- The FILE HANDLE command must be used if the FILE subcommand is specified on KEYED DATA LIST.
- KEYED DATA LIST can be specified in an input program, or it can be used as a transformation language to change an existing active dataset. This differs from all other input commands, such as GET and DATA LIST, which create new active datasets.

Operations

- Variable names are stored in the active dataset dictionary.
- Formats are stored in the active dataset dictionary and are used to display and write the values. To change output formats of numeric variables, use the FORMATS command.

Examples

Specifying a Key Variable

```
FILE HANDLE EMPL/ file specifications.
KEYED DATA LIST FILE=EMPL KEY=#NXTCASE IN=#FOUND
          /YRHIRED 1-2 SEX 3 JOBCLASS 4.
```

- FILE HANDLE defines the handle for the data file to be read by KEYED DATA LIST. The handle is specified on the FILE subcommand of KEYED DATA LIST.
- KEY on KEYED DATA LIST specifies the variable to be used as the access key. For a direct-access file, the value of the variable must be between 1 and the number of records in the file. For a keyed file, the value must be a string.
- IN creates the logical scratch variable *#FOUND*, whose value will be 1 if the record is successfully read, or 0 if the record is not found.
- The variable definitions are the same as those used for DATA LIST.

Reading a Direct-Access File

```
* Reading a direct-access file: sampling 1 out of every 25 records.

FILE HANDLE    EMPL/ file specifications.
INPUT PROGRAM.
COMPUTE #INTRVL = TRUNC(UNIF(48))+1. /* Mean interval = 25
COMPUTE #NXTCASE = #NXTCASE+#INTRVL. /* Next record number
COMPUTE #EOF = #NXTCASE > 1000.      /* End of file check
DO IF   #EOF.
+  END FILE.
ELSE.
+  KEYED DATA LIST  FILE=EMPL, KEY=#NXTCASE, IN=#FOUND, NOTABLE
                   /YRHIRED 1-2 SEX 3 JOBCLASS 4.
```

```
+  DO IF       #FOUND.
+     END CASE.                      /* Return a case
+  ELSE.
+     PRINT / 'Oops. #NXTCASE=' #NXTCASE.
+  END IF.
END IF.
END INPUT PROGRAM.
EXECUTE.
```

- FILE HANDLE defines the handle for the data file to be read by the KEYED DATA LIST command. The record numbers for this example are generated by the transformation language; they are not based on data taken from another file.
- The INPUT PROGRAM and END INPUT PROGRAM commands begin and end the block of commands that build cases from the input file. Since the session generates cases, an input program is required.
- The first two COMPUTE statements determine the number of the next record to be selected. This is done in two steps. First, the integer portion is taken from the sum of 1 and a uniform pseudo-random number between 1 and 49. The result is a mean interval of 25. Second, the variable *#NXTCASE* is added to this number to generate the next record number. This record number, *#NXTCASE*, will be used for the key variable on the KEYED DATA LIST command. The third COMPUTE creates a logical scratch variable, *#EOF*, that has a value of 0 if the record number is less than or equal to 1000, or 1 if the value of the record number is greater than 1000.
- The DO IF–END IF structure controls the building of cases. If the record number is greater than 1000, *#EOF* equals 1, and the END FILE command tells the program to stop reading data and end the file.
- If the record number is less than or equal to 1000, the record is read via KEYED DATA LIST using the value of *#NXTCASE*. A case is generated if the record exists (*#FOUND* equals 1). If not, the program displays the record number and continues to the next case. The sample will have about 40 records.
- EXECUTE causes the transformations to be executed.
- This example illustrates the difference between DATA LIST, which always reads the next record in a file, and KEYED DATA LIST, which reads only specified records. The record numbers must be generated by another command or be contained in the active dataset.

Reading a Keyed File

```
* Reading a keyed file: reading selected records.

GET FILE=STUDENTS/KEEP=AGE,SEX,COURSE.
FILE HANDLE COURSES/ file specifications.
STRING #KEY(A4).
COMPUTE #KEY = STRING(COURSE,N4). /* Create a string key
KEYED DATA LIST FILE=COURSES KEY=#KEY IN=#FOUND NOTABLE
     /PERIOD 13 CREDITS 16.
SELECT IF #FOUND.
LIST.
```

- GET reads the *STUDENTS* file, which contains information on students, including a course identification for each student. The course identification will be used as the key for selecting one record from a file of courses.
- The FILE HANDLE command defines a file handle for the file of courses.

- The STRING and COMPUTE commands transform the course identification from numeric to string for use as a key. For keyed files, the key variable must be a string.
- KEYED DATA LIST uses the value of the newly created string variable *#KEY* as the key to search the course file. If a record that matches the value of *#KEY* is found, *#FOUND* is set to 1; otherwise, it is set to 0. Note that KEYED DATA LIST appears outside an input program in this example.
- If the course file contains the requested record, *#FOUND* equals 1. The variables *PERIOD* and *CREDITS* are added to the case and the case is selected via the SELECT IF command; otherwise, the case is dropped.
- LIST lists the values of the selected cases.
- This example shows how existing cases can be updated on the basis of information read from a keyed file.
- This task could also be accomplished by reading the entire course file with DATA LIST and combining it with the student file via the MATCH FILES command. The technique you should use depends on the percentage of the records in the course file that need to be accessed. If fewer than 10% of the course file records are read, KEYED DATA LIST is probably more efficient. As the percentage of the records that are read increases, reading the entire course file and using MATCH makes more sense.

FILE Subcommand

FILE specifies the handle for the direct-access or keyed data file. The file handle must have been defined on a previous FILE HANDLE command (or, in the case of the IBM OS environment, on a DD statement in the JCL).

KEY Subcommand

KEY specifies the variable whose value will be used as the key. This variable must already exist as the result of a prior DATA LIST, KEYED DATA LIST, GET, or transformation command.

- KEY is required. Its only specification is a single variable. The variable can be a permanent variable or a scratch variable.
- For direct-access files, the key variable must be numeric, and its value must be between 1 and the number of records in the file.
- For keyed files, the key variable must be string. If the keys are numbers, such as social security numbers, the STRING function can be used to convert the numbers to strings. For example, the following might be required to get the value of a numeric key into exactly the same format as used on the keyed file:

```
COMPUTE #KEY=STRING(123,IB4).
```

IN Subcommand

IN creates a numeric variable whose value indicates whether or not the specified record is found.

- IN is required. Its only specification is a single numeric variable. The variable can be a permanent variable or a scratch variable.
- The value of the variable is 1 if the record is successfully read or 0 if the record is not found. The IN variable can be used to select all cases that have been updated by KEYED DATA LIST.

Example

```
FILE HANDLE EMPL/ file specifications.
KEYED DATA LIST FILE=EMPL KEY=#NXTCASE IN=#FOUND
          /YRHIRED 1-2 SEX 3 JOBCLASS 4.
```

- IN creates the logical scratch variable *#FOUND*. The values of *#FOUND* will be 1 if the record indicated by the key value in *#NXTCASE* is found or 0 if the record does not exist.

TABLE and NOTABLE Subcommands

TABLE and NOTABLE determine whether the program displays a table that summarizes the variable definitions. TABLE, the default, displays the table. NOTABLE suppresses the table.

- TABLE and NOTABLE are optional and mutually exclusive.
- The only specification for TABLE or NOTABLE is the subcommand keyword. Neither subcommand has additional specifications.

ENCODING Subcommand

ENCODING specifies the encoding format of the file. The keyword is followed by an equals sign and a quoted encoding specification.

- In Unicode mode, the default is UTF8. For more information, see SET command, UNICODE subcommand.
- In code page mode, the default is the current locale setting. For more information, see SET command, LOCALE subcommand.
- The quoted encoding value can be: Locale (the current locale setting), UTF8, UTF16, UTF16BE (big endian), UTF16LE (little endian), a numeric Windows code page value (for example, '1252'), or an IANA code page value (for example, 'iso8859-1' or cp1252).
- In Unicode mode, the defined width of string variables is tripled for code page and UTF-16 text data files. Use ALTER TYPE to automatically adjust the defined width of string variables.

KM

KM is available in the Advanced Models option.

```
KM varname [BY factor varname]

   /STATUS = varname [EVENT](vallist) [LOST(vallist)]

   [/STRATA = varname]

   [/PLOT = {[SURVIVAL][LOGSURV][HAZARD][OMS] }]

   [/ID  = varname]

   [/PRINT = [TABLE**][MEAN**][NONE]]

   [/PERCENTILE = [(]{25, 50, 75 }[)]]
                    {value list }

   [/TEST = [LOGRANK**][BRESLOW][TARONE]]

   [/COMPARE = [{OVERALL**}][{POOLED**}]]
               {PAIRWISE }  {STRATA  }

   [/TREND = [(METRIC)]]

   [/SAVE = tempvar[(newvar)],...]
```

**Default if the subcommand or keyword is omitted.

Temporary variables created by Kaplan-Meier are:

SURVIVAL

HAZARD

SE

CUMEVENT

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
KM LENGTH BY SEXRACE
 /STATUS=EMPLOY  EVENT (1) LOST (2)
 /STRATA=LOCATION.
```

Overview

KM (alias K-M) uses the Kaplan-Meier (product-limit) technique to describe and analyze the length of time to the occurrence of an event, often known as **survival time**. KM is similar to SURVIVAL in that it produces nonparametric estimates of the survival functions. However, instead of dividing the period of time under examination into arbitrary intervals, KM evaluates the survival function at the observed event times. For analysis of survival times with covariates, including time-dependent covariates, see the COXREG command.

Options

KM Tables. You can include one factor variable on the KM command. A KM table is produced for each level of the factor variable. You can also suppress the KM tables in the output with the PRINT subcommand.

Survival Status. You can specify the code(s) indicating that an event has occurred as well as code(s) for cases lost to follow-up using the STATUS subcommand.

Plots. You can plot the survival functions on a linear or log scale or plot the hazard function for each combination of factor and stratum with the PLOT subcommand.

Test Statistics. When a factor variable is specified, you can specify one or more tests of equality of survival distributions for the different levels of the factor using the TEST subcommand. You can also specify a trend metric for the requested tests with the TREND subcommand.

Display ID and Percentiles. You can specify an ID variable on the ID subcommand to identify each case. You can also request the display of percentiles in the output with the PERCENTILES subcommand.

Comparisons. When a factor variable is specified, you can use the COMPARE subcommand to compare the different levels of the factor, either pairwise or across all levels, and either pooled across all strata or within a stratum.

Add New Variables to Active Dataset. You can save new variables appended to the end of the active dataset with the SAVE subcommand.

Basic Specification

- The basic specification requires a survival variable and the STATUS subcommand naming a variable that indicates whether the event occurred.
- The basic specification prints one survival table followed by the mean and median survival time with standard errors and 95% confidence intervals.

Subcommand Order

- The survival variable and the factor variable (if there is one) must be specified first.
- Remaining subcommands can be specified in any order.

Syntax Rules

- Only one survival variable can be specified. To analyze multiple survival variables, use multiple KM commands.
- Only one factor variable can be specified following the BY keyword. If you have multiple factors, use the transformation language to create a single factor variable before invoking KM.
- Only one status variable can be listed on the STATUS subcommand. You must specify the value(s) indicating that the event occurred.
- Only one variable can be specified on the STRATA subcommand. If you have more than one stratum, use the transformation language to create a single variable to specify on the STRATA subcommand.

Operations

- KM deletes all cases that have negative values for the survival variable.
- KM estimates the survival function and associated statistics for each combination of factor and stratum.
- Three statistics can be computed to test the equality of survival functions across factor levels within a stratum or across all factor levels while controlling for strata. The statistics are the log rank (Mantel-Cox), generalized Wilcoxon (Breslow), and Tarone-Ware tests.
- When the PLOTS subcommand is specified, KM produces one plot of survival functions for each stratum, with all factor levels represented by different symbols or colors.

Limitations

- A maximum of 500 factor levels (symbols) can appear in a plot.

Examples

```
KM LENGTH BY SEXRACE
 /STATUS=EMPLOY EVENT (1) LOST (2)
 /STRATA=LOCATION.
```

- Survival analysis is used to examine the length of unemployment. The survival variable *LENGTH* contains the number of months a subject is unemployed. The factor variable *SEXRACE* combines sex and race factors.
- A value of 1 on the variable *EMPLOY* indicates the occurrence of the event (employment). All other observed cases are censored. A value of 2 on *EMPLOY* indicates cases lost to follow-up. Cases with other values for *EMPLOY* are known to have remained unemployed during the course of the study. KM separates the two types of censored cases in the KM table if LOST is specified.
- For each combination of *SEXRACE* and *LOCATION*, one KM table is produced, followed by the mean and median survival times with standard errors and confidence intervals.

Survival and Factor Variables

You must identify the survival and factor variables for the analysis.

- The minimum specification is one, and only one, survival variable.
- Only one factor variable can be specified using the BY keyword. If you have more than one factor, create a new variable combining all factors. There is no limit to the factor levels.

Example

```
DO IF SEX = 1.
+ COMPUTE SEXRACE = RACE.
ELSE.
+ COMPUTE SEXRACE = RACE + SEX.
END IF.
KM LENGTH BY SEXRACE
 /STATUS=EMPLOY EVENT (1) LOST (2).
```

- The two control variables, *SEX* and *RACE*, each with two values, 1 and 2, are combined into one factor variable, *SEXRACE*, with four values, 1 to 4.
- KM specifies *LENGTH* as the survival variable and *SEXRACE* as the factor variable.
- One KM table is produced for each factor level.

STATUS Subcommand

To determine whether the terminal event has occurred for a particular observation, KM checks the value of a status variable. STATUS lists the status variable and the code(s) for the occurrence of the event. The code(s) for cases lost to follow-up can also be specified.

- Only one status variable can be specified. If multiple STATUS subcommands are specified, KM uses the last specification and displays a warning.
- The keyword EVENT is optional, but the value list in parentheses must be specified. Use EVENT for clarity's sake, especially when LOST is specified.
- The value list must be enclosed in parentheses. All cases with non-negative times that do not have a code within the range specified after EVENT are classified as **censored cases**—that is, cases for which the event has not yet occurred.
- The keyword LOST and the following value list are optional. LOST cannot be omitted if the value list for lost cases is specified.
- When LOST is specified, all cases with non-negative times that have a code within the specified value range are classified as lost to follow-up. Cases lost to follow-up are treated as censored in the analysis, and the statistics do not change, but the two types of censored cases are listed separately in the KM table.
- The value lists on EVENT or LOST can be one value, a list of values separated by blanks or commas, a range of values using the keyword THRU, or a combination.
- The status variable can be either numeric or string. If a string variable is specified, the EVENT or LOST values must be enclosed in apostrophes, and the keyword THRU cannot be used.

Example

