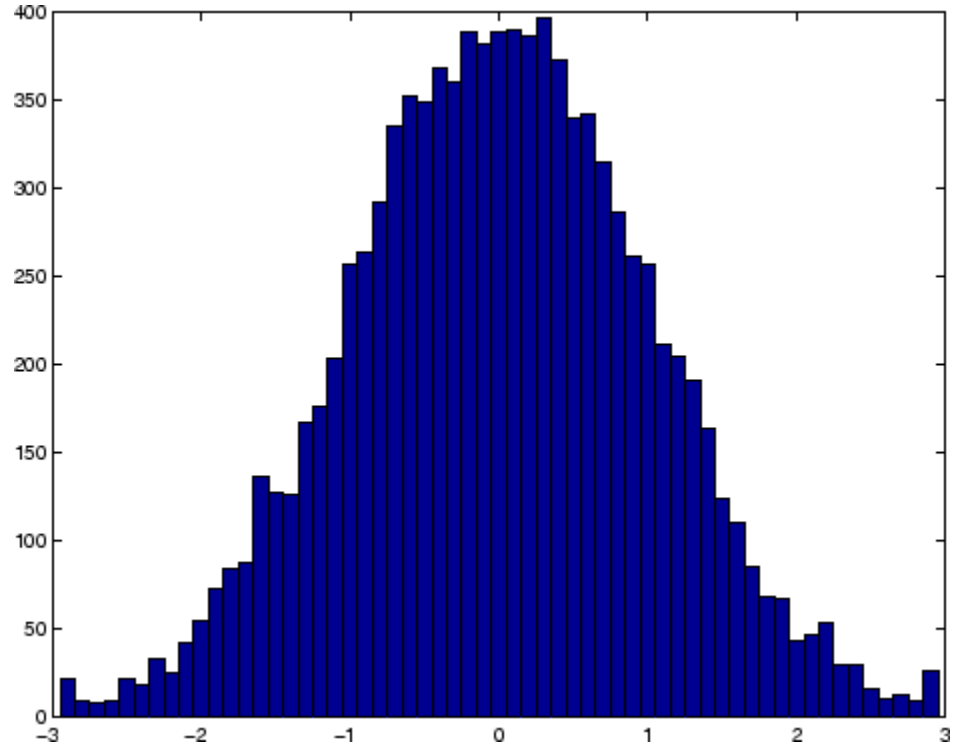
The `hist` function does not work with data that contain `inf` values.

The histogram is created with a patch graphics object. If you want to change the color of the graph, you can set patch properties. See the examples for more information. By default, the graph color is controlled by the current colormap, which maps the bin color to the first color in the colormap.

Examples

Generate a bell-curve histogram from Gaussian data.

```
x = -2.9:0.1:2.9;
y = randn(10000,1);
hist(y,x)
```



Change the color of the graph so that the bins are red and the edges of the bins are white.

```
h = findobj(gca,'Type','patch');
set(h,'FaceColor','r','EdgeColor','w')
```

"Specialized Plotting" on page 1-88 for related functions

"Histograms" for examples

Purpose

Histogram count

Syntax

```
n = histc(x,edges)
n = histc(x,edges,dim)
[n,bin] = histc(...)
```

Description

`n = histc(x,edges)` counts the number of values in vector `x` that fall between the elements in the `edges` vector (which must contain monotonically nondecreasing values). `n` is a `length(edges)` vector containing these counts. No elements of `x` can be complex.

`n(k)` counts the value `x(i)` if `edges(k) <= x(i) < edges(k+1)`. The last bin counts any values of `x` that match `edges(end)`. Values outside the values in `edges` are not counted. Use `-inf` and `inf` in `edges` to include all non-`NaN` values.

For matrices, `histc(x,edges)` returns a matrix of column histogram counts. For N-D arrays, `histc(x,edges)` operates along the first nonsingleton dimension.

`n = histc(x,edges,dim)` operates along the dimension `dim`.

`[n,bin] = histc(...)` also returns an index matrix `bin`. If `x` is a vector, `n(k) = sum(bin==k)`. `bin` is zero for out of range values. If `x` is an `M`-by-`N` matrix, then

```
for j=1:N,
n(k,j) = sum(bin(:,j)==k);
end
```

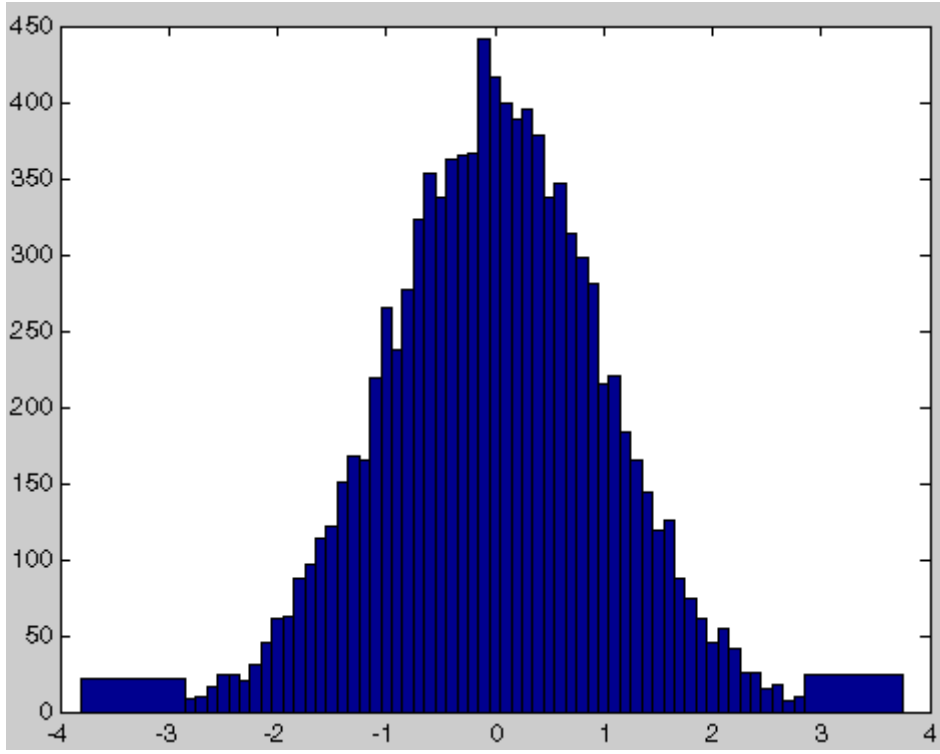
To plot the histogram, use the `bar` command.

Examples

Generate a cumulative histogram of a distribution.

Consider the following distribution:

```
x = -2.9:0.1:2.9;
y = randn(10000,1);
figure(1), hist(y,x)
```



Calculate number of elements in each bin

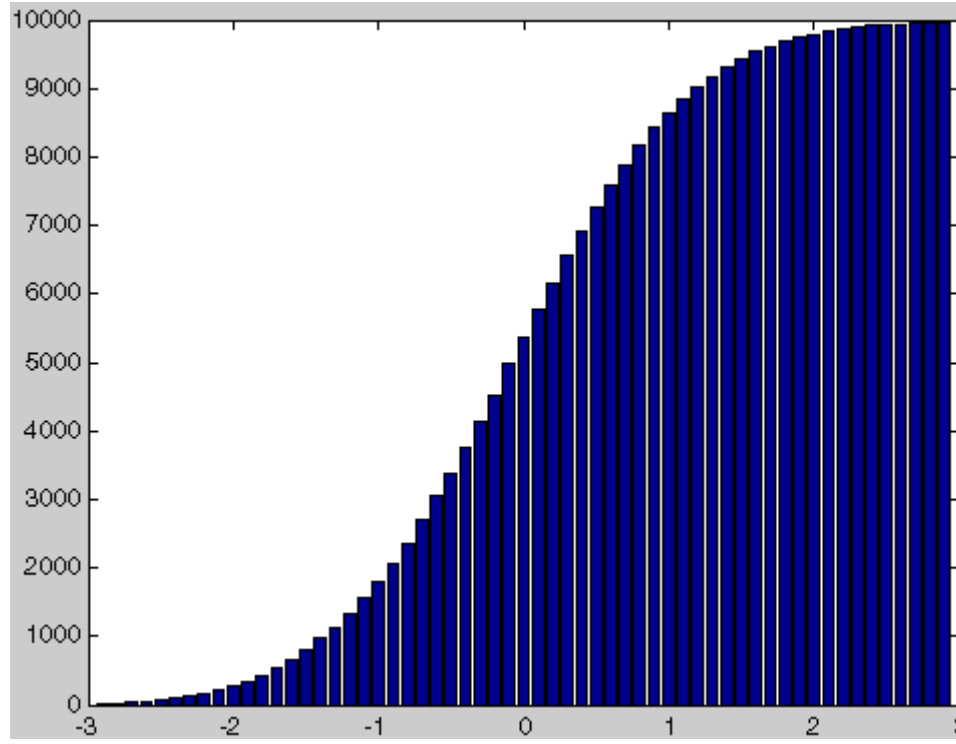
```
n_elements = histc(y,x);
```

Calculate the cumulative sum of these elements using `cumsum`

```
c_elements = cumsum(n_elements)
```

Plot the cumulative histogram

```
figure(2),bar(x,c_elements)
```



See Also

`hist`, `mode`

"Specialized Plotting" on page 1-88 for related functions

hold

Purpose

Retain current graph in figure

Syntax

```
hold on
hold off
hold all
hold
hold(axes_handle,...)
```

Description

The `hold` function determines whether new graphics objects are added to the graph or replace objects in the graph.

`hold on` retains the current plot and certain axes properties so that subsequent graphing commands add to the existing graph.

`hold off` resets axes properties to their defaults before drawing new plots. `hold off` is the default.

`hold all` holds the plot and the current line color and line style so that subsequent plotting commands do not reset the `ColorOrder` and `LineStyleOrder` property values to the beginning of the list. Plotting commands continue cycling through the predefined colors and linestyles from where the last plot stopped in the list.

`hold` toggles the hold state between adding to the graph and replacing the graph.

`hold(axes_handle,...)` applies the hold to the axes identified by the handle `axes_handle`.

Remarks

Test the hold state using the `ishold` function.

Although the hold state is `on`, some axes properties change to accommodate additional graphics objects. For example, the axes' limits increase when the data requires them to do so.

The `hold` function sets the `NextPlot` property of the current figure and the current axes. If several axes objects exist in a figure window, each axes has its own hold state. `hold` also creates an axes if one does not exist.

`hold on` sets the `NextPlot` property of the current figure and axes to `add`.

`hold off` sets the `NextPlot` property of the current axes to `replace`.

`hold` toggles the `NextPlot` property between the `add` and `replace` states.

The `NextPlot` property of axes and figure graphics objects

"Basic Plots and Graphs" on page 1-86 for related functions

home

Purpose

Move cursor to upper-left corner of Command Window

Syntax

```
home
```

Description

`home` moves the cursor to the upper-left corner of the Command Window. You can use the scroll bar to see the history of previous functions.

Examples

Use `home` in an M-file to return the cursor to the upper-left corner of the screen.

See Also

`clc`

Purpose

Concatenate arrays horizontally

Syntax

```
C = horzcat(A1, A2, ...)
```

Description

`C = horzcat(A1, A2, ...)` horizontally concatenates matrices `A1`, `A2`, and so on. All matrices in the argument list must have the same number of rows.

`horzcat` concatenates N-dimensional arrays along the second dimension. The first and remaining dimensions must match.

MATLAB calls `C = horzcat(A1, A2,...)` for the syntax `C = [A1 A2 ...]` when any of `A1`, `A2`, etc., is an object.

Examples

Create a 3-by-5 matrix, `A`, and a 3-by-3 matrix, `B`. Then horizontally concatenate `A` and `B`.

```
A = magic(5);            % Create 3-by-5 matrix, A
A(4:5,:) = []

A =

    17    24     1     8    15
    23     5     7    14    16
     4     6    13    20    22

B = magic(3)*100       % Create 3-by-3 matrix, B

B =

   800   100   600
   300   500   700
   400   900   200

C = horzcat(A, B)      % Horizontally concatenate A and B
```

```
C =

    17    24     1     8    15   800   100   600
    23     5     7    14    16   300   500   700
     4     6    13    20    22   400   900   200
```

See Also

vertcat, cat

Purpose

Horizontal concatenation for `tscollection` objects

Syntax

```
tsc = horzcat(tsc1,tsc2,...)
```

Description

`tsc = horzcat(tsc1,tsc2,...)` performs horizontal concatenation for `tscollection` objects:

```
tsc = [tsc1 tsc2 ...]
```

This operation combines multiple `tscollection` objects, which must have the same time vectors, into one `tscollection` containing `timeseries` objects from all concatenated collections.

See Also

`tscollection`, `vertcat (tscollection)`

hostid

Purpose

MATLAB server host identification number

Syntax

```
id = hostid
```

Description

`id = hostid` usually returns a single element cell array containing the identifier as a string. UNIX systems may have more than one identifier. In this case, `hostid` returns a cell array with an identifier in each cell.

Purpose

Convert HSV colormap to RGB colormap

Syntax

```
M = hsv2rgb(H)
rgb_image = hsv2rgb(hsv_image)
```

Description

`M = hsv2rgb(H)` converts a hue-saturation-value (HSV) colormap to a red-green-blue (RGB) colormap. `H` is an *m*-by-3 matrix, where *m* is the number of colors in the colormap. The columns of `H` represent hue, saturation, and value, respectively. `M` is an *m*-by-3 matrix. Its columns are intensities of red, green, and blue, respectively.

`rgb_image = hsv2rgb(hsv_image)` converts the HSV image to the equivalent RGB image. HSV is an *m*-by-*n*-by-3 image array whose three planes contain the hue, saturation, and value components for the image. RGB is returned as an *m*-by-*n*-by-3 image array whose three planes contain the red, green, and blue components for the image.

Remarks

As `H(:,1)` varies from 0 to 1, the resulting color varies from red through yellow, green, cyan, blue, and magenta, and returns to red. When `H(:,2)` is 0, the colors are unsaturated (i.e., shades of gray). When `H(:,2)` is 1, the colors are fully saturated (i.e., they contain no white component). As `H(:,3)` varies from 0 to 1, the brightness increases.

The MATLAB `hsv` colormap uses `hsv2rgb([huesaturationvalue])` where `hue` is a linear ramp from 0 to 1, and `saturation` and `value` are all 1's.

See Also

`brighten`, `colormap`, `rgb2hsv`

"Color Operations" on page 1-98 for related functions

hypot

Purpose

Square root of sum of squares

Syntax

```
c = hypot(a,b)
```

Description

`c = hypot(a,b)` returns the element-wise result of the following equation, computed to avoid underflow and overflow:

```
c = sqrt(abs(a).^2 + abs(b).^2)
```

Inputs `a` and `b` must follow these rules:

- Both `a` and `b` must be single- or double-precision, floating-point arrays.
- The sizes of the `a` and `b` arrays must either be equal, or one a scalar and the other nonscalar. In the latter case, `hypot` expands the scalar input to match the size of the nonscalar input.
- If `a` or `b` is an empty array (0-by-N or N-by-0), the other must be the same size or a scalar. The result `c` is an empty array having the same size as the empty input(s).

`hypot` returns the following in output `c`, depending upon the types of inputs:

- If the inputs to `hypot` are complex (`w+xi` and `y+zi`), then the statement `c = hypot(w+xi,y+zi)` returns the *positive real* result

  ```
  c = sqrt(abs(w).^2+abs(x).^2+abs(y).^2+abs(z).^2)
  ```

- If `a` or `b` is `–Inf`, `hypot` returns `Inf`.
- If neither `a` nor `b` is `Inf`, but one or both inputs is `NaN`, `hypot` returns `NaN`.
- If all inputs are finite, the result is finite. The one exception is when both inputs are very near the value of the MATLAB constant `realmax`. The reason for this is that the equation `c =`

`hypot(realmax,realmax)` is theoretically `sqrt(2)*realmax`, which overflows to `Inf`.

Examples

Example 1

To illustrate the difference between using the `hypot` function and coding the basic `hypot` equation in M-code, create an anonymous function that performs the same function as `hypot`, but without the consideration to underflow and overflow that `hypot` offers:

```
myhypot = @(a,b)sqrt(abs(a).^2+abs(b).^2);
```

Find the upper limit at which your coded function returns a useful value. You can see that this test function reaches its maximum at about `1e154`, returning an infinite result at that point:

```
myhypot(1e153,1e153)
ans =
    1.4142e+153

myhypot(1e154,1e154)
ans =
   Inf
```

Do the same using the `hypot` function, and observe that `hypot` operates on values up to about `1e308`, which is approximately equal to the value for `realmax` on your computer (the largest double-precision floating-point number you can represent on a particular computer):

```
hypot(1e308,1e308)
ans =
  1.4142e+308

hypot(1e309,1e309)
ans =
   Inf
```

Example 2

`hypot(a,a)` theoretically returns `sqrt(2)*abs(a)`, as shown in this example:

```
x = 1.271161e308;

y = x * sqrt(2)
y =
  1.7977e+308

y = hypot(x,x)
y =
  1.7977e+308
```

Algorithm

`hypot` uses FDLIBM, which was developed at SunSoft, a Sun Microsystems, Inc. business, by Kwok C. Ng, and others. For information about FDLIBM, see `http://www.netlib.org`.

See Also

`sqrt`, `abs`, `norm`

Purpose

Imaginary unit

Syntax

```
i
a+bi
x+i*y
```

Description

As the basic imaginary unit `sqrt(-1)`, `i` is used to enter complex numbers. Since `i` is a function, it can be overridden and used as a variable. This permits you to use `i` as an index in `for` loops, etc.

If desired, use the character `i` without a multiplication sign as a suffix in forming a complex numerical constant.

You can also use the character `j` as the imaginary unit.

Examples

```
Z = 2+3i
Z = x+i*y
Z = r*exp(i*theta)
```

See Also

`conj`, `imag`, `j`, `real`

idealfilter (timeseries)

Purpose

Apply ideal (noncausal) filter to `timeseries` object

Syntax

```
ts2 = idealfilter(ts1,Interval,FilterType)
ts2 = idealfilter(ts1,Interval,FilterType,Index)
```

Description

`ts2 = idealfilter(ts1,Interval,FilterType)` applies an ideal filter of `FilterType` `'pass'` or `'notch'` to one or more frequency intervals specified by `Interval` for the `timeseries` object `ts1`. You specify several frequency intervals as an `n`-by-2 array of start and end frequencies, where `n` represents the number of intervals.

`ts2 = idealfilter(ts1,Interval,FilterType,Index)` applies an ideal filter and uses the optional `Index` integer array to specify the columns or rows to filter. When `ts.IsTimeFirst` is set to `true`, `Index` specifies one or more data columns. When `ts.IsTimeFirst` is set to `false`, Index specifies one or more data rows.

Remarks

When to Use the Ideal Filter

You use the ideal *notch* filter when you want to remove variations in a specific frequency range. Alternatively, you use the ideal *pass* filter to allow only the variations in a specific frequency range.

These filters are ideal in the sense that they are not realizable; an ideal filter is noncausal and the ends of the filter amplitude are perfectly flat in the frequency domain.

Requirement for Uniform Samples in Time

If the time-series data is sampled nonuniformly, filtering resamples this data on a uniform time vector.

Interpolation of NaN Values

All `NaN`s in the time series are interpolated before filtering using the interpolation method you assigned to the `timeseries` object.

Examples

You will apply an ideal notch filter to the data in `count.dat`.

1. Load the matrix `count` into the workspace.

```
load count.dat;
```

2 Create a `timeseries` object based on this matrix. The time vector ranges from 1 to 24 seconds in 1-second intervals.

```
count1=timeseries(count(:,1),1:24);
```

3 Enter the frequency interval in hertz.

```
interval=[0.08 0.2];
```

4 Call the filter function:

```
idealfilter_count = idealfilter(count1,interval,'notch')
```

5 Compare the original data and the shaped data with an overlaid plot of the two curves.

```
plot(count1,'-.'), grid on, hold on
plot(filter_count,'-')
legend('Original Data','Shaped Data',2)
```

See Also

`filter (timeseries)`, `timeseries`

Purpose

Integer division with rounding option

Syntax

```
C = idivide(A, B, opt)
C = idivide(A, B)
C = idivide(A, B, 'fix')
C = idivide(A, B, 'round')
C = idivide(A, B, 'floor')
C = idivide(A, B, 'ceil')
```

Description

`C = idivide(A, B, opt)` is the same as `A./B` for integer classes except that fractional quotients are rounded to integers using the optional rounding mode specified by `opt`. The default rounding mode is `'fix'`. Inputs `A` and `B` must be real and must have the same dimensions unless one is a scalar. At least one of the arguments `A` and `B` must belong to an integer class, and the other must belong to the same integer class or be a scalar double. The result `C` belongs to the integer class.

`C = idivide(A, B)` is the same as `A./B` except that fractional quotients are rounded toward zero to the nearest integers.

`C = idivide(A, B, 'fix')` is the same as the syntax shown immediately above.

`C = idivide(A, B, 'round')` is the same as `A./B` for integer classes. Fractional quotients are rounded to the nearest integers.

`C = idivide(A, B, 'floor')` is the same as `A./B` except that fractional quotients are rounded toward negative infinity to the nearest integers.

`C = idivide(A, B, 'ceil')` is the same as `A./B` except that the fractional quotients are rounded toward infinity to the nearest integers.

Examples

```
a = int32([-2 2]);
b = int32(3);

idivide(a,b)             % Returns [0 0]
idivide(a,b,'floor')     % Returns [-1 0]
idivide(a,b,'ceil')      % Returns [0 1]
```

```
idivide(a,b,'round')     % Returns [-1 1]
```

See Also

ldivide, rdivide, mldivide, mrdivide

Purpose

Execute statements if condition is true

Syntax

```
if expression, statements, end
```

Description

`if expression, statements, end` evaluates *`expression`* and, if the evaluation yields logical `1` (`true`) or a nonzero result, executes one or more MATLAB commands denoted here as *`statements`*.

`expression` is a MATLAB expression, usually consisting of variables or smaller expressions joined by relational operators (e.g., `count < limit`), or logical functions (e.g., `isreal(A)`). Simple expressions can be combined by logical operators (`&&`, `||`, `~`) into compound expressions such as the following. MATLAB evaluates compound expressions from left to right, adhering to operator precedence rules.

```
(count < limit) && ((height - offset) >= 0)
```

Nested `if` statements must each be paired with a matching `end`.

The `if` function can be used alone or with the `else` and `elseif` functions. When using `elseif` and/or `else` within an `if` statement, the general form of the statement is

```
if expression1
    statements1
elseif expression2
    statements2
else
    statements3
end
```

See “Program Control Statements” in the MATLAB Programming documentation for more information on controlling the flow of your program code.

Remarks

Nonscalar Expressions

If the evaluated `expression` yields a nonscalar value, then every element of this value must be true or nonzero for the entire expression to be considered true. For example, the statement `if (A < B)` is true only if each element of matrix `A` is less than its corresponding element in matrix `B`. See Example 2, below.

Partial Evaluation of the expression Argument

Within the context of an `if` or `while` expression, MATLAB does not necessarily evaluate all parts of a logical expression. In some cases it is possible, and often advantageous, to determine whether an expression is true or false through only partial evaluation.

For example, if `A` equals zero in statement 1 below, then the expression evaluates to `false`, regardless of the value of `B`. In this case, there is no need to evaluate `B` and MATLAB does not do so. In statement 2, if `A` is nonzero, then the expression is true, regardless of `B`. Again, MATLAB does not evaluate the latter part of the expression.

```
1)   if (A && B)              2)   if (A || B)
```

You can use this property to your advantage to cause MATLAB to evaluate a part of an expression only if a preceding part evaluates to the desired state. Here are some examples.

```
while (b ~= 0) && (a/b > 18.5)
if exist('myfun.m') && (myfun(x) >= y)
if iscell(A) && all(cellfun('isreal', A))
```

Empty Arrays

In most cases, using `if` on an empty array treats the array as `false`. There are some conditions however under which `if` evaluates as `true` on an empty array. Two examples of this, where `A` is equal to `[]`, are

```
if all(A), do_something, end
if 1|A, do_something, end
```

The latter expression is `true` because of short-circuiting, which causes MATLAB to ignore the right side operand of an OR statement whenever the left side evaluates to `true`.

Short-Circuiting Behavior

When used in the context of an `if` or `while` expression, and only in this context, the element-wise `|` and `&` operators use short-circuiting in evaluating their expressions. That is, `A|B` and `A&B` ignore the second operand, `B`, if the first operand, `A`, is sufficient to determine the result.

See "Short-Circuiting in Elementwise Operators" for more information on this.

Examples

Example 1 - Simple if Statement

In this example, if both of the conditions are satisfied, then the student passes the course.

```
if ((attendance >= 0.90) && (grade_average >= 60))
   pass = 1;
end;
```

Example 2 - Nonscalar Expression

Given matrices `A` and `B`,

```
A =                 B =
     1     0             1     1
     2     3             3     4
```

Expression	Evaluates As	Because
`A < B`	`false`	A(1,1) is not less than B(1,1).
`A < (B + 1)`	`true`	Every element of A is less than that same element of B with 1 added.

Expression	Evaluates As	Because
`A & B`	`false`	A(1,2) is false, and B is ignored due to short-circuiting.
`B < 5`	`true`	Every element of B is less than 5.

Purpose

Inverse discrete Fourier transform

Syntax

```
y = ifft(X)
y = ifft(X,n)
y = ifft(X,[],dim)
y = ifft(X,n,dim)
y = ifft(..., 'symmetric')
y = ifft(..., 'nonsymmetric')
```

Description

`y = ifft(X)` returns the inverse discrete Fourier transform (DFT) of vector `X`, computed with a fast Fourier transform (FFT) algorithm. If `X` is a matrix, `ifft` returns the inverse DFT of each column of the matrix.

`ifft` tests `X` to see whether vectors in `X` along the active dimension are *conjugate symmetric*. If so, the computation is faster and the output is real. An `N`-element vector `x` is conjugate symmetric if `x(i) = conj(x(mod(N-i+1,N)+1))` for each element of `x`.

If `X` is a multidimensional array, `ifft` operates on the first non-singleton dimension.

`y = ifft(X,n)` returns the `n`-point inverse DFT of vector `X`.

`y = ifft(X,[],dim)` and `y = ifft(X,n,dim)` return the inverse DFT of `X` across the dimension `dim`.

`y = ifft(..., 'symmetric')` causes `ifft` to treat `X` as conjugate symmetric along the active dimension. This option is useful when `X` is not exactly conjugate symmetric, merely because of round-off error.