```
KM LENGTH BY SEXRACE
 /STATUS=EMPLOY  EVENT (1) LOST (3,5 THRU 8).
```

- STATUS specifies that *EMPLOY* is the status variable.
- A value of 1 for *EMPLOY* means that the event (employment) occurred for the case.
- Values of 3 and 5 through 8 for *EMPLOY* mean that contact was lost with the case. The different values code different causes for the loss of contact.
- The summary table in the output includes columns for number lost and percentage lost, as well as for number censored and percentage censored.

STRATA Subcommand

STRATA identifies a **stratification variable**—that is, a variable whose values are used to form subgroups (strata) within the categories of the factor variable. Analysis is done within each level of the strata variable for each factor level, and estimates are pooled over strata for an overall comparison of factor levels.

- The minimum specification is the subcommand keyword with one, and only one, variable name.
- If you have more than one strata variable, create a new variable to combine the levels on separate variables before invoking the KM command.
- There is no limit to the number of levels for the strata variable.

Example

```
KM LENGTH BY SEXRACE
 /STATUS=EMPLOY EVENT (1) LOST (3,5 THRU 8)
 /STRATA=LOCATION.
```

- STRATA specifies *LOCATION* as the stratification variable. Analysis of the length of unemployment is done for each location within each sex and race subgroup.

PLOT Subcommand

PLOT plots the cumulative survival distribution on a linear or logarithmic scale or plots the cumulative hazard function. A separate plot with all factor levels is produced for each stratum. Each factor level is represented by a different symbol or color. Censored cases are indicated by markers.

- When PLOT is omitted, no plots are produced. The default is NONE.
- When PLOT is specified without a keyword, the default is SURVIVAL. A plot of survival functions for each stratum is produced.
- To request specific plots, specify, following the PLOT subcommand, any combination of the keywords defined below.
- Multiple keywords can be used on the PLOT subcommand, each requesting a different plot. The effect is cumulative.

SURVIVAL	*Plot the cumulative survival distribution on a linear scale.* SURVIVAL is the default when PLOT is specified without a keyword.
LOGSURV	*Plot the cumulative survival distribution on a logarithmic scale.*
HAZARD	*Plot the cumulative hazard function.*
OMS	*Plot the one-minus-survival function.*

Example

```
KM LENGTH BY SEXRACE
 /STATUS=EMPLOY EVENT (1) LOST (3,5 THRU 8)
 /STRATA=LOCATION
```

```
 /PLOT = SURVIVAL HAZARD.
```

- PLOT produces one plot of the cumulative survival distribution on a linear scale and one plot of the cumulative hazard rate for each value of *LOCATION*.

ID Subcommand

ID specifies a variable used for labeling cases. If the ID variable is a string, KM uses the string values as case identifiers in the KM table. If the ID variable is numeric, KM uses value labels or numeric values if value labels are not defined.

- ID is the first column of the KM table displayed for each combination of factor and stratum.
- If a string value or a value label exceeds 20 bytes in width, KM truncates the case identifier and displays a warning.

PRINT Subcommand

By default, KM prints survival tables and the mean and median survival time with standard errors and confidence intervals if PRINT is omitted. If PRINT is specified, only the specified keyword is in effect. Use PRINT to suppress tables or the mean statistics.

TABLE *Print the KM tables.* If PRINT is not specified, TABLE, together with MEAN, is the default. Specify TABLE on PRINT to suppress the mean statistics.

MEAN *Print the mean statistics.* KM prints the mean and median survival time with standard errors and confidence intervals. If PRINT is not specified, MEAN, together with TABLE, is the default. Specify MEAN on PRINT to suppress the KM tables.

NONE *Suppress both the KM tables and the mean statistics.* Only plots and comparisons are printed.

Example

```
KM LENGTH BY SEXRACE
 /STATUS=EMPLOY EVENT (1) LOST (3,5 THRU 8)
 /STRATA=LOCATION
 /PLOT=SURVIVAL HAZARD
 /PRINT=NONE.
```

- PRINT=NONE suppresses both the KM tables and the mean statistics.

PERCENTILES Subcommand

PERCENTILES displays percentiles for each combination of factor and stratum. Percentiles are not displayed without the PERCENTILES subcommand. If the subcommand is specified without a value list, the default is 25, 50, and 75 for quartile display. You can specify any values between 0 and 100.

TEST Subcommand

TEST specifies the test statistic to use for testing the equality of survival distributions for the different levels of the factor.

- TEST is valid only when a factor variable is specified. If no factor variable is specified, KM issues a warning and TEST is not executed.
- If TEST is specified without a keyword, the default is LOGRANK. If a keyword is specified on TEST, only the specified test is performed.
- Each of the test statistics has a chi-square distribution with one degree of freedom.

LOGRANK	*Perform the log rank (Mantel-Cox) test.*
BRESLOW	*Perform the Breslow (generalized Wilcoxon) test.*
TARONE	*Perform the Tarone-Ware test.*

COMPARE Subcommand

COMPARE compares the survival distributions for the different levels of the factor. Each of the keywords specifies a different method of comparison.

- COMPARE is valid only when a factor variable is specified. If no factor variable is specified, KM issues a warning and COMPARE is not executed.
- COMPARE uses whatever tests are specified on the TEST subcommand. If no TEST subcommand is specified, the log rank test is used.
- If COMPARE is not specified, the default is OVERALL and POOLED. All factor levels are compared across strata in a single test. The test statistics are displayed after the summary table at the end of output.
- Multiple COMPARE subcommands can be specified to request different comparisons.

OVERALL	*Compare all factor levels in a single test.* OVERALL, together with POOLED, is the default when COMPARE is not specified.
PAIRWISE	*Compare each pair of factor levels.* KM compares all distinct pairs of factor levels.
POOLED	*Pool the test statistics across all strata.* The test statistics are displayed after the summary table for all strata. POOLED, together with OVERALL, is the default when COMPARE is not specified.
STRATA	*Compare the factor levels for each stratum.* The test statistics are displayed for each stratum separately.

- If a factor variable has different levels across strata, you cannot request a pooled comparison. If you specify POOLED on COMPARE, KM displays a warning and ignores the request.

Example

```
KM LENGTH BY SEXRACE
 /STATUS=EMPLOY EVENT (1) LOST (3,5 THRU 8)
 /STRATA=LOCATION
 /TEST = BRESLOW
 /COMPARE = PAIRWISE.
```

- TEST specifies the Breslow test.
- COMPARE uses the Breslow test statistic to compare all distinct pairs of *SEXRACE* values and pools the test results over all strata defined by *LOCATION*.
- Test statistics are displayed at the end of output for all strata.

TREND Subcommand

TREND specifies that there is a trend across factor levels. This information is used when computing the tests for equality of survival functions specified on the TEST subcommand.

- The minimum specification is the subcommand keyword by itself. The default metric is chosen as follows:

  If g is even,

  $(-(g-1), ..., -3, -1, 1, 3, ..., (g-1))$

  otherwise,

  $\left(-\frac{g-1}{2}, ..., -1, 0, 1, ..., \frac{g-1}{2}\right)$

  where g is the number of levels for the factor variable.
- If TREND is specified but COMPARE is not, KM performs the default log rank test with the trend metric for an OVERALL POOLED comparison.
- If the metric specified on TREND is longer than required by the factor levels, KM displays a warning and ignores extra values.

Example

```
KM LENGTH BY SEXRACE
 /STATUS=EMPLOY EVENT (1) LOST (3,5 THRU 8)
 /STRATA=LOCATION
 /TREND.
```

- TREND is specified by itself. KM uses the default metric. Since *SEXRACE* has four levels, the default is (–3, –1, 1, 3).
- Even though no TEST or COMPARE subcommand is specified, KM performs the default log rank test with the trend metric and does a default OVERALL POOLED comparison.

SAVE Subcommand

SAVE saves the temporary variables created by KM. The following temporary variables can be saved:

SURVIVAL	*Survival function evaluated at current case.*
SE	*Standard error of the survival function.*
HAZARD	*Cumulative hazard function evaluated at current case.*
CUMEVENT	*Cumulative number of events.*

- To specify variable names for the new variables, assign the new names in parentheses following each temporary variable name.
- Assigned variable names must be unique in the active dataset. Scratch or system variable names cannot be used (that is, variable names cannot begin with # or $).
- If new variable names are not specified, KM generates default names. The default name is composed of the first three characters of the name of the temporary variable (two for *SE*), followed by an underscore and a number to make it unique.
- A temporary variable can be saved only once on the same SAVE subcommand.

Example

```
KM LENGTH BY SEXRACE
 /STATUS=EMPLOY EVENT (1) LOST (3,5 THRU 8)
 /STRATA=LOCATION
 /SAVE SURVIVAL HAZARD.
```

- KM saves cumulative survival and cumulative hazard rates in two new variables, *SUR_1* and *HAZ_1*, provided that neither name exists in the active dataset. If one does, the numeric suffixes will be incremented to make a distinction.

LEAVE

```
LEAVE varlist
```

This command does not read the active dataset. It is stored, pending execution with the next command that reads the dataset. For more information, see Command Order on p. 36.

Example

```
COMPUTE TSALARY=TSALARY+SALARY.
LEAVE TSALARY.
FORMAT TSALARY (DOLLAR8)/ SALARY (DOLLAR7).
EXECUTE.
```

Overview

Normally, the program reinitializes variables each time it prepares to read a new case. LEAVE suppresses reinitialization and retains the current value of the specified variable or variables when the program reads the next case. It also sets the initial value received by a numeric variable to 0 instead of system-missing. LEAVE is frequently used with COMPUTE to create a variable to store an accumulating sum. LEAVE is also used to spread a variable's values across multiple cases when VECTOR is used within an input program to restructure a data file.

LEAVE cannot be used with scratch variables. For more information, see Scratch Variables on p. 46.

Basic Specification

The basic specification is the variable(s) whose values are not to be reinitialized as each new case is read.

Syntax Rules

- Variables named on LEAVE must be new variables that do not already exist in the active dataset prior to the transformation block that defines them, but they must be defined in the transformation block prior to the LEAVE command that specifies them. For more information, see Examples on p. 937.
- Variables named on LEAVE cannot be scratch variables (but scratch variables can be used to obtain functionality equivalent to LEAVE). For more information, see Scratch Variables on p. 46.
- Multiple variables can be named. The keyword TO can be used to refer to a list of consecutive variables.
- String and numeric variables can be specified on the same LEAVE command.

Operations

- Numeric variables named on LEAVE are initialized to 0 for the first case, and string variables are initialized to blanks. These variables are not reinitialized when new cases are read.

Examples

Correct vs. Invalid Specifications for LEAVE

```
DATA LIST LIST /Var1 Var2 Var3.
BEGIN DATA
1 2 3
4 5 6
7 8 9
END DATA.

*this is the correct form.
COMPUTE TotalVar1=TotalVar1+Var1.
LEAVE TotalVar1.

*this will change the value of Var2 but LEAVE will fail,
 generating an error because Var2 already exists.
COMPUTE Var2=Var2+Var2.
LEAVE Var2.

*this will fail, generating an error because the LEAVE command
 occurs before the command that defines the variable named on LEAVE.
LEAVE TotalVar3.
COMPUTE TotalVar3=TotalVar3+Var3.

LIST.
```

Running Total

```
COMPUTE TSALARY=TSALARY+SALARY.
LEAVE TSALARY.
FORMAT TSALARY (DOLLAR8)/ SALARY (DOLLAR7).
```

- These commands keep a running total of salaries across all cases. *SALARY* is the variable containing the employee's salary, and *TSALARY* is the new variable containing the cumulative salaries for all previous cases.
- For the first case, *TSALARY* is initialized to 0, and *TSALARY* equals *SALARY*. For the rest of the cases, *TSALARY* stores the cumulative totals for *SALARY*.
- LEAVE follows COMPUTE because *TSALARY* must first be defined before it can be specified on LEAVE.
- If LEAVE were not specified for this computation, *TSALARY* would be initialized to system-missing for all cases. *TSALARY* would remain system-missing because its value would be missing for every computation.

Separate Sums for Each Category of a Grouping Variable

```
SORT CASES DEPT.
IF DEPT NE LAG(DEPT,1) TSALARY=0.   /*Initialize for new dept
COMPUTE TSALARY=TSALARY+SALARY.     /*Sum salaries
LEAVE TSALARY.                    /*Prevent  initialization  each case
FORMAT TSALARY (DOLLAR8)/ SALARY (DOLLAR7).
```

- These commands accumulate a sum across cases for each department.
- `SORT` first sorts cases by the values of variable *DEPT*.
- `IF` specifies that if the value of *DEPT* for the current case is not equal to the value of *DEPT* for the previous case, *TSALARY* equals 0. Thus, *TSALARY* is reset to 0 each time the value of *DEPT* changes. (For the first case in the file, the logical expression on `IF` is missing. However, the desired effect is obtained because `LEAVE` initializes *TSALARY* to 0 for the first case, independent of the `IF` statement.)
- `LEAVE` prevents *TSALARY* from being initialized for cases within the same department.

LIST

```
LIST [VARIABLES={ALL**  }] [/FORMAT=[{WRAP**}] [{UNNUMBERED**}]]
                {varlist}             {SINGLE}   {NUMBERED    }

 [/CASES=[FROM {1**}] [TO {eof**}] [BY {1**}]]
               {n  }      {n    }      {n  }
```

**Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
LIST VARIABLES=V1 V2.
```

Overview

LIST displays case values for variables in the active dataset. The output is similar to the output produced by the PRINT command. However, LIST is a procedure and reads data, whereas PRINT is a transformation and requires a procedure (or the EXECUTE command) to execute it.

Options

Selecting and Ordering Variables. You can specify a list of variables to be listed using the VARIABLES subcommand.

Format. You can limit each case listing to a single line, and you can display the case number for each listed case with the FORMAT subcommand.

Selecting Cases. You can limit the listing to a particular sequence of cases using the CASES subcommand.

Basic Specification

- The basic specification is simply LIST, which displays the values for all variables in the active dataset.
- By default, cases wrap to multiple lines if all the values do not fit within the page width (the page width is determined by the SET WIDTH command). Case numbers are not displayed for the listed cases.

Subcommand Order

All subcommands are optional and can be named in any order.

Operations

- If VARIABLES is not specified, variables are listed in the order in which they appear in the active dataset.
- LIST does not display values for scratch or system variables.
- LIST uses print formats contained in the dictionary of the active dataset. Alternative formats cannot be specified on LIST. See FORMATS or PRINT FORMATS for information on changing print formats.
- LIST output uses the width specified on SET.
- If a numeric value is longer than its defined width, the program first attempts to list the value by removing punctuation characters, then uses scientific notation, and finally prints asterisks.
- If a long string variable cannot be listed within the output width, it is truncated.
- Values of the variables listed for a case are always separated by at least one blank.
- System-missing values are displayed as a period for numeric variables and a blank for string variables.
- If cases fit on one line, the column width for each variable is determined by the length of the variable name or the format, whichever is greater. If the variable names do not fit on one line, they are printed vertically.
- If cases do not fit on one line within the output width specified on SET, they are wrapped. LIST displays a table illustrating the location of the variables in the output and prints the name of the first variable in each line at the beginning of the line.
- Each execution of LIST begins at the top of a new page. If SPLIT FILE is in effect, each split also begins at the top of a new page.

Examples

LIST with No Subcommands

```
LIST.
```

- LIST by itself requests a display of the values for all variables in the active dataset.

Controlling Listed Cases with CASES Subcommand

```
LIST VARIABLES=V1 V2 /CASES=FROM 10 TO 100 BY 2.
```

- LIST produces a list of every second case for variables *V1* and *V2*, starting with case 10 and stopping at case 100.

VARIABLES Subcommand

VARIABLES specifies the variables to be listed.

- The variables must already exist, and they cannot be scratch or system variables.
- If VARIABLES is used, only the specified variables are listed.
- Variables are listed in the order in which they are named on VARIABLES.

- If a variable is named more than once, it is listed more than once.
- The keyword ALL (the default) can be used to request all variables. ALL can also be used with a variable list (see example below).

ALL *List all user-defined variables.* Variables are listed in the order in which they appear in the active dataset. This is the default if VARIABLES is omitted.

Example

```
LIST VARIABLES=V15 V31 ALL.
```

- VARIABLES is used to list values for *V15* and *V31* before all other variables. The keyword ALL then lists all variables, including *V15* and *V31*, in the order in which they appear in the active dataset. Values for *V15* and *V31* are therefore listed twice.

FORMAT Subcommand

FORMAT controls whether cases wrap if they cannot fit on a single line and whether the case number is displayed for each listed case. The default display uses more than one line per case (if necessary) and does not number cases.

- The minimum specification is a single keyword.
- WRAP and SINGLE are alternatives, as are NUMBERED and UNNUMBERED. Only one of each pair can be specified.
- If SPLIT FILE is in effect for NUMBERED, case numbering restarts at each split. To get sequential numbering regardless of splits, create a variable and set it equal to the system variable *$CASENUM* and then name this variable as the first variable on the VARIABLES subcommand. An appropriate format should be specified for the new variable before it is used on LIST.

WRAP *Wrap cases if they do not fit on a single line.* Page width is determined by the SET WIDTH command. This is the default.

SINGLE *Limit each case to one line.* Only variables that fit on a single line are displayed.

UNNUMBERED *Do not include the sequence number of each case.* This is the default.

NUMBERED *Include the sequence number of each case.* The sequence number is displayed to the left of the listed values.

CASES Subcommand

CASES limits the number of cases listed. By default, all cases in the active dataset are listed.

- Any or all of the keywords below can be used. Defaults that are not changed remain in effect.
- If LIST is preceded by a SAMPLE or SELECT IF command, case selections specified by CASES are taken from those cases that were selected by SAMPLE or SELECT IF.

- If SPLIT FILE is in effect, case selections specified by CASES are restarted for each split.

FROM n	*Number of the first case to be listed.* The default is 1.
TO n	*Number of the last case to be listed.* The default is the end of the active dataset. CASES 100 is interpreted as CASES TO 100.
BY n	*Increment used to choose cases for listing.* The default is 1.

Example

```
LIST CASES BY 3 /FORMAT=NUMBERED.
```

- Every third case is listed for all variables in the active dataset. The listing begins with the first case and includes every third case up to the end of the file.
- FORMAT displays the case number of each listed case.

Example

```
LIST CASES FROM 10 TO 20.
```

- Cases from case 10 through case 20 are listed for all variables in the active dataset.

LOGISTIC REGRESSION

LOGISTIC REGRESSION is available in the Regression Models option.

```
LOGISTIC REGRESSION VARIABLES = dependent var
        [WITH independent varlist [BY var [BY var] ... ]]

[/CATEGORICAL = var1, var2, ... ]

[/CONTRAST (categorical var) = [{INDICATOR [(refcat)]    }]]
                               {DEVIATION [(refcat)]    }
                               {SIMPLE [(refcat)]       }
                               {DIFFERENCE              }
                               {HELMERT                 }
                               {REPEATED                }
                               {POLYNOMIAL[({1,2,3...})]}
                                          {metric  }
                               {SPECIAL (matrix)        }

 [/METHOD = {ENTER**       }   [{ALL    }]]
            {BSTEP [{COND}]}    {varlist}
                    {LR  }
                    {WALD}
            {FSTEP [{COND}]}
                    {LR  }
                    {WALD}

 [/SELECT = {ALL**                 }]
            {varname relation value}

 [/{NOORIGIN**}]
   {ORIGIN    }

 [/ID = [variable]]

 [/PRINT = [DEFAULT**] [SUMMARY] [CORR] [ALL] [ITER [({1})]] [GOODFIT]]
                                                    {n}
           [CI(level)]

 [/CRITERIA = [BCON ({0.001**})] [ITERATE({20**})] [LCON({0**   })]
                     {value  }            {n   }         {value }

              [PIN({0.05**})] [POUT({0.10**})] [EPS({.00000001**})]]
                   {value }         {value }        {value      }

              [CUT[{O.5**  }]]
                   [value  }

 [/CLASSPLOT]

 [/MISSING = {EXCLUDE **}]
             {INCLUDE   }

 [/CASEWISE = [tempvarlist]  [OUTLIER({2    })]]
                                    {value}

 [/SAVE = tempvar[(newname)] tempvar[(newname)]...]

 [/OUTFILE = [{MODEL    }(filename)]]
              {PARAMETER}

 [/EXTERNAL]
```

**Default if the subcommand or keyword is omitted.

Temporary variables that are created by LOGISTIC REGRESSION are as follows:

PRED	*LEVER*	*COOK*
PGROUP	*LRESID*	*DFBETA*
RESID	*SRESID*	
DEV	*ZRESID*	

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Release History

Release 13.0

- OUTFILE subcommand introduced.

Release 14.0

- Modification to the method of recoding string variables. For more information, see Overview on p. 944.

Example

```
LOGISTIC REGRESSION VARIABLES = PROMOTED WITH AGE, JOBTIME, JOBRATE.
```

Overview

LOGISTIC REGRESSION regresses a dichotomous dependent variable on a set of independent variables. Categorical independent variables are replaced by sets of contrast variables, each set entering and leaving the model in a single step.

Options

Processing of Independent Variables. You can specify which independent variables are categorical in nature on the CATEGORICAL subcommand. You can control treatment of categorical independent variables by the CONTRAST subcommand. Seven methods are available for entering independent variables into the model. You can specify any one of them on the METHOD subcommand. You can also use the keyword BY between variable names to enter interaction terms.

Selecting Cases. You can use the SELECT subcommand to define subsets of cases to be used in estimating a model.

Regression through the Origin. You can use the ORIGIN subcommand to exclude a constant term from a model.

Specifying Termination and Model-Building Criteria. You can further control computations when building the model by specifying criteria on the CRITERIA subcommand.

Adding New Variables to the Active Dataset. You can save the residuals, predicted values, and diagnostics that are generated by LOGISTIC REGRESSION in the active dataset.

Output. You can use the PRINT subcommand to print optional output, use the CASEWISE subcommand to request analysis of residuals, and use the ID subcommand to specify a variable whose values or value labels identify cases in output. You can request plots of the actual values and predicted values for each case with the CLASSPLOT subcommand.

Basic Specification

- The minimum specification is the VARIABLES subcommand with one dichotomous dependent variable. You must specify a list of independent variables either following the keyword WITH on the VARIABLES subcommand or on a METHOD subcommand.
- The default output includes goodness-of-fit tests for the model (–2 log-likelihood, goodness-of-fit statistic, Cox and Snell R^2, and Nagelkerke R^2) and a classification table for the predicted and observed group memberships. The regression coefficient, standard error of the regression coefficient, Wald statistic and its significance level, and a multiple correlation coefficient adjusted for the number of parameters (Atkinson, 1980) are displayed for each variable in the equation.

Subcommand Order

- Subcommands can be named in any order. If the VARIABLES subcommand is not specified first, a slash (/) must precede it.
- The ordering of METHOD subcommands determines the order in which models are estimated. Different sequences may result in different models.

Syntax Rules

- Only one dependent variable can be specified for each LOGISTIC REGRESSION.
- Any number of independent variables may be listed. The dependent variable may not appear on this list.
- The independent variable list is required if any of the METHOD subcommands are used without a variable list or if the METHOD subcommand is not used. The keyword TO cannot be used on any variable list.
- If you specify the keyword WITH on the VARIABLES subcommand, all independent variables must be listed.
- If the keyword WITH is used on the VARIABLES subcommand, interaction terms do not have to be specified on the variable list, but the individual variables that make up the interactions must be listed.
- Multiple METHOD subcommands are allowed.
- The minimum truncation for this command is LOGI REG.

Operations

- Independent variables that are specified on the CATEGORICAL subcommand are replaced by sets of contrast variables. In stepwise analyses, the set of contrast variables associated with a categorical variable is entered or removed from the model as a single step.
- Independent variables are screened to detect and eliminate redundancies.

- If the linearly dependent variable is one of a set of contrast variables, the set will be reduced by the redundant variable or variables. A warning will be issued, and the reduced set will be used.
- For the forward stepwise method, redundancy checking is done when a variable is to be entered into the model.
- When backward stepwise or direct-entry methods are requested, all variables for each METHOD subcommand are checked for redundancy before that analysis begins.

Compatibility

Prior to version 14.0, the order of recoded string values was dependent on the order of values in the data file. For example, when recoding the dependent variable, the first string value encountered was recoded to 0, and the second string value encountered was recoded to 1. Beginning with version 14.0, the procedure recodes string variables so that the order of recoded values is the alphanumeric order of the string values. Thus, the procedure may recode string variables differently than in previous versions.

Limitations

- The dependent variable must be dichotomous for each split-file group. Specifying a dependent variable with more or less than two nonmissing values per split-file group will result in an error.

Examples

```
LOGISTIC REGRESSION VARIABLES = PASS WITH GPA, MAT, GRE.
```

- *PASS* is specified as the dependent variable.
- *GPA*, *MAT*, and *GRE* are specified as independent variables.
- LOGISTIC REGRESSION produces the default output for the logistic regression of *PASS* on *GPA*, *MAT*, and *GRE*.

VARIABLES Subcommand

VARIABLES specifies the dependent variable and, optionally, all independent variables in the model. The dependent variable appears first on the list and is separated from the independent variables by the keyword WITH.

- One VARIABLES subcommand is allowed for each Logistic Regression procedure.
- The dependent variable must be dichotomous—that is, it must have exactly two values other than system-missing and user-missing values for each split-file group.
- The dependent variable may be a string variable if its two values can be differentiated by their first eight characters.
- You can indicate an interaction term on the variable list by using the keyword BY to separate the individual variables.
- If all METHOD subcommands are accompanied by independent variable lists, the keyword WITH and the list of independent variables may be omitted.

- If the keyword WITH is used, *all* independent variables must be specified. For interaction terms, only the individual variable names that make up the interaction (for example, X1, X2) need to be specified. Specifying the actual interaction term (for example, X1 BY X2) on the VARIABLES subcommand is optional if you specify it on a METHOD subcommand.

Example

```
LOGISTIC REGRESSION VARIABLES = PROMOTED WITH AGE,JOBTIME,JOBRATE,
    AGE BY JOBTIME.
```

- *PROMOTED* is specified as the dependent variable.
- *AGE*, *JOBTIME*, *JOBRATE*, and the interaction *AGE* by *JOBTIME* are specified as the independent variables.
- Because no METHOD is specified, all three single independent variables and the interaction term are entered into the model.
- LOGISTIC REGRESSION produces the default output.

CATEGORICAL Subcommand

CATEGORICAL identifies independent variables that are nominal or ordinal. Variables that are declared to be categorical are automatically transformed to a set of contrast variables as specified on the CONTRAST subcommand. If a variable that is coded as 0 – 1 is declared as categorical, its coding scheme is given indicator contrasts by default.

- Independent variables that are not specified on CATEGORICAL are assumed to be at least interval level, except for string variables.
- Any variable that is specified on CATEGORICAL is ignored if it does not appear either after WITH on the VARIABLES subcommand or on any METHOD subcommand.
- Variables that are specified on CATEGORICAL are replaced by sets of contrast variables. If the categorical variable has *n* distinct values, there will be $n-1$ contrast variables generated. The set of contrast variables associated with a categorical variable is entered or removed from the model as a step.
- If any one of the variables in an interaction term is specified on CATEGORICAL, the interaction term is replaced by contrast variables.
- All string variables are categorical. Only the first eight characters of each value of a string variable are used in distinguishing between values. Thus, if two values of a string variable are identical for the first eight characters, the values are treated as though they were the same.

Example

```
LOGISTIC REGRESSION VARIABLES = PASS WITH GPA, GRE, MAT, CLASS, TEACHER
 /CATEGORICAL = CLASS,TEACHER.
```

- The dichotomous dependent variable *PASS* is regressed on the interval-level independent variables *GPA*, *GRE*, and *MAT* and the categorical variables *CLASS* and *TEACHER*.

CONTRAST Subcommand

CONTRAST specifies the type of contrast that is used for categorical independent variables. The interpretation of the regression coefficients for categorical variables depends on the contrasts that are used. The default is INDICATOR. The categorical independent variable is specified in parentheses following CONTRAST. The closing parenthesis is followed by one of the contrast-type keywords.

- If the categorical variable has *n* values, there will be *n*−1 rows in the contrast matrix. Each contrast matrix is treated as a set of independent variables in the analysis.
- Only one categorical independent variable can be specified per CONTRAST subcommand, but multiple CONTRAST subcommands can be specified.

The following contrast types are available (Finn, 1974), (Kirk, 1982).