`y = ifft(..., 'nonsymmetric')` is the same as calling `ifft(...)` without the argument `'nonsymmetric'`.

For any `X`, `ifft(fft(X))` equals `X` to within roundoff error.

Algorithm

The algorithm for `ifft(X)` is the same as the algorithm for `fft(X)`, except for a sign change and a scale factor of `n = length(X)`. As for `fft`, the execution time for `ifft` depends on the length of the transform. It is fastest for powers of two. It is almost as fast for lengths that have

only small prime factors. It is typically several times slower for lengths that are prime or which have large prime factors.

Note You might be able to increase the speed of `ifft` using the utility function `fftw`, which controls how MATLAB optimizes the algorithm used to compute an FFT of a particular size and dimension.

Data Type Support

`ifft` supports inputs of data types `double` and `single`. If you call `ifft` with the syntax `y = ifft(X, ...)`, the output `y` has the same data type as the input `X`.

See Also

`dftmtx` and `freqz`, in the Signal Processing Toolbox

Purpose

2-D inverse discrete Fourier transform

Syntax

```
Y = ifft2(X)
Y = ifft2(X,m,n)
y = ifft2(..., 'symmetric')
y = ifft2(..., 'nonsymmetric')
```

Description

`Y = ifft2(X)` returns the two-dimensional inverse discrete Fourier transform (DFT) of `X`, computed with a fast Fourier transform (FFT) algorithm. The result `Y` is the same size as `X`.

`ifft2` tests `X` to see whether it is *conjugate symmetric*. If so, the computation is faster and the output is real. An `M`-by-`N` matrix `X` is conjugate symmetric if `X(i,j) = conj(X(mod(M-i+1, M) + 1, mod(N-j+1, N) + 1))` for each element of `X`.

`Y = ifft2(X,m,n)` returns the `m`-by-`n` inverse fast Fourier transform of matrix `X`.

`y = ifft2(..., 'symmetric')` causes `ifft2` to treat `X` as conjugate symmetric. This option is useful when `X` is not exactly conjugate symmetric, merely because of round-off error.

`y = ifft2(..., 'nonsymmetric')` is the same as calling `ifft2(...)` without the argument `'nonsymmetric'`.

For any `X`, `ifft2(fft2(X))` equals `X` to within roundoff error.

Algorithm

The algorithm for `ifft2(X)` is the same as the algorithm for `fft2(X)`, except for a sign change and scale factors of `[m,n] = size(X)`. The execution time for `ifft2` depends on the length of the transform. It is fastest for powers of two. It is almost as fast for lengths that have only small prime factors. It is typically several times slower for lengths that are prime or which have large prime factors.

Note You might be able to increase the speed of `ifft2` using the utility function `fftw`, which controls how MATLAB optimizes the algorithm used to compute an FFT of a particular size and dimension.

Data Type Support

`ifft2` supports inputs of data types `double` and `single`. If you call `ifft2` with the syntax `y = ifft2(X, ...)`, the output `y` has the same data type as the input `X`.

`fft2`, `fftw`, `fftshift`, `ifft`, `ifftn`, `ifftshift`

Purpose

N-D inverse discrete Fourier transform

Syntax

```
Y = ifftn(X)
Y = ifftn(X,siz)
y = ifftn(..., 'symmetric')
y = ifftn(..., 'nonsymmetric')
```

Description

`Y = ifftn(X)` returns the n-dimensional inverse discrete Fourier transform (DFT) of `X`, computed with a multidimensional fast Fourier transform (FFT) algorithm. The result `Y` is the same size as `X`.

`ifftn` tests `X` to see whether it is *conjugate symmetric*. If so, the computation is faster and the output is real. An `N1-by-N2-by- ... Nk` array `X` is conjugate symmetric if

```
X(i1,i2, ...,ik) = conj(X(mod(N1-i1+1,N1)+1, mod(N2-i2+1,N2)+1,
... mod(Nk-ik+1,Nk)+1))
```

for each element of `X`.

`Y = ifftn(X,siz)` pads `X` with zeros, or truncates `X`, to create a multidimensional array of size `siz` before performing the inverse transform. The size of the result `Y` is `siz`.

`y = ifftn(..., 'symmetric')` causes `ifftn` to treat `X` as conjugate symmetric. This option is useful when `X` is not exactly conjugate symmetric, merely because of round-off error.

`y = ifftn(..., 'nonsymmetric')` is the same as calling `ifftn(...)` without the argument `'nonsymmetric'`.

Remarks

For any `X`, `ifftn(fftn(X))` equals `X` within roundoff error.

Algorithm

`ifftn(X)` is equivalent to

```
Y = X;
for p = 1:length(size(X))
    Y = ifft(Y,[],p);
end
```

This computes in-place the one-dimensional inverse DFT along each dimension of `X`.

The execution time for `ifftn` depends on the length of the transform. It is fastest for powers of two. It is almost as fast for lengths that have only small prime factors. It is typically several times slower for lengths that are prime or which have large prime factors.

Note You might be able to increase the speed of `ifftn` using the utility function `fftw`, which controls how MATLAB optimizes the algorithm used to compute an FFT of a particular size and dimension.

Data Type Support

`ifftn` supports inputs of data types `double` and `single`. If you call `ifftn` with the syntax `y = ifftn(X, ...)`, the output `y` has the same data type as the input `X`.

See Also

`fftn`, `fftw`, `ifft`, `ifft2`, `ifftshift`

Purpose

Inverse FFT shift

Syntax

```
ifftshift(X)
ifftshift(X,dim)
```

Description

`ifftshift(X)` swaps the left and right halves of the vector `X`. For matrices, `ifftshift(X)` swaps the first quadrant with the third and the second quadrant with the fourth. If `X` is a multidimensional array, `ifftshift(X)` swaps "half-spaces" of `X` along each dimension.

`ifftshift(X,dim)` applies the `ifftshift` operation along the dimension `dim`.

Note `ifftshift` undoes the results of `fftshift`. If the matrix `X` contains an odd number of elements, `ifftshift(fftshift(X))` must be done to obtain the original `X`. Simply performing `fftshift(X)` twice will not produce `X`.

`fft`, `fft2`, `fftn`, `fftshift`

Purpose

Sparse incomplete LU factorization

Syntax

```
ilu(A,setup)
[L,U] = ilu(A,setup)
[L,U,P] = ilu(A,setup)
```

Description

`ilu` produces a unit lower triangular matrix, an upper triangular matrix, and a permutation matrix.

`ilu(A,setup)` computes the incomplete LU factorization of `A`. `setup` is an input structure with up to five setup options. The fields must be named exactly as shown in the table below. You can include any number of these fields in the structure and define them in any order. Any additional fields are ignored.

Field Name	Description
`type`	Type of factorization. Values for `type` include: • `'nofill'`—Performs ILU factorization with `0` level of fill in, known as ILU(0). With `type` set to `'nofill'`, only the `milu` setup option is used; all other fields are ignored. • `'crout'`—Performs the Crout version of ILU factorization, known as ILUC. With `type` set to `'crout'`, only the `droptol` and `milu` setup options are used; all other fields are ignored. • `'ilutp'` (default)—Performs ILU factorization with threshold and pivoting. If `type` is not specified, the ILU factorization with pivoting ILUTP is performed. Pivoting is never performed with `type` set to `'nofill'` or `'crout'`.

Field Name	Description

`droptol`	Drop tolerance of the incomplete LU factorization. `droptol` is a non-negative scalar. The default value is `0`, which produces the complete LU factorization.
	
	The nonzero entries of `U` satisfy
	
	`abs(U(i,j)) >= droptol*norm((A:,j)),`
	
	with the exception of the diagonal entries, which are retained regardless of satisfying the criterion. The entries of `L` are tested against the local drop tolerance before being scaled by the pivot, so for nonzeros in `L`
	
	`abs(L(i,j)) >= droptol*norm(A(:,j))/U(j,j).`

`milu`	Modified incomplete LU factorization. Values for `milu` include: • `'row'`—Produces the row-sum modified incomplete LU factorization. Entries from the newly-formed column of the factors are subtracted from the diagonal of the upper triangular factor, `U`, preserving column sums. That is, `A*e = L*U*e`, where `e` is the vector of ones. • `'col'`—Produces the column-sum modified incomplete LU factorization. Entries from the newly-formed column of the factors are subtracted from the diagonal of the upper triangular factor, `U`, preserving column sums. That is, `e'*A = e'*L*U`. • `'off'` (default)—No modified incomplete LU factorization is produced.

Field Name	Description
udiag	If udiag is 1, any zeros on the diagonal of the upper triangular factor are replaced by the local drop tolerance. The default is 0.
thresh	Pivot threshold between 0 (forces diagonal pivoting) and 1, the default, which always chooses the maximum magnitude entry in the column to be the pivot.

`ilu(A,setup)` returns `L+U-speye(size(A))`, where `L` is a unit lower triangular matrix and `U` is an upper triangular matrix.

`[L,U] = ilu(A,setup)` returns a unit lower triangular matrix in `L` and an upper triangular matrix in `U`.

`[L,U,P] = ilu(A,setup)` returns a unit lower triangular matrix in `L`, an upper triangular matrix in `U`, and a permutation matrix in `P`.

Remarks

These incomplete factorizations may be useful as preconditioners for a system of linear equations being solved by iterative methods such as BICG (BiConjugate Gradients), GMRES (Generalized Minimum Residual Method).

Limitations

`ilu` works on sparse square matrices only.

Examples

Start with a sparse matrix and compute the LU factorization.

```
A = gallery('neumann', 1600) + speye(1600);
setup.type = 'crout';
setup.milu = 'row';
setup.droptol = 0.1;
[L,U] = ilu(A,setup);
e = ones(size(A,2),1);
norm(A*e-L*U*e)

ans =
```

```
    1.4251e-014
```

This shows that `A` and `L*U`, where `L` and `U` are given by the modified Crout `ILU`, have the same row-sum.

Start with a sparse matrix and compute the LU factorization.

```
A = gallery('neumann', 1600) + speye(1600);
setup.type = 'nofill';
nnz(A)
ans =

        7840

nnz(lu(A))
ans =

      126478

nnz(ilu(A,setup))
ans =

        7840
```

This shows that `A` has `7840` nonzeros, the complete LU factorization has `126478` nonzeros, and the incomplete LU factorization, with `0` level of fill-in, has `7840` nonzeros, the same amount as `A`.

im2frame

Purpose

Convert image to movie frame

Syntax

```
f = im2frame(X,map)
f = im2frame(X)
```

Description

`f = im2frame(X,map)` converts the indexed image `X` and associated colormap `map` into a movie frame `f`. If `X` is a truecolor (m-by-n-by-3) image, then `map` is optional and has no effect.

Typical usage:

```
M(1) = im2frame(X1,map);
M(2) = im2frame(X2,map);
  ...
M(n) = im2frame(Xn,map);
movie(M)
```

`f = im2frame(X)` converts the indexed image `X` into a movie frame `f` using the current colormap if `X` contains an indexed image.

`frame2im`, `movie`

"Bit-Mapped Images" on page 1-92 for related functions

Purpose

Convert image to Java image

Syntax

```
jimage = im2java(I)
jimage = im2java(X,MAP)
jimage = im2java(RGB)
```

Description

To work with a MATLAB image in the Java environment, you must convert the image from its MATLAB representation into an instance of the Java image class, `java.awt.Image`.

`jimage = im2java(I)` converts the intensity image `I` to an instance of the Java image class, `java.awt.Image`.

`jimage = im2java(X,MAP)` converts the indexed image `X`, with colormap `MAP`, to an instance of the Java image class, `java.awt.Image`.

`jimage = im2java(RGB)` converts the RGB image `RGB` to an instance of the Java image class, `java.awt.Image`.

Class Support

The input image can be of class `uint8`, `uint16`, or `double`.

Note Java requires `uint8` data to create an instance of the Java image class, `java.awt.Image`. If the input image is of class `uint8`, `jimage` contains the same `uint8` data. If the input image is of class `double` or `uint16`, `im2java` makes an equivalent image of class `uint8`, rescaling or offsetting the data as necessary, and then converts this `uint8` representation to an instance of the Java image class, `java.awt.Image`.

Example

This example reads an image into the MATLAB workspace and then uses `im2java` to convert it into an instance of the Java image class.

```
I = imread('ngc6543a.jpg');
javaImage = im2java(I);
frame = javax.swing.JFrame;
icon = javax.swing.ImageIcon(javaImage);
label = javax.swing.JLabel(icon);
```

```
frame.getContentPane.add(label);
frame.pack
frame.show
```

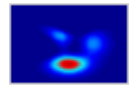
image

Purpose

Display image object



GUI Alternatives

To plot a selected matrix as an image use the Plot Selector  in the Workspace Browser, or use the Figure Palette Plot Catalog. Manipulate image characteristics in *plot edit* mode with the Property Editor. For details, see Plotting Tools — Interactive Plotting in the MATLAB Graphics documentation and Creating Graphics from the Workspace Browser in the MATLAB Desktop Tools documentation.

Syntax

```
image(C)
image(x,y,C)
image(x,y,C,'PropertyName',PropertyValue,...)
image('PropertyName',PropertyValue,...)
handle = image(...)
```

Description

`image` creates an image graphics object by interpreting each element in a matrix as an index into the figure's colormap or directly as RGB values, depending on the data specified.

The `image` function has two forms:

- A high-level function that calls `newplot` to determine where to draw the graphics objects and sets the following axes properties:
  - `XLim` and `YLim` to enclose the image
  - `Layer` to `top` to place the image in front of the tick marks and grid lines
  - `YDir` to `reverse`
  - `View` to `[0 90]`

- A low-level function that adds the image to the current axes without calling `newplot`. The low-level function argument list can contain only property name/property value pairs.

You can specify properties as property name/property value pairs, structure arrays, and cell arrays (see set and get for examples of how to specify these data types).

`image(C)` displays matrix `C` as an image. Each element of `C` specifies the color of a rectangular segment in the image.

`image(x,y,C)`, where `x` and `y` are two-element vectors, specifies the range of the *x*- and *y*-axis labels, but produces the same image as `image(C)`. This can be useful, for example, if you want the axis tick labels to correspond to real physical dimensions represented by the image.

`image(x,y,C,'`*`PropertyName`*`',PropertyValue,...)` is a high-level function that also specifies property name/property value pairs. This syntax calls `newplot` before drawing the image.

`image('`*`PropertyName`*`',PropertyValue,...)` is the low-level syntax of the `image` function. It specifies only property name/property value pairs as input arguments.

`handle = image(...)` returns the handle of the image object it creates. You can obtain the handle with all forms of the `image` function.

Remarks

Image data can be either indexed or true color. An indexed image stores colors as an array of indices into the figure colormap. A true color image does not use a colormap; instead, the color values for each pixel are stored directly as RGB triplets. In MATLAB, the `CData` property of a truecolor image object is a three-dimensional (`m`-by-`n`-by-3) array. This array consists of three `m`-by-`n` matrices (representing the red, green, and blue color planes) concatenated along the third dimension.

The `imread` function reads image data into MATLAB arrays from graphics files in various standard formats, such as TIFF. You can write MATLAB image data to graphics files using the `imwrite` function.

`imread` and `imwrite` both support a variety of graphics file formats and compression schemes.

When you read image data into MATLAB using `imread`, the data is usually stored as an array of 8-bit integers. However, `imread` also supports reading 16-bit-per-pixel data from TIFF and PNG files. These are more efficient storage methods than the double-precision (64-bit) floating-point numbers that MATLAB typically uses. However, it is necessary for MATLAB to interpret 8-bit and 16-bit image data differently from 64-bit data. This table summarizes these differences.

You cannot interactively pan or zoom outside the *x*-limits or *y*-limits of an image, unless the axes limits are already been set outside the bounds of the image, in which case there is no such restriction. If other objects (such as lineseries) occupy the axes and extend beyond the bounds of the image, you can pan or zoom to the bounds of the other objects, but no further.

Image Type	Double-Precision Data (double Array)	8-Bit Data (uint8 Array) 16-Bit Data (uint16 Array)
Indexed (colormap)	Image is stored as a two-dimensional (`m`-by-`n`) array of integers in the range [1, `length(colormap)`]; `colormap` is an `m`-by-3 array of floating-point values in the range [0, 1].	Image is stored as a two-dimensional (`m`-by-`n`) array of integers in the range [0, 255] (`uint8`) or [0, 65535] (`uint16`); `colormap` is an `m`-by-3 array of floating-point values in the range [0, 1].
True color (RGB)	Image is stored as a three-dimensional (`m`-by-`n`-by-3) array of floating-point values in the range [0, 1].	Image is stored as a three-dimensional (`m`-by-`n`-by-3) array of integers in the range [0, 255] (`uint8`) or [0, 65535] (`uint16`).

Indexed Images

In an indexed image of class `double`, the value 1 points to the first row in the colormap, the value 2 points to the second row, and so on. In a `uint8` or `uint16` indexed image, there is an offset; the value 0 points to the first row in the colormap, the value 1 points to the second row, and so on.

If you want to convert a `uint8` or `uint16` indexed image to `double`, you need to add 1 to the result. For example,

```
X64 = double(X8) + 1;
```

or

```
X64 = double(X16) + 1;
```

To convert from `double` to `uint8` or `uint16`, you need to first subtract 1, and then use `round` to ensure all the values are integers.

```
X8 = uint8(round(X64 - 1));
```

or

```
X16 = uint16(round(X64 - 1));
```

When you write an indexed image using `imwrite`, MATLAB automatically converts the values if necessary.

Colormaps

Colormaps in MATLAB are always `m`-by-3 arrays of double-precision floating-point numbers in the range [0, 1]. In most graphics file formats, colormaps are stored as integers, but MATLAB does not support colormaps with integer values. `imread` and `imwrite` automatically convert colormap values when reading and writing files.

True Color Images

In a true color image of class `double`, the data values are floating-point numbers in the range [0, 1]. In a true color image of class `uint8`, the data values are integers in the range [0, 255], and for true color images of class `uint16` the data values are integers in the range [0, 65535].

If you want to convert a true color image from one data type to the other, you must rescale the data. For example, this statement converts a `uint8` true color image to `double`.

```
RGB64 = double(RGB8)/255;
```

or for `uint16` images,

```
RGB64 = double(RGB16)/65535;
```

This statement converts a `double` true color image to `uint8`:

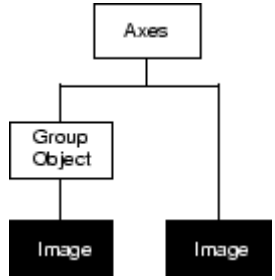
```
RGB8 = uint8(round(RGB64*255));
```

or to obtain `uint16` images, type

```
RGB16 = uint16(round(RGB64*65535));
```

When you write a true color image using `imwrite`, MATLAB automatically converts the values if necessary.

Object Hierarchy



Setting Default Properties

You can set default image properties on the axes, figure, and root levels:

```
set(0,'DefaultImageProperty',PropertyValue...)
set(gcf,'DefaultImageProperty',PropertyValue...)
set(gca,'DefaultImageProperty',PropertyValue...)
```

where *Property* is the name of the image property and PropertyValue is the value you are specifying. Use set and get to access image properties.

Example

Example 1

Load a mat-file containing a photograph of a colorful primate. Display the indexed image using its associated colormap.

```
load mandrill
figure('color','k')
image(X)
colormap(map)
axis off          % Remove axis ticks and numbers
axis image        % Set aspect ratio to obtain square pixels
```

Example 2

Load a JPEG image file of the Cat's Eye Nebula from the Hubble Space Telescope (image courtesy NASA). Display the original image using its RGB color values (left) as a subplot. Create a linked subplot (same

size and scale) to display the transformed intensity image as a heat map (right).

```
figure
ax(1) = subplot(1,2,1);
rgb = imread('ngc6543a.jpg');
image(rgb); title('RGB image')
ax(2) = subplot(122);
im = mean(rgb,3);
image(im); title('Intensity Heat Map')
colormap(hot(256))
linkaxes(ax,'xy')
axis(ax,'image')
```

"Bit-Mapped Images" on page 1-92 for related functions

Image Properties for property descriptions

Purpose

Define image properties

Modifying Properties

You can set and query graphics object properties in two ways:

- "The Property Editor" is an interactive tool that enables you to see and change object property values.
- The `set` and `get` commands enable you to set and query the values of properties.

To change the default values of properties, see "Setting Default Property Values".

See "Core Graphics Objects" for general information about this type of object.

Image Properties

This section lists property names along with the types of values each property accepts.

`AlphaData`

m-by-n matrix of `double` or `uint8`

The transparency data. A matrix of non-NaN values specifying the transparency of each face or vertex of the object. The `AlphaData` can be of class double or uint8.

MATLAB determines the transparency in one of three ways:

- Using the elements of `AlphaData` as transparency values (`AlphaDataMapping` set to `none`)
- Using the elements of `AlphaData` as indices into the current alphamap (`AlphaDataMapping` set to `direct`)
- Scaling the elements of `AlphaData` to range between the minimum and maximum values of the axes `ALim` property (`AlphaDataMapping` set to `scaled`, the default)

`AlphaDataMapping`
`{none} | direct| scaled`

Transparency mapping method. This property determines how MATLAB interprets indexed alpha data. It can be any of the following:

- `none` — The transparency values of `AlphaData` are between 0 and 1 or are clamped to this range (the default).
- `scaled` — Transform the `AlphaData` to span the portion of the alphamap indicated by the axes `ALim` property, linearly mapping data values to alpha values.
- `direct` — Use the `AlphaData` as indices directly into the alphamap. When not scaled, the data are usually integer values ranging from `1` to `length(alphamap)`. MATLAB maps values less than `1` to the first alpha value in the alphamap, and values greater than `length(alphamap)` to the last alpha value in the alphamap. Values with a decimal portion are fixed to the nearest, lower integer. If `AlphaData` is an array of `uint8` integers, then the indexing begins at `0` (i.e., MATLAB maps a value of `0` to the first alpha value in the alphamap).

`Annotation`
`hg.Annotation` object Read Only

Control the display of image objects in legends. The `Annotation` property enables you to specify whether this image object is represented in a figure legend.

Querying the `Annotation` property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the image object is displayed in a figure legend:

IconDisplayStyle Value	Purpose
`on`	Represent this image object in a legend (default)
`off`	Do not include this image object in a legend
`children`	Same as `on` because image objects do not have children

Setting the `IconDisplayStyle` property

These commands set the `IconDisplayStyle` of a graphics object with handle `hobj` to `off`:

```
hAnnotation = get(hobj,'Annotation');
hLegendEntry = get(hAnnotation','LegendInformation');
set(hLegendEntry,'IconDisplayStyle','off')
```

Using the `IconDisplayStyle` property

See “Controlling Legends” for more information and examples.

`BeingDeleted`
`on | {off}` Read Only

This object is being deleted. The `BeingDeleted` property provides a mechanism that you can use to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object’s delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object’s delete function might call other functions that act on a number of different objects. These functions might not need to perform actions on objects if the objects are going to be deleted, and therefore, can check the object’s `BeingDeleted` property before acting.

`BusyAction`
`cancel | {queue}`

Callback routine interruption. The `BusyAction` property enables you to control how MATLAB handles events that potentially interrupt executing callbacks. If there is a callback function executing, callbacks invoked subsequently always attempt to interrupt it.

If the `Interruptible` property of the object whose callback is executing is set to `on` (the default), then interruption occurs at the next point where the event queue is processed. If the `Interruptible` property is `off`, the `BusyAction` property (of the object owning the executing callback) determines how MATLAB handles the event. The choices are

- `cancel` — Discard the event that attempted to execute a second callback routine.
- `queue` — Queue the event that attempted to execute a second callback routine until the current callback finishes.

`ButtonDownFcn`
string or function handle

Button press callback function. A callback that executes whenever you press a mouse button while the pointer is over this object, but not over another graphics object. See the `HitTestArea` property for information about selecting objects of this type.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

This property can be

- A string that is a valid MATLAB expression
- The name of an M-file
- A function handle

Set this property to a function handle that references the callback. The expressions execute in the MATLAB workspace.

See “Function Handle Callbacks” for information on how to use function handles to define the callbacks.

`CData`

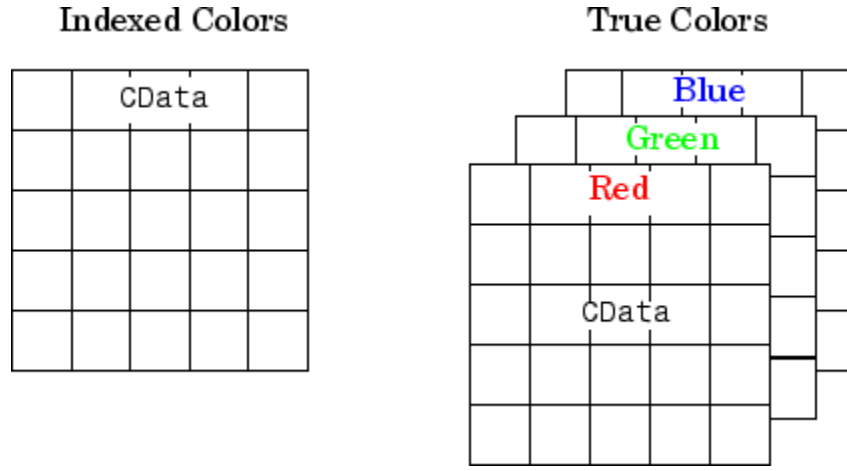
matrix or m-by-n-by-3 array

The image data. A matrix or 3-D array of values specifying the color of each rectangular area defining the image. `image(C)` assigns the values of `C` to `CData`. MATLAB determines the coloring of the image in one of three ways:

- Using the elements of `CData` as indices into the current colormap (the default) (`CDataMapping` set to `direct`)
- Scaling the elements of `CData` to range between the values `min(get(gca,'CLim'))` and `max(get(gca,'CLim'))` (`CDataMapping` set to `scaled`)
- Interpreting the elements of `CData` directly as RGB values (true color specification)

Note that the behavior of `NaN`s in image `CData` is not defined. See the image `AlphaData` property for information on using transparency with images.

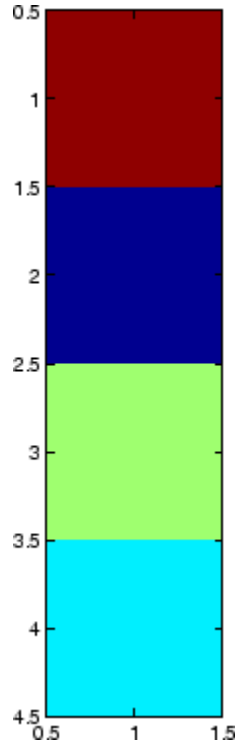
A true color specification for `CData` requires an m-by-n-by-3 array of RGB values. The first page contains the red component, the second page the green component, and the third page the blue component of each element in the image. RGB values range from 0 to 1. The following picture illustrates the relative dimensions of `CData` for the two color models.



If `CData` has only one row or column, the height or width respectively is always one data unit and is centered about the first `YData` or `XData` element respectively. For example, using a 4-by-1 matrix of random data,

```
C = rand(4,1);
image(C,'CDataMapping','scaled')
axis image
```

produces



`CDataMapping`
`scaled | {direct}`

Direct or scaled indexed colors. This property determines whether MATLAB interprets the values in `CData` as indices into the figure colormap (the default) or scales the values according to the values of the axes `CLim` property.

When `CDataMapping` is `direct`, the values of `CData` should be in the range 1 to `length(get(gcf,'Colormap'))`. If you use true color specification for `CData`, this property has no effect.

`Children`
handles

The empty matrix; image objects have no children.

`Clipping`
`on | off`

Clipping mode. By default, MATLAB clips images to the axes rectangle. If you set `Clipping` to `off`, the image can be displayed outside the axes rectangle. For example, if you create an image, set `hold` to `on`, freeze axis scaling (with `axis manual`), and then create a larger image, it extends beyond the axis limits.

`CreateFcn`
string or function handle

Callback routine executed during object creation. This property defines a callback routine that executes when MATLAB creates an image object. You must define this property as a default value for images or in a call to the `image` function to create a new image object. For example, the statement

```
set(0,'DefaultImageCreateFcn','axis image')
```

defines a default value on the root level that sets the aspect ratio and the axis limits so the image has square pixels. MATLAB executes this routine after setting all image properties. Setting this property on an existing image object has no effect.

The handle of the object whose `CreateFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

`DeleteFcn`
string or function handle

Callback executed during object deletion. A callback that executes when this object is deleted (e.g., this might happen when you issue

a `delete` command on the object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object's properties so the callback routine can query these values.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which can be queried using `gcbo`.

See "Function Handle Callbacks" for information on how to use function handles to define the callback function.

See the `BeingDeleted` property for related information.

`DisplayName`
string (default is empty string)

String used by legend for this image object. The `legend` function uses the string defined by the `DisplayName` property to label this image object in the legend.

- If you specify string arguments with the `legend` function, `DisplayName` is set to this image object's corresponding string and that string is used for the legend.
- If `DisplayName` is empty, legend creates a string of the form, `['data' n]`, where *n* is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, `DisplayName` is set to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add programmatically a legend that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See “Controlling Legends” for more examples.

`EraseMode`

`{normal} | none | xor | background`

Erase mode. This property controls the technique MATLAB uses to draw and erase objects and their children. Alternative erase modes are useful for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to ensure that all objects are rendered correctly. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- `none` — Do not erase objects when they are moved or destroyed. While the objects are still visible on the screen after erasing with `EraseMode none`, you cannot print these objects because MATLAB stores no information about their former locations.
- `xor` — Draw and erase the object by performing an exclusive OR (XOR) with each pixel index of the screen behind it. Erasing the object does not damage the color of the objects behind it. However, the color of the erased object depends on the color of the screen behind it and it is correctly colored only when it is over the axes background color (or the figure background color if the axes `Color` property is set to `none`). That is, it isn't erased correctly if there are objects behind it.
- `background` — Erase the graphics objects by redrawing them in the axes background color, (or the figure background color if the axes `Color` property is set to `none`). This damages other graphics objects that are behind the erased object, but the erased object is always properly colored.

Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB can mathematically combine layers of colors (e.g., performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

Set the axes background color with the axes `Color` property. Set the figure background color with the figure `Color` property.

You can use the MATLAB `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

`HandleVisibility`

```
{on} | callback | off
```

Control access to object's handle by command-line users and GUIs. This property determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally accessing objects that you need to protect for some reason.

- `on` — Handles are always visible when `HandleVisibility` is `on`.
- `callback` — Setting `HandleVisibility` to `callback` causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Setting `HandleVisibility` to `off` makes handles invisible at all times. This might be necessary when a callback invokes a function that might potentially damage the GUI (such as evaluating a user-typed string) and so temporarily hides its own handles during the execution of that function.

Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

Properties Affected by Handle Visibility

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

Overriding Handle Visibility

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings (this does not affect the values of the `HandleVisibility` properties). See also `findall`.

Handle Validity

Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

Note If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

`HitTest`

`{on} | off`

Selectable by mouse click. `HitTest` determines whether this object can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the objects that compose the area graph. If `HitTest` is `off`, clicking this object selects the object below it (which is usually the axes containing it).

`Interruptible`

`{on} | off`

Callback routine interruption mode. The `Interruptible` property controls whether an object's callback can be interrupted by callbacks invoked subsequently.

Only callbacks defined for the `ButtonDownFcn` property are affected by the `Interruptible` property. MATLAB checks for events that can interrupt a callback only when it encounters a `drawnow`, `figure`, `getframe`, or `pause` command in the routine. See the `BusyAction` property for related information.

Setting `Interruptible` to `on` allows any graphics object's callback to interrupt callback routines originating from a bar property. Note that MATLAB does not save the state of variables or the display (e.g., the handle returned by the `gca` or `gcf` command) when an interruption occurs.

`Parent`

handle of parent axes, hggroup, or hgtransform

Parent of this object. This property contains the handle of the object's parent. The parent is normally the axes, hggroup, or hgtransform object that contains the object.

See "Objects That Can Contain Other Objects" for more information on parenting graphics objects.

`Selected`
`on | {off}`

Is object selected? When you set this property to `on`, MATLAB displays selection "handles" at the corners and midpoints if the `SelectionHighlight` property is also `on` (the default). You can, for example, define the `ButtonDownFcn` callback to set this property to `on`, thereby indicating that this particular object is selected. This property is also set to `on` when an object is manually selected in plot edit mode.

`SelectionHighlight`
`{on} | off`

Objects are highlighted when selected. When the `Selected` property is `on`, MATLAB indicates the selected state by drawing four edge handles and four corner handles. When `SelectionHighlight` is `off`, MATLAB does not draw the handles except when in plot edit mode and objects are selected manually.

`Tag`
string

User-specified object label. The `Tag` property provides a means to identify graphics objects with a user-specified label. This is particularly useful when you are constructing interactive graphics programs that would otherwise need to define object handles as global variables or pass them as arguments between callbacks. You can define `Tag` as any string.

For example, you might create an areaseries object and set the `Tag` property.

```
t = area(Y,'Tag','area1')
```

When you want to access objects of a given type, you can use `findobj` to find the object's handle. The following statement changes the `FaceColor` property of the object whose `Tag` is `area1`.

```
set(findobj('Tag','area1'),'FaceColor','red')
```

`Type`
string (read only)

Type of graphics object. This property contains a string that identifies the class of graphics object. For image objects, `Type` is always '`image`'.

`UIContextMenu`
handle of a uicontextmenu object

Associate a context menu with this object. Assign this property the handle of a uicontextmenu object created in the object's parent figure. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the object.

`UserData`
array

User-specified data. This property can be any data you want to associate with this object (including cell arrays and structures). The object does not set values for this property, but you can access it using the `set` and `get` functions.

`Visible`
`{on} | off`

Visibility of this object and its children. By default, a new object's visibility is `on`. This means all children of the object are visible unless the child object's `Visible` property is set to `off`. Setting an object's `Visible` property to `off` prevents the object from being displayed. However, the object still exists and you can set and query its properties.

`XData`
`[1 size(CData,2)]` by default

Control placement of image along x-axis. A vector specifying the locations of the centers of the elements `CData(1,1)` and `CData(m,n)`, where `CData` has a size of `m`-by-`n`. Element `CData(1,1)` is centered over the coordinate defined by the first elements in `XData` and `YData`. Element `CData(m,n)` is centered over the coordinate defined by the last elements in `XData` and `YData`. The centers of the remaining elements of `CData` are evenly distributed between those two points.

The width of each `CData` element is determined by the expression

```
(XData(2)-XData(1))/(size(CData,2)-1)
```

You can also specify a single value for `XData`. In this case, `image` centers the first element at this coordinate and centers each following element one unit apart.

`YData`

`[1 size(CData,1)]` by default

Control placement of image along y-axis. A vector specifying the locations of the centers of the elements `CData(1,1)` and `CData(m,n)`, where `CData` has a size of `m`-by-`n`. Element `CData(1,1)` is centered over the coordinate defined by the first elements in `XData` and `YData`. Element `CData(m,n)` is centered over the coordinate defined by the last elements in `XData` and `YData`. The centers of the remaining elements of `CData` are evenly distributed between those two points.

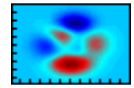
The height of each `CData` element is determined by the expression

```
(YData(2)-YData(1))/(size(CData,1)-1)
```

You can also specify a single value for `YData`. In this case, `image` centers the first element at this coordinate and centers each following element one unit apart.

Purpose

Scale data and display image object



GUI Alternatives

To plot a selected matrix as an image use the Plot Selector  in the Workspace Browser, or use the Figure Palette Plot Catalog. Manipulate image characteristics in *plot edit* mode with the Property Editor. For details, see Plotting Tools — Interactive Plotting in the MATLAB Graphics documentation and Creating Graphics from the Workspace Browser in the MATLAB Desktop Tools documentation.

Syntax

```
imagesc(C)
imagesc(x,y,C)
imagesc(...,clims)
h = imagesc(...)
```

Description

The `imagesc` function scales image data to the full range of the current colormap and displays the image. (See “Examples” on page 2-1650 for an illustration.)

`imagesc(C)` displays `C` as an image. Each element of `C` corresponds to a rectangular area in the image. The values of the elements of `C` are indices into the current colormap that determine the color of each patch.

`imagesc(x,y,C)` displays `C` as an image and specifies the bounds of the *x*- and *y*-axis with vectors `x` and `y`.

`imagesc(...,clims)` normalizes the values in `C` to the range specified by `clims` and displays `C` as an image. `clims` is a two-element vector that limits the range of data values in `C`. These values map to the full range of values in the current colormap.

`h = imagesc(...)` returns the handle for an image graphics object.

Remarks

`x` and `y` do not affect the elements in `C`; they only affect the annotation of the axes. If `length(x) > 2` or `length(y) > 2`, `imagesc` ignores all except the first and last elements of the respective vector.

`imagesc` creates an image with `CDataMapping` set to scaled, and sets the axes `CLim` property to the value passed in `clims`.

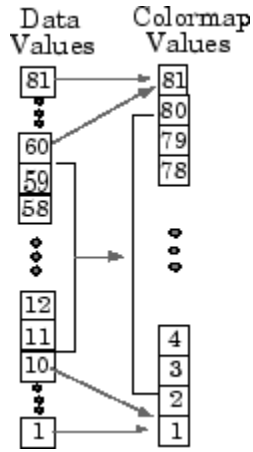
You cannot interactively pan or zoom outside the *x*-limits or *y*-limits of an image.

Examples

You can expand midrange color resolution by mapping low values to the first color and high values to the last color in the colormap by specifying color value limits (`clims`). If the size of the current colormap is 81-by-3, the statements

```
clims = [ 10 60 ]
imagesc(C,clims)
```

map the data values in C to the colormap as shown in this illustration and the code that follows:



In this example, the left image maps to the `gray` colormap using the statements

```
load clown
imagesc(X)
colormap(gray)
```

The right image has values between 10 and 60 scaled to the full range of the gray colormap using the statements

```
load clown
clims = [10 60];
imagesc(X,clims)
colormap(gray)
```

image, imfinfo, imread, imwrite, colorbar, colormap, pcolor, surface, surf

"Bit-Mapped Images" on page 1-92 for related functions

Purpose

Information about graphics file

Syntax

```
info = imfinfo(filename,fmt)
info = imfinfo(filename)
info = imfino(URL,...)
```

Description

`info = imfinfo(filename,fmt)` returns a structure, `info`, whose fields contain information about an image in a graphics file. `filename` is a string that specifies the name of the graphics file, and *`fmt`* is a string that specifies the format of the file. The file must be in the current directory or in a directory on the MATLAB path. If `imfinfo` cannot find a file named `filename`, it looks for a file named `filename.`*`fmt`*. The possible values for *`fmt`* are contained in the MATLAB file format registry. To view of list of these formats, run the `imformats` command.

If `filename` is a TIFF, HDF, ICO, GIF, or CUR file containing more than one image, `info` is a structure array with one element for each image in the file. For example, `info(3)` would contain information about the third image in the file.

`info = imfinfo(filename)` attempts to infer the format of the file from its contents.

`info = imfino(URL,...)` reads the image from the specified Internet `URL`. The URL must include the protocol type (e.g., `http://`)

Information Returned

The set of fields in `info` depends on the individual file and its format. However, the first nine fields are always the same. This table lists these common fields, in the order they appear in the structure, and describes their values.

Field	Value
`Filename`	A string containing the name of the file; if the file is not in the current directory, the string contains the full pathname of the file.

Field	Value
`FileModDate`	A string containing the date when the file was last modified
`FileSize`	An integer indicating the size of the file in bytes
`Format`	A string containing the file format, as specified by *`fmt`*; for JPEG and TIFF files, the three-letter variant is returned.
`FormatVersion`	A string or number describing the version of the format
`Width`	An integer indicating the width of the image in pixels
`Height`	An integer indicating the height of the image in pixels
`BitDepth`	An integer indicating the number of bits per pixel
`ColorType`	A string indicating the type of image; either `'truecolor'` for a truecolor RGB image, `'grayscale'` for a grayscale intensity image, or `'indexed'` for an indexed image

Example

```
info = imfinfo('canoe.tif')

info =

                    Filename: [1x76 char]
                FileModDate: '04-Dec-2000 13:57:55'
                    FileSize: 69708
                      Format: 'tif'
                FormatVersion: []
                       Width: 346
                      Height: 207
                    BitDepth: 8
                   ColorType: 'indexed'
```

```
                FormatSignature: [73 73 42 0]
                      ByteOrder: 'little-endian'
                 NewSubFileType: 0
                  BitsPerSample: 8
                    Compression: 'PackBits'
PhotometricInterpretation: 'RGB Palette'
                   StripOffsets: [9x1 double]
               SamplesPerPixel: 1
                  RowsPerStrip: 23
               StripByteCounts: [9x1 double]
                   XResolution: 72
                   YResolution: 72
                ResolutionUnit: 'Inch'
                      Colormap: [256x3 double]

`imformats`, `imread`, `imwrite`

“Bit-Mapped Images” on page 1-92 for related functions

Purpose

Manage image file format registry

Syntax

```
imformats
formats = imformats
formats = imformats('fmt')
formats = imformats(format_struct)
formats = imformats('factory')
```

Description

`imformats` displays a table of information listing all the values in the MATLAB file format registry. This registry determines which file formats are supported by the `imfinfo`, `imread`, and `imwrite` functions.

`formats = imformats` returns a structure containing all the values in the MATLAB file format registry. The following tables lists the fields in the order they appear in the structure.

Field	Value
`ext`	A cell array of strings that specify filename extensions that are valid for this format
`isa`	A string specifying the name of the function that determines if a file is a certain format. This can also be a function handle.
`info`	A string specifying the name of the function that reads information about a file. This can also be a function handle.
`read`	A string specifying the name of the function that reads image data in a file. This can also be a function handle.
`write`	A string specifying the name of the function that writes MATLAB data to a file. This can also be a function handle.
`alpha`	Returns `1` if the format has an alpha channel, `0` otherwise
`description`	A text description of the file format

Note The values for the `isa`, `info`, `read`, and `write` fields must be functions on the MATLAB search path or function handles.

`formats = imformats('fmt')` searches the known formats in the MATLAB file format registry for the format associated with the filename extension `'fmt'`. If found, `imformats` returns a structure containing the characteristics and function names associated with the format. Otherwise, it returns an empty structure.

`formats = imformats(format_struct)` sets the MATLAB file format registry to the values in `format_struct`. The output structure, `formats`, contains the new registry settings.

Caution Using `imformats` to specify values in the MATLAB file format registry can result in the inability to load any image files. To return the file format registry to a working state, use `imformats` with the `'factory'` setting.

`formats = imformats('factory')` resets the MATLAB file format registry to the default format registry values. This removes any user-specified settings.

Changes to the format registry do not persist between MATLAB sessions. To have a format always available when you start MATLAB, add the appropriate `imformats` command to the MATLAB startup file, `startup.m`, located in `$MATLAB/toolbox/local` on UNIX systems, or `$MATLAB\toolbox\local` on Windows systems.

Example

```
formats = imformats;
formats(1)

ans =

            ext: {'bmp'}
```

```
          isa: @isbmp
         info: @imbmpinfo
         read: @readbmp
        write: @writebmp
        alpha: 0
  description: 'Windows Bitmap (BMP)'
```

See Also

`fileformats`, `imfinfo`, `imread`, `imwrite`, `path`

"Bit-Mapped Images" on page 1-92 for related functions

import

Purpose

Add package or class to current Java import list

Syntax

```
import package_name.*
import class_name
import cls_or_pkg_name1 cls_or_pkg_name2...
import
L = import
```

Description

`import package_name.*` adds all the classes in *`package_name`* to the current import list. Note that *`package_name`* must be followed by `.*`.

`import class_name` adds a single class to the current import list. Note that *`class_name`* must be fully qualified (that is, it must include the package name).

`import cls_or_pkg_name1 cls_or_pkg_name2...` adds all named classes and packages to the current import list. Note that each class name must be fully qualified, and each package name must be followed by `.*`.

`import` with no input arguments displays the current import list, without adding to it.

`L = import` with no input arguments returns a cell array of strings containing the current import list, without adding to it.

The `import` command operates exclusively on the import list of the function from which it is invoked. When invoked at the command prompt, `import` uses the import list for the MATLAB command environment. If `import` is used in a script invoked from a function, it affects the import list of the function. If `import` is used in a script that is invoked from the command prompt, it affects the import list for the command environment.

The import list of a function is persistent across calls to that function and is only cleared when the function is cleared.

To clear the current import list, use the following command.

```
clear import
```

This command may only be invoked at the command prompt. Attempting to use `clear import` within a function results in an error.

Remarks

The only reason for using `import` is to allow your code to refer to each imported class with the immediate class name only, rather than with the fully qualified class name. `import` is particularly useful in streamlining calls to constructors, where most references to Java classes occur.

Examples

This example shows importing and using the single class, `java.lang.String`, and two complete packages, `java.util` and `java.awt`.

```
import java.lang.String
import java.util.* java.awt.*
f = Frame;             % Create java.awt.Frame object
s = String('hello');   % Create java.lang.String object
methods Enumeration    % List java.util.Enumeration methods
```

See Also

`clear`, `importdata`

importdata

Purpose

Load data from disk file

Syntax

```
importdata(filename)
A = importdata(filename)
A = importdata(filename,delimiter)
A = importdata(filename,delimiter,headerline)
[A D] = importdata(...)
[A D H] = importdata(...)
[...] = importdata('-pastespecial', ...)
```

Description

`importdata(filename)` loads data from `filename` into the workspace. The `filename` input is a string enclosed in single quotes.

`A = importdata(filename)` loads data from `filename` into structure `A`.

`A = importdata(filename,delimiter)` loads data from `filename` using `delimiter` as the column separator. The `delimiter` argument must be a string enclosed in single quotes. Use `'\t'` for tab. When importing from an ASCII file, `delimiter` only separates numeric data.

`A = importdata(filename,delimiter,headerline)` where `headerline` is a number that indicates on which line of the file the header text is located, loads data from line `headerline+1` to the end of the file.

`[A D] = importdata(...)` returns the output structure in `A`, and the delimiter character in `D`.

`[A D H] = importdata(...)` returns the output structure in `A`, the delimiter character in `D`, and the line number of the header in `H`.

`[...] = importdata('-pastespecial', ...)` loads data from your computer's paste buffer rather than from a file.

Remarks

`importdata` looks at the file extension to determine which helper function to use. If it can recognize the file extension, `importdata` calls the appropriate helper function, specifying the maximum number of output arguments. If it cannot recognize the file extension, `importdata` calls `finfo` to determine which helper function to use. If no helper

function is defined for this file extension, `importdata` treats the file as delimited text. `importdata` removes from the result empty outputs returned from the helper function.

Examples

Example 1 — A Simple Import

Import data from file `ding.wav`:

```
s = importdata('ding.wav')
s =

    data: [11554x1 double]
      fs: 22050
```

Example 2 — Importing with Delimiter and Header

Use `importdata` to read in a text file. The third input argument is `colheaders`, which is the number of lines that belong to the header:

```
type 'myfile.txt'

 Day1  Day2  Day3  Day4  Day5  Day6  Day7
95.01 76.21 61.54 40.57  5.79 20.28  1.53
23.11 45.65 79.19 93.55 35.29 19.87 74.68
60.68  1.85 92.18 91.69 81.32 60.38 44.51
48.60 82.14 73.82 41.03  0.99 27.22 93.18
89.13 44.47 17.63 89.36 13.89 19.88 46.60
```

Import from the file, specifying the space character as the delimiter and 1 row for the column header. Assign the output to variable `M`:

```
M = importdata('myfile.txt', ' ', 1);
```

Print out columns 3 and 5, including the header for those columns:

```
for k=3:2:5
   M.colheaders(1,k)
   M.data(:,k)
   disp ' '
end
```

```
ans =
    'Day3'
ans =
   61.5400
   79.1900
   92.1800
   73.8200
   17.6300

ans =
    'Day5'
ans =
    5.7900
   35.2900
   81.3200
    0.9900
   13.8900
```

See Also

load

Purpose

Read image from graphics file

Syntax