INDICATOR(refcat) *Indicator variables.* Contrasts indicate the presence or absence of category membership. By default, refcat is the last category (represented in the contrast matrix as a row of zeros). To omit a category (other than the last category), specify the sequence number of the omitted category (which is not necessarily the same as its value) in parentheses after the keyword INDICATOR.

DEVIATION(refcat) *Deviations from the overall effect.* The effect for each category of the independent variable (except one category) is compared to the overall effect. Refcat is the category for which parameter estimates are not displayed (they must be calculated from the others). By default, refcat is the last category. To omit a category (other than the last category), specify the sequence number of the omitted category (which is not necessarily the same as its value) in parentheses after the keyword DEVIATION.

SIMPLE(refcat) *Each category of the independent variable (except the last category) is compared to the last category.* To use a category other than the last as the omitted reference category, specify its sequence number (which is not necessarily the same as its value) in parentheses following the keyword SIMPLE.

DIFFERENCE *Difference or reverse Helmert contrasts.* The effects for each category of the independent variable (except the first category) are compared to the mean effects of the previous categories.

HELMERT *Helmert contrasts.* The effects for each category of the independent variable (except the last category) are compared to the mean effects of subsequent categories.

POLYNOMIAL(metric) *Polynomial contrasts.* The first degree of freedom contains the linear effect across the categories of the independent variable, the second degree of freedom contains the quadratic effect, and so on. By default, the categories are assumed to be equally spaced; unequal spacing can be specified by entering a metric consisting of one integer for each category of the independent variable in parentheses after the keyword POLYNOMIAL. For example, CONTRAST(STIMULUS)=POLYNOMIAL(1,2,4) indicates that the three levels of STIMULUS are actually in the proportion 1:2:4. The default metric is always (1,2, ..., *k*), where *k* categories are involved. Only the relative differences between the terms of the metric matter: (1,2,4) is the same metric as (2,3,5) or (20,30,50) because the difference between the second and third numbers is twice the difference between the first and second numbers in each instance.

REPEATED	*Comparison of adjacent categories.* Each category of the independent variable (except the last category) is compared to the next category.
SPECIAL(matrix)	*A user-defined contrast.* After this keyword, a matrix is entered in parentheses with *k*−1 rows and *k* columns (where *k* is the number of categories of the independent variable). The rows of the contrast matrix contain the special contrasts indicating the desired comparisons between categories. If the special contrasts are linear combinations of each other, LOGISTIC REGRESSION reports the linear dependency and stops processing. If *k* rows are entered, the first row is discarded and only the last *k*−1 rows are used as the contrast matrix in the analysis.

Example

```
LOGISTIC REGRESSION VARIABLES = PASS WITH GRE, CLASS
 /CATEGORICAL = CLASS
 /CONTRAST(CLASS)=HELMERT.
```

- A logistic regression analysis of the dependent variable *PASS* is performed on the interval independent variable *GRE* and the categorical independent variable *CLASS*.
- *PASS* is a dichotomous variable representing course pass/fail status and *CLASS* identifies whether a student is in one of three classrooms. A HELMERT contrast is requested.

Example

```
LOGISTIC REGRESSION VARIABLES = PASS WITH GRE, CLASS
 /CATEGORICAL = CLASS
 /CONTRAST(CLASS)=SPECIAL(2 -1 -1
                          0  1 -1).
```

- In this example, the contrasts are specified with the keyword SPECIAL.

METHOD Subcommand

METHOD indicates how the independent variables enter the model. The specification is the METHOD subcommand followed by a single method keyword. The keyword METHOD can be omitted. Optionally, specify the independent variables and interactions for which the method is to be used. Use the keyword BY between variable names of an interaction term.

- If no variable list is specified, or if the keyword ALL is used, all of the independent variables following the keyword WITH on the VARIABLES subcommand are eligible for inclusion in the model.
- If no METHOD subcommand is specified, the default method is ENTER.
- Variables that are specified on CATEGORICAL are replaced by sets of contrast variables. The set of contrast variables associated with a categorical variable is entered or removed from the model as a single step.
- Any number of METHOD subcommands can appear in a Logistic Regression procedure. METHOD subcommands are processed in the order in which they are specified. Each method starts with the results from the previous method. If BSTEP is used, all remaining eligible

variables are entered at the first step. All variables are then eligible for entry and removal unless they have been excluded from the METHOD variable list.

- The beginning model for the first METHOD subcommand is either the constant variable (by default or if NOORIGIN is specified) or an empty model (if ORIGIN is specified).

The available METHOD keywords are as follows:

ENTER *Forced entry.* All variables are entered in a single step. This setting is the default if the METHOD subcommand is omitted.

FSTEP *Forward stepwise.* The variables (or interaction terms) that are specified on FSTEP are tested for entry into the model one by one, based on the significance level of the score statistic. The variable with the smallest significance less than PIN is entered into the model. After each entry, variables that are already in the model are tested for possible removal, based on the significance of the conditional statistic, the Wald statistic, or the likelihood-ratio criterion. The variable with the largest probability greater than the specified POUT value is removed, and the model is reestimated. Variables in the model are then evaluated again for removal. When no more variables satisfy the removal criterion, covariates that are not in the model are evaluated for entry. Model building stops when no more variables meet entry or removal criteria or when the current model is the same as a previous model.

BSTEP *Backward stepwise.* As a first step, the variables (or interaction terms) that are specified on BSTEP are entered into the model together and are tested for removal one by one. Stepwise removal and entry then follow the same process as described for FSTEP until no more variables meet entry or removal criteria or when the current model is the same as a previous model.

The statistic that is used in the test for removal can be specified by an additional keyword in parentheses following FSTEP or BSTEP. If FSTEP or BSTEP is specified by itself, the default is COND.

COND *Conditional statistic.* This setting is the default if FSTEP or BSTEP is specified by itself.

WALD *Wald statistic.* The removal of a variable from the model is based on the significance of the Wald statistic.

LR *Likelihood ratio.* The removal of a variable from the model is based on the significance of the change in the log-likelihood. If LR is specified, the model must be reestimated without each of the variables in the model. This process can substantially increase computational time. However, the likelihood-ratio statistic is the best criterion for deciding which variables are to be removed.

Example

```
LOGISTIC REGRESSION
  VARIABLES = PROMOTED WITH AGE JOBTIME JOBRATE RACE SEX AGENCY
 /CATEGORICAL RACE SEX AGENCY
 /METHOD ENTER AGE  JOBTIME
 /METHOD BSTEP (LR) RACE SEX JOBRATE AGENCY.
```

- *AGE*, *JOBTIME*, *JOBRATE*, *RACE*, *SEX*, and *AGENCY* are specified as independent variables. *RACE*, *SEX*, and *AGENCY* are specified as categorical independent variables.
- The first METHOD subcommand enters *AGE* and *JOBTIME* into the model.
- Variables in the model at the termination of the first METHOD subcommand are included in the model at the beginning of the second METHOD subcommand.

- The second METHOD subcommand adds the variables *RACE*, *SEX*, *JOBRATE*, and *AGENCY* to the previous model.
- Backward stepwise logistic regression analysis is then done with only the variables on the BSTEP variable list tested for removal by using the LR statistic.
- The procedure continues until all variables from the BSTEP variable list have been removed or the removal of a variable will not result in a decrease in the log-likelihood with a probability larger than POUT.

SELECT Subcommand

By default, all cases in the active dataset are considered for inclusion in LOGISTIC REGRESSION. Use the optional SELECT subcommand to include a subset of cases in the analysis.

- The specification is either a logical expression or keyword ALL. ALL is the default. Variables that are named on VARIABLES, CATEGORICAL, or METHOD subcommands cannot appear on SELECT.
- In the logical expression on SELECT, the relation can be EQ, NE, LT, LE, GT, or GE. The variable must be numeric, and the value can be any number.
- Only cases for which the logical expression on SELECT is true are included in calculations. All other cases, including those cases with missing values for the variable that is named on SELECT, are unselected.
- Diagnostic statistics and classification statistics are reported for both selected and unselected cases.
- Cases that are deleted from the active dataset with the SELECT IF or SAMPLE command are not included among either the selected or unselected cases.

Example

```
LOGISTIC REGRESSION VARIABLES=GRADE WITH GPA,TUCE,PSI
 /SELECT SEX EQ 1 /CASEWISE=RESID.
```

- Only cases with the value 1 for *SEX* are included in the logistic regression analysis.
- Residual values that are generated by CASEWISE are displayed for both selected and unselected cases.

ORIGIN and NOORIGIN Subcommands

ORIGIN and NOORIGIN control whether the constant is included. NOORIGIN (the default) includes a constant term (intercept) in all equations. ORIGIN suppresses the constant term and requests regression through the origin. (NOCONST can be used as an alias for ORIGIN.)

- The only specification is either ORIGIN or NOORIGIN.
- ORIGIN or NOORIGIN can be specified only once per Logistic Regression procedure, and it affects all METHOD subcommands.

Example

```
LOGISTIC REGRESSION VARIABLES=PASS WITH GPA,GRE,MAT /ORIGIN.
```

- `ORIGIN` suppresses the automatic generation of a constant term.

ID Subcommand

`ID` specifies a variable whose values or value labels identify the casewise listing. By default, cases are labeled by their case number.

- The only specification is the name of a single variable that exists in the active dataset.
- Only the first eight characters of the variable's value labels are used to label cases. If the variable has no value labels, the values are used.
- Only the first eight characters of a string variable are used to label cases.

PRINT Subcommand

`PRINT` controls the display of optional output. If `PRINT` is omitted, `DEFAULT` output (defined below) is displayed.

- The minimum specification is `PRINT` followed by a single keyword.
- If `PRINT` is used, only the requested output is displayed.

DEFAULT	*Goodness-of-fit tests for the model, classification tables, and statistics for the variables in and not in the equation at each step.* Tables and statistics are displayed for each split file and `METHOD` subcommand.
SUMMARY	*Summary information.* This output is the same output as `DEFAULT`, except that the output for each step is not displayed.
CORR	*Correlation matrix of parameter estimates for the variables in the model.*
ITER(value)	*Iterations at which parameter estimates are to be displayed.* The value in parentheses controls the spacing of iteration reports. If the value is *n*, the parameter estimates are displayed for every *n*th iteration, starting at 0. If a value is not supplied, intermediate estimates are displayed at each iteration.
GOODFIT	*Hosmer-Lemeshow goodness-of-fit statistic* (Hosmer and Lemeshow, 2000).
CI(level)	*Confidence interval for exp(B).* The value in parentheses must be an integer between 1 and 99.
ALL	*All available output.*

Example

```
LOGISTIC REGRESSION VARIABLES=PASS WITH GPA,GRE,MAT
 /METHOD FSTEP
 /PRINT CORR SUMMARY ITER(2).
```

- A forward stepwise logistic regression analysis of *PASS* on *GPA*, *GRE*, and *MAT* is specified.
- The `PRINT` subcommand requests the display of the correlation matrix of parameter estimates for the variables in the model (`CORR`), classification tables and statistics for the variables in and not in the equation for the final model (`SUMMARY`), and parameter estimates at every second iteration (`ITER(2)`).

CRITERIA Subcommand

CRITERIA controls the statistical criteria that are used in building the logistic regression models. The way in which these criteria are used depends on the method that is specified on the METHOD subcommand. The default criteria are noted in the description of each keyword below. Iterations will stop if the criterion for BCON, LCON, or ITERATE is satisfied.

BCON(value) *Change in parameter estimates to terminate iteration.* Iteration terminates when the parameters change by less than the specified value. The default is 0.001. To eliminate this criterion, specify a value of 0.

ITERATE *Maximum number of iterations.* The default is 20.

LCON(value) *Percentage change in the log-likelihood ratio for termination of iterations.* If the log-likelihood decreases by less than the specified value, iteration terminates. The default is 0, which is equivalent to not using this criterion.

PIN(value) *Probability of score statistic for variable entry.* The default is 0.05. The larger the specified probability, the easier it is for a variable to enter the model.

POUT(value) *Probability of conditional, Wald, or LR statistic to remove a variable.* The default is 0.1. The larger the specified probability, the easier it is for a variable to remain in the model.

EPS(value) *Epsilon value used for redundancy checking.* The specified value must be less than or equal to 0.05 and greater than or equal to 10^{-12}. The default is 10^{-8}. Larger values make it harder for variables to pass the redundancy check—that is, they are more likely to be removed from the analysis.

CUT(value) *Cutoff value for classification.* A case is assigned to a group when the predicted event probability is greater than or equal to the cutoff value. The cutoff value affects the value of the dichotomous derived variable in the classification table, the predicted group (PGROUP on CASEWISE), and the classification plot (CLASSPLOT). The default cutoff value is 0.5. You can specify a value between 0 and 1 (0 < value < 1).

Example

```
LOGISTIC REGRESSION VARIABLES = PROMOTED WITH AGE JOBTIME RACE
 /CATEGORICAL RACE
 /METHOD BSTEP
 /CRITERIA BCON(0.01) PIN(0.01) POUT(0.05).
```

- A backward stepwise logistic regression analysis is performed for the dependent variable *PROMOTED* and the independent variables *AGE*, *JOBTIME*, and *RACE*.
- CRITERIA alters four of the statistical criteria that control the building of a model.
- BCON specifies that if the change in the absolute value of all of the parameter estimates is less than 0.01, the iterative estimation process should stop. Larger values lower the number of required iterations. Notice that the ITER and LCON criteria remain unchanged and that if either of them is met before BCON, iterations will terminate. (LCON can be set to 0 if only BCON and ITER are to be used.)

- POUT requires that the probability of the statistic that is used to test whether a variable should remain in the model be smaller than 0.05. This requirement is more stringent than the default value of 0.1.
- PIN requires that the probability of the score statistic that is used to test whether a variable should be included be smaller than 0.01. This requirement makes it more difficult for variables to be included in the model than the default value of 0.05.

CLASSPLOT Subcommand

CLASSPLOT generates a classification plot of the actual and predicted values of the dichotomous dependent variable at each step.

- Keyword CLASSPLOT is the only specification.
- If CLASSPLOT is not specified, plots are not generated.

Example

```
LOGISTIC REGRESSION VARIABLES = PROMOTED WITH JOBTIME RACE
 /CATEGORICAL RACE
 /CLASSPLOT.
```

- A logistic regression model is constructed for the dichotomous dependent variable *PROMOTED* and the independent variables *JOBTIME* and *RACE*.
- CLASSPLOT produces a classification plot for the dependent variable *PROMOTED*. The vertical axis of the plot is the frequency of the variable *PROMOTED*. The horizontal axis is the predicted probability of membership in the second of the two levels of *PROMOTED*.