```
A = imread(filename, fmt)
[X, map] = imread(...)
[...]  = imread(filename)
[...]  = imread(URL,...)
[...]  = imread(..., idx)  CUR or ICO
[A, map, alpha] = imread(...)  CUR or ICO
[...]  = imread(..., idx)  GIF
[...]  = imread(..., 'frames', idx)  GIF
[...]  = imread(..., ref)  HDF4
[...]  = imread(...,'BackgroundColor',BG) PNG
[A, map, alpha] = imread(...)  PNG
[...]  = imread(..., idx)  TIFF
[...]  = imread(..., 'PixelRegion', {ROWS, COLS})  TIFF
```

Description

`A = imread(filename, fmt)` reads a grayscale or color image from the file specified by the string `filename`. If the file is not in the current directory, or in a directory on the MATLAB path, specify the full pathname.

The text string *`fmt`* specifies the format of the file by its standard file extension. For example, specify `'gif'` for Graphics Interchange Format files. To see a list of supported formats, with their file extensions, use the `imformats` function. If `imread` cannot find a file named `filename`, it looks for a file named `filename.fmt`.

The return value `A` is an array containing the image data. If the file contains a grayscale image, `A` is an M-by-N array. If the file contains a truecolor image, `A` is an M-by-N-by-3 array. For TIFF files containing color images that use the CMYK color space, `A` is an M-by-N-by-4 array. See TIFF in the Format-Specific Information section for more information.

The class of `A` depends on the bits-per-sample of the image data, rounded to the next byte boundary. For example, `imread` returns 24-bit color data as an array of `uint8` data because the sample size for

each color component is 8 bits. See "Remarks" on page 2-1664 for a discussion of bitdepths, and see "Format-Specific Information" on page 2-1664 for more detail about supported bitdepths and sample sizes for a particular format.

`[X, map] = imread(...)` reads the indexed image in `filename` into `X` and its associated colormap into `map`. Colormap values in the image file are automatically rescaled into the range `[0,1]`.

`[...] = imread(filename)` attempts to infer the format of the file from its content.

`[...] = imread(URL,...)` reads the image from an Internet URL. The `URL` must include the protocol type (e.g., `http://`).

See the format-specific sections for additional syntaxes.

Remarks

Bitdepth is the number of bits used to represent each image pixel. Bitdepth is calculated by multiplying the bits-per-sample with the samples-per-pixel. Thus, a format that uses 8-bits for each color component (or sample) and three samples per pixel has a bitdepth of 24. Sometimes the sample size associated with a bitdepth can be ambiguous: does a 48-bit bitdepth represent six 8-bit samples, four 12-bit samples, or three 16-bit samples? The following format-specific sections provide sample size information to avoid this ambiguity.

Format-Specific Information

The following sections provide information about the support for specific formats, listed in alphabetical order by format name. These sections include information about format-specific syntaxes, if they exist. The following is a list of links to the various sections.

BMP — Windows Bitmap

The following table lists the supported bitdepths, compression, and output classes for BMP data.

Supported Bitdepths	No Compression	RLE Compression	Output Class	Notes
1-bit	x	–	logical	
4-bit	x	x	`uint8`	
8-bit	x	x	`uint8`	
16-bit	x	–	`uint8`	1 sample/pixel
24-bit	x	–	`uint8`	3 samples/pixel
32-bit	x	–	`uint8`	3 samples/pixel (1 byte padding)

CUR — Cursor File

The following table lists the supported bitdepths, compression, and output classes for Cursor files and Icon files.

Supported Bitdepths	No Compression	Compression	Output Class
1-bit	x	–	logical
4-bit	x	–	`uint8`
8-bit	x	–	`uint8`

The following are format-specific syntaxes for Cursor files and Icon files.

`[...] = imread(..., idx)` `CUR or ICO` reads in one image from a multi-image icon or cursor file. `idx` is an integer value that specifies the order that the image appears in the file. For example, if `idx` is `3`, `imread` reads the third image in the file. If you omit this argument, `imread` reads the first image in the file.

`[A, map, alpha] = imread(...)` `CUR or ICO` returns the AND mask for the resource, which can be used to determine the transparency information. For cursor files, this mask may contain the only useful data.

Note By default, Microsoft Windows cursors are 32-by-32 pixels. MATLAB pointers must be 16-by-16. You will probably need to scale your image. If you have Image Processing Toolbox, you can use the `imresize` function.

GIF — Graphics Interchange Format

The following table lists the supported bitdepths, compression, and output classes for GIF files.

Supported Bitdepths	No Compression	Compression	Output Class
1-bit	x	–	logical
2-bit to 8-bit	x	–	`uint8`

The following are format-specific syntaxes for GIF files.

`[...] = imread(..., idx)` `GIF` reads in one or more frames from a multiframe (i.e., animated) GIF file. `idx` must be an integer scalar or vector of integer values. For example, if `idx` is `3`, `imread` reads the third image in the file. If `idx` is `1:5`, `imread` returns only the first five frames.

`[...] = imread(..., 'frames', idx)` `GIF` is the same as the syntax above except that `idx` can be `'all'`. In this case, all the frames are read and returned in the order that they appear in the file.

Note Because of the way that GIF files are structured, all the frames must be read when a particular frame is requested. Consequently, it is much faster to specify a vector of frames or `'all'` for `idx` than to call `imread` in a loop when reading multiple frames from the same GIF file.

HDF4 — Hierarchical Data Format

The following table lists the supported bitdepths, compression, and output classes for HDF4 files.

Supported Bitdepths	Raster Image with colormap	Raster image without colormap	Output Class	Notes
8-bit	x	x	`uint8`	
24-bit	–	–	`uint8`	3 samples/pixel

The following are format-specific syntaxes for HDF4 files.

`[...] = imread(..., ref)` `HDF4` reads in one image from a multi-image HDF4 file. `ref` is an integer value that specifies the reference number used to identify the image. For example, if `ref` is `12`, `imread` reads the image whose reference number is 12. (Note that in an HDF4 file the reference numbers do not necessarily correspond to the order of the images in the file. You can use `imfinfo` to match image

order with reference number.) If you omit this argument, `imread` reads the first image in the file.

ICO — Icon File

See CUR – Cursor File

JPEG — Joint Photographic Experts Group

`imread` can read any baseline JPEG image as well as JPEG images with some commonly used extensions. The following table lists the supported bitdepths, compression, and output classes for JPEG files.

Supported Bitdepths	Lossy Compression	Lossless Compression	Output Class	Notes
8-bit	x	x	`uint8`	Grayscale or RGB
12-bit	x	x	`uint16`	Grayscale
16-bit	–	x	`uint16`	Grayscale
36-bit	x	x	`uint16`	RGB Three 12-bit samples/pixel

PBM — Portable Bitmap

The following table lists the supported bitdepths, compression, and output classes for PBM files.

Supported Bitdepths	Raw Binary	ASCII (Plain) Encoded	Output Class
1-bit	x	x	logical

PCX — Windows Paintbrush

The following table lists the supported bitdepths, compression, and output classes for PCX files.

Supported Bitdepths	Output Class	Notes
1-bit	`logical`	Grayscale only
8-bit	`uint8`	Grayscale or indexed
24-bit	`uint8`	RGB Three 8-bit samples/pixel

PGM — Portable Graymap

The following table lists the supported bitdepths, compression, and output classes for PGM files.

Supported Bitdepths	Raw Binary	ASCII (Plain) Encoded	Output Class
Up to 16-bit	x	–	`uint8`
Arbitrary	–	x	

PNG — Portable Network Graphics

The following table lists the supported bitdepths, compression, and output classes for PNG data.

Supported Bitdepths	Output Class	Notes
1-bit	`logical`	Grayscale
2-bit	`uint8`	Grayscale
4-bit	`uint8`	Grayscale
8-bit	`uint8`	Grayscale or Indexed
16-bit	`uint16`	Grayscale or Indexed

Supported Bitdepths	Output Class	Notes
24-bit	`uint8`	RGB Three 8-bit samples/pixel.
48-bit	`uint16`	RGB Three 16-bit samples/pixel.

The following are format-specific syntaxes for PNG files.

`[...] = imread(...,'BackgroundColor',BG)` `PNG` composites any transparent pixels in the input image against the color specified in `BG`. If `BG` is `'none'`, then no compositing is performed. If the input image is indexed, `BG` must be an integer in the range `[1,P]` where `P` is the colormap length. If the input image is grayscale, `BG` should be an integer in the range `[0,1]`. If the input image is RGB, `BG` should be a three-element vector whose values are in the range `[0,1]`. The string `'BackgroundColor'` may be abbreviated.

`[A, map, alpha] = imread(...)` `PNG` returns the alpha channel if one is present; otherwise `alpha` is `[]`. Note that `map` may be empty if the file contains a grayscale or truecolor image.

If the `alpha` output argument is specified, `BG` defaults to `'none'`, if not specified by the user. Otherwise, if the PNG file contains a background color chunk, that color is used as the default value for `BG`. If `alpha` is not used and the file does not contain a background color chunk, then the default value for `BG` is `1` for indexed images; `0` for grayscale images; and `[0 0 0]` for truecolor images.

PPM — Portable Pixmap

The following table lists the supported bitdepths, compression, and output classes for PPM files.

Supported Bitdepths	Raw Binary	ASCII (Plain) Encoded	Output Class
Up to 16-bit	x	–	`uint8`
Arbitrary	–	x	

RAS — Sun Raster

The following table lists the supported bitdepths, compression, and output classes for RAS files.

Supported Bitdepths	Output Class	Notes
1-bit	`logical`	Bitmap
8-bit	`uint8`	Indexed
24-bit	`uint8`	RGB Three 8-bit samples/pixel
32-bit	`uint8`	RGB with Alpha Four 8-bit samples/pixel

TIFF — Tagged Image File Format

`imread` supports the following TIFF capabilities:

- Any number of samples-per-pixel
- CCITT group 3 and 4 FAX, Packbits, JPEG, LZW, Deflate, ThunderScan compression, and uncompressed images
- Logical, grayscale, indexed color, truecolor and hyperspectral images
- RGB, CMYK, CIELAB, ICCLAB color spaces
- Data organized into tiles or scanlines

The following table lists the supported bit/sample and corresponding output classes for TIFF files.

Bits-per-Sample	Sample Format	Output Class
1	integer	logical
2 – 8	integer	uint8
9 – 16	integer	uint16
17 – 32	integer	uint32
32	float	single
33 – 64	integer	uint64
64	float	double

The following are format-specific syntaxes for TIFF files.

`A = imread(...)` returns color data that uses the RGB, CIELAB, ICCLAB, or CMYK color spaces. If the color image uses the CMYK color space, A is an M-by-N-by-4 array.

`[...] = imread(..., idx)` reads in one image from a multi-image TIFF file. `idx` is an integer value that specifies the order in which the image appears in the file. For example, if `idx` is `3`, `imread` reads the third image in the file. If you omit this argument, `imread` reads the first image in the file.

`[...] = imread(..., 'PixelRegion', {ROWS, COLS})` returns the subimage specified by the boundaries in `ROWS` and `COLS`. For tiled TIFF images, `imread` reads only the tiles that encompass the region specified by `ROWS` and `COLS`, improving memory efficiency and performance. `ROWS` and `COLS` must be either two or three element vectors. If two elements are provided, they denote the 1-based indices `[START STOP]`. If three elements are provided, the indices `[START INCREMENT STOP]` allow image downsampling.

For TIFF files, `imread` can read color data represented in the RGB, CIELAB, or ICCLAB color spaces. To determine which color space is used, look at the value of the `PhotometricInterpretation` field returned by `imfinfo`. Note, however, that if a file contains CIELAB color data, `imread` converts it to ICCLAB before bringing it into the MATLAB workspace. 8- or 16-bit TIFF CIELAB-encoded values use a

mixture of signed and unsigned data types that cannot be represented as a single MATLAB array.

XWD — X Window Dump

The following table lists the supported bitdepths, compression, and output classes for XWD files.

Supported Bitdepths	ZPixmaps	XYBitmaps	XYPixmaps	Output Class
1-bit	x	–	x	`logical`
8-bit	x	–	–	`uint8`

Class Support

For most image file formats, `imread` uses 8 or fewer bits per color plane to store image pixels. The following table lists the class of the returned array for the data types used by the file formats.

Data Type Used in File	Class of Array Returned by imread
1-bit per pixel	`logical`
2- to 8-bits per color plane	`uint8`
9- to 16-bit per pixel	`uint16` (`BMP`, `JPEG`, `PNG`, and `TIFF`) For the 16-bit BMP packed format (5-6-5), MATLAB returns `uint8`

Note For indexed images, `imread` always reads the colormap into an array of class `double`, even though the image array itself may be of class `uint8` or `uint16`.

Examples

This example reads the sixth image in a TIFF file.

```
[X,map] = imread('your_image.tif',6);
```

This example reads the fourth image in an HDF4 file.

```
info = imfinfo('your_hdf_file.hdf');
[X,map] = imread('your_hdf_file.hdf',info(4).Reference);
```

This example reads a 24-bit PNG image and sets any of its fully transparent (alpha channel) pixels to red.

```
bg = [255 0 0];
A = imread('your_image.png','BackgroundColor',bg);
```

This example returns the alpha channel (if any) of a PNG image.

```
[A,map,alpha] = imread('your_image.png');
```

This example reads an ICO image, applies a transparency mask, and then displays the image.

```
[a,b,c] = imread('your_icon.ico');
% Augment colormap for background color (white).
b2 = [b; 1 1 1];
% Create new image for display.
d = ones(size(a)) * (length(b2) - 1);
% Use the AND mask to mix the background and
% foreground data on the new image
d(c == 0) = a(c == 0);
% Display new image
image(uint8(d)), colormap(b2)
```

See Also

`double`, `fread`, `image`, `imfinfo`, `imformats`, `imwrite`, `uint8`, `uint16`

“Bit-Mapped Images” on page 1-92 for related functions

Purpose

Write image to graphics file

Syntax

```
imwrite(A,filename,fmt)
imwrite(X,map,filename,fmt)
imwrite(...,filename)
imwrite(...,Param1,Val1,Param2,Val2...)
```

Description

`imwrite(A,filename,fmt)` writes the image `A` to the file specified by `filename` in the format specified by *`fmt`*.

`A` can be an M-by-N (grayscale image) or M-by-N-by-3 (truecolor image) array. `A` cannot be an empty array. If the format specified is TIFF, `imwrite` can also accept an M-by-N-by-4 array containing color data that uses the CMYK color space. For information about the class of the input array and the output image, see "Class Support" on page 2-1687.

`filename` is a string that specifies the name of the output file.

`fmt` can be any of the text strings listed in the table in "Supported Formats" on page 2-1676. This list of supported formats is determined by the MATLAB image file format registry. See `imformats` for more information about this registry.

`imwrite(X,map,filename,fmt)` writes the indexed image in `X` and its associated colormap `map` to `filename` in the format specified by *`fmt`*. If `X` is of class `uint8` or `uint16`, `imwrite` writes the actual values in the array to the file. If `X` is of class `double`, the `imwrite` function offsets the values in the array before writing, using `uint8(X 1)`. The `map` parameter must be a valid MATLAB colormap. Note that most image file formats do not support colormaps with more than 256 entries.

`imwrite(...,filename)` writes the image to `filename`, inferring the format to use from the filename's extension. The extension must be one of the values for `fmt`, listed in "Supported Formats" on page 2-1676.

`imwrite(...,Param1,Val1,Param2,Val2...)` specifies parameters that control various characteristics of the output file for HDF, JPEG, PBM, PGM, PNG, PPM, and TIFF files. For example, if you are writing a JPEG file, you can specify the quality of the output image. For the

lists of parameters available for each format, see “Format-Specific Parameters” on page 2-1678.

Supported Formats

This table summarizes the types of images that `imwrite` can write. The MATLAB file format registry determines which file formats are supported. See `imformats` for more information about this registry. Note that, for certain formats, `imwrite` may take additional parameters, described in “Format-Specific Parameters” on page 2-1678.

Format	Full Name	Variants
`'bmp'`	Windows Bitmap (BMP)	1-bit, 8-bit, and 24-bit uncompressed images
`'gif'`	Graphics Interchange Format (GIF)	8-bit images
`'hdf'`	Hierarchical Data Format (HDF4)	8-bit raster image data sets, with or without associated colormap, 24-bit raster image data sets; uncompressed or with RLE or JPEG compression
`'jpg'` or `'jpeg'`	Joint Photographic Experts Group (JPEG)	8-bit, 12-bit, and 16-bit Baseline JPEG images **Note** Indexed images are converted to RGB before writing out JPEG files, because the JPEG format does not support indexed images.
`pbm`	Portable Bitmap (PBM)	Any 1-bit PBM image, ASCII (plain) or raw (binary) encoding

Format	Full Name	Variants
'pcx'	Windows Paintbrush (PCX)	8-bit images
'pgm'	Portable Graymap (PGM)	Any standard PGM image; ASCII (plain) encoded with arbitrary color depth; raw (binary) encoded with up to 16 bits per gray value
'png'	Portable Network Graphics (PNG)	1-bit, 2-bit, 4-bit, 8-bit, and 16-bit grayscale images; 8-bit and 16-bit grayscale images with alpha channels; 1-bit, 2-bit, 4-bit, and 8-bit indexed images; 24-bit and 48-bit truecolor images; 24-bit and 48-bit truecolor images with alpha channels
'pnm'	Portable Anymap (PNM)	Any of the PPM/PGM/PBM formats, chosen automatically
'ppm'	Portable Pixmap (PPM)	Any standard PPM image. ASCII (plain) encoded with arbitrary color depth; raw (binary) encoded with up to 16 bits per color component
'ras'	Sun Raster (RAS)	Any RAS image, including 1-bit bitmap, 8-bit indexed, 24-bit truecolor and 32-bit truecolor with alpha

Format	Full Name	Variants
`'tif'` or `'tiff'`	Tagged Image File Format (TIFF)	Baseline TIFF images, including 1-bit, 8-bit, 16-bit, and 24-bit uncompressed images; 1-bit, 8-bit, 16-bit, and 24-bit images with packbits compression; 1-bit images with CCITT 1D, Group 3, and Group 4 compression; CIELAB, ICCLAB, and CMYK images
`'xwd'`	X Windows Dump (XWD)	8-bit ZPixmaps

Format-Specific Parameters

The following tables list parameters that can be used with specific file formats.

GIF-Specific Parameters

This table describes the available parameters for GIF files.

Parameter	Values
`'BackgroundColor'`	A scalar integer. This value specifies which index in the colormap should be treated as the transparent color for the image and is used for certain disposal methods in animated GIFs. If `X` is `uint8` or `logical`, then indexing starts at `0`. If `X` is `double`, then indexing starts at `1`.
`'Comment'`	A string or cell array of strings containing a comment to be added to the image. For a cell array of strings, a carriage return is added after each row.
`'DelayTime'`	A scalar value between 0 and 655 inclusive, that specifies the delay in seconds before displaying the next image.
`'DisposalMethod'`	One of the following strings, which sets the disposal method of an animated GIF: `'leaveInPlace'`, `'restoreBG'`, `'restorePrevious'`, or `'doNotSpecify'`.

Parameter	Values
`'LoopCount'`	A finite integer between 0 and 65535 or the value `Inf` (the default) which specifies the number of times to repeat the animation. By default, the animation loops continuously. For a value of 0, the animation will be played once. For a value of 1, the animation will be played twice, etc.
`'TransparentColor'`	A scalar integer. This value specifies which index in the colormap should be treated as the transparent color for the image. If X is `uint8` or `logical`, then indexing starts at `0`. If X is double, then indexing starts at `1`.
`'WriteMode'`	One of these strings: `'overwrite'` (the default) or `'append'`. In append mode, a single frame is added to the existing file.

HDF4-Specific Parameters

This table describes the available parameters for HDF4 files.

Parameter	Values
`'Compression'`	One of these strings: `'none'` (the default) `'jpeg'`(valid only for grayscale and RGB images) `'rle'` (valid only for grayscale and indexed images)

Parameter	Values
'Quality'	A number between 0 and 100; this parameter applies only if 'Compression' is 'jpeg'. Higher numbers mean higher *quality* (less image degradation due to compression), but the resulting file size is larger. The default value is 75.
'WriteMode'	One of these strings: 'overwrite' (the default) 'append'

JPEG-Specific Parameters

This table describes the available parameters for JPEG files.

Parameter	Values	Default
'Bitdepth'	A scalar value indicating desired bitdepth; for grayscale images this can be 8, 12, or 16; for color images this can be 8 or 12.	8 (grayscale) and 8 bit per plane for color images
'Comment'	A column vector cell array of strings or a character matrix. Each row of input is written out as a comment in the JPEG file.	Empty
'Mode'	Specifies the type of compression used; value can be either of these strings: 'lossy' or 'lossless'	'lossy'
'Quality'	A number between 0 and 100; higher numbers mean higher quality (less image degradation due to compression), but the resulting file size is larger.	75

PBM-, PGM-, and PPM-Specific Parameters

This table describes the available parameters for PBM, PGM, and PPM files.

Parameter	Values	Default
`'Encoding'`	One of these strings: `'ASCII'` for plain encoding `'rawbits'` for binary encoding	`'rawbits'`
`'MaxValue'`	A scalar indicating the maximum gray or color value. Available only for PGM and PPM files. For PBM files, this value is always `1`.	Default is `65535` if image array is `'uint16'`; `255` otherwise.

PNG-Specific Parameters

The following table lists the available parameters for PNG files, in alphabetical order. In addition to these PNG parameters, you can use any parameter name that satisfies the PNG specification for keywords; that is, uses only printable characters, contains 80 or fewer characters, and no contains no leading or trailing spaces. The value corresponding to these user-specified parameters must be a string that contains no control characters other than linefeed.

Parameter	Values
`'Alpha'`	A matrix specifying the transparency of each pixel individually. The row and column dimensions must be the same as the data array; they can be `uint8`, `uint16`, or `double`, in which case the values should be in the range [0,1].
`'Author'`	A string
`'Background'`	The value specifies background color to be used when compositing transparent pixels. For indexed images: an integer in the range [1,`P`], where `P` is the colormap length. For grayscale images: a scalar in the range [0,1]. For truecolor images: a three-element vector in the range [0,1].
`'bitdepth'`	A scalar value indicating desired bit depth. For grayscale images this can be 1, 2, 4, 8, or 16. For grayscale images with an alpha channel this can be 8 or 16. For indexed images this can be 1, 2, 4, or 8. For truecolor images with or without an alpha channel this can be 8 or 16. By default, `imwrite` uses 8 bits per pixel, if image is double or `uint8`; 16 bits per pixel if image is `uint16`; 1 bit per pixel if image is `logical`.

Parameter	Values
'Chromaticities'	An eight-element vector [wx wy rx ry gx gy bx by] that specifies the reference white point and the primary chromaticities
'Comment'	A string
'Copyright'	A string
'CreationTime'	A string
'Description'	A string
'Disclaimer'	A string
'Gamma'	A nonnegative scalar indicating the file gamma
'ImageModTime'	A MATLAB serial date number (see the datenum function) or a string convertible to a date vector via the datevec function. Values should be in Coordinated Universal Time (UTC).
'InterlaceType'	Either 'none' (the default) or 'adam7'
'ResolutionUnit'	Either 'unknown' or 'meter'
'SignificantBits'	A scalar or vector indicating how many bits in the data array should be regarded as significant; values must be in the range [1,BitDepth]. For indexed images: a three-element vector. For grayscale images: a scalar. For grayscale images with an alpha channel: a two-element vector. For truecolor images: a three-element vector. For truecolor images with an alpha channel: a four-element vector.
'Software'	A string
'Source'	A string

Parameter	Values
`'Transparency'`	This value is used to indicate transparency information only when no alpha channel is used. Set to the value that indicates which pixels should be considered transparent. (If the image uses a colormap, this value represents an index number to the colormap.) For indexed images: a `Q`-element vector in the range [0,1], where `Q` is no larger than the colormap length and each value indicates the transparency associated with the corresponding colormap entry. In most cases, `Q = 1`. For grayscale images: a scalar in the range [0,1]. The value indicates the grayscale color to be considered transparent. For truecolor images: a three-element vector in the range [0,1]. The value indicates the truecolor color to be considered transparent. **Note** You cannot specify `'Transparency'` and `'Alpha'` at the same time.
`'Warning'`	A string
`'XResolution'`	A scalar indicating the number of pixels/unit in the horizontal direction
`'YResolution'`	A scalar indicating the number of pixels/unit in the vertical direction

RAS-Specific Parameters

This table describes the available parameters for RAS files.

Parameter	Values	Default
`'Alpha'`	A matrix specifying the transparency of each pixel individually; the row and column dimensions must be the same as the data array; can be `uint8`, `uint16`, or `double`. Can only be used with truecolor images.	Empty matrix (`[]`)
`'Type'`	One of these strings: `'standard'` (uncompressed, b-g-r color order with truecolor images) `'rgb'` (like `'standard'`, but uses r-g-b color order for truecolor images) `'rle'` (run-length encoding of 1-bit and 8-bit images)	`'standard'`

TIFF-Specific Parameters

This table describes the available parameters for TIFF files.

Parameter	Values	Default
`'ColorSpace'`	Specifies one of the following color spaces used to represent the color data. `'rgb'` `'cielab'` `'icclab'` See for more information about this parameter.	`'rgb'`
`'Compression'`	One of these strings: `'none'`, `'packbits'`, `'ccitt'`, `'fax3'`, or `'fax4'` The `'ccitt'`, `'fax3'`, and `'fax4'` compression schemes are valid for binary images only.	`'ccitt'` for binary images; `'packbits'` for nonbinary images
`'Description'`	Any string; fills in the `ImageDescription` field returned by `imfinfo`	Empty

Parameter	Values	Default
'Resolution'	A two-element vector containing the XResolution and YResolution, or a scalar indicating both resolutions	72
'WriteMode'	One of these strings: 'overwrite' 'append'	'overwrite'

L*a*b* Color Data

For TIFF files only, imwrite can write a color image that uses the $L^*a^*b^*$ color space. The 1976 CIE $L^*a^*b^*$ specification defines numeric values that represent luminance (L^*) and chrominance (a^* and b^*) information.

To store $L^*a^*b^*$ color data in a TIFF file, the values must be encoded to fit into either 8-bit or 16-bit storage. imwrite can store $L^*a^*b^*$ color data in a TIFF file using these encodings:

- 8-bit and 16-bit encodings defined by the TIFF specification, called the CIELAB encodings
- 8-bit and 16-bit encodings defined by the International Color Consortium, called ICCLAB encodings

The output class and encoding used by imwrite to store color data depends on the class of the input array and the value you specify for the TIFF-specific ColorSpace parameter. The following table explains these options. (The 8-bit and 16-bit CIELAB encodings cannot be input arrays because they use a mixture of signed and unsigned values and cannot be represented as a single MATLAB array.)

Input Class and Encoding	ColorSpace Parameter Value	Output Class and Encoding
8-bit ICCLAB [1]	'icclab'	8-bit ICCLAB
	'cielab'	8-bit CIELAB
16-bit ICCLAB [2]	'icclab'	16-bit ICCLAB

Input Class and Encoding	ColorSpace Parameter Value	Output Class and Encoding
	'cielab'	16-bit CIELAB
Double-precision 1976 CIE $L^*a^*b^*$ values [3]	'icclab'	8-bit ICCLAB
	'cielab'	8-bit CIELAB

[1] 8-bit ICCLAB represents values as integers in the range [0 255]. L^* values are multiplied by `255/100`; `128` is added to both the a^* and b^* values.

[2] 16-bit ICCLAB multiplies L^* values by `65280/100` and represents the values as integers in the range [0, 65280]. `32768` is added to both the a^* and b^* values, which are represented as integers in the range [0,65535].

[3] L^* is in the dynamic range [0, 100]. a^* and b^* can take any value. Setting a* and b^* to 0 (zero) produces a neutral color (gray).

Class Support

The input array `A` can be of class `logical`, `uint8`, `uint16`, or `double`. Indexed images (`X`) can be of class `uint8`, `uint16`, or `double`; the associated colormap, `map`, must be of class `double`. Input values must be full (non-sparse).

The class of the image written to the file depends on the format specified. For most formats, if the input array is of class `uint8`, `imwrite` outputs the data as 8-bit values. If the input array is of class `uint16` and the format supports 16-bit data (JPEG, PNG, and TIFF), `imwrite` outputs the data as 16-bit values. If the format does not support 16-bit values, `imwrite` issues an error. Several formats, such as JPEG and PNG, support a parameter that lets you specify the bit depth of the output data.

If the input array is of class `double`, and the image is a grayscale or RGB color image, `imwrite` assumes the dynamic range is [0,1] and

automatically scales the data by 255 before writing it to the file as 8-bit values.

If the input array is of class `double`, and the image is an indexed image, `imwrite` converts the indices to zero-based indices by subtracting 1 from each element, and then writes the data as `uint8`.

If the input array is of class `logical`, `imwrite` assumes the data is a binary image and writes it to the file with a bit depth of 1, if the format allows it. BMP, PNG, or TIFF formats accept binary images as input arrays.

Example

This example appends an indexed image `X` and its colormap `map` to an existing uncompressed multipage HDF4 file.

```
imwrite(X,map,'your_hdf_file.hdf','Compression','none',...
'WriteMode','append')
```

"Bit-Mapped Images" on page 1-92 for related functions

Purpose

Convert indexed image to RGB image

Syntax

```
RGB = ind2rgb(X,map)
```

Description

`RGB = ind2rgb(X,map)` converts the matrix `X` and corresponding colormap `map` to RGB (truecolor) format.

Class Support

`X` can be of class `uint8`, `uint16`, or `double`. RGB is an m-by-n-by-3 array of class `double`.

`image`

"Bit-Mapped Images" on page 1-92 for related functions

ind2sub

Purpose

Subscripts from linear index

Syntax

```
[I,J] = ind2sub(siz,IND)
[I1,I2,I3,...,In] = ind2sub(siz,IND)
```

Description

The `ind2sub` command determines the equivalent subscript values corresponding to a single index into an array.

`[I,J] = ind2sub(siz,IND)` returns the matrices `I` and `J` containing the equivalent row and column subscripts corresponding to each linear index in the matrix `IND` for a matrix of size `siz`. `siz` is a 2-element vector, where `siz(1)` is the number of rows and `siz(2)` is the number of columns.

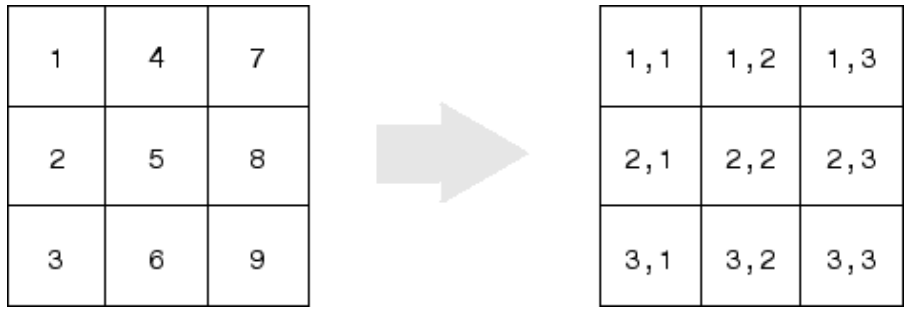
Note For matrices, `[I,J] = ind2sub(size(A),find(A>5))` returns the same values as `[I,J] = find(A>5)`.

`[I1,I2,I3,...,In] = ind2sub(siz,IND)` returns `n` subscript arrays `I1,I2,...,In` containing the equivalent multidimensional array subscripts equivalent to `IND` for an array of size `siz`. `siz` is an `n`-element vector that specifies the size of each array dimension.

Examples

Example 1 — Two-Dimensional Matrices

The mapping from linear indexes to subscript equivalents for a 3-by-3 matrix is



This code determines the row and column subscripts in a 3-by-3 matrix, of elements with linear indices 3, 4, 5, 6.

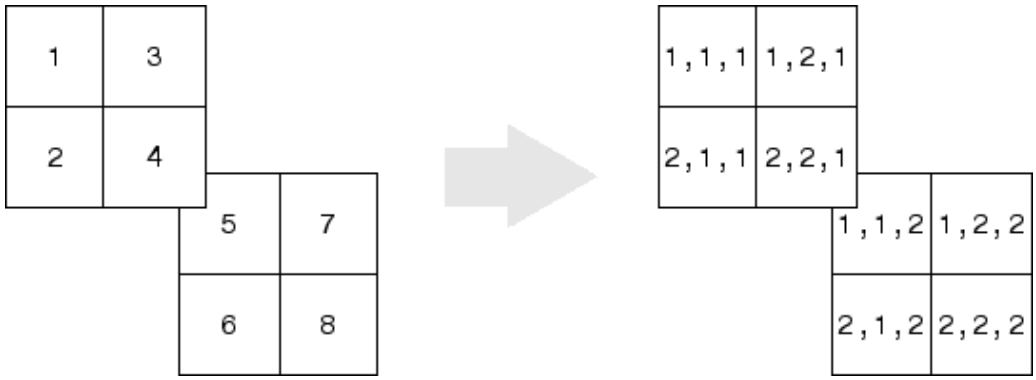
```
IND = [3 4 5 6]
s = [3,3];
[I,J] = ind2sub(s,IND)

I =
     3     1     2     3

J =
     1     2     2     2
```

Example 2 — Three-Dimensional Matrices

The mapping from linear indexes to subscript equivalents for a 2-by-2-by-2 array is



This code determines the subscript equivalents in a 2-by-2-by-2 array, of elements whose linear indices 3, 4, 5, 6 are specified in the `IND` matrix.

```
IND = [3 4;5 6];
s = [2,2,2];
[I,J,K] = ind2sub(s,IND)

I =
     1     2
     1     2

J =
     2     2
     1     1

K =
     1     1
     2     2
```

Example 3 — Effects of Returning Fewer Outputs

When calling `ind2sub` for an N-dimensional matrix, you would typically supply N output arguments in the call: one for each dimension of the matrix. This example shows what happens when you return three, two, and one output when calling `ind2sub` on a 3-dimensional matrix.

The matrix is 2-by-2-by-2 and the linear indices are 1 through 8:

```
dims = [2 2 2];
indices = [1 2 3 4 5 6 7 8];
```

The 3-output call to `ind2sub` returns the expected subscripts for the 2-by-2-by-2 matrix:

```
[rowsub colsub pagsub] = ind2sub(dims, indices)
rowsub =
     1     2     1     2     1     2     1     2
colsub =
     1     1     2     2     1     1     2     2
pagsub =
     1     1     1     1     2     2     2     2
```

If you specify only two outputs (row and column), `ind2sub` still returns a subscript for each specified index, but drops the third dimension from the matrix, returning subscripts for a 2-dimensional, 2-by-4 matrix instead:

```
[rowsub colsub] = ind2sub(dims, indices)
rowsub =
     1     2     1     2     1     2     1     2
colsub =
     1     1     2     2     3     3     4     4
```

If you specify one output (row), `ind2sub` drops both the second and third dimensions from the matrix, and returns subscripts for a 1-dimensional, 1-by-8 matrix instead:

```
[rowsub] = ind2sub(dims, indices)
rowsub =
     1     2     3     4     5     6     7     8
```

Inf

Purpose

Infinity

Syntax

```
Inf
Inf('double')
Inf('single')
Inf(n)
Inf(m,n)
Inf(m,n,p,...)
Inf(...,classname)
```

Description

`Inf` returns the IEEE arithmetic representation for positive infinity. Infinity results from operations like division by zero and overflow, which lead to results too large to represent as conventional floating-point values.

`Inf('double')` is the same as `Inf` with no inputs.

`Inf('single')` is the single precision representation of `Inf`.

`Inf(n)` is an `n`-by-`n` matrix of `Inf`s.

`Inf(m,n)` or `inf([m,n])` is an `m`-by-`n` matrix of `Inf`s.

`Inf(m,n,p,...)` or `Inf([m,n,p,...])` is an `m`-by-`n`-by-`p`-by-... array of `Inf`s.

Note The size inputs `m`, `n`, `p`, `...` should be nonnegative integers. Negative integers are treated as 0.

`Inf(...,classname)` is an array of `Inf`s of class specified by `classname`. `classname` must be either `'single'` or `'double'`.

Examples

`1/0`, `1.e1000`, `2^2000`, and `exp(1000)` all produce `Inf`.

`log(0)` produces `-Inf`.

`Inf-Inf` and `Inf/Inf` both produce `NaN` (Not-a-Number).

See Also

`isinf`, `NaN`

inferiorto

Purpose

Establish inferior class relationship

Syntax

```
inferiorto('class1', 'class2', ...)
```

Description

The `inferiorto` function establishes a hierarchy that determines the order in which MATLAB calls object methods.

`inferiorto('class1', 'class2', ...)` invoked within a class constructor method (say `myclass.m`) indicates that `myclass`'s method should not be invoked if a function is called with an object of class `myclass` and one or more objects of class `class1`, `class2`, and so on.

Remarks

Suppose `A` is of class `'class_a'`, `B` is of class `'class_b'` and `C` is of class `'class_c'`. Also suppose the constructor `class_c.m` contains the statement `inferiorto('class_a')`. Then `e = fun(a, c)` or `e = fun(c, a)` invokes `class_a/fun`.

If a function is called with two objects having an unspecified relationship, the two objects are considered to have equal precedence, and the leftmost object's method is called. So `fun(b, c)` calls `class_b/fun`, while `fun(c, b)` calls `class_c/fun`.

`help`, `version`

inline

Purpose

Construct inline object

Syntax

```
inline(expr)
inline(expr,arg1,arg2,...)
inline(expr,n)
```

Description

`inline(expr)` constructs an inline function object from the MATLAB expression contained in the string `expr`. The input argument to the inline function is automatically determined by searching `expr` for an isolated lower case alphabetic character, other than `i` or `j`, that is not part of a word formed from several alphabetic characters. If no such character exists, `x` is used. If the character is not unique, the one closest to `x` is used. If two characters are found, the one later in the alphabet is chosen.

`inline(expr,arg1,arg2,...)` constructs an inline function whose input arguments are specified by the strings `arg1`, `arg2`,.... Multicharacter symbol names may be used.

`inline(expr,n)` where `n` is a scalar, constructs an inline function whose input arguments are `x`, `P1`, `P2`, ...

Remarks

Three commands related to `inline` allow you to examine an inline function object and determine how it was created.

`char(fun)` converts the inline function into a character array. This is identical to `formula(fun)`.

`argnames(fun)` returns the names of the input arguments of the inline object `fun` as a cell array of strings.

`formula(fun)` returns the formula for the inline object `fun`.

A fourth command `vectorize(fun)` inserts a `.` before any `^`, `*` or `/` in the formula for `fun`. The result is a vectorized version of the inline function.

Examples

Example 1

This example creates a simple inline function to square a number.

```
g = inline('t^2')
g =

     Inline function:
     g(t) = t^2
```

You can convert the result to a string using the `char` function.

```
char(g)

ans =

t^2
```

Example 2

This example creates an inline function to represent the formula $f = 3\sin(2x^2)$. The resulting inline function can be evaluated with the `argnames` and `formula` functions.

```
f = inline('3*sin(2*x.^2)')

f =
     Inline function:
     f(x) = 3*sin(2*x.^2)

argnames(f)

ans =
    'x'

formula(f)
ans =

3*sin(2*x.^2)
```

Example 3

This call to `inline` defines the function `f` to be dependent on two variables, `alpha` and `x`:

```
f = inline('sin(alpha*x)')

f =
     Inline function:
     f(alpha,x) = sin(alpha*x)
```

If `inline` does not return the desired function variables or if the function variables are in the wrong order, you can specify the desired variables explicitly with the `inline` argument list.

```
g = inline('sin(alpha*x)','x','alpha')

g =

     Inline function:
     g(x,alpha) = sin(alpha*x)
```

Purpose

Names of M-files, MEX-files, Java classes in memory

Syntax

```
M = inmem
[M, X] = inmem
[M, X, J] = inmem
[...] = inmem('-completenames')
```

Description

`M = inmem` returns a cell array of strings containing the names of the M-files that are currently loaded.

`[M, X] = inmem` returns an additional cell array `X` containing the names of the MEX-files that are currently loaded.

`[M, X, J] = inmem` also returns a cell array `J` containing the names of the Java classes that are currently loaded.

`[...] = inmem('-completenames')` returns not only the names of the currently loaded M- and MEX-files, but the path and filename extension for each as well. No additional information is returned for loaded Java classes.

Examples

Example 1

This example lists the M-files that are required to run `erf`.

```
clear all;        % Clear the workspace
erf(0.5);

M = inmem
M =
   'erf'
```

Example 2

Generate a plot, and then find the M- and MEX-files that had been loaded to perform this operation:

```
clear all
surf(peaks)
```

```
[m x] = inmem('-completenames');

m(1:5)
ans =
    'F:\matlab\toolbox\matlab\ops\ismember.m'
    'F:\matlab\toolbox\matlab\datatypes\@opaque\double.m'
    'F:\matlab\toolbox\matlab\datatypes\isfield.m'
    'F:\matlab\toolbox\matlab\graphics\gcf.m'
    'F:\matlab\toolbox\matlab\elmat\meshgrid.m'

x(1:end)
ans =
    'F:\matlab\toolbox\matlab\graph2d\private\lineseriesmex.dll'
```

See Also

clear

Purpose

Points inside polygonal region

Syntax

```
IN = inpolygon(X,Y,xv,yv)
[IN ON] = inpolygon(X,Y,xv,yv)
```

Description

`IN = inpolygon(X,Y,xv,yv)` returns a matrix `IN` the same size as `X` and `Y`. Each element of `IN` is assigned the value 1 or 0 depending on whether the point `(X(p,q),Y(p,q))` is inside the polygonal region whose vertices are specified by the vectors `xv` and `yv`. In particular:

`IN(p,q) = 1`	If `(X(p,q),Y(p,q))` is inside the polygonal region or on the polygon boundary
`IN(p,q) = 0`	If `(X(p,q),Y(p,q))` is outside the polygonal region

`[IN ON] = inpolygon(X,Y,xv,yv)` returns a second matrix `ON` the same size as `X` and `Y`. Each element of `ON` is assigned the value 1 or 0 depending on whether the point `(X(p,q),Y(p,q))` is on the boundary of the polygonal region whose vertices are specified by the vectors `xv` and `yv`. In particular:

`ON(p,q) = 1`	If `(X(p,q),Y(p,q))` is on the polygon boundary
`ON(p,q) = 0`	If `(X(p,q),Y(p,q))` is inside or outside the polygon boundary

Examples

```
L = linspace(0,2.*pi,6); xv = cos(L)';yv = sin(L)';
xv = [xv ; xv(1)]; yv = [yv ; yv(1)];
x = randn(250,1); y = randn(250,1);
in = inpolygon(x,y,xv,yv);
plot(xv,yv,x(in),y(in),'r+',x(~in),y(~in),'bo')
```

Purpose

Request user input

Syntax

```
user_entry = input('prompt')
user_entry = input('prompt', 's')
```

Description

The response to the `input` prompt can be any MATLAB expression, which is evaluated using the variables in the current workspace.

`user_entry = input('prompt')` displays *`prompt`* as a prompt on the screen, waits for input from the keyboard, and returns the value entered in `user_entry`.

`user_entry = input('prompt', 's')` returns the entered string as a text variable rather than as a variable name or numerical value.

Remarks

If you press the **Return** key without entering anything, `input` returns an empty matrix.

The text string for the prompt can contain one or more `'\n'` characters. The `'\n'` means to skip to the next line. This allows the prompt string to span several lines. To display just a backslash, use `'\\'`.

If you enter an invalid expression at the prompt, MATLAB displays the relevant error message and then prompts you again to enter input.

Examples

Press **Return** to select a default value by detecting an empty matrix:

```
reply = input('Do you want more? Y/N [Y]: ', 's');
if isempty(reply)
    reply = 'Y';
end
```

See Also

`keyboard`, `menu`, `ginput`, `uicontrol`

inputdlg

Purpose

Create and open input dialog box

Syntax

```
answer = inputdlg(prompt)
answer = inputdlg(prompt,dlg_title)
answer = inputdlg(prompt,dlg_title,num_lines)
answer = inputdlg(prompt,dlg_title,num_lines,defAns)
answer = inputdlg(prompt,dlg_title,num_lines,defAns,options)
```

Description

`answer = inputdlg(prompt)` creates a modal dialog box and returns user input for multiple prompts in the cell array. `prompt` is a cell array containing prompt strings.

Note A modal dialog box prevents the user from interacting with other windows before responding. For more information, see `WindowStyle` in the MATLAB Figure Properties.

Note `inputdlg` uses the `uiwait` function to suspend execution until the user responds.

`answer = inputdlg(prompt,dlg_title)` `dlg_title` specifies a title for the dialog box.

`answer = inputdlg(prompt,dlg_title,num_lines)` `num_lines` specifies the number of lines for each user-entered value. `num_lines` can be a scalar, column vector, or matrix.

- If `num_lines` is a scalar, it applies to all prompts.
- If `num_lines` is a column vector, each element specifies the number of lines of input for a prompt.
- If `num_lines` is a matrix, it should be size m-by-2, where m is the number of prompts on the dialog box. Each row refers to a prompt.

The first column specifies the number of lines of input for a prompt. The second column specifies the width of the field in characters.

`answer = inputdlg(prompt,dlg_title,num_lines,defAns)` `defAns` specifies the default value to display for each prompt. `defAns` must contain the same number of elements as `prompt` and all elements must be strings.

`answer = inputdlg(prompt,dlg_title,num_lines,defAns,options)` If `options` is the string `'on'`, the dialog is made resizable in the horizontal direction. If options is a structure, the fields shown in the following table are recognized:

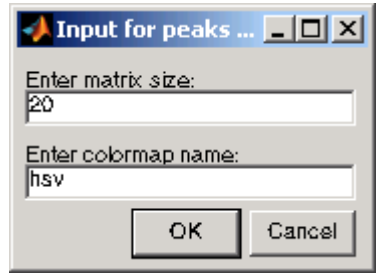
Field	Description
`Resize`	Can be `'on'` or `'off'` (default). If `'on'`, the window is resizable horizontally.
`WindowStyle`	Can be either `'normal'` or `'modal'` (default).
`Interpreter`	Can be either `'none'` (default) or `'tex'`. If the value is `'tex'`, the prompt strings are rendered using LaTeX.

Example

Example 1

Create a dialog box to input an integer and colormap name. Allow one line for each value.

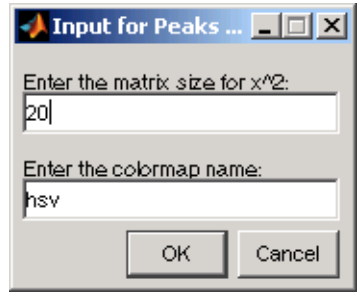
```
prompt = {'Enter matrix size:','Enter colormap name:'};
dlg_title = 'Input for peaks function';
num_lines = 1;
def = {'20','hsv'};
answer = inputdlg(prompt,dlg_title,num_lines,def);
```



Example 2

Create a dialog box using the default options. Then use the options to make it resizable and not modal, and to interpret the text using LaTeX.

```
prompt={'Enter the matrix size for x^2:',...
        'Enter the colormap name:'};
name='Input for Peaks function';
numlines=1;
defaultanswer={'20','hsv'};
answer=inputdlg(prompt,name,numlines,defaultanswer);
```



```
options.Resize='on';
options.WindowStyle='normal';
options.Interpreter='tex';

answer=inputdlg(prompt,name,numlines,defaultanswer,options);
```

`figure`, `uiwait`, `uiresume`

“Predefined Dialog Boxes” on page 1-104 for related functions

inputname

Purpose

Variable name of function input

Syntax

```
inputname(argnum)
```

Description

This command can be used only inside the body of a function.

`inputname(argnum)` returns the workspace variable name corresponding to the argument number *`argnum`*. If the input argument has no name (for example, if it is an expression instead of a variable), the `inputname` command returns the empty string (`''`).

Examples

Suppose the function `myfun.m` is defined as

```
function c = myfun(a,b)
disp(sprintf('First calling variable is "%s".', inputname(1))
```

Then

```
x = 5;  y = 3;  myfun(x,y)
```

produces

```
First calling variable is "x".
```

But

```
myfun(pi+1, pi-1)
```

produces

```
First calling variable is "".
```

See Also

`nargin`, `nargout`, `nargchk`

Purpose

Construct input parser object

Syntax

```
p = inputParser
```

Description

`p = inputParser` constructs an empty `inputParser` object. Use this utility object to parse and validate input arguments to the functions that you develop. The input parser object follows handle semantics; that is, methods called on it affect the original object, not a copy of it.

MATLAB configures `inputParser` objects to recognize an input schema. Use any of the following methods to create the schema for parsing a particular function.

For more information on the `inputParser` class, see "Parsing Inputs with inputParser" in the MATLAB Programming documentation.

Methods

Method	Description
`addOptional`	Add an optional argument to the schema
`addParamValue`	Add a parameter-value pair argument to the schema
`addRequired`	Add a required argument to the schema
`createCopy`	Create a copy of the `inputParser` object
`parse`	Parse and validate the named inputs

Properties

Property	Description
`CaseSensitivity`	Enable or disable case-sensitive matching of argument names
`FunctionName`	Function name to be included in error messages
`KeepUnmatched`	Enable or disable errors on unmatched arguments

Property	Description
`Parameters`	Names of arguments defined in `inputParser` schema
`Results`	Names and values of arguments passed in function call that are in the schema for this function
`StructExpand`	Enable or disable passing arguments in a structure
`Unmatched`	Names and values of arguments passed in function call that are not in the schema for this function
`UsingDefaults`	Names of arguments not passed in function call that are given default values

Property Descriptions

Properties of the `inputParser` class are described below.

CaseSensitivity

Purpose — Enable or disable case sensitive matching of argument names

`p.CaseSensitivity = TF` enables or disables case-sensitivity when matching entries in the argument list with argument names in the schema. Set `CaseSensitivity` to logical 1 (`true`) to enable case-sensitive matching, or to logical 0 (`false`) to disable it. By default, case-sensitive matching is disabled.

FunctionName

Purpose — Function name to be included in error messages

`p.FunctionName = name` stores a function `name` that is to be included in error messages that might be thrown in the process of validating input arguments to the function. The `name` input is a string containing the name of the function for which you are parsing inputs with `inputParser`.

KeepUnmatched

Purpose — Enable or disable errors on unmatched arguments

`p.KeepUnmatched = TF` controls whether MATLAB throws an error when the function being called is passed an argument that has not been defined in the `inputParser` schema for this file. When this property is set to logical 1 (`true`), MATLAB does not throw an error, but instead stores the names and values of unmatched arguments in the `Unmatched` property of object p. When `KeepUnmatched` is set to logical 0 (false), MATLAB does throw an error whenever this condition is encountered and the `Unmatched` property is not affected.

Parameters

Purpose — Names of arguments defined in `inputParser` schema

`c = p.Parameters` is a cell array of strings containing the names of those arguments currently defined in the schema for the object. Each row of the `Parameters` cell array is a string containing the full name of a known argument.

Results

Purpose — Names and values of arguments passed in function call that are in the schema for this function

`arglist = p.Results` is a structure containing the results of the most recent parse of the input argument list. Each argument passed to the function is represented by a field in the `Results` structure, and the value of that argument is represented by the value of that field.

StructExpand

Purpose — Enable or disable passing arguments in a structure

`p.StructExpand = TF`, when set to logical 1 (`true`), tells MATLAB to accept a structure as an input in place of individual parameter-value arguments. If `StructExpand` is set to logical 0 (`false`), a structure is treated as a regular, single input.

Unmatched

Purpose — Names and values of arguments passed in function call that are not in the schema for this function

`c = p.Unmatched` is a structure array containing the names and values of all arguments passed in a call to the function that are not included in the schema for the function. `Unmatched` only contains this list of the `KeepUnmatched` property is set to true. If `KeepUnmatched` is set to `false`, MATLAB throws an error when unmatched arguments are passed in the function call. The `Unmatched` structure has the same format as the `Results` property of the `inputParser` class.

UsingDefaults

Purpose — Names of arguments not passed in function call that are given default values

`defaults = p.UsingDefaults` is a cell array of strings containing the names of those arguments that were not passed in the call to this function and consequently are set to their default values.

Examples

Write an M-file function called `publish_ip`, based on the MATLAB `publish` function, to illustrate the use of the `inputParser` class. Construct an instance of `inputParser` and assign it to variable `p`:

```
function publish_ip(script, varargin)
p = inputParser;   % Create an instance of the inputParser class.
```

Add arguments to the schema. See the reference pages for the `addRequired`, `addOptional`, and `addParamValue` methods for help with this:

```
p.addRequired('script', @ischar);
p.addOptional('format', 'html', ...
    @(x)any(strcmpi(x,{'html','ppt','xml','latex'})));
p.addParamValue('outputDir', pwd, @ischar);
p.addParamValue('maxHeight', [], @(x)x>0 && mod(x,1)==0);
p.addParamValue('maxWidth', [], @(x)x>0 && mod(x,1)==0);
```

Call the `parse` method of the object to read and validate each argument in the schema:

```
p.parse(script, varargin{:});
```

Execution of the `parse` method validates each argument and also builds a structure from the input arguments. The name of the structure is `Results`, which is accessible as a property of the object. To get the value of any input argument, type

```
p.Results.argname
```

Continuing with the `publish_ip` exercise, add the following lines to your M-file:

```
% Parse and validate all input arguments.
p.parse(script, varargin{:});

% Display the value for maxHeight.
disp(sprintf('\nThe maximum height is %d.\n', p.Results.maxHeight))

% Display all arguments.
disp 'List of all arguments:'
disp(p.Results)
```

When you call the program, MATLAB assigns those values you pass in the argument list to the appropriate fields of the `Results` structure. Save the M-file and execute it at the MATLAB command prompt with this command:

```
publish_ip('ipscript.m', 'ppt', 'outputDir', 'C:/matlab/test', ...
    'maxWidth', 500, 'maxHeight', 300);

The maximum height is 300.