CASEWISE Subcommand

CASEWISE produces a casewise listing of the values of the temporary variables that are created by LOGISTIC REGRESSION.

The following keywords are available for specifying temporary variables (see Fox, 1984). When CASEWISE is specified by itself, the default is to list *PRED*, *PGROUP*, *RESID*, and *ZRESID*. If a list of variable names is given, only those named temporary variables are displayed.

PRED	*Predicted probability.* For each case, the predicted probability of having the second of the two values of the dichotomous dependent variable.
PGROUP	*Predicted group.* The group to which a case is assigned based on the predicted probability.
RESID	*Difference between observed and predicted probabilities.*
DEV	*Deviance values.* For each case, a log-likelihood-ratio statistic, which measures how well the model fits the case, is computed.
LRESID	*Logit residual.* Residual divided by the product of *PRED* and 1–*PRED*.
SRESID	*Studentized residual.*
ZRESID	*Normalized residual.* Residual divided by the square root of the product of *PRED* and 1–*PRED*.
LEVER	*Leverage value.* A measure of the relative influence of each observation on the model's fit.

COOK *Analog of Cook's influence statistic.*

DFBETA *Difference in beta.* The difference in the estimated coefficients for each independent variable if the case is omitted.

The following keyword is available for restricting the cases to be displayed, based on the absolute value of *SRESID*:

OUTLIER (value) *Cases with absolute values of SRESID greater than or equal to the specified value are displayed.* If `OUTLIER` is specified with no value, the default is 2.

Example

```
LOGISTIC REGRESSION VARIABLES = PROMOTED WITH JOBTIME SEX RACE
 /CATEGORICAL SEX RACE
 /METHOD ENTER
 /CASEWISE SRESID LEVER DFBETA.
```

- `CASEWISE` produces a casewise listing of the temporary variables *SRESID*, *LEVER*, and *DFBETA*.
- There will be one *DFBETA* value for each parameter in the model. The continuous variable *JOBTIME*, the two-level categorical variable *SEX*, and the constant each require one parameter, while the four-level categorical variable *RACE* requires three parameters. Thus, six values of *DFBETA* will be produced for each case.

MISSING Subcommand

`LOGISTIC REGRESSION` excludes all cases with missing values on any of the independent variables. For a case with a missing value on the dependent variable, predicted values are calculated if it has nonmissing values on all independent variables. The `MISSING` subcommand controls the processing of user-missing values. If the subcommand is not specified, the default is `EXCLUDE`.

EXCLUDE *Delete cases with user-missing values as well as system-missing values.* This setting is the default.

INCLUDE *Include user-missing values in the analysis.*

OUTFILE Subcommand

The `OUTFILE` subcommand allows you to specify files to which output is written.

- Only one `OUTFILE` subcommand is allowed. If you specify more than one subcommand, only the last subcommand is executed.

- You must specify at least one keyword and a valid filename in parentheses. There is no default.
- MODEL cannot be used if split-file processing is on (SPLIT FILE command) or if more than one dependent variable is specified (DEPENDENT subcommand).

MODEL(filename) *Write parameter estimates and their covariances to an XML file.* Specify the filename in full. LOGISTIC REGRESSION does not supply an extension. SmartScore and SPSS Server (a separate product) can use this model file to apply the model information to other data files for scoring purposes.

PARAMETER(filename) *Write parameter estimates only to an XML file.* Specify the filename in full. LOGISTIC REGRESSION does not supply an extension. SmartScore and SPSS Server (a separate product) can use this model file to apply the model information to other data files for scoring purposes.

SAVE Subcommand

SAVE saves the temporary variables that are created by LOGISTIC REGRESSION. To specify variable names for the new variables, assign the new names in parentheses following each temporary variable name. If new variable names are not specified, LOGISTIC REGRESSION generates default names.

- Assigned variable names must be unique in the active dataset. Scratch or system variable names (that is, names that begin with # or $) cannot be used.
- A temporary variable can be saved only once on the same SAVE subcommand.

Example

```
LOGISTIC REGRESSION VARIABLES = PROMOTED WITH JOBTIME AGE
 /SAVE PRED (PREDPRO) DFBETA (DF).
```

- A logistic regression analysis of *PROMOTED* on the independent variables *JOBTIME* and *AGE* is performed.
- SAVE adds four variables to the active dataset: one variable named *PREDPRO*, containing the predicted value from the specified model for each case, and three variables named *DF0*, *DF1*, and *DF2*, containing, respectively, the *DFBETA* values for each case of the constant, the independent variable *JOBTIME*, and the independent variable *AGE*.

EXTERNAL Subcommand

EXTERNAL indicates that the data for each split-file group should be held in an external scratch file during processing. This process can help conserve memory resources when running complex analyses or analyses with large data sets.

- The keyword EXTERNAL is the only specification.
- Specifying EXTERNAL may result in slightly longer processing time.
- If EXTERNAL is not specified, all data are held internally, and no scratch file is written.

LOGLINEAR

LOGLINEAR is available in the Advanced Models option.

The syntax for LOGLINEAR is available only in a syntax window, not from the dialog box interface. See GENLOG for information on the LOGLINEAR command available from the dialog box interface.

```
LOGLINEAR varlist(min,max)...[BY] varlist(min,max)

          [WITH covariate varlist]

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
LOGLINEAR JOBSAT (1,2) ZODIAC (1,12) /DESIGN=JOBSAT.
```

Overview

LOGLINEAR is a general procedure for model fitting, hypothesis testing, and parameter estimation for any model that has categorical variables as its major components. As such, LOGLINEAR subsumes a variety of related techniques, including general models of multiway contingency tables, logit models, logistic regression on categorical variables, and quasi-independence models.

LOGLINEAR models cell frequencies using the multinomial response model and produces maximum likelihood estimates of parameters by means of the Newton-Raphson algorithm (Haberman, 1978). HILOGLINEAR, which uses an iterative proportional-fitting algorithm, is more efficient for hierarchical models, but it cannot produce parameter estimates for unsaturated models, does not permit specification of contrasts for parameters, and does not display a correlation matrix of the parameter estimates.

Comparison of the GENLOG and LOGLINEAR Commands

The General Loglinear Analysis and Logit Loglinear Analysis dialog boxes are both associated with the GENLOG command. In previous releases, these dialog boxes were associated with the LOGLINEAR command. The LOGLINEAR command is now available only as a syntax command. The differences are described below.

Distribution Assumptions

- GENLOG can handle both Poisson and multinomial distribution assumptions for observed cell counts.
- LOGLINEAR assumes only multinomial distribution.

Approach

- GENLOG uses a regression approach to parameterize a categorical variable in a design matrix.
- LOGLINEAR uses contrasts to reparameterize a categorical variable. The major disadvantage of the reparameterization approach is in the interpretation of the results when there is a redundancy in the corresponding design matrix. Also, the reparameterization approach may result in incorrect degrees of freedom for an incomplete table, leading to incorrect analysis results.

Contrasts and Generalized Log-Odds Ratios (GLOR)

- GENLOG doesn't provide contrasts to reparameterize the categories of a factor. However, it offers generalized log-odds ratios (GLOR) for cell combinations. Often, comparisons among categories of factors can be derived from GLOR.
- LOGLINEAR offers contrasts to reparameterize the categories of a factor.

Deviance Residual

- GENLOG calculates and displays the deviance residual and its normal probability plot in addition to the other residuals.
- LOGLINEAR does not calculate the deviance residual.

Factor-by-Covariate Design

- When there is a factor-by-covariate term in the design, GENLOG generates one regression coefficient of the covariate for each combination of factor values. The estimates of these regression coefficients are calculated and displayed.
- LOGLINEAR estimates and displays the contrasts of these regression coefficients.

Partition Effect

- In GENLOG, the term *partition effect* refers to the category of a factor.
- In LOGLINEAR, the term *partition effect* refers to a particular contrast.

Options

Model Specification. You can specify the model or models to be fit using the DESIGN subcommand.

Cell Weights. You can specify cell weights, such as structural zeros, for the model with the CWEIGHT subcommand.

Output Display. You can control the output display with the PRINT subcommand.

Optional Plots. You can produce plots of adjusted residuals against observed and expected counts, normal plots, and detrended normal plots with the PLOT subcommand.

Linear Combinations. You can calculate linear combinations of observed cell frequencies, expected cell frequencies, and adjusted residuals using the GRESID subcommand.

Contrasts. You can indicate the type of contrast desired for a factor using the CONTRAST subcommand.

Criteria for Algorithm. You can control the values of algorithm-tuning parameters with the CRITERIA subcommand.

Basic Specification

The basic specification is two or more variables that define the crosstabulation. The minimum and maximum values for each variable must be specified in parentheses after the variable name.

By default, LOGLINEAR estimates the saturated model for a multidimensional table. Output includes the factors or effects, their levels, and any labels; observed and expected frequencies and percentages for each factor and code; residuals, standardized residuals, and adjusted residuals; two goodness-of-fit statistics (the likelihood-ratio chi-square and Pearson's chi-square); and estimates of the parameters with accompanying *z* values and 95% confidence intervals.

Limitations

- A maximum of 10 independent (factor) variables
- A maximum of 200 covariates

Subcommand Order

- The variables specification must come first.
- The subcommands that affect a specific model must be placed before the DESIGN subcommand specifying the model.

- All subcommands can be used more than once and, with the exception of the DESIGN subcommand, are carried from model to model unless explicitly overridden.
- If the last subcommand is not DESIGN, LOGLINEAR generates a saturated model in addition to the explicitly requested model(s).

Examples

Example: Main Effects General Loglinear Model

```
LOGLINEAR JOBSAT (1,2) ZODIAC (1,12) /DESIGN=JOBSAT, ZODIAC.
```

- The variable list specifies two categorical variables, *JOBSAT* and *ZODIAC*. *JOBSAT* has values 1 and 2. *ZODIAC* has values 1 through 12.
- DESIGN specifies a model with main effects only.

Example: Saturated General Loglinear Model

```
LOGLINEAR DPREF (2,3) RACE CAMP (1,2).
```

- *DPREF* is a categorical variable with values 2 and 3. *RACE* and *CAMP* are categorical variables with values 1 and 2.
- This is a general loglinear model because no BY keyword appears. The design defaults to a saturated model that includes all main effects and interaction effects.

Example: Logit Loglinear Model

```
LOGLINEAR GSLEVEL (4,8) BY EDUC (1,4) SEX (1,2)
  /DESIGN=GSLEVEL, GSLEVEL BY EDUC, GSLEVEL BY SEX.
```

- *GSLEVEL* is a categorical variable with values 4 through 8. *EDUC* is a categorical variable with values 1 through 4. *SEX* has values 1 and 2.
- The keyword BY on the variable list specifies a logit model in which *GSLEVEL* is the dependent variable and *EDUC* and *SEX* are the independent variables.
- DESIGN specifies a model that can test for the absence of a joint effect of *SEX* and *EDUC* on *GSLEVEL*.

Variable List

The variable list specifies the variables to be included in the model. LOGLINEAR analyzes two classes of variables: categorical and continuous. Categorical variables are used to define the cells of the table. Continuous variables are used as cell covariates. Continuous variables can be specified only after the keyword WITH following the list of categorical variables.

- The list of categorical variables must be specified first. Categorical variables must be numeric and integer.
- A range must be defined for each categorical variable by specifying, in parentheses after each variable name, the minimum and maximum values for that variable. Separate the two values with at least one space or a comma.

- To specify the same range for a list of variables, specify the list of variables followed by a single range. The range applies to all variables on the list.
- To specify a logit model, use the keyword BY (see Logit Model on p. 962). A variable list without the keyword BY generates a general loglinear model.
- Cases with values outside the specified range are excluded from the analysis. Non-integer values within the range are truncated for the purpose of building the table.

Logit Model

- To segregate the independent (factor) variables from the dependent variables in a logit model, use the keyword BY. The categorical variables preceding BY are the dependent variables; the categorical variables following BY are the independent variables.
- A total of 10 categorical variables can be specified. In most cases, one of them is dependent.
- A DESIGN subcommand should be used to request the desired logit model.
- LOGLINEAR displays an analysis of dispersion and two measures of association: entropy and concentration. These measures are discussed elsewhere (Haberman, 1982) and can be used to quantify the magnitude of association among the variables. Both are proportional reduction in error measures. The entropy statistic is analogous to Theil's entropy measure, while the concentration statistic is analogous to Goodman and Kruskal's tau-*b*. Both statistics measure the strength of association between the dependent variable and the predictor variable set.

Cell Covariates

- Continuous variables can be used as covariates. When used, the covariates must be specified after the keyword WITH following the list of categorical variables. Ranges are not specified for the continuous variables.
- A variable cannot be named as both a categorical variable and a cell covariate.
- To enter cell covariates into a model, the covariates must be specified on the DESIGN subcommand.
- Cell covariates are not applied on a case-by-case basis. The mean covariate value for a cell in the contingency table is applied to that cell.

Example

```
LOGLINEAR DPREF(2,3) RACE CAMP (1,2) WITH CONSTANT
  /DESIGN=DPREF RACE CAMP CONSTANT.
```

- The variable *CONSTANT* is a continuous variable specified as a cell covariate. Cell covariates must be specified after the keyword WITH following the variable list. No range is defined for cell covariates.
- To include the cell covariate in the model, the variable *CONSTANT* is specified on DESIGN.

CWEIGHT Subcommand

CWEIGHT specifies cell weights, such as structural zeros, for a model. By default, cell weights are equal to 1.

- The specification is either one numeric variable or a matrix of weights enclosed in parentheses.
- If a matrix of weights is specified, the matrix must contain the same number of elements as the product of the levels of the categorical variables. An asterisk can be used to signify repetitions of the same value.
- If weights are specified for a multiple-factor model, the index value of the rightmost factor increments the most rapidly.
- If a numeric variable is specified, only one CWEIGHT subcommand can be used on LOGLINEAR.
- To use multiple cell weights on the same LOGLINEAR command, specify all weights in matrix format. Each matrix must be specified on a separate CWEIGHT subcommand, and each CWEIGHT specification remains in effect until explicitly overridden by another CWEIGHT subcommand.
- CWEIGHT can be used to impose structural, or *a priori*, zeros on the model. This feature is useful in the analysis of symmetric tables.

Example

```
COMPUTE  CWT=1.
IF (HUSED EQ WIFED) CWT=0.
LOGLINEAR HUSED WIFED(1,4) WITH DISTANCE
  /CWEIGHT=CWT
  /DESIGN=HUSED WIFED DISTANCE.
```

- COMPUTE initially assigns *CWT* the value 1 for all cases.
- IF assigns *CWT* the value 0 when *HUSED* equals *WIFED*.
- CWEIGHT imposes structural zeros on the diagonal of the symmetric crosstabulation. Because a variable name is specified, only one CWEIGHT can be used.

Example

```
LOGLINEAR  HUSED WIFED(1,4) WITH DISTANCE
  /CWEIGHT=(0, 4*1, 0, 4*1, 0, 4*1, 0)
  /DESIGN=HUSED WIFED DISTANCE
  /CWEIGHT=(16*1)
  /DESIGN=HUSED WIFED DISTANCE.
```

- The first CWEIGHT matrix specifies the same values as variable *CWT* provided in the first example. The specified matrix is as follows:

  0 1 1 1

  1 0 1 1

  1 1 0 1

  1 1 1 0

- The same matrix can be specified in full as (0 1 1 1 1 0 1 1 1 1 0 1 1 1 1 0).
- By using the matrix format on CWEIGHT rather than a variable name, a different CWEIGHT subcommand can be used for the second model.

GRESID Subcommand

GRESID (generalized residual) calculates linear combinations of observed cell frequencies, expected cell frequencies, and adjusted residuals.

- The specification is either a numeric variable or a matrix whose contents are coefficients of the desired linear combinations.
- If a matrix of coefficients is specified, the matrix must contain the same number of elements as the number of cells implied by the variables specification. An asterisk can be used to signify repetitions of the same value.
- Each GRESID subcommand specifies a single linear combination. Each matrix or variable must be specified on a separate GRESID subcommand. All GRESID subcommands specified are displayed for each design.

Example

```
LOGLINEAR  MONTH(1,18) WITH Z
 /GRESID=(6*1,12*0)
 /GRESID=(6*0,6*1,6*0)
 /GRESID=(12*0,6*1)
 /DESIGN=Z.
```

- The first GRESID subcommand combines the first six months into a single effect. The second GRESID subcommand combines the second six months, and the third GRESID subcommand combines the last six months.
- For each effect, LOGLINEAR displays the observed and expected counts, the residual, and the adjusted residual.

CONTRAST Subcommand

CONTRAST indicates the type of contrast desired for a factor, where a factor is any categorical dependent or independent variable. The default contrast is DEVIATION for each factor.

- The specification is CONTRAST, which is followed by a variable name in parentheses and the contrast-type keyword.
- To specify a contrast for more than one factor, use a separate CONTRAST subcommand for each specified factor. Only one contrast can be in effect for each factor on each DESIGN.
- A contrast specification remains in effect for subsequent designs until explicitly overridden by another CONTRAST subcommand.
- The design matrix used for the contrasts can be displayed by specifying the keyword DESIGN on the PRINT subcommand. However, this matrix is the basis matrix that is used to determine contrasts; it is not the contrast matrix itself.
- CONTRAST can be used for a multinomial logit model, in which the dependent variable has more than two categories.
- CONTRAST can be used for fitting linear logit models. The keyword BASIS is not appropriate for such models.
- In a logit model, CONTRAST is used to transform the independent variable into a metric variable. Again, the keyword BASIS is not appropriate.

The following contrast types are available:

DEVIATION(refcat)	*Deviations from the overall effect.* DEVIATION is the default contrast if the CONTRAST subcommand is not used. Refcat is the category for which parameter estimates are not displayed (they are the negative of the sum of the others). By default, refcat is the last category of the variable.
DIFFERENCE	*Levels of a factor with the average effect of previous levels of a factor.* Also known as reverse Helmert contrasts.
HELMERT	*Levels of a factor with the average effect of subsequent levels of a factor.*
SIMPLE(refcat)	*Each level of a factor to the reference level.* By default, LOGLINEAR uses the last category of the factor variable as the reference category. Optionally, any level can be specified as the reference category enclosed in parentheses after the keyword SIMPLE. The sequence of the level, not the actual value, must be specified.
REPEATED	*Adjacent comparisons across levels of a factor.*
POLYNOMIAL(metric)	*Orthogonal polynomial contrasts.* The default is equal spacing. Optionally, the coefficients of the linear polynomial can be specified in parentheses, indicating the spacing between levels of the treatment measured by the given factor.
[BASIS]SPECIAL(matrix)	*User-defined contrast.* As many elements as the number of categories squared must be specified. If BASIS is specified before SPECIAL, a basis matrix is generated for the special contrast, which makes the coefficients of the contrast equal to the special matrix. Otherwise, the matrix specified is transposed and then used as the basis matrix to determine coefficients for the contrast matrix.

Example

```
LOGLINEAR  A(1,4) BY B(1,4)
 /CONTRAST(B)=POLYNOMIAL
 /DESIGN=A A BY B(1)
 /CONTRAST(B)=SIMPLE
 /DESIGN=A A BY B(1).
```

- The first CONTRAST subcommand requests polynomial contrasts of *B* for the first design.
- The second CONTRAST subcommand requests the simple contrast of *B*, with the last category (value 4) used as the reference category for the second DESIGN subcommand.

Example

```
* Multinomial logit model

LOGLINEAR  PREF(1,5) BY RACE ORIGIN CAMP(1,2)
  /CONTRAST(PREF)=SPECIAL(5*1, 1 1 1 1 -4, 3 -1 -1 -1 0,
        0 1 1 -2 0, 0 1 -1 0 0).
```

- LOGLINEAR builds special contrasts among the five categories of the dependent variable *PREF*, which measures preference for training camps among Army recruits. For *PREF*, 1=stay, 2=move to north, 3=move to south, 4=move to unnamed camp, and 5=undecided.
- The four contrasts are: (1) move or stay versus undecided, (2) stay versus move, (3) named camp versus unnamed, and (4) northern camp versus southern. Because these contrasts are orthogonal, SPECIAL and BASIS SPECIAL produce equivalent results.

Example

```
* Contrasts for a linear logit model

LOGLINEAR RESPONSE(1,2) BY YEAR(0,20)
 /PRINT=DEFAULT ESTIM
 /CONTRAST(YEAR)=SPECIAL(21*1, -10, -9, -8, -7, -6, -5, -4,
                         -3, -2, -1, 0, 1, 2, 3, 4, 5, 6, 7,
                          8, 9, 10, 399*1)
 /DESIGN=RESPONSE RESPONSE BY YEAR(1).
```

- *YEAR* measures years of education and ranges from 0 through 20. Therefore, allowing for the constant effect, *YEAR* has 20 estimable parameters associated with it.
- The SPECIAL contrast specifies the constant—that is, 21*1—and the linear effect of *YEAR*—that is, –10 to 10. The other 399 1's fill out the 21*21 matrix.

Example

```
* Contrasts for a logistic regression model

LOGLINEAR RESPONSE(1,2) BY TIME(1,4)
  /CONTRAST(TIME) = SPECIAL(4*1, 7 14 27 51, 8*1)
  /PRINT=ALL /PLOT=DEFAULT
  /DESIGN=RESPONSE, TIME(1) BY RESPONSE.
```

- CONTRAST is used to transform the independent variable into a metric variable.
- *TIME* represents elapsed time in days. Therefore, the weights in the contrast represent the metric of the passage of time.

CRITERIA Subcommand

CRITERIA specifies the values of some constants in the Newton-Raphson algorithm. Defaults or specifications remain in effect until overridden with another CRITERIA subcommand.

CONVERGE(n) *Convergence criterion.* Specify a value for the convergence criterion. The default is 0.001.

ITERATE(n) *Maximum number of iterations.* Specify the maximum number of iterations for the algorithm. The default number is 20.

DELTA(n) *Cell delta value.* The value of delta is added to each cell frequency for the first iteration. For saturated models, it remains in the cell. The default value is 0.5. LOGLINEAR does not display parameter estimates or correlation matrices of parameter estimates if any sampling zero cells exist in the expected table after delta is added. Parameter estimates and correlation matrices can be displayed in the presence of structural zeros.

DEFAULT *Default values are used.* DEFAULT can be used to reset the parameters to the default.

Example

```
LOGLINEAR  DPREF(2,3) BY RACE ORIGIN CAMP(1,2)
 /CRITERIA=ITERATION(50) CONVERGE(.0001).
```

- ITERATION increases the maximum number of iterations to 50.
- CONVERGE lowers the convergence criterion to 0.0001.

PRINT Subcommand

PRINT requests statistics that are not produced by default.

- By default, LOGLINEAR displays the frequency table and residuals. The parameter estimates of the model are also displayed if DESIGN is not used.
- Multiple PRINT subcommands are permitted. The specifications are cumulative.

The following keywords can be used on PRINT:

FREQ	*Observed and expected cell frequencies and percentages.* This is displayed by default.
RESID	*Raw, standardized, and adjusted residuals.* This is displayed by default.
DESIGN	*The design matrix of the model, showing the basis matrix corresponding to the contrasts used.*
ESTIM	*The parameter estimates of the model.* If you do not specify a design on the DESIGN subcommand, LOGLINEAR generates a saturated model and displays the parameter estimates for the saturated model. LOGLINEAR does not display parameter estimates or correlation matrices of parameter estimates if any sampling zero cells exist in the expected table after delta is added. Parameter estimates and a correlation matrix are displayed when structural zeros are present.
COR	*The correlation matrix of the parameter estimates.* Alias COV.
ALL	*All available output.*
DEFAULT	*FREQ and RESID.* ESTIM is also displayed by default if the DESIGN subcommand is not used.
NONE	*The design information and goodness-of-fit statistics only.* This option overrides all other specifications on the PRINT subcommand. The NONE option applies only to the PRINT subcommand.

Example

```
LOGLINEAR A(1,2) B(1,2)
 /PRINT=ESTIM
 /DESIGN=A,B,A BY B
 /PRINT=ALL
 /DESIGN=A,B.
```

- The first design is the saturated model. The parameter estimates are displayed with ESTIM specified on PRINT.
- The second design is the main-effects model, which tests the hypothesis of no interaction. The second PRINT subcommand displays all available display output for this model.

PLOT Subcommand

PLOT produces optional plots. No plots are displayed if PLOT is not specified or is specified without any keyword. Multiple PLOT subcommands can be used. The specifications are cumulative.

RESID	*Plots of adjusted residuals against observed and expected counts.*
NORMPROB	*Normal and detrended normal plots of the adjusted residuals.*

NONE	*No plots.*
DEFAULT	*RESID and NORMPROB.* Alias ALL.

Example

```
LOGLINEAR  RESPONSE(1,2) BY TIME(1,4)
  /CONTRAST(TIME)=SPECIAL(4*1, 7 14 27 51, 8*1)
  /PLOT=DEFAULT
  /DESIGN=RESPONSE TIME(1) BY RESPONSE
  /PLOT=NONE
  /DESIGN.
```

- RESID and NORMPROB plots are displayed for the first design.
- No plots are displayed for the second design.

MISSING Subcommand

MISSING controls missing values. By default, LOGLINEAR excludes all cases with system- or user-missing values on any variable. You can specify INCLUDE to include user-missing values. If INCLUDE is specified, user-missing values must also be included in the value range specification.

EXCLUDE	*Delete cases with user-missing values.* This is the default if the subcommand is omitted. You can also specify the keyword DEFAULT.
INCLUDE	*Include user-missing values.* Only cases with system-missing values are deleted.

Example

```
MISSING VALUES A(0).
LOGLINEAR A(0,2) B(1,2) /MISSING=INCLUDE
 /DESIGN=B.
```

- Even though 0 was specified as missing, it is treated as a nonmissing category of *A* in this analysis.

DESIGN Subcommand

DESIGN specifies the model or models to be fit. If DESIGN is omitted or used with no specifications, the saturated model is produced. The saturated model fits all main effects and all interaction effects.

- To specify more than one model, use more than one DESIGN subcommand. Each DESIGN specifies one model.
- To obtain main-effects models, name all the variables listed on the variables specification.
- To obtain interactions, use the keyword BY to specify each interaction, as in A BY B and C BY D. To obtain the single-degree-of-freedom partition of a specified contrast, specify the partition in parentheses following the factor (see the example below).
- To include cell covariates in the model, first identify them on the variable list by naming them after the keyword WITH, and then specify the variable names on DESIGN.
- To specify an equiprobability model, name a cell covariate that is actually a constant of 1.

Example

```
* Testing the linear effect of the dependent variable

COMPUTE X=MONTH.
LOGLINEAR MONTH (1,12) WITH X
  /DESIGN X.
```

- The variable specification identifies *MONTH* as a categorical variable with values 1 through 12. The keyword `WITH` identifies *X* as a covariate.
- `DESIGN` tests the linear effect of *MONTH*.

Example

```
* Specifying main effects models

LOGLINEAR A(1,4) B(1,5)
  /DESIGN=A
  /DESIGN=A,B.
```

- The first design tests the homogeneity of category probabilities for *B*; it fits the marginal frequencies on *A*, but assumes that membership in any of the categories of *B* is equiprobable.
- The second design tests the independence of *A* and *B*. It fits the marginals on both *A* and *B*.

Example

```
* Specifying interactions

LOGLINEAR A(1,4) B(1,5) C(1,3)
  /DESIGN=A,B,C, A BY B.
```

- This design consists of the *A* main effect, the *B* main effect, the *C* main effect, and the interaction of *A* and *B*.

Example

```
* Single-degree-of-freedom partitions
 LOGLINEAR A(1,4) BY B(1,5)
  /CONTRAST(B)=POLYNOMIAL
  /DESIGN=A,A BY B(1).
```

- The value 1 following *B* refers to the first partition of *B*, which is the linear effect of *B*; this follows from the contrast specified on the `CONTRAST` subcommand.

Example

```
* Specifying cell covariates

LOGLINEAR HUSED WIFED(1,4) WITH DISTANCE
   /DESIGN=HUSED WIFED DISTANCE.
```

- The continuous variable *DISTANCE* is identified as a cell covariate by specifying it after `WITH` on the variable list. The cell covariate is then included in the model by naming it on `DESIGN`.

Example

```
* Equiprobability model

COMPUTE  X=1.
LOGLINEAR  MONTH(1,18) WITH X
  /DESIGN=X.
```

- This model tests whether the frequencies in the 18-cell table are equal by using a cell covariate that is a constant of 1.

LOOP-END LOOP

```
LOOP [varname=n TO m [BY {1**}]]  [IF [()]logical expression[()]]
                         {n  }

transformation commands

END LOOP [IF [()]logical expression[()]]
```

**Default if the subcommand is omitted.

This command does not read the active dataset. It is stored, pending execution with the next command that reads the dataset. For more information, see Command Order on p. 36.