List of all arguments:
              format: 'ppt'
           maxHeight: 300
```

```
                maxWidth: 500
               outputDir: 'C:/matlab/test'
                  script: 'ipscript.m'
```

addRequired(inputParser), addOptional(inputParser), addParamValue(inputParser), parse(inputParser), createCopy(inputParser), varargin, nargchk, nargin

Purpose

Open Property Inspector

Syntax

```
inspect
inspect(h)
inspect([h1,h2,...])
```

Description

`inspect` creates a separate Property Inspector window to enable the display and modification of the properties of any object you select in the figure window or Layout Editor. If no object is selected, the Property Inspector is blank.

`inspect(h)` creates a Property Inspector window for the object whose handle is `h`.

`inspect([h1,h2,...])` displays properties that objects `h1` and `h2` have in common, or a blank window if there are no such properties; any number of objects can be inspected and edited in this way (for example, handles returned by the `bar` command).

The Property Inspector has the following behaviors:

- Only one Property Inspector window is active at any given time; when you inspect a new object, its properties replace those of the object last inspected.
- When the Property Inspector is open and plot edit mode is on, clicking any object in the figure window displays the properties of that object (or set of objects) in the Property Inspector.
- When you select and inspect two or more objects of different types, the Property Inspector only shows the properties that all objects have in common.
- To change the value of any property, click on the property name shown at the left side of the window, and then enter the new value in the field at the right.

The Property Inspector provides two different views:

- List view — properties are ordered alphabetically (default); this is the only view available for annotation objects.
- Group view — properties are grouped under classified headings (Handle Graphics objects only)

To view alphabetically, click the "AZ" Icon  in the Property Inspector toolbar. To see properties in groups, click

the "++" icon  . When properties are grouped, the "-" and "+" icons are enabled; click  to expand all categories and click  to collapse all categories. You can also expand and collapse individual categories by clicking on the "+" next to the category name. Some properties expand and collapse

---

Notes To see a complete description of any property, right-click on its name or value and select **What's This**; a help window opens that displays the reference page entry for it.

The Property Inspector displays most, but not all, properties of Handle Graphics objects. For example, the `parent` and `children` of HG objects are not shown. `inspect h` displays a Property Inspector window that enables modification of the string `'h'`, not the object whose handle is `h`. If you modify properties at the MATLAB command line, you must refresh the Property Inspector window to see the change reflected there. Refresh the Property Inspector by reinvoking `inspect` on the object.

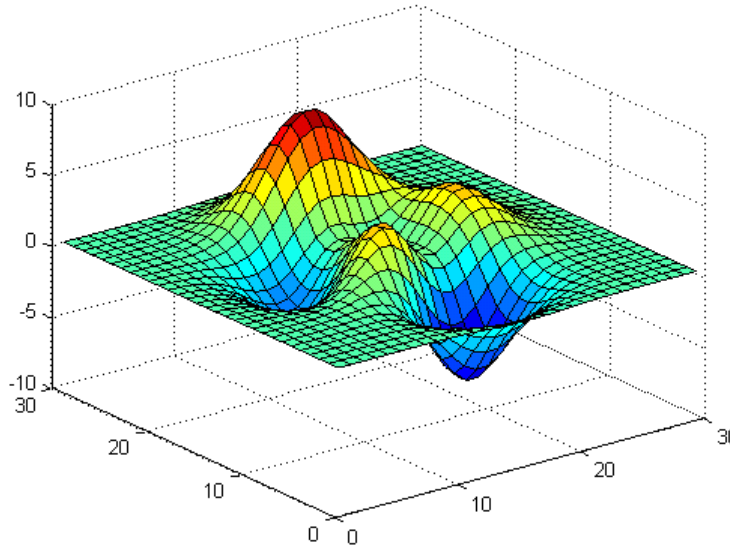
Examples

Example 1

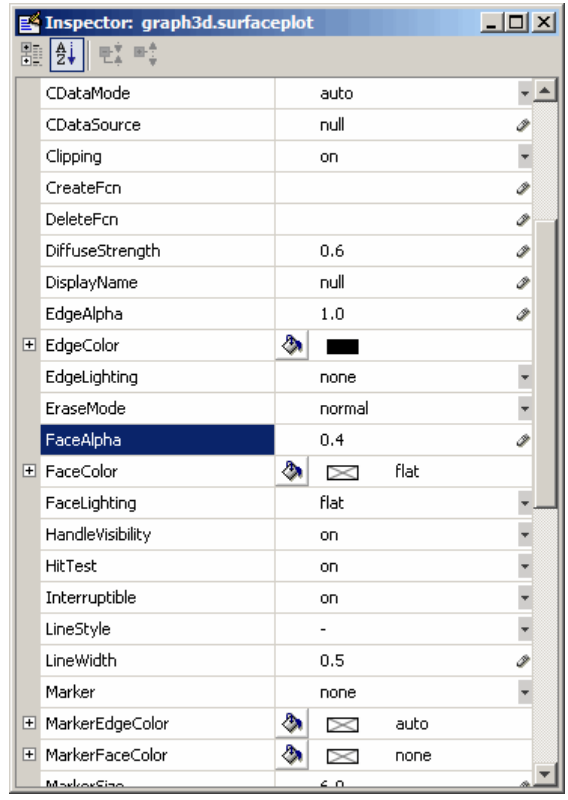
Create a surface mesh plot and view its properties with the Property Inspector:

```
Z = peaks(30);
h = surf(Z)
```

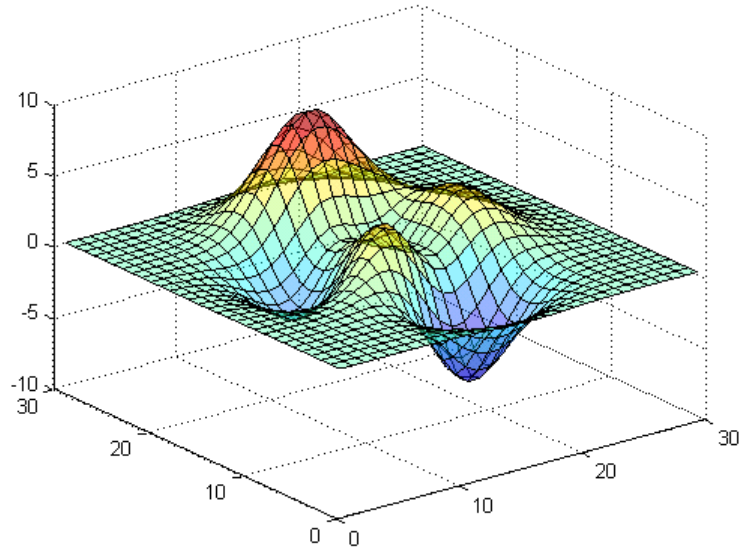
```
inspect(h)
```



Use the Property Inspector to change the `FaceAlpha` property from `1.0` to `0.4` (equivalent to the command `set(h,'FaceAlpha',0.4)`). `FaceAlpha` controls the tranparency of patch faces.



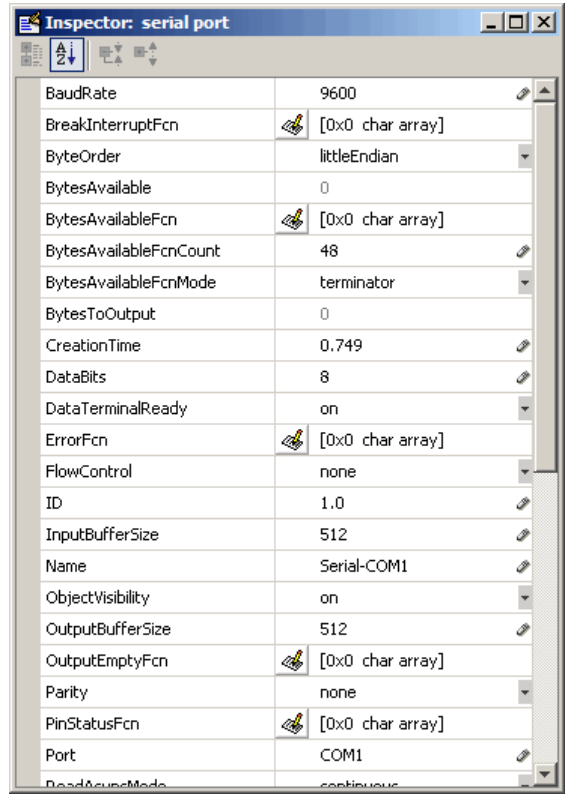
When you press **Enter** or click a different field, the `FaceAlpha` property of the surface object is updated:



Example 2

Create a serial port object for `COM1` and use the Property Inspector to peruse its properties:

```
s = serial('COM1');
inspect(s)
```



Because COM objects do not define property groupings, only the alphabetical list view of their properties is available.

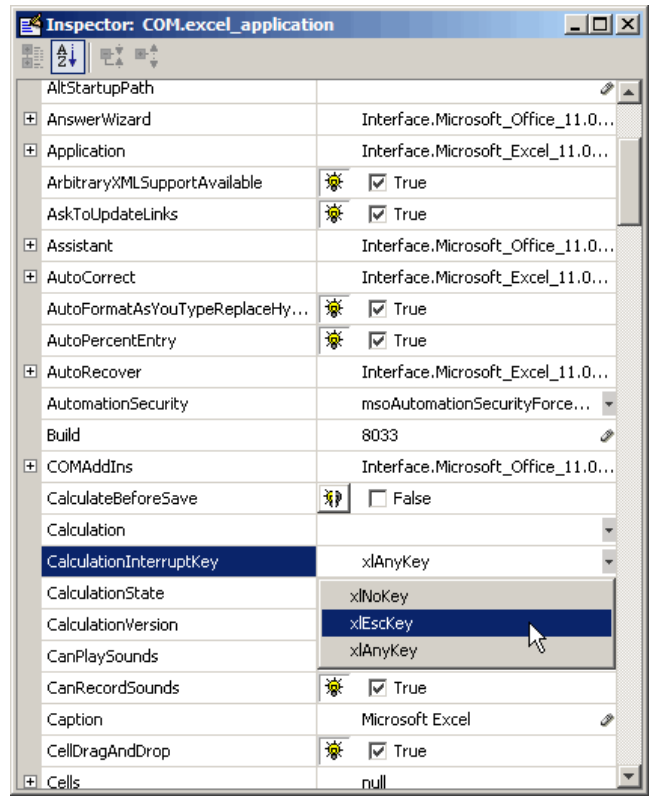
Example 3

Create a COM Excel server and open a Property Inspector window with `inspect`:

```
h = actxserver('excel.application');
inspect(h)
```

Scroll down until you see the `CalculationInterruptKey` property, which by default is `xlAnyKey`. Click on the down-arrow in the right

margin of the property inspector and select `xlEscKey` from the drop-down menu, as shown below:



Check this field in the MATLAB command window using `get` to confirm that it has changed:

```
get(h,'CalculationInterruptKey')

ans =
xlEscKey
```

instrcallback

Purpose

Event information when event occurs

Syntax

```
instrcallback(obj,event)
```

Arguments

`obj`	An serial port object.
`event`	The event that caused the callback to execute.

Description

`instrcallback(obj,event)` displays a message that contains the event type, the time the event occurred, and the name of the serial port object that caused the event to occur.

For error events, the error message is also displayed. For pin status events, the pin that changed value and its value are also displayed.

Remarks

You should use `instrcallback` as a template from which you create callback functions that suit your specific application needs.

Example

The following example creates the serial port objects `s`, and configures `s` to execute `instrcallback` when an output-empty event occurs. The event occurs after the `*IDN?` command is written to the instrument.

```
s = serial('COM1');
set(s,'OutputEmptyFcn',@instrcallback)
fopen(s)
fprintf(s,'*IDN?','async')
```

The resulting display from `instrcallback` is shown below.

```
OutputEmpty event occurred at 08:37:49 for the object:
Serial-COM1.
```

Read the identification information from the input buffer and end the serial port session.

```
idn = fscanf(s);
fclose(s)
```

```
delete(s)
clear s
```

instrfind

Purpose

Read serial port objects from memory to MATLAB workspace

Syntax

```
out = instrfind
out = instrfind('PropertyName',PropertyValue,...)
out = instrfind(S)
out = instrfind(obj,'PropertyName',PropertyValue,...)
```

Arguments

`'PropertyName'`	A property name for `obj`.
`PropertyValue`	A property value supported by *`PropertyName`*.
`S`	A structure of property names and property values.
`obj`	A serial port object, or an array of serial port objects.
`out`	An array of serial port objects.

Description

`out = instrfind` returns all valid serial port objects as an array to `out`.

`out = instrfind('PropertyName',PropertyValue,...)` returns an array of serial port objects whose property names and property values match those specified.

`out = instrfind(S)` returns an array of serial port objects whose property names and property values match those defined in the structure `S`. The field names of `S` are the property names, while the field values are the associated property values.

`out = instrfind(obj,'PropertyName',PropertyValue,...)` restricts the search for matching property name/property value pairs to the serial port objects listed in `obj`.

Remarks

Refer to "Displaying Property Names and Property Values" for a list of serial port object properties that you can use with `instrfind`.

You must specify property values using the same format as the `get` function returns. For example, if `get` returns the `Name` property value as `MyObject`, `instrfind` will not find an object with a `Name` property value of `myobject`. However, this is not the case for properties that have a

finite set of string values. For example, `instrfind` will find an object with a `Parity` property value of `Even` or `even`.

You can use property name/property value string pairs, structures, and cell array pairs in the same call to `instrfind`.

Example

Suppose you create the following two serial port objects.

```
s1 = serial('COM1');
s2 = serial('COM2');
set(s2,'BaudRate',4800)
fopen([s1 s2])
```

You can use `instrfind` to return serial port objects based on property values.

```
out1 = instrfind('Port','COM1');
out2 = instrfind({'Port','BaudRate'},{'COM2',4800});
```

You can also use `instrfind` to return cleared serial port objects to the MATLAB workspace.

```
clear s1 s2
newobjs = instrfind

   Instrument Object Array
   Index:   Type:          Status:     Name:
   1        serial         open        Serial-COM1
   2        serial         open        Serial-COM2
```

To close both `s1` and `s2`

```
fclose(newobjs)
```

See Also

Functions

`clear`, `get`

instrfindall

Purpose

Find visible and hidden serial port objects

Syntax

```
out = instrfindall
out = instrfindall('P1',V1,...)
out = instrfindall(s)
out = instrfindall(objs,'P1',V1,...)
```

Arguments

`'P1'`	Name of a serial port object property.
`V1`	Value allowed for corresponding *P1*.
`s`	A structure of property names and property values.
`objs`	An array of serial port objects.
`out`	An array of returned serial port objects.

Description

`out = instrfindall` finds all serial port objects, regardless of the value of the objects' `ObjectVisibility` property. The object or objects are returned to `out`.

`out = instrfindall('P1',V1,...)` returns an array, `out`, of serial port objects whose property names and corresponding property values match those specified as arguments.

`out = instrfindall(s)` returns an array, `out`, of serial port objects whose property names and corresponding property values match those specified in the structure `s`, where the field names correspond to property names and the field values correspond to the current value of the respective property.

`out = instrfindall(objs,'P1',V1,...)` restricts the search for objects with matching property name/value pairs to the serial port objects listed in `objs`.

Note that you can use string property name/property value pairs, structures, and cell array property name/property value pairs in the same call to `instrfindall`.

Remarks

`instrfindall` differs from `instrfind` in that it finds objects whose `ObjectVisibility` property is set to `off`.

Property values are case sensitive. You must specify property values using the same format as that returned by the `get` function. For example, if `get` returns the `Name` property value as `'MyObject'`, `instrfindall` will not find an object with a `Name` property value of `'myobject'`. However, this is not the case for properties that have a finite set of string values. For example, `instrfindall` will find an object with a `Parity` property value of `'Even'` or `'even'`.

Examples

Suppose you create the following serial port objects:

```
s1 = serial('COM1');
s2 = serial('COM2');
set(s2,'ObjectVisibility','off')
```

Because object `s2` has its `ObjectVisibility` set to `'off'`, it is not visible to commands like `instrfind`:

```
instrfind

   Serial Port Object : Serial-COM1
```

However, `instrfindall` finds all objects regardless of the value of `ObjectVisibility`:

```
instrfindall

 Instrument Object Array
 Index:   Type:          Status:     Name:
 1        serial         closed      Serial-COM1
 2        serial         closed      Serial-COM2
```

The following statements use `instrfindall` to return objects with specific property settings, which are passed as cell arrays:

```
props = {'PrimaryAddress','SecondaryAddress};
vals = {2,0};
```

```
obj = instrfindall(props,vals);
```

You can use `instrfindall` as an argument when you want to apply the command to all objects, visible and invisible. For example, the following statement makes all objects visible:

```
set(instrfindall,'ObjectVisibility','on')
```

See Also

Functions

`get`, `instrfind`

Properties

`ObjectVisibility`

Purpose

Convert integer to string

Syntax

```
str = int2str(N)
```

Description

`str = int2str(N)` converts an integer to a string with integer format. The input `N` can be a single integer or a vector or matrix of integers. Noninteger inputs are rounded before conversion.

Examples

`int2str(2+3)` is the string `'5'`.

One way to label a plot is

```
title(['case number ' int2str(n)])
```

For matrix or vector inputs, `int2str` returns a string matrix:

```
int2str(eye(3))

ans =

1  0  0
0  1  0
0  0  1
```

See Also

`fprintf`, `num2str`, `sprintf`

Purpose

Convert to signed integer

Syntax

```
I = int8(X)
I = int16(X)
I = int32(X)
I = int64(X)
```

Description

`I = int*(X)` converts the elements of array `X` into signed integers. `X` can be any numeric object (such as a `double`). The results of an `int*` operation are shown in the next table.

Operation	Output Range	Output Type	Bytes per Element	Output Class
`int8`	-128 to 127	Signed 8-bit integer	1	`int8`
`int16`	-32,768 to 32,767	Signed 16-bit integer	2	`int16`
`int32`	-2,147,483,648 to 2,147,483,647	Signed 32-bit integer	4	`int32`
`int64`	-9,223,372,036,854,775,808 to 9,223,372,036,854,775,807	Signed 64-bit integer	8	`int64`

`double` and `single` values are rounded to the nearest `int*` value on conversion. A value of `X` that is above or below the range for an integer class is mapped to one of the endpoints of the range. For example,

```
int16(40000)
ans =
   32767
```

If X is already a signed integer of the same class, then int* has no effect.

You can define or overload your own methods for int* (as you can for any object) by placing the appropriately named method in an @int* directory within a directory on your path. Type help datatypes for the names of the methods you can overload.

Remarks

Most operations that manipulate arrays without changing their elements are defined for integer values. Examples are reshape, size, the logical and relational operators, subscripted assignment, and subscripted reference.

Some arithmetic operations are defined for integer arrays on interaction with other integer arrays of the same class (e.g., where both operands are int16). Examples of these operations are +, -, .*, ./, .\ and .^. If at least one operand is scalar, then *, /, \, and ^ are also defined. Integer arrays may also interact with scalar double variables, including constants, and the result of the operation is an integer array of the same class. Integer arrays saturate on overflow in arithmetic.

A particularly efficient way to initialize a large array is by specifying the data type (i.e., class name) for the array in the zeros, ones, or eye function. For example, to create a 100-by-100 int64 array initialized to zero, type

```
I = zeros(100, 100, 'int64');
```

An easy way to find the range for any MATLAB integer type is to use the intmin and intmax functions as shown here for int32:

```
intmin('int32')              intmax('int32')
ans =                        ans =
   -2147483648                  2147483647
```

See Also

double, single, uint8, uint16, uint32, uint64, intmax, intmin

interfaces

Purpose

List custom interfaces to COM server

Syntax

```
C = h.interfaces
C = interfaces(h)
```

Description

`C = h.interfaces` returns cell array of strings `C` listing all custom interfaces implemented by the component in a specific COM server. The server is designated by input argument, `h`, which is the handle returned by the `actxcontrol` or `actxserver` function when creating that server.

`C = interfaces(h)` is an alternate syntax for the same operation.

Note `interfaces` only lists the custom interfaces; it does not return any interfaces. Use the `invoke` function to return a handle to a specific custom interface.

Examples

Once you have created a COM server, you can query the server component to see if any custom interfaces are implemented. Use the `interfaces` function to return a list of all available custom interfaces:

```
h = actxserver('mytestenv.calculator')
h =
   COM.mytestenv.calculator

customlist = h.interfaces
customlist =
   ICalc1
   ICalc2
   ICalc3
```

To get a handle to the custom interface you want, use the `invoke` function, specifying the handle returned by `actxcontrol` or `actxserver` and also the name of the custom interface:

```
c1 = h.invoke('ICalc1')
c1 =
```

```
Interface.Calc_1.0_Type_Library.ICalc_Interface
```

You can now use this handle with most of the COM client functions to access the properties and methods of the object through the selected custom interface. For example, to list the properties available through the `ICalc1` interface, use

```
c1.get
     background: 'Blue'
         height: 10
          width: 0
```

To list the methods, use

```
c1.invoke
   Add = double Add(handle, double, double)
   Divide = double Divide(handle, double, double)
   Multiply = double Multiply(handle, double, double)
   Subtract = double Subtract(handle, double, double)
```

Add and multiply numbers using the `Add` and `Multiply` methods of the custom object `c1`:

```
sum = c1.Add(4, 7)
sum =
    11

prod = c1.Multiply(4, 7)
prod =
    28
```

`actxcontrol`, `actxserver`, `invoke`, `get`

Purpose

1-D data interpolation (table lookup)

Syntax

```
yi = interp1(x,Y,xi)
yi = interp1(Y,xi)
yi = interp1(x,Y,xi,method)
yi = interp1(x,Y,xi,method,'extrap')
yi = interp1(x,Y,xi,method,extrapval)
pp = interp1(x,Y,method,'pp')
```

Description

`yi = interp1(x,Y,xi)` interpolates to find `yi`, the values of the underlying function `Y` at the points in the vector or array `xi`. `x` must be a vector. Y can be a scalar, a vector, or an array of any dimension, subject to the following conditions:

- If `Y` is a scalar or vector, it must have the same length as `x`. A scalar value for `Y` is expanded to have the same length as `x`. `xi` can be a scalar, a vector, or a multidimensional array, and `yi` has the same size as `xi`.
- If `Y` is an array that is not a vector, the size of `Y` must have the form `[n,d1,d2,...,dk]`, where `n` is the length of `x`. The interpolation is performed for each `d1`-by-`d2`-by-...-`dk` value in `Y`. The sizes of `xi` and `yi` are related as follows:
  - If `xi` is a scalar or vector, `size(yi)` equals `[length(xi), d1, d2, ..., dk]`.
  - If `xi` is an array of size `[m1,m2,...,mj]`, `yi` has size `[m1,m2,...,mj,d1,d2,...,dk]`.

`yi = interp1(Y,xi)` assumes that `x = 1:N`, where `N` is the length of `Y` for vector `Y`, or `size(Y,1)` for matrix `Y`.

`yi = interp1(x,Y,xi,method)` interpolates using alternative methods:

`'nearest'`	Nearest neighbor interpolation
`'linear'`	Linear interpolation (default)

'spline'	Cubic spline interpolation
'pchip'	Piecewise cubic Hermite interpolation
'cubic'	(Same as 'pchip')
'v5cubic'	Cubic interpolation used in MATLAB 5. This method does not extrapolate. Also, if x is not equally spaced, 'spline' is used/

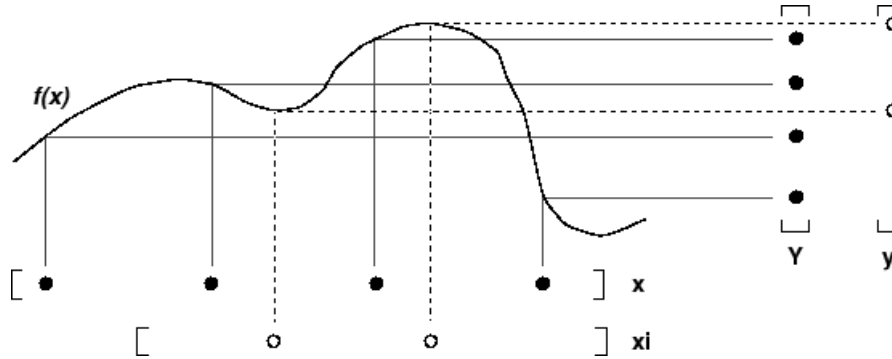
For the 'nearest', 'linear', and 'v5cubic' methods, interp1(x,Y,xi,method) returns NaN for any element of xi that is outside the interval spanned by x. For all other methods, interp1 performs extrapolation for out of range values.

yi = interp1(x,Y,xi,method,'extrap') uses the specified method to perform extrapolation for out of range values.

yi = interp1(x,Y,xi,method,extrapval) returns the scalar extrapval for out of range values. NaN and 0 are often used for extrapval.

pp = interp1(x,Y,method,'pp') uses the specified method to generate the piecewise polynomial form (ppform) of Y. You can use any of the methods in the preceding table, except for 'v5cubic'. pp can then be evaluated via ppval. ppval(pp,xi) is the same as interp1(x,Y,xi,method,'extrap').

The interp1 command interpolates between data points. It finds values at intermediate points, of a one-dimensional function $f(x)$ that underlies the data. This function is shown below, along with the relationship between vectors x, Y, xi, and yi.



Interpolation is the same operation as *table lookup*. Described in table lookup terms, the *table* is `[x,Y]` and `interp1` *looks up* the elements of `xi` in `x`, and, based upon their locations, returns values `yi` interpolated within the elements of `Y`.

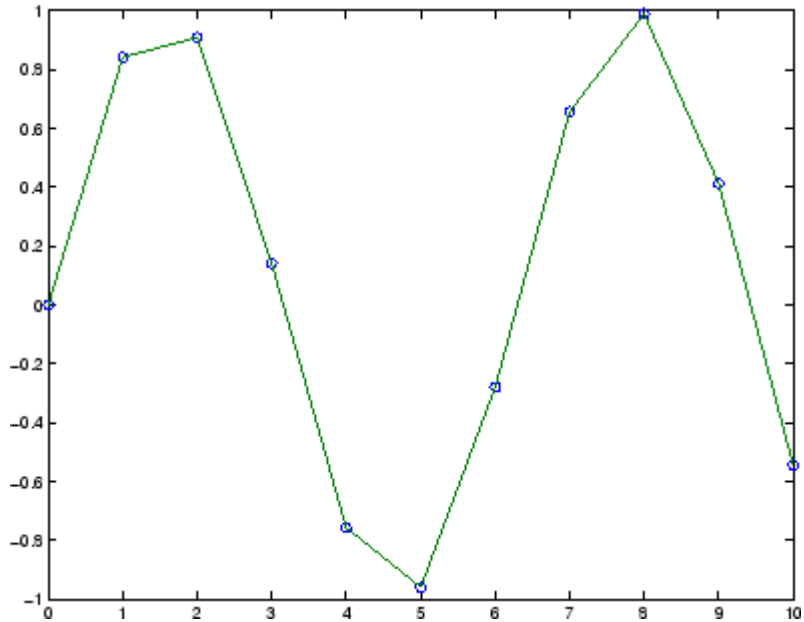
Note `interp1q` is quicker than `interp1` on non-uniformly spaced data because it does no input checking. For `interp1q` to work properly, `x` must be a monotonically increasing column vector and `Y` must be a column vector or matrix with `length(X)` rows. Type `help interp1q` at the command line for more information.

Examples

Example 1

Generate a coarse sine curve and interpolate over a finer abscissa.

```
x = 0:10;
y = sin(x);
xi = 0:.25:10;
yi = interp1(x,y,xi);
plot(x,y,'o',xi,yi)
```



Example 2

The following multidimensional example creates 2-by-2 matrices of interpolated function values, one matrix for each of the three functions x^2, x^3, and x^4.

```
x = [1:10]'; y = [ x.^2, x.^3, x.^4 ];
xi = [1.5, 1.75; 7.5, 7.75];
yi = interp1(x,y,xi);
```

The result `yi` has size 2-by-2-by-3.

```
size(yi)

ans =

     2     2     3
```

Example 3

Here are two vectors representing the census years from 1900 to 1990 and the corresponding United States population in millions of people.

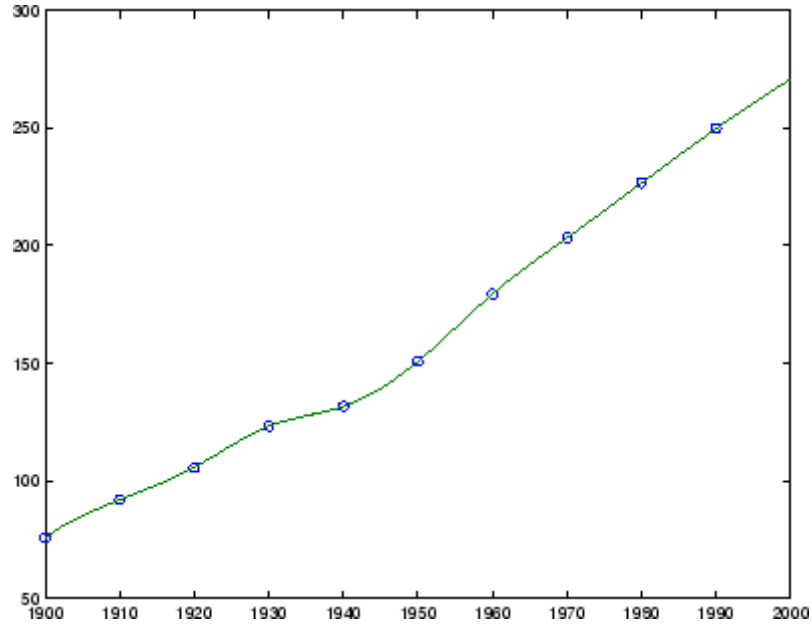
```
t = 1900:10:1990;
p = [75.995  91.972  105.711  123.203  131.669...
     150.697  179.323  203.212  226.505  249.633];
```

The expression `interp1(t,p,1975)` interpolates within the census data to estimate the population in 1975. The result is

```
ans =
    214.8585
```

Now interpolate within the data at every year from 1900 to 2000, and plot the result.