Examples

```
SET MXLOOPS=10. /*Maximum number of loops allowed
LOOP. /*Loop with no limit other than MXLOOPS
COMPUTE X=X+1.
END LOOP.

LOOP #I=1 TO 5. /*Loop five times
COMPUTE X=X+1.
END LOOP.
```

Overview

The LOOP-END LOOP structure performs repeated transformations specified by the commands within the loop until they reach a specified cutoff. The cutoff can be specified by an indexing clause on the LOOP command, an IF clause on the END LOOP command, or a BREAK command within the loop structure (see BREAK). In addition, the maximum number of iterations within a loop can be specified on the MXLOOPS subcommand on SET. The default MXLOOPS is 40.

The IF clause on the LOOP command can be used to perform repeated transformations on a subset of cases. The effect is similar to nesting the LOOP-END LOOP structure within a DO IF-END IF structure, but using IF on LOOP is simpler and more efficient. You have to use the DO IF-END IF structure, however, if you want to perform different transformations on different subsets of cases. You can also use IF on LOOP to specify the cutoff, especially when the cutoff may be reached before the first iteration.

LOOP and END LOOP are usually used within an input program or with the VECTOR command. Since the loop structure repeats transformations on a single case or on a single input record containing information on multiple cases, it allows you to read complex data files or to generate data for a active dataset. For more information, see INPUT PROGRAM-END INPUT PROGRAM and VECTOR.

The loop structure repeats transformations on single cases across variables. It is different from the DO REPEAT-END REPEAT structure, which replicates transformations on a specified set of variables. When both can be used to accomplish a task, such as selectively transforming data for some cases on some variables, LOOP and END LOOP are generally more efficient and

more flexible, but DO REPEAT allows selection of nonadjacent variables and use of replacement values with different intervals.

Options

Missing Values. You can prevent cases with missing values for any of the variables used in the loop structure from entering the loop. For more information, see Missing Values on p. 979.

Creating Data. A loop structure within an input program can be used to generate data. For more information, see Creating Data on p. 980.

Defining Complex File Structures. A loop structure within an input program can be used to define complex files that cannot be handled by standard file definition facilities.

Basic Specification

The basic specification is LOOP followed by at least one transformation command. The structure must end with the END LOOP command. Commands within the loop are executed until the cutoff is reached.

Syntax Rules

- If LOOP and END LOOP are specified before an active dataset exists, they must be specified within an input program.
- If both an indexing and an IF clause are used on LOOP, the indexing clause must be first.
- Loop structures can be nested within other loop structures or within DO IF structures, and vice versa.

Operations

- The LOOP command defines the beginning of a loop structure and the END LOOP command defines its end. The LOOP command returns control to LOOP unless the cutoff has been reached. When the cutoff has been reached, control passes to the command immediately following END LOOP.
- When specified within a loop structure, definition commands (such as MISSING VALUES and VARIABLE LABELS) and utility commands (such as SET and SHOW) are invoked only once, when they are encountered for the first time within the loop.
- An indexing clause (e.g., LOOP #i=1 to 1000) will override the SET MXLOOPS limit, but a loop with an IF condition will terminate if the MXLOOPS limit is reached before the condition is satisfied.

Examples

Example

```
SET MXLOOPS=10.
LOOP. /*Loop with no limit other than MXLOOPS
COMPUTE X=X+1.
END LOOP.
```

- This and the following examples assume that an active dataset and all of the variables mentioned in the loop exist.
- The SET MXLOOPS command limits the number of times the loop is executed to 10. The function of MXLOOPS is to prevent infinite loops when there is no indexing clause.
- Within the loop structure, each iteration increments *X* by 1. After 10 iterations, the value of *X* for all cases is increased by 10, and, as specified on the SET command, the loop is terminated.

Example

```
*Assume MXLOOPS set to default value of 40.
COMPUTE newvar1=0.
LOOP IF newvar1<100.
COMPUTE newvar1=newvar1+1.
END LOOP.

PRESERVE.
SET MXLOOPS 500.
COMPUTE newvar2=0.
LOOP IF newvar2<100.
COMPUTE newvar2=newvar2+1.
END LOOP.
RESTORE.

COMPUTE newvar3=0.
LOOP #i=1 to 1000.
COMPUTE newvar3=newvar3+1.
END LOOP.
EXECUTE.
```

- In the first loop, the value of *newvar1* will reach 40, at which point the loop will terminate because the MXLOOPS limit has been exceeded.
- In the second loop, the value of MXLOOPS is increased to 500, and the loop will continue to iterate until the value of *newvar2* reaches 100, at which point the IF condition is reached and the loop terminates.
- In the third loop, the indexing clause overrides the MXLOOPS setting, and the loop will iterate 1,000 times.

IF Keyword

The keyword IF and a logical expression can be specified on LOOP or on END LOOP to control iterations through the loop.

- The specification on IF is a logical expression enclosed in parentheses.

Example

```
LOOP.
COMPUTE X=X+1.
END LOOP IF (X EQ 5). /*Loop until X is 5
```

- Iterations continue until the logical expression on END LOOP is true, which for every case is when *X* equals 5. Each case does not go through the same number of iterations.

- This corresponds to the programming notion of DO UNTIL. The loop is always executed at least once.

Example

```
LOOP IF (X LT 5). /*Loop while X is less than 5
COMPUTE X=X+1.
END LOOP.
```

- The IF clause is evaluated each trip through the structure, so looping stops once *X* equals 5.
- This corresponds to the programming notion of DO WHILE. The loop may not be executed at all.

Example

```
LOOP IF (Y GT 10). /*Loop only for cases with Y GT 10
COMPUTE X=X+1.
END LOOP IF (X EQ 5). /*Loop until X IS 5
```

- The IF clause on LOOP allows transformations to be performed on a subset of cases. *X* is increased by 5 only for cases with values greater than 10 for *Y*. *X* is not changed for all other cases.

Indexing Clause

The indexing clause limits the number of iterations for a loop by specifying the number of times the program should execute commands within the loop structure. The indexing clause is specified on the LOOP command and includes an indexing variable followed by initial and terminal values.

- The program sets the *indexing variable* to the *initial value* and increases it by the specified increment each time the loop is executed for a case. When the indexing variable reaches the specified *terminal value*, the loop is terminated for that case.
- By default, the program increases the indexing variable by 1 for each iteration. The keyword BY overrides this increment.
- The indexing variable can have any valid variable name. Unless you specify a scratch variable, the indexing variable is treated as a permanent variable and is saved in the active dataset. If the indexing variable is assigned the same name as an existing variable, the values of the existing variable are altered by the LOOP structure as it is executed, and the original values are lost. For more information, see Creating Data on p. 980.
- The indexing clause overrides the maximum number of loops specified by SET MXLOOPS.
- The initial and terminal values of the indexing clause can be numeric expressions. Noninteger and negative expressions are allowed.
- If the expression for the initial value is greater than the terminal value, the loop is not executed. For example, #J=X TO Y is a zero-trip loop if *X* is 0 and *Y* is –1.
- If the expressions for the initial and terminal values are equal, the loop is executed once. #J=0 TO Y is a one-trip loop when *Y* is 0.

- If the loop is exited via BREAK or a conditional clause on the END LOOP statement, the iteration variable is not updated. If the LOOP statement contains both an indexing clause and a conditional clause, the indexing clause is executed first, and the iteration variable is updated regardless of which clause causes the loop to terminate.

Example

```
LOOP #I=1 TO 5. /*LOOP FIVE TIMES
COMPUTE X=X+1.
END LOOP.
```

- The scratch variable *#I* (the indexing variable) is set to the initial value of 1 and increased by 1 each time the loop is executed for a case. When *#I* increases beyond the terminal value 5, no further loops are executed. Thus, the value of *X* will be increased by 5 for every case.

Example

```
LOOP #I=1 TO 5 IF (Y GT 10). /*Loop to X=5 only if Y GT 10
COMPUTE X=X+1.
END LOOP.
```

- Both an indexing clause and an IF clause are specified on LOOP. *X* is increased by 5 for all cases where *Y* is greater than 10.

Example

```
LOOP #I=1 TO Y. /*Loop to the value of Y
COMPUTE X=X+1.
END LOOP.
```

- The number of iterations for a case depends on the value of the variable *Y* for that case. For a case with value 0 for the variable *Y*, the loop is not executed and *X* is unchanged. For a case with value 1 for the variable *Y*, the loop is executed once and *X* is increased by 1.

Example

```
* Factorial routine.

DATA LIST FREE / X.
BEGIN DATA
1 2 3 4 5 6 7
END DATA.

COMPUTE FACTOR=1.
LOOP #I=1 TO X.
COMPUTE FACTOR=FACTOR * #I.
END LOOP.
LIST.
```

- The loop structure computes *FACTOR* as the factorial value of *X*.

Example

```
* Example of nested loops:
  compute every possible combination of values for each variable.
```

```
INPUT PROGRAM.
-LOOP #I=1 TO 4. /* LOOP TO NUMBER OF VALUES FOR I
- LOOP #J=1 TO 3. /* LOOP TO NUMBER OF VALUES FOR J
-  LOOP #K=1 TO 4. /* LOOP TO NUMBER OF VALUES FOR K
-   COMPUTE I=#I.
-   COMPUTE J=#J.
-   COMPUTE K=#K.
-   END CASE.
-  END LOOP.
- END LOOP.
-END LOOP.
END FILE.
END INPUT PROGRAM.
LIST.
```

- The first loop iterates four times. The first iteration sets the indexing variable *#I* equal to 1 and then passes control to the second loop. *#I* remains 1 until the second loop has completed all of its iterations.
- The second loop is executed 12 times, three times for each value of *#I*. The first iteration sets the indexing variable *#J* equal to 1 and then passes control to the third loop. *#J* remains 1 until the third loop has completed all of its iterations.
- The third loop results in 48 iterations (4 × 3 × 4). The first iteration sets `#K` equal to 1. The `COMPUTE` statements set the variables *I, J,* and *K* each to 1, and `END CASE` creates a case. The third loop iterates a second time, setting *#K* equal to 2. Variables *I, J*, and *K* are then computed with values 1, 1, 2, respectively, and a second case is created. The third and fourth iterations of the third loop produce cases with *I, J,* and *K*, equal to 1, 1, 3 and 1, 1, 4, respectively. After the fourth iteration within the third loop, control passes back to the second loop.
- The second loop is executed again. *#I* remains 1, while *#J* increases to 2, and control returns to the third loop. The third loop completes its iterations, resulting in four more cases with *I* equal to 1, *J* to 2, and *K* increasing from 1 to 4. The second loop is executed a third time, resulting in cases with *I*=1, *J*=3, and *K* increasing from 1 to 4. Once the second loop has completed three iterations, control passes back to the first loop, and the entire cycle is repeated for the next increment of *#I*.
- Once the first loop completes four iterations, control passes out of the looping structures to `END FILE`. `END FILE` defines the resulting cases as a data file, the input program terminates, and the `LIST` command is executed.
- This example does not require a `LEAVE` command because the iteration variables are scratch variables. If the iteration variables were *I, J,* and *K*, `LEAVE` would be required because the variables would be reinitialized after each `END CASE` command.

Example

```
* Modifying the loop iteration variable.

INPUT PROGRAM.
PRINT SPACE    2.
LOOP           A = 1 TO 3. /*Simple iteration
+  PRINT          /'A WITHIN LOOP: ' A(F1).
+  COMPUTE        A = 0.
END LOOP.
PRINT          /'A AFTER LOOP:  ' A(F1).

NUMERIC        #B.
LOOP           B = 1 TO 3. /*Iteration + UNTIL
```

```
+  PRINT          /'B WITHIN LOOP: ' B(F1).
+  COMPUTE        B = 0.
+  COMPUTE        #B = #B+1.
END LOOP       IF #B = 3.
PRINT          /'B AFTER LOOP:  ' B(F1).

NUMERIC        #C.
LOOP           C = 1 TO 3 IF #C NE 3. /*Iteration + WHILE
+  PRINT          /'C WITHIN LOOP: ' C(F1).
+  COMPUTE        C = 0.
+  COMPUTE        #C = #C+1.
END LOOP.
PRINT          /'C AFTER LOOP:  ' C(F1).

NUMERIC        #D.
LOOP           D = 1 TO 3. /*Iteration + BREAK
+  PRINT          /'D WITHIN LOOP: ' D(F1).
+  COMPUTE        D = 0.
+  COMPUTE        #D = #D+1.
+  DO IF          #D = 3.
+     BREAK.
+  END IF.
END LOOP.
PRINT          /'D AFTER LOOP:  ' D(F1).

LOOP           E = 3 TO 1. /*Zero-trip iteration
+  PRINT          /'E WITHIN LOOP: ' E(F1).
+  COMPUTE        E = 0.
END LOOP.
PRINT          /'E AFTER LOOP:  ' E(F1).
END FILE.
END INPUT PROGRAM.
EXECUTE.
```

- If a loop is exited via `BREAK` or a conditional clause on the `END LOOP` statement, the iteration variable is not updated.
- If the `LOOP` statement contains both an indexing clause and a conditional clause, the indexing clause is executed first, and the actual iteration variable will be updated regardless of which clause causes termination of the loop.

The output from this example is shown below.

Figure 116-1
Modifying the loop iteration value

```
A WITHIN LOOP: 1
A WITHIN LOOP: 2
A WITHIN LOOP: 3
A AFTER LOOP:  4
B WITHIN LOOP: 1
B WITHIN LOOP: 2
B WITHIN LOOP: 3
B AFTER LOOP:  0
C WITHIN LOOP: 1
C WITHIN LOOP: 2
C WITHIN LOOP: 3
C AFTER LOOP:  4
D WITHIN LOOP: 1
D WITHIN LOOP: 2
D WITHIN LOOP: 3
D AFTER LOOP:  0
E AFTER LOOP:  3
```

BY Keyword

By default, the program increases the indexing variable by 1 for each iteration. The keyword `BY` overrides this increment.

- The *increment value* can be a numeric expression and can therefore be non-integer or negative. Zero causes a warning and results in a zero-trip loop.
- If the initial value is greater than the terminal value and the increment is positive, the loop is never entered. `#I=1 TO 0 BY 2` results in a zero-trip loop.
- If the initial value is less than the terminal value and the increment is negative, the loop is never entered. `#I=1 TO 2 BY -1` also results in a zero-trip loop.
- Order is unimportant: `2 BY 2 TO 10` is equivalent to `2 TO 10 BY 2`.