```
x = 1900:1:2000;
y = interp1(t,p,x,'spline');
plot(t,p,'o',x,y)
```



Sometimes it is more convenient to think of interpolation in table lookup terms, where the data are stored in a single table. If a portion of the census data is stored in a single 5-by-2 table,

```
tab =
    1950    150.697
    1960    179.323
    1970    203.212
    1980    226.505
    1990    249.633
```

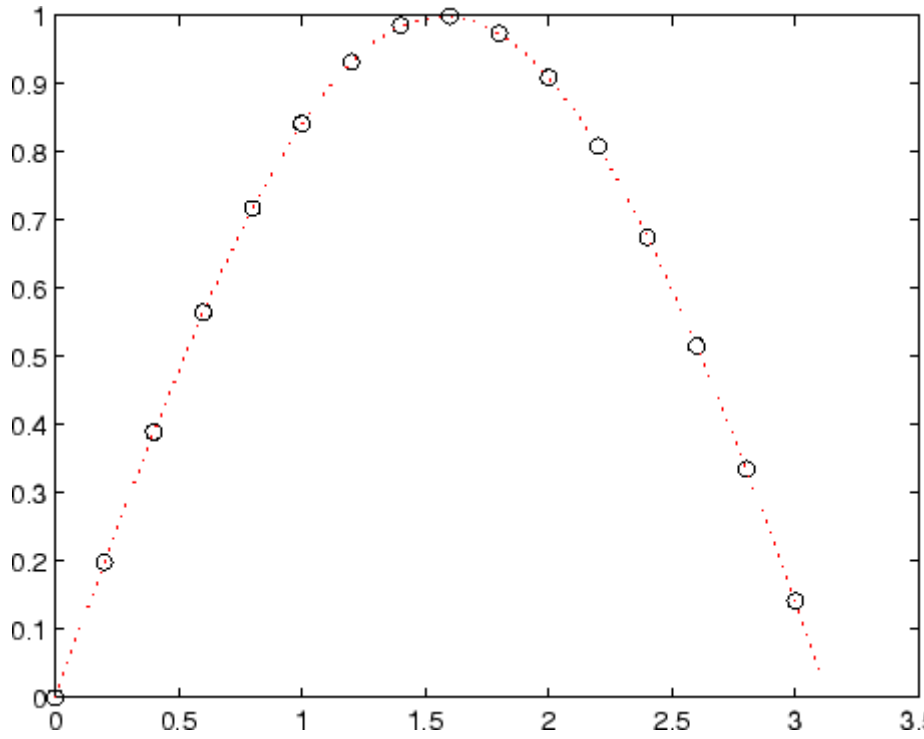
then the population in 1975, obtained by table lookup within the matrix `tab`, is

```
p = interp1(tab(:,1),tab(:,2),1975)
p =
    214.8585
```

Example 4

The following example uses the `'cubic'` method to generate the piecewise polynomial form (ppform) of `Y`, and then evaluates the result using `ppval`.

```
x = 0:.2:pi; y = sin(x);
pp = interp1(x,y,'cubic','pp');
xi = 0:.1:pi;
yi = ppval(pp,xi);
plot(x,y,'ko'), hold on, plot(xi,yi,'r:'), hold off
```



Algorithm

The `interp1` command is a MATLAB M-file. The `'nearest'` and `'linear'` methods have straightforward implementations.

For the 'spline' method, interp1 calls a function spline that uses the functions ppval, mkpp, and unmkpp. These routines form a small suite of functions for working with piecewise polynomials. spline uses them to perform the cubic spline interpolation. For access to more advanced features, see the spline reference page, the M-file help for these functions, and the Spline Toolbox.

For the 'pchip' and 'cubic' methods, interp1 calls a function pchip that performs piecewise cubic interpolation within the vectors x and y. This method preserves monotonicity and the shape of the data. See the pchip reference page for more information.

Interpolating Complex Data

For Real x and Complex Y. For interp1(x,Y,...) where x is real and Y is complex, you can use any interp1 method except for 'pchip'. The shape-preserving aspect of the 'pchip' algorithm involves the signs of the slopes between the data points. Because there is no notion of sign with complex data, it is impossible to talk about whether a function is increasing or decreasing. Consequently, the 'pchip' algorithm does not generalize to complex data.

The 'spline' method is often a good choice because piecewise cubic splines are derived purely from smoothness conditions. The second derivative of the interpolant must be continuous across the interpolating points. This does not involve any notion of sign or shape and so generalizes to complex data.

For Complex x. For interp1(x,Y,...) where x is complex and Y is either real or complex, use the two-dimensional interpolation routine interp2(REAL(x), IMAG(x),Y,...) instead.

interp1q

Purpose

Quick 1-D linear interpolation

Syntax

```
yi = interp1q(x,Y,xi)
```

Description

`yi = interp1q(x,Y,xi)` returns the value of the 1-D function `Y` at the points of column vector `xi` using linear interpolation. The vector `x` specifies the coordinates of the underlying interval. The length of output `yi` is equal to the length of `xi`.

`interp1q` is quicker than `interp1` on non-uniformly spaced data because it does no input checking.

For `interp1q` to work properly,

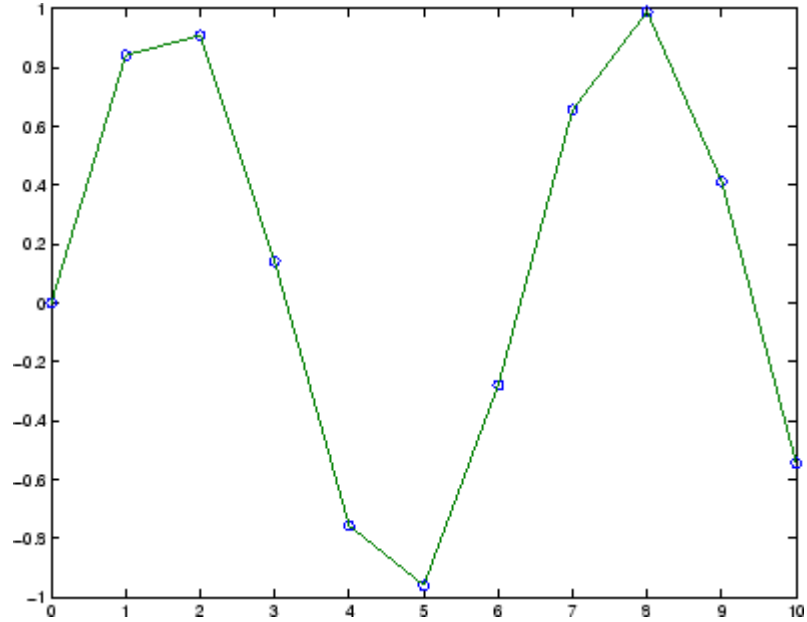
- `x` must be a monotonically increasing column vector.
- `Y` must be a column vector or matrix with `length(x)` rows.
- `xi` must be a column vector

`interp1q` returns NaN for any values of `xi` that lie outside the coordinates in `x`. If `Y` is a matrix, then the interpolation is performed for each column of `Y`, in which case `yi` is `length(xi)-by-size(Y,2)`.

Example

Generate a coarse sine curve and interpolate over a finer abscissa.

```
x = 0:10';
y = sin(x);
xi = (0:.25:10)';
yi = interp1q(x,y,xi);
plot(x,y,'o',xi,yi)
```



See Also

`interp1`, `interp2`, `interp3`, `interpn`

Purpose

2-D data interpolation (table lookup)

Syntax

```
ZI = interp2(X,Y,Z,XI,YI)
ZI = interp2(Z,XI,YI)
ZI = interp2(Z,ntimes)
ZI = interp2(X,Y,Z,XI,YI,method)
ZI = interp2(...,method, extrapval)
```

Description

`ZI = interp2(X,Y,Z,XI,YI)` returns matrix `ZI` containing elements corresponding to the elements of `XI` and `YI` and determined by interpolation within the two-dimensional function specified by matrices `X`, `Y`, and `Z`. `X` and `Y` must be monotonic, and have the same format ("plaid") as if they were produced by `meshgrid`. Matrices `X` and `Y` specify the points at which the data `Z` is given. Out of range values are returned as `NaN`s.

`XI` and `YI` can be matrices, in which case `interp2` returns the values of `Z` corresponding to the points `(XI(i,j),YI(i,j))`. Alternatively, you can pass in the row and column vectors `xi` and `yi`, respectively. In this case, `interp2` interprets these vectors as if you issued the command `meshgrid(xi,yi)`.

`ZI = interp2(Z,XI,YI)` assumes that `X = 1:n` and `Y = 1:m`, where `[m,n] = size(Z)`.

`ZI = interp2(Z,ntimes)` expands `Z` by interleaving interpolates between every element, working recursively for `ntimes`. `interp2(Z)` is the same as `interp2(Z,1)`.

`ZI = interp2(X,Y,Z,XI,YI,method)` specifies an alternative interpolation method:

`'nearest'`	Nearest neighbor interpolation
`'linear'`	Linear interpolation (default)

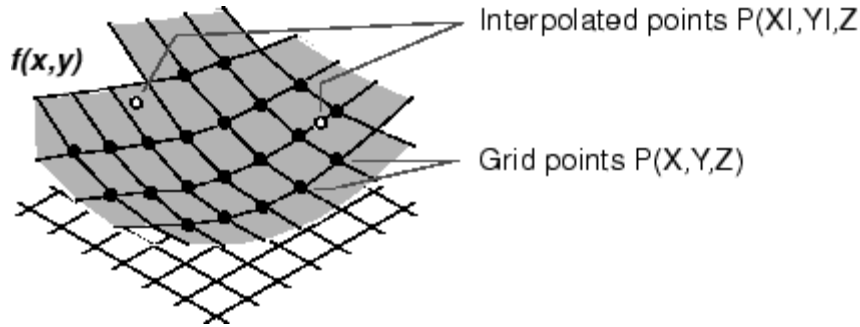
'spline'	Cubic spline interpolation
'cubic'	Cubic interpolation, as long as data is uniformly-spaced. Otherwise, this method is the same as 'spline'.

All interpolation methods require that X and Y be monotonic, and have the same format ("plaid") as if they were produced by meshgrid. If you provide two monotonic vectors, interp2 changes them to a plaid internally. Variable spacing is handled by mapping the given values in X, Y, XI, and YI to an equally spaced domain before interpolating. For faster interpolation when X and Y are equally spaced and monotonic, use the methods '*linear', '*cubic', '*spline', or '*nearest'.

ZI = interp2(...,method, extrapval) specifies a method and a scalar value for ZI outside of the domain created by X and Y. Thus, ZI equals extrapval for any value of YI or XI that is not spanned by Y or X respectively. A method must be specified to use extrapval. The default method is 'linear'.

Remarks

The interp2 command interpolates between data points. It finds values of a two-dimensional function $f(x, y)$ underlying the data at intermediate points.



Interpolation is the same operation as table lookup. Described in table lookup terms, the table is tab = [NaN,Y;X,Z] and interp2 looks up

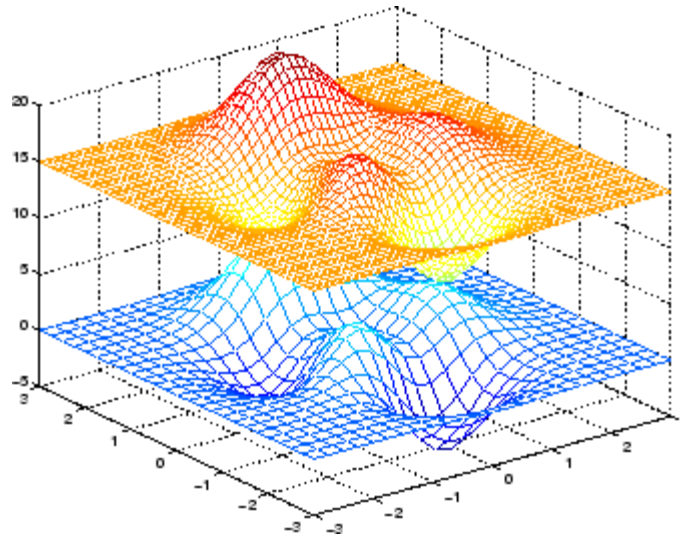
the elements of XI in X, YI in Y, and, based upon their location, returns values ZI interpolated within the elements of Z.

Examples

Example 1

Interpolate the peaks function over a finer grid.

```
[X,Y] = meshgrid(-3:.25:3);
Z = peaks(X,Y);
[XI,YI] = meshgrid(-3:.125:3);
ZI = interp2(X,Y,Z,XI,YI);
mesh(X,Y,Z), hold, mesh(XI,YI,ZI+15)
hold off
axis([-3 3 -3 3 -5 20])
```



Example 2

Given this set of employee data,

```
years = 1950:10:1990;
service = 10:10:30;
```

```
wage = [150.697 199.592 187.625
179.323 195.072 250.287
203.212 179.092 322.767
226.505 153.706 426.730
249.633 120.281 598.243];
```

it is possible to interpolate to find the wage earned in 1975 by an employee with 15 years' service:

```
w = interp2(service,years,wage,15,1975)
w =
  190.6287
```

See Also

griddata, interp1, interp1q, interp3, interpn, meshgrid

Purpose

3-D data interpolation (table lookup)

Syntax

```
VI = interp3(X,Y,Z,V,XI,YI,ZI)
VI = interp3(V,XI,YI,ZI)
VI = interp3(V,ntimes)
VI = interp3(...,method)
VI = interp3(...,method,extrapval)
```

Description

`VI = interp3(X,Y,Z,V,XI,YI,ZI)` interpolates to find `VI`, the values of the underlying three-dimensional function `V` at the points in arrays `XI`, `YI` and `ZI`. `XI`,`YI`, `ZI` must be arrays of the same size, or vectors. Vector arguments that are not the same size, and have mixed orientations (i.e. with both row and column vectors) are passed through `meshgrid` to create the `Y1`, `Y2`, `Y3` arrays. Arrays `X`, `Y`, and `Z` specify the points at which the data `V` is given. Out of range values are returned as `NaN`.

`VI = interp3(V,XI,YI,ZI)` assumes `X=1:N`, `Y=1:M`, `Z=1:P` where `[M,N,P]=size(V)`.

`VI = interp3(V,ntimes)` expands `V` by interleaving interpolates between every element, working recursively for `ntimes` iterations. The command `interp3(V)` is the same as `interp3(V,1)`.

`VI = interp3(...,method)` specifies alternative methods:

'nearest'	Nearest neighbor interpolation
'linear'	Linear interpolation (default)
'spline'	Cubic spline interpolation
'cubic'	Cubic interpolation, as long as data is uniformly-spaced. Otherwise, this method is the same as `'spline'`.

`VI = interp3(...,method,extrapval)` specifies a method and a value for `VI` outside of the domain created by `X`, `Y` and `Z`. Thus, `VI` equals `extrapval` for any value of `XI`, `YI` or `ZI` that is not spanned by `X`, `Y`, and `Z`, respectively. You must specify a method to use `extrapval`. The default method is `'linear'`.

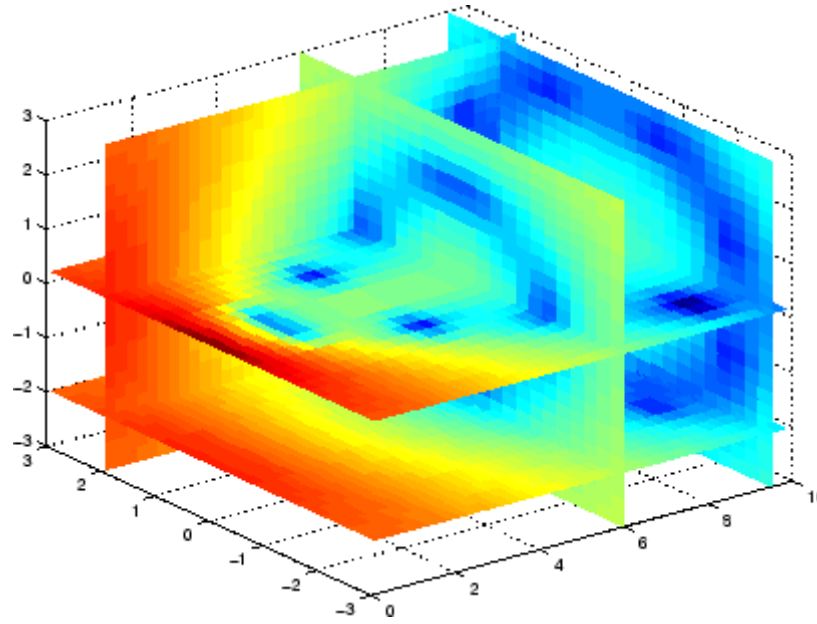
Discussion

All the interpolation methods require that `X`,`Y` and `Z` be monotonic and have the same format ("plaid") as if they were created using `meshgrid`. `X`, `Y`, and `Z` can be non-uniformly spaced. For faster interpolation when `X`, `Y`, and `Z` are equally spaced and monotonic, use the methods '`*linear`', '`*cubic`', or '`*nearest`'.

Examples

To generate a coarse approximation of `flow` and interpolate over a finer mesh:

```
[x,y,z,v] = flow(10);
[xi,yi,zi] = meshgrid(.1:.25:10, -3:.25:3, -3:.25:3);
vi = interp3(x,y,z,v,xi,yi,zi); % vi is 25-by-40-by-25
slice(xi,yi,zi,vi,[6 9.5],2,[-2 .2]), shading flat
```



See Also

`interp1`, `interp1q`, `interp2`, `interpn`, `meshgrid`

interpft

Purpose

1-D interpolation using FFT method

Syntax

```
y = interpft(x,n)
y = interpft(x,n,dim)
```

Description

`y = interpft(x,n)` returns the vector `y` that contains the value of the periodic function `x` resampled to `n` equally spaced points.

If `length(x) = m`, and `x` has sample interval `dx`, then the new sample interval for `y` is `dy = dx*m/n`. Note that `n` cannot be smaller than `m`.

If `X` is a matrix, `interpft` operates on the columns of `X`, returning a matrix `Y` with the same number of columns as `X`, but with `n` rows.

`y = interpft(x,n,dim)` operates along the specified dimension.

Algorithm

The `interpft` command uses the FFT method. The original vector `x` is transformed to the Fourier domain using `fft` and then transformed back with more points.

Examples

Interpolate a triangle-like signal using an interpolation factor of 5. First, set up signal to be interpolated:

```
y = [0 .5 1 1.5 2 1.5 1 .5 0 -.5 -1 -1.5 -2 -1.5 -1 -.5 0];
N = length(y);
```

Perform the interpolation:

```
L = 5;
M = N*L;
x = 0:L:L*N-1;
xi = 0:M-1;
yi = interpft(y,M);
plot(x,y,'o',xi,yi,'*')
legend('Original data','Interpolated data')
```

See Also

`interp1`

Purpose

N-D data interpolation (table lookup)

Syntax

```
VI = interpn(X1,X2,X3,...,V,Y1,Y2,Y3,...)
VI = interpn(V,Y1,Y2,Y3,...)
VI = interpn(V,ntimes)
VI = interpn(...,method)
VI = interpn(...,method,extrapval)
```

Description

`VI = interpn(X1,X2,X3,...,V,Y1,Y2,Y3,...)` interpolates to find `VI`, the values of the underlying multidimensional function `V` at the points in the arrays `Y1`, `Y2`, `Y3`, etc. For an n-dimensional array `V`, `interpn` is called with `2*N+1` arguments. Arrays `X1`, `X2`, `X3`, etc. specify the points at which the data `V` is given. Out of range values are returned as `NaN`s. `Y1`, `Y2`, `Y3`, etc. must be arrays of the same size, or vectors. Vector arguments that are not the same size, and have mixed orientations (i.e. with both row and column vectors) are passed through `ndgrid` to create the `Y1`, `Y2`, `Y3`, etc. arrays. `interpn` works for all n-dimensional arrays with 2 or more dimensions.

`VI = interpn(V,Y1,Y2,Y3,...)` interpolates as above, assuming `X1 = 1:size(V,1)`, `X2 = 1:size(V,2)`, `X3 = 1:size(V,3)`, etc.

`VI = interpn(V,ntimes)` expands `V` by interleaving interpolates between each element, working recursively for `ntimes` iterations. `interpn(V)` is the same as `interpn(V,1)`.

`VI = interpn(...,method)` specifies alternative methods:

'nearest'	Nearest neighbor interpolation
'linear'	Linear interpolation (default)
'spline'	Cubic spline interpolation
'cubic'	Cubic interpolation, as long as data is uniformly-spaced. Otherwise, this method is the same as `'spline'`.

`VI = interpn(...,method,extrapval)` specifies a method and a value for `VI` outside of the domain created by `X1`, `X2`, `...`. Thus, `VI` equals

`extrapval` for any value of `Y1`, `Y2`,... that is not spanned by `X1`, `X2`,... respectively. You must specify a method to use `extrapval`. The default method is `'linear'`.

`interpn` requires that `X1`, `X2`, `X3`, ... be monotonic and plaid (as if they were created using `ndgrid`). `X1`, `X2`, `X3`, and so on can be non-uniformly spaced.

Discussion

All the interpolation methods require that `X1`,`X2`, `X3` ... be monotonic and have the same format ("plaid") as if they were created using `ndgrid`. `X1`,`X2`,`X3`,... and `Y1`, `Y2`, `Y3`, etc. can be non-uniformly spaced. For faster interpolation when `X1`, `X2`, `X3`, etc. are equally spaced and monotonic, use the methods '`*linear`', '`*cubic`', or '`*nearest`'.

Examples

Start by defining an anonymous function to compute $f = te^{-x^2-y^2-z^2}$:

```
f = @(x,y,z,t) t.*exp(-x.^2 - y.^2 - z.^2);
```

Build the lookup table by evaluating the function `f` on a grid constructed by `ndgrid`:

```
[x,y,z,t] = ndgrid(-1:0.2:1,-1:0.2:1,-1:0.2:1,0:2:10);
v = f(x,y,z,t);
```

Now construct a finer grid:

```
[xi,yi,zi,ti] = ndgrid(-1:0.05:1,-1:0.08:1,-1:0.05:1, ...
                       0:0.5:10);
```

Compute the spline interpolation at `xi`, `yi`, `zi`, and `ti`:

```
vi = interpn(x,y,z,t,v,xi,yi,zi,ti,'spline');
```

Plot the interpolated function, and then create a movie from the plot:

```
nframes = size(ti, 4);
for j = 1:nframes
   slice(yi(:,:,:,j), xi(:,:,:,j), zi(:,:,:,j), ...
```

```
            vi(:,:,:,j),0,0,0);
    caxis([0 10]);
    M(j) = getframe;
end
movie(M);
```

`interp1`, `interp2`, `interp3`, `ndgrid`

interpstreamspeed

Purpose

Interpolate stream-line vertices from flow speed

Syntax

```
interpstreamspeed(X,Y,Z,U,V,W,vertices)
interpstreamspeed(U,V,W,vertices)
interpstreamspeed(X,Y,Z,speed,vertices)
interpstreamspeed(speed,vertices)
interpstreamspeed(X,Y,U,V,vertices)
interpstreamspeed(U,V,vertices)
interpstreamspeed(X,Y,speed,vertices)
interpstreamspeed(speed,vertices)
interpstreamspeed(...,sf)
vertsout = interpstreamspeed(...)
```

Description

`interpstreamspeed(X,Y,Z,U,V,W,vertices)` interpolates streamline vertices based on the magnitude of the vector data `U`, `V`, `W`. The arrays `X`, `Y`, `Z` define the coordinates for `U`, `V`, `W` and must be monotonic and 3-D plaid (as if produced by `meshgrid`).

`interpstreamspeed(U,V,W,vertices)` assumes `X`, `Y`, and `Z` are determined by the expression

```
[X Y Z] = meshgrid(1:n,1:m,1:p)
```

where `[m n p] = size(U)`.

`interpstreamspeed(X,Y,Z,speed,vertices)` uses the 3-D array `speed` for the speed of the vector field.

`interpstreamspeed(speed,vertices)` assumes `X`, `Y`, and `Z` are determined by the expression

```
[X Y Z] = meshgrid(1:n,1:m,1:p)
```

where `[m n p]=size(speed)`.

`interpstreamspeed(X,Y,U,V,vertices)` interpolates streamline vertices based on the magnitude of the vector data `U`, `V`. The arrays `X`, `Y` define the coordinates for `U`, `V` and must be monotonic and 2-D plaid (as if produced by `meshgrid`).

`interpstreamspeed(U,V,vertices)` assumes `X` and `Y` are determined by the expression

```
[X Y] = meshgrid(1:n,1:m)
```

where `[M N]=size(U)`.

`interpstreamspeed(X,Y,speed,vertices)` uses the 2-D array `speed` for the speed of the vector field.

`interpstreamspeed(speed,vertices)` assumes `X` and `Y` are determined by the expression

```
[X Y] = meshgrid(1:n,1:m)
```

where `[M,N]= size(speed)`.

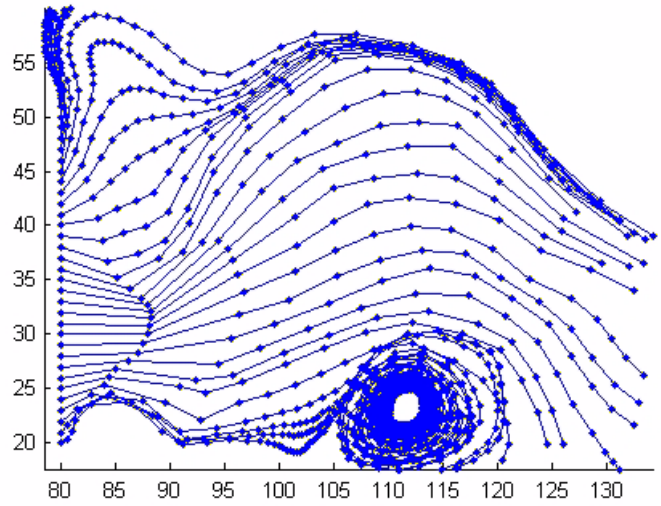
`interpstreamspeed(...,sf)` uses `sf` to scale the magnitude of the vector data and therefore controls the number of interpolated vertices. For example, if `sf` is 3, then `interpstreamspeed` creates only one-third of the vertices.

`vertsout = interpstreamspeed(...)` returns a cell array of vertex arrays.

Examples

This example draws streamlines using the vertices returned by `interpstreamspeed`. Dot markers indicate the location of each vertex. This example enables you to visualize the relative speeds of the flow data. Streamlines having widely spaced vertices indicate faster flow; those with closely spaced vertices indicate slower flow.

```
load wind
[sx sy sz] = meshgrid(80,20:1:55,5);
verts = stream3(x,y,z,u,v,w,sx,sy,sz);
iverts = interpstreamspeed(x,y,z,u,v,w,verts,.2);
sl = streamline(iverts);
set(sl,'Marker','.')
axis tight; view(2); daspect([1 1 1])
```



This example plots streamlines whose vertex spacing indicates the value of the gradient along the streamline.

```
z = membrane(6,30);
[u v] = gradient(z);
[verts averts] = streamslice(u,v);
iverts = interpstreamspeed(u,v,verts,15);
sl = streamline(iverts);
set(sl,'Marker','.')
hold on; pcolor(z); shading interp
axis tight; view(2); daspect([1 1 1])
```

`stream2`, `stream3`, `streamline`, `streamslice`, `streamparticles`

"Volume Visualization" on page 1-102 for related functions

intersect

Purpose

Find set intersection of two vectors

Syntax

```
c = intersect(A, B)
c = intersect(A, B, 'rows')
[c, ia, ib] = intersect(a, b)
```

Description

`c = intersect(A, B)` returns the values common to both `A` and `B`. In set theoretic terms, this is A[[INTERSECT]] B. Inputs `A` and `B` can be numeric or character vectors or cell arrays of strings. The resulting vector is sorted in ascending order.

`c = intersect(A, B, 'rows')` when `A` and `B` are matrices with the same number of columns returns the rows common to both `A` and `B`.

`[c, ia, ib] = intersect(a, b)` also returns column index vectors `ia` and `ib` such that `c = a(ia)` and `c = b(ib)` (or `c = a(ia,:)` and `c = b(ib,:)`).

Remarks

Because NaN is considered to be not equal to itself, it is never included in the result `c`.

Examples

```
A = [1 2 3 6]; B = [1 2 3 4 6 10 20];
[c, ia, ib] = intersect(A, B);
disp([c; ia; ib])
     1     2     3     6
     1     2     3     4
     1     2     3     5
```

See Also

`ismember`, `issorted`, `setdiff`, `setxor`, `union`, `unique`

Purpose

Largest value of specified integer type

Syntax

```
v = intmax
v = intmax('classname')
```

Description

`v = intmax` is the largest positive value that can be represented in MATLAB with a 32-bit integer. Any value larger than the value returned by `intmax` saturates to the `intmax` value when cast to a 32-bit integer.

`v = intmax('classname')` is the largest positive value in the integer class `classname`. Valid values for the string `classname` are

`'int8'`	`'int16'`	`'int32'`	`'int64'`
`'uint8'`	`'uint16'`	`'uint32'`	`'uint64'`

`intmax('int32')` is the same as `intmax` with no arguments.

Examples

Find the maximum value for a 64-bit signed integer:

```
v = intmax('int64')
v =
  9223372036854775807
```

Convert this value to a 32-bit signed integer:

```
x = int32(v)
x =
  2147483647
```

Compare the result with the default value returned by `intmax`:

```
isequal(x, intmax)
ans =
     1
```

intmin

Purpose

Smallest value of specified integer type

Syntax

```
v = intmin
v = intmin('classname')
```

Description

`v = intmin` is the smallest value that can be represented in MATLAB with a 32-bit integer. Any value smaller than the value returned by `intmin` saturates to the `intmin` value when cast to a 32-bit integer.

`v = intmin('classname')` is the smallest positive value in the integer class `classname`. Valid values for the string `classname` are

`'int8'`	`'int16'`	`'int32'`	`'int64'`
`'uint8'`	`'uint16'`	`'uint32'`	`'uint64'`

`intmin('int32')` is the same as `intmin` with no arguments.

Examples

Find the minimum value for a 64-bit signed integer:

```
v = intmin('int64')
v =
 -9223372036854775808
```

Convert this value to a 32-bit signed integer:

```
x = int32(v)
x =
  2147483647
```

Compare the result with the default value returned by `intmin`:

```
isequal(x, intmin)
ans =
     1
```

See Also

`intmax`, `realmin`, `realmax`, `int8`, `uint8`, `isa`, `class`

Purpose

Control state of integer warnings

Syntax

```
intwarning('action')
s = intwarning('action')
intwarning(s)
sOld = intwarning(sNew)
```

Description

MATLAB has four types of integer warnings. The `intwarning` function enables, disables, or returns information on these warnings:

- `MATLAB:intConvertNaN` — Warning on an attempt to convert NaN (Not a Number) to an integer. The result of the operation is zero.
- `MATLAB:intConvertNonIntVal` — Warning on an attempt to convert a non-integer value to an integer. The result is that the input value is rounded to the nearest integer for that class.
- `MATLAB:intConvertOverflow` — Warning on overflow when attempting to convert from a numeric class to an integer class. The result is the maximum value for the target class.
- `MATLAB:intMathOverflow` — Warning on overflow when attempting an integer arithmetic operation. The result is the maximum value for the class of the input value. MATLAB also issues this warning when NaN is computed (e.g., `int8(0)/0`).

`intwarning('action')` sets or displays the state of integer warnings in MATLAB according to the string, *`action`*. There are three possible actions, as shown here. The default state is `'off'`.

Action	Description
`off`	Disable the display of integer warnings
`on`	Enable the display of integer warnings
`query`	Display the state of all integer warnings

`s = intwarning('action')` sets the state of integer warnings in MATLAB according to the string *`action`*, and then returns the previous

state in a 4-by-1 structure array, `s`. The return structure array has two fields: `identifier` and `state`.

`intwarning(s)` sets the state of integer warnings in MATLAB according to the `identifier` and `state` fields in structure array `s`.

`sOld = intwarning(sNew)` sets the state of integer warnings in MATLAB according to `sNew`, and then returns the previous state in `sOld`.

Remarks

Caution Enabling the `MATLAB:intMathOverflow` warning slows down integer arithmetic. It is recommended that you enable this particular warning only when you need to diagnose unusual behavior in your code, and disable it during normal program operation. The other integer warnings listed here do not affect program performance.

Examples

General Usage

Examples of the four types of integer warnings are shown here:

- **MATLAB:intConvertNaN**

Attempt to convert NaN (Not a Number) to an unsigned integer:

```
uint8(NaN);
Warning: NaN converted to uint8(0).
```

- **MATLAB:intConvertNonIntVal**

Attempt to convert a floating point number to an unsigned integer:

```
uint8(2.7);
Warning: Conversion rounded non-integer floating point
   value to nearest uint8 value.
```

- **MATLAB:intConvertOverflow**

Attempt to convert a large unsigned integer to a signed integer, where the operation overflows:

```
int8(uint8(200));
Warning: Out of range value converted to intmin('int8')
   or intmax('int8').
```

- **MATLAB:intMathOverflow**

Attempt an integer arithmetic operation that overflows:

```
intmax('uint8') + 5;
Warning: Out of range value or NaN computed in
integer arithmetic.
```

Example 1

Check the initial state of integer warnings:

```
intwarning('query')
The state of warning 'MATLAB:intConvertNaN' is 'off'.
The state of warning 'MATLAB:intConvertNonIntVal' is 'off'.
The state of warning 'MATLAB:intConvertOverflow' is 'off'.
The state of warning 'MATLAB:intMathOverflow' is 'off'.
```

Convert a floating point value to an 8-bit unsigned integer. MATLAB does the conversion, but that requires rounding the resulting value. Because all integer warnings have been disabled, no warning is displayed:

```
uint8(2.7)
ans =
    3
```

Store this state in structure array `iwState`:

```
iwState = intwarning('query');
```

Change the state of the `ConvertNonIntVal` warning to `'on'` by first setting the state to `'on'` in the `iwState` structure array, and then

loading `iwState` back into the internal integer warning settings for your MATLAB session:

```
maxintwarn = 4;

for k = 1:maxintwarn
   if strcmp(iwState(k).identifier, ...
             'MATLAB:intConvertNonIntVal')
      iwState(k).state = 'on';
      intwarning(iwState);
   end
end
```

Verify that the state of `ConvertNonIntVal` has changed:

```
intwarning('query')
The state of warning 'MATLAB:intConvertNaN' is 'off'.
The state of warning 'MATLAB:intConvertNonIntVal' is 'on'.
The state of warning 'MATLAB:intConvertOverflow' is 'off'.
The state of warning 'MATLAB:intMathOverflow' is 'off'.
```

Now repeat the conversion from floating point to integer. This time MATLAB displays the warning:

```
uint8(2.7)
Warning: Conversion rounded non-integer floating point
   value to nearest uint8 value.
ans =
    3
```

See Also

`warning`, `lastwarn`

Purpose

Matrix inverse

Syntax

```
Y = inv(X)
```

Description

`Y = inv(X)` returns the inverse of the square matrix `X`. A warning message is printed if `X` is badly scaled or nearly singular.

In practice, it is seldom necessary to form the explicit inverse of a matrix. A frequent misuse of `inv` arises when solving the system of linear equations $Ax = b$. One way to solve this is with `x = inv(A)*b`. A better way, from both an execution time and numerical accuracy standpoint, is to use the matrix division operator `x = A\b`. This produces the solution using Gaussian elimination, without forming the inverse. See `\` and `/` for further information.

Examples

Here is an example demonstrating the difference between solving a linear system by inverting the matrix with `inv(A)*b` and solving it directly with `A\b`. A random matrix `A` of order 500 is constructed so that its condition number, `cond(A)`, is `1.e10`, and its norm, `norm(A)`, is `1`. The exact solution `x` is a random vector of length 500 and the right-hand side is `b = A*x`. Thus the system of linear equations is badly conditioned, but consistent.

On a 300 MHz, laptop computer the statements

```
n = 500;
Q = orth(randn(n,n));
d = logspace(0,-10,n);
A = Q*diag(d)*Q';
x = randn(n,1);
b = A*x;
tic, y = inv(A)*b; toc
err = norm(y-x)
res = norm(A*y-b)
```

produce

```
elapsed_time =
```

```
    1.4320
err =
    7.3260e-006
res =
    4.7511e-007
```

while the statements

```
tic, z = A\b, toc
err = norm(z-x)
res = norm(A*z-b)
```

produce

```
elapsed_time =
    0.6410
err =
    7.1209e-006
res =
    4.4509e-015
```

It takes almost two and one half times as long to compute the solution with `y = inv(A)*b` as with `z = A\b`. Both produce computed solutions with about the same error, `1.e-6`, reflecting the condition number of the matrix. But the size of the residuals, obtained by plugging the computed solution back into the original equations, differs by several orders of magnitude. The direct solution produces residuals on the order of the machine accuracy, even though the system is badly conditioned.

The behavior of this example is typical. Using `A\b` instead of `inv(A)*b` is two to three times as fast and produces residuals on the order of machine accuracy, relative to the magnitude of the data.

Algorithm

Inputs of Type Double

For inputs of type `double`, `inv` uses the following LAPACK routines to compute the matrix inverse:

Matrix	Routine
Real	DLANGE, DGETRF, DGECON, DGETRI
Complex	ZLANGE, ZGETRF, ZGECON, ZGETRI

Inputs of Type Single

For inputs of type `single`, `inv` uses the following LAPACK routines to compute the matrix inverse:

Matrix	Routine
Real	SLANGE, SGETRF, SGECON, SGETRI
Complex	CLANGE, CGETRF, CGECON, CGETRI

invhilb

Purpose

Inverse of Hilbert matrix

Syntax

```
H = invhilb(n)
```

Description

`H = invhilb(n)` generates the exact inverse of the exact Hilbert matrix for `n` less than about 15. For larger `n`, `invhilb(n)` generates an approximation to the inverse Hilbert matrix.

Limitations

The exact inverse of the exact Hilbert matrix is a matrix whose elements are large integers. These integers may be represented as floating-point numbers without roundoff error as long as the order of the matrix, `n`, is less than 15.

Comparing `invhilb(n)` with `inv(hilb(n))` involves the effects of two or three sets of roundoff errors:

- The errors caused by representing `hilb(n)`
- The errors in the matrix inversion process
- The errors, if any, in representing `invhilb(n)`

It turns out that the first of these, which involves representing fractions like 1/3 and 1/5 in floating-point, is the most significant.

Examples

`invhilb(4)` is

```
    16   -120    240   -140
  -120   1200  -2700   1680
   240  -2700   6480  -4200
  -140   1680  -4200   2800
```

Purpose

Invoke method on object or interface, or display methods

Syntax

```
S = h.invoke
S = h.invoke('methodname')
S = h.invoke('methodname', arg1, arg2, ...)
S = h.invoke('custominterfacename')
S = invoke(h, ...)
```

Description

`S = h.invoke` returns structure array `S` containing a list of all methods supported by the object or interface, `h`, along with the prototypes for these methods.

If `S` is empty, either there are no properties or methods in the object, or MATLAB cannot read the object's type library. Refer to the COM vendor's documentation. For Automation objects, if the vendor provides documentation for specific properties or methods, use the `S = invoke(h, ...)` syntax to call them.

`S = h.invoke('methodname')` invokes the method specified in the string `methodname`, and returns an output value, if any, in `S`. The data type of the return value is dependent upon the specific method being invoked and is determined by the specific control or server.

`S = h.invoke('methodname', arg1, arg2, ...)` invokes the method specified in the string `methodname` with input arguments `arg1`, `arg2`, etc.

`S = h.invoke('custominterfacename')` returns an `Interface` object that serves as a handle to a custom interface implemented by the COM component. The `h` argument is a handle to the COM object. The `custominterfacename` argument is a quoted string returned by the `interfaces` function.

`S = invoke(h, ...)` is an alternate syntax for the same operation.

Remarks

If the method returns a COM interface, then `invoke` returns a new MATLAB COM object that represents the interface returned. See "Handling COM Data in MATLAB" in the External Interfaces

documentation for a description of how MATLAB converts COM data types.

Examples

Example 1 — Invoking a Method

Create an `mwsamp` control and invoke its `Redraw` method:

```
f = figure ('position', [100 200 200 200]);
h = actxcontrol ('mwsamp.mwsampctrl.1', [0 0 200 200], f);

h.Radius = 100;
h.invoke('Redraw');
```

Here is a simpler way to use `invoke`. Just call the method directly, passing the handle, and any arguments:

```
h.Redraw;
```

Call `invoke` with only the handle argument to display a list of all `mwsamp` methods:

```
h.invoke
ans =
   AboutBox = void AboutBox(handle)
   Beep = void Beep(handle)
   FireClickEvent = void FireClickEvent(handle)
             .
             .
            etc.
```

Example 2 — Getting a Custom Interface

Once you have created a COM server, you can query the server component to see if any custom interfaces are implemented. Use the `interfaces` function to return a list of all available custom interfaces:

```
h = actxserver('mytestenv.calculator')
h =
   COM.mytestenv.calculator
```

```
customlist = h.interfaces
customlist =
   ICalc1
   ICalc2
   ICalc3
```

To get a handle to the custom interface you want, use the `invoke` function, specifying the handle returned by `actxcontrol` or `actxserver` and also the name of the custom interface:

```
c1 = h.invoke('ICalc1')
c1 =
   Interface.Calc_1.0_Type_Library.ICalc_Interface
```

You can now use this handle with most of the COM client functions to access the properties and methods of the object through the selected custom interface.

See Also

`methods`, `ismethod`, `interfaces`

ipermute

Purpose

Inverse permute dimensions of N-D array

Syntax

```
A = ipermute(B,order)
```

Description

`A = ipermute(B,order)` is the inverse of `permute`. `ipermute` rearranges the dimensions of `B` so that `permute(A,order)` will produce `B`. `B` has the same values as `A` but the order of the subscripts needed to access any particular element are rearranged as specified by `order`. All the elements of `order` must be unique.

Remarks

`permute` and `ipermute` are a generalization of transpose (`.'`) for multidimensional arrays.

Examples

Consider the 2-by-2-by-3 array `a`:

```
a = cat(3,eye(2),2*eye(2),3*eye(2))

a(:,:,1) =              a(:,:,2) =
     1     0                   2     0
     0     1                   0     2

a(:,:,3) =
     3     0
     0     3
```

Permuting and inverse permuting `a` in the same fashion restores the array to its original form:

```
B = permute(a,[3 2 1]);
C = ipermute(B,[3 2 1]);
isequal(a,C)
ans=

   1
```

See Also

`permute`

Purpose

Interquartile range of `timeseries` data

Syntax

```
ts_iqr = iqr(ts)
iqr(ts,'PropertyName1',PropertyValue1,...)
```

Description

`ts_iqr = iqr(ts)` returns the interquartile range of `ts.Data`. When `ts.Data` is a vector, ts_iqr is the difference between the 75th and the 25th percentiles of the `ts.Data` values. When `ts.Data` is a matrix, ts_iqr is a row vector containing the interquartile range of each column of `ts.Data` (when `IsTimeFirst` is `true` and the first dimension of `ts` is aligned with time). For the N-dimensional `ts.Data` array, `iqr` always operates along the first nonsingleton dimension of `ts.Data`.

`iqr(ts,'PropertyName1',PropertyValue1,...)` specifies the following optional input arguments:

- `'MissingData'` property has two possible values, `'remove'` (default) or `'interpolate'`, indicating how to treat missing data during the calculation.
- `'Quality'` values are specified by a vector of integers, indicating which quality codes represent missing samples (for vector data) or missing observations (for data arrays with two or more dimensions).
- `'Weighting'` property has two possible values, `'none'` (default) or `'time'`. When you specify `'time'`, larger time values correspond to larger weights.

Examples

Create a time series with a missing value, represented by `NaN`.

```
ts = timeseries([3.0 NaN 5 6.1 8], 1:5);
```

Calculate the interquartile range of `ts.Data` after removing the missing value from the calculation.

```
iqr(ts,'MissingData','remove')
```

```
ans =

    3.0500
```

timeseries

Purpose

Detect state

Description

These functions detect the state of MATLAB entities:

`isa`	Detect object of given MATLAB class or Java class
`isappdata`	Determine if object has specific application-defined data
`iscell`	Determine if input is cell array
`iscellstr`	Determine if input is cell array of strings
`ischar`	Determine if input is character array
`iscom`	Determine if input is Component Object Model (COM) object
`isdir`	Determine if input is directory
`isempty`	Determine if input is empty array
`isequal`	Determine if arrays are numerically equal
`isequalwithequalnans`	Determine if arrays are numerically equal, treating `NaN`s as equal
`isevent`	Determine if input is object event
`isfield`	Determine if input is MATLAB structure array field
`isfinite`	Detect finite elements of array
`isfloat`	Determine if input is floating-point array
`isglobal`	Determine if input is global variable
`ishandle`	Detect valid graphics object handles
`ishold`	Determine if graphics hold state is on
`isinf`	Detect infinite elements of array
`isinteger`	Determine if input is integer array
`isinterface`	Determine if input is Component Object Model (COM) interface

isjava	Determine if input is Java object
iskeyword	Determine if input is MATLAB keyword
isletter	Detect elements that are alphabetic letters
islogical	Determine if input is logical array
ismember	Detect members of specific set
ismethod	Determine if input is object method
isnan	Detect elements of array that are not a number (NaN)
isnumeric	Determine if input is numeric array
isobject	Determine if input is MATLAB OOPs object
ispc	Determine if PC (Windows) version of MATLAB
isprime	Detect prime elements of array
isprop	Determine if input is object property
isreal	Determine if all array elements are real numbers
isscalar	Determine if input is scalar
issorted	Determine if set elements are in sorted order
isspace	Detect space characters in array
issparse	Determine if input is sparse array
isstrprop	Determine if string is of specified category
isstruct	Determine if input is MATLAB structure array
isstudent	Determine if Student Version of MATLAB
isunix	Determine if UNIX version of MATLAB
isvarname	Determine if input is valid variable name
isvector	Determine if input is vector

See Also

isa

Purpose

Determine whether input is object of given class

Syntax

```
K = isa(obj, 'class_name')
```

Description

`K = isa(obj, 'class_name')` returns logical `1` (`true`) if `obj` is of class (or a subclass of) *`class_name`*, and logical `0` (`false`) otherwise.

The argument `obj` is a MATLAB object or a Java object. The argument *`class_name`* is the name of a MATLAB (predefined or user-defined) or a Java class. Predefined MATLAB classes include

`logical`	Logical array of `true` and `false` values
`char`	Characters array
`numeric`	Integer or floating-point array
`integer`	Signed or unsigned integer array
`int8`	8-bit signed integer array
`uint8`	8-bit unsigned integer array
`int16`	16-bit signed integer array
`uint16`	16-bit unsigned integer array
`int32`	32-bit signed integer array
`uint32`	32-bit unsigned integer array
`int64`	64-bit signed integer array
`uint64`	64-bit unsigned integer array
`float`	Single- or double-precision floating-point array
`single`	Single-precision floating-point array
`double`	Double-precision floating-point array
`cell`	Cell array
`struct`	Structure array

`function_handle`	Function handle
'*`class_name`*'	Custom MATLAB object class or Java class

To check for a sparse array, use `issparse`. To check for a complex array, use `~isreal`.

Examples

```
isa(rand(3,4),'double')
ans =
    1
```

The following example creates an instance of the user-defined MATLAB class named `polynom`. The `isa` function identifies the object as being of the `polynom` class.

```
polynom_obj = polynom([1 0 -2 -5]);
isa(polynom_obj, 'polynom')
ans =
     1
```

See Also

`class`, `is*`

Purpose

True if application-defined data exists

Syntax

```
isappdata(h,name)
```

Description

`isappdata(h,name)` returns `1` if application-defined data with the specified `name` exists on the object specified by handle `h`, and returns `0` otherwise.

See Also

`getappdata`, `rmappdata`, `setappdata`

iscell

Purpose

Determine whether input is cell array

Syntax

```
tf = iscell(A)
```

Description

`tf = iscell(A)` returns logical `1` (`true`) if `A` is a cell array and logical `0` (`false`) otherwise.

Examples

```
A{1,1} = [1 4 3; 0 5 8; 7 2 9];
A{1,2} = 'Anne Smith';
A{2,1} = 3+7i;
A{2,2} = -pi:pi/10:pi;

iscell(A)

ans =

     1
```

See Also

`cell`, `iscellstr`, `isstruct`, `isnumeric`, `islogical`, `isobject`, `isa`, `is*`

Purpose

Determine whether input is cell array of strings

Syntax

```
tf = iscellstr(A)
```

Description

`tf = iscellstr(A)` returns logical `1` (`true`) if `A` is a cell array of strings and logical `0` (`false`) otherwise. A cell array of strings is a cell array where every element is a character array.

Examples

```
A{1,1} = 'Thomas Lee';
A{1,2} = 'Marketing';
A{2,1} = 'Allison Jones';
A{2,2} = 'Development';

iscellstr(A)

ans =

     1
```

See Also

`cellstr`, `iscell`, `isstrprop`, `strings`, `char`, `isstruct`, `isa`, `is*`

ischar

Purpose

Determine whether item is character array

Syntax

```
tf = ischar(A)
```

Description

`tf = ischar(A)` returns logical `1` (`true`) if `A` is a character array and logical `0` (`false`) otherwise.

Examples

Given the following cell array,

```
C{1,1} = magic(3);           % double array
C{1,2} = 'John Doe';         % char array
C{1,3} = 2 + 4i              % complex double

C =

    [3x3 double]    'John Doe'    [2.0000+ 4.0000i]
```

`ischar` shows that only `C{1,2}` is a character array.

```
for k = 1:3
x(k) = ischar(C{1,k});
end

x

x =

     0     1     0
```

See Also

`char`, `strings`, `isletter`, `isspace`, `isstrprop`, `iscellstr`, `isnumeric`, `isa`, `is*`

Purpose

Is input COM object

Syntax

```
tf = h.iscom
tf = iscom(h)
```

Description

`tf = h.iscom` returns logical `1` (`true`) if the input handle, `h`, is a COM or ActiveX object. Otherwise, `iscom` returns logical `0` (`false`) .

`tf = iscom(h)` is an alternate syntax for the same operation.

Examples

Create a COM server running Microsoft Excel. The `actxserver` function returns a handle `h` to the server object. Testing this handle with `iscom` returns `true`:

```
h = actxserver('excel.application');

h.iscom
ans =
   1
```

Create an interface to `workbooks`, returning handle `w`. Testing this handle with `iscom` returns `false`:

```
w = h.get('workbooks');

w.iscom
ans =
   0
```

See Also

`isinterface`

isdir

Purpose

Determine whether input is a directory

Syntax

```
tf = isdir('A')
```

Description

`tf = isdir('A')` returns logical `1` (`true`) if `A` is a directory and logical `0` (`false`) otherwise.

Examples

Type

```
tf=isdir('mymfiles/results')
```

and MATLAB returns

```
tf =
 1
```

indicating that `mymfiles/results` is a directory.

See Also

`dir`, `is*`

Purpose

Determine whether array is empty

Syntax

```
TF = isempty(A)
```

Description

`TF = isempty(A)` returns logical 1 (`true`) if `A` is an empty array and logical 0 (`false`) otherwise. An empty array has at least one dimension of size zero, for example, 0-by-0 or 0-by-5.

Examples

```
B = rand(2,2,2);
B(:,:,:) = [];

isempty(B)

ans = 1
```

See Also

`is*`

isempty (timeseries)

Purpose

Determine whether `timeseries` object is empty

Syntax

```
isempty(ts)
```

Description

`isempty(ts)` returns a logical value for `timeseries` object `ts`, as follows:

- `1` — When `ts` contains no data samples or `ts.Data` is empty.
- `0` — When `ts` contains data samples

See Also

`length (timeseries)`, `size (timeseries)`, `timeseries`, `tsprops`

Purpose

Determine whether `tscollection` object is empty

Syntax

```
isempty(tsc)
```

Description

`isempty(tsc)` returns a logical value for `tscollection` object `tsc`, as follows:

- `1` — When `tsc` contains neither `timeseries` members nor a time vector
- `0` — When `tsc` contains either `timeseries` members or a time vector

See Also

`length (tscollection)`, `size (tscollection)`, `timeseries`, `tscollection`

isequal

Purpose

Test arrays for equality

Syntax

```
tf = isequal(A, B, ...)
```

Description

`tf = isequal(A, B, ...)` returns logical `1` (`true`) if the input arrays have the same contents, and logical `0` (`false`) otherwise. Nonempty arrays must be of the same data type and size.

Remarks