Example

```
LOOP #I=2 TO 10 BY 2. /*Loop five times by 2'S
COMPUTE X=X+1.
END LOOP.
```

- The scratch variable *#I* starts at 2 and increases by 2 for each of five iterations until it equals 10 for the last iteration.

Example

```
LOOP #I=1 TO Y BY Z. /*Loop to Y incrementing by Z
COMPUTE X=X+1.
END LOOP.
```

- The loop is executed once for a case with *Y* equal to 2 and *Z* equal to 2 but twice for a case with *Y* equal to 3 and *Z* equal to 2.

Example

```
* Repeating data using LOOP.

INPUT PROGRAM.
DATA LIST      NOTABLE/ ORDER 1-4(N) #BKINFO 6-71(A).
LEAVE ORDER.
LOOP           #I = 1 TO 66 BY 6 IF SUBSTR(#BKINFO,#I,6) <> ' '.
+  REREAD         COLUMN = #I+5.
+  DATA LIST      NOTABLE/ ISBN 1-3(N) QUANTITY 4-5.
+  END CASE.
END LOOP.
END INPUT PROGRAM.
SORT CASES     BY ISBN ORDER.
BEGIN DATA
1045 182 2 155 1 134 1 153 5
1046 155 3 153 5 163 1
1047 161 5 182 2 163 4 186 6
1048 186 2
1049 155 2 163 2 153 2 074 1 161 1
END DATA.

DO IF          $CASENUM = 1.
+  PRINT EJECT    /'Order' 1  'ISBN' 7  'Quantity' 13.
END IF.
PRINT          /ORDER 2-5(N) ISBN 8-10(N) QUANTITY 13-17.
```

```
EXECUTE.
```

- This example uses LOOP to simulate a REPEATING DATA command.
- DATA LIST specifies the scratch variable *#BKINFO* as a string variable (format A) to allow blanks in the data.
- LOOP is executed if the SUBSTR function returns anything other than a blank or null value. SUBSTR returns a six-character substring of *#BKINFO*, beginning with the character in the position specified by the value of the indexing variable *#I*. As specified on the indexing clause, *#I* begins with a value of 1 and is increased by 6 for each iteration of LOOP, up to a maximum *#I* value of 61 (1 + 10 × 6 = 61). The next iteration would exceed the maximum *#I* value (1 + 11 × 6 = 67).

Missing Values

- If the program encounters a case with a missing value for the initial, terminal, or increment value or expression, or if the conditional expression on the LOOP command returns missing, a zero-trip loop results and control is passed to the first command after the END LOOP command.
- If a case has a missing value for the conditional expression on an END LOOP command, the loop is terminated after the first iteration.
- To prevent cases with missing values for any variable used in the loop structure from entering the loop, use the IF clause on the LOOP command (see third example below).

Example

```
LOOP #I=1 TO Z  IF (Y GT 10). /*Loop to X=Z for cases with Y GT 10
COMPUTE X=X+1.
END LOOP.
```

- The value of *X* remains unchanged for cases with a missing value for *Y* or a missing value for *Z* (or if *Z* is less than 1).

Example

```
MISSING VALUES X(5).
LOOP.
COMPUTE X=X+1.
END LOOP IF (X GE 10). /*Loop until X is at least 10 or missing
```

- Looping is terminated when the value of *X* is 5 because 5 is defined as missing for *X*.

Example

```
LOOP IF NOT MISSING(Y). /*Loop only when Y isn't missing
COMPUTE X=X+Y.
END LOOP IF (X GE 10). /*Loop until X is at least 10
```

- The variable *X* is unchanged for cases with a missing value for *Y*, since the loop is never entered.

Creating Data

A loop structure and an END CASE command within an input program can be used to create data without any data input. The END FILE command must be used outside the loop (but within the input program) to terminate processing.

Example

```
INPUT PROGRAM.
LOOP #I=1 TO 20.
COMPUTE AMOUNT=RND(UNIFORM(5000))/100.
END CASE.
END LOOP.
END FILE.
END INPUT PROGRAM.

PRINT FORMATS AMOUNT (DOLLAR6.2).
PRINT /AMOUNT.
EXECUTE.
```

- This example creates 20 cases with a single variable, *AMOUNT*. *AMOUNT* is a uniformly distributed number between 0 and 5,000, rounded to an integer and divided by 100 to provide a variable in dollars and cents.
- The END FILE command is required to terminate processing once the loop structure is complete.

Scratch vs. Permanent Index Variables

Permanent variables are reinitialized to system-missing for each case, but scratch variables are initialized to 0 and are not reinitialized for each case; instead they retain their previous values. For loops that don't span cases, this is not an important factor, but in an input program a nested loop can persist across cases. In such instances, the index counter is not affected because it is cached and restored after execution of the loop, but the results of commands within the loop that use the value of the index variables will be different for scratch and permanent index variables.

```
*using scratch index variables.
INPUT PROGRAM.
LOOP #i=1 to 3.
- LOOP #j=#i to 4.
-  COMPUTE var1=#i.
-  COMPUTE var2=#j.
-  END CASE.
- END LOOP.
END LOOP.
END FILE.
END INPUT PROGRAM.
LIST.

*using non-scratch index variables.
INPUT PROGRAM.
LOOP i=1 to 3.
- LOOP j=i to 4.
-  COMPUTE var1=i.
-  COMPUTE var2=j.
-  END CASE.
- END LOOP.
END LOOP.
END FILE.
```

```
END INPUT PROGRAM.
LIST.
```

Figure 116-2
Case listing from loop using scratch variables

var1	var2
1.00	1.00
1.00	2.00
1.00	3.00
1.00	4.00
2.00	2.00
2.00	3.00
2.00	4.00
3.00	3.00
3.00	4.00

Figure 116-3
Case listing from loop using permanent variables

i	j	var1	var2
1.00	1.00	1.00	1.00
.	2.00	.	2.00
.	3.00	.	3.00
.	4.00	.	4.00
2.00	2.00	2.00	2.00
.	3.00	.	3.00
.	4.00	.	4.00
3.00	3.00	3.00	3.00
.	4.00	.	4.00

- Aside from the fact that the use of permanent variables as index variables results in the creation (or replacement) of those variables in the active dataset, note that many of the value for *var1* (and *i*) are missing in the results from the input program that uses permanent variables as index variables, while none are missing from the one that uses scratch variables.
- In both cases, the inner loop ends with the `END CASE` command, which causes the permanent variable *i* to be reinitialized to system-missing for subsequent iterations of the inner loop, but the scratch variable *#i* retains its previous value.
- When control passes to the outer loop again, the cached index value is used to set and increment *i*; so it has a non-missing value for the first iteration of the inner loop, but once `END CASE` is encountered, it becomes missing again until control passes to the outer loop again.

For more information, see Scratch Variables on p. 46.

MANOVA

MANOVA is available in the Advanced Models option.

```

Overview

MANOVA (multivariate analysis of variance) is a generalized procedure for analysis of variance and covariance. MANOVA is a powerful procedure and can be used for both univariate and multivariate designs. MANOVA allows you to perform the following tasks:

- Specify nesting of effects.
- Specify individual error terms for effects in mixed-model analyses.
- Estimate covariate-by-factor interactions to test the assumption of homogeneity of regressions.
- Obtain parameter estimates for a variety of contrast types, including irregularly spaced polynomial contrasts with multiple factors.
- Test user-specified special contrasts with multiple factors.
- Partition effects in models.
- Pool effects in models.

MANOVA and General Linear Model (GLM)

MANOVA is available only in syntax. GLM (general linear model), the other generalized procedure for analysis of variance and covariance, is available both in syntax and via the dialog boxes. The major distinction between GLM and MANOVA in terms of statistical design and functionality is that GLM uses a non-full-rank, or overparameterized, indicator variable approach to parameterization of linear models (instead of the full-rank reparameterization approach that is used in MANOVA). GLM uses a generalized inverse approach and uses the aliasing of redundant parameters to zero to allow greater flexibility in handling a variety of data situations, particularly situations involving empty cells. For features that are provided by GLM but unavailable in MANOVA, refer to General Linear Model (GLM) and MANOVA on p. 800.

To simplify the presentation, MANOVA reference material is divided into three sections: *univariate* designs with one dependent variable; *multivariate* designs with several interrelated dependent variables; and *repeated measures* designs in which the dependent variables represent the same types of measurements, taken at more than one time.

The full syntax diagram for MANOVA is presented here. The sections that follow include partial syntax diagrams that show the subcommands and specifications that are discussed in that section. Individually, those diagrams are incomplete. Subcommands that are listed for univariate designs are available for any analysis, and subcommands that are listed for multivariate designs can be used in any multivariate analysis, including repeated measures.

MANOVA was designed and programmed by Philip Burns of Northwestern University.

MANOVA: Univariate

MANOVA is available in the Advanced Models option.

MANOVA YIELD BY SEED(1,4) FERT(1,3)
  /DESIGN.
```

Overview

This section describes the use of MANOVA for univariate analyses. However, the subcommands that are described here can be used in any type of analysis with MANOVA. For additional subcommands that are used in multivariate analysis, see *MANOVA: Multivariate*. For additional subcommands that are used in repeated measures analysis, see *MANOVA: Repeated Measures*. For basic specification, syntax rules, and limitations of the MANOVA procedures, see *MANOVA*.

Options

Design Specification. You can use the DESIGN subcommand to specify which terms to include in the design. This ability allows you to estimate a model other than the default full factorial model, incorporate factor-by-covariate interactions, indicate nesting of effects, and indicate specific error terms for each effect in mixed models. You can specify a different continuous variable as a dependent variable or work with a subset of the continuous variables with the ANALYSIS subcommand.

Contrast Types. You can specify contrasts other than the default deviation contrasts on the CONTRAST subcommand. You can also subdivide the degrees of freedom associated with a factor (using the PARTITION subcommand) and test the significance of a specific contrast or group of contrasts.

Optional Output. You can choose from a variety of optional output on the PRINT subcommand or suppress output using the NOPRINT subcommand. Output that is appropriate to univariate designs includes cell means, design or other matrices, parameter estimates, and tests for homogeneity of variance across cells. Using the OMEANS, PMEANS, RESIDUAL, and PLOT subcommands, you can also request tables of observed and/or predicted means, casewise values and residuals for your model, and various plots that are useful in checking assumptions. In addition, you can use the POWER subcommand to request observed power values (based on fixed-effect assumptions), and you can use the CINTERVAL subcommand to request simultaneous confidence intervals for each parameter estimate and regression coefficient.

Matrix Materials. You can write matrices of intermediate results to a matrix data file, and you can read such matrices in performing further analyses by using the MATRIX subcommand.

Basic Specification

- The basic specification is a variable list that identifies the dependent variable, the factors (if any), and the covariates (if any).
- By default, MANOVA uses a full factorial model, which includes all main effects and all possible interactions among factors. Estimation is performed by using the cell-means model and UNIQUE (regression-type) sums of squares, adjusting each effect for all other effects in the model. Parameters are estimated by using DEVIATION contrasts to determine whether their categories differ significantly from the mean.

Subcommand Order

- The variable list must be specified first.

- Subcommands that are applicable to a specific design must be specified before that DESIGN subcommand. Otherwise, subcommands can be used in any order.

Syntax Rules

- For many analyses, the MANOVA variable list and the DESIGN subcommand are the only specifications that are needed. If a full factorial design is desired, DESIGN can be omitted.
- All other subcommands apply only to designs that follow. If you do not enter a DESIGN subcommand, or if the last subcommand is not DESIGN, MANOVA uses a full factorial model.
- Unless replaced, MANOVA subcommands (other than DESIGN) remain in effect for all subsequent models.
- MISSING can be specified only once.
- The following words are reserved as keywords or internal commands in the MANOVA procedure: AGAINST, CONSPLUS, CONSTANT, CONTIN, MUPLUS, MWITHIN, POOL, R, RESIDUAL, RW, VERSUS, VS, W, WITHIN, and WR. Variable names that duplicate these words should be changed before you invoke MANOVA.
- If you enter one of the multivariate specifications in a univariate analysis, MANOVA will ignore it.

Limitations

- A maximum of 20 factors is in place.
- A maximum of 200 dependent variables is in place.
- Memory requirements depend primarily on the number of cells in the design. For the default full factorial model, the number of cells equals the product of the number of levels or categories in each factor.

Example

```
MANOVA YIELD BY SEED(1,4) FERT(1,3) WITH RAINFALL
  /PRINT=CELLINFO(MEANS) PARAMETERS(ESTIM)
  /DESIGN.
```

- *YIELD* is the dependent variable; *SEED* (with values 1, 2, 3, and 4) and *FERT* (with values 1, 2, and 3) are factors; *RAINFALL* is a covariate.
- The PRINT subcommand requests the means of the dependent variable for each cell and the default deviation parameter estimates.
- The DESIGN subcommand requests the default design, a full factorial model. This subcommand could have been omitted or could have been specified in full as:

  /DESIGN = SEED, FERT, SEED BY FERT.

MANOVA Variable List

The variable list specifies all variables that will be used in any subsequent analyses.

- The dependent variable must be the first specification on MANOVA.

- By default, MANOVA treats a list of dependent variables as jointly dependent, implying a multivariate design. However, you can use the ANALYSIS subcommand to change the role of a variable or its inclusion status in the analysis.
- The names of the factors follow the dependent variable. Use the keyword BY to separate the factors from the dependent variable.
- Factors must have adjacent integer values, and you must supply the minimum and maximum values in parentheses after the factor name(s).
- If several factors have the same value range, you can specify a list of factors followed by a single value range in parentheses.
- Certain one-cell designs, such as univariate and multivariate regression analysis, canonical correlation, and one-sample Hotelling's T^2, do not require a factor specification. To perform these analyses, omit the keyword BY and the factor list.
- Enter the covariates, if any, following the factors and their ranges. Use the keyword WITH to separate covariates from factors (if any) and the dependent variable.

Example

```
MANOVA DEPENDNT BY FACTOR1 (1,3) FACTOR2, FACTOR3 (1,2).
```

- In this example, three factors are specified.
- *FACTOR1* has values 1, 2, and 3, while *FACTOR2* and *FACTOR3* have values 1 and 2.
- A default full factorial model is used for the analysis.

Example

```
MANOVA Y BY A(1,3) WITH X
  /DESIGN.
```

- In this example, the *A* effect is tested after adjusting for the effect of the covariate *X*. It is a test of equality of adjusted *A* means.
- The test of the covariate *X* is adjusted for *A*. The test is a test of the pooled within-groups regression of *Y* on *X*.

ERROR Subcommand

ERROR allows you to specify or change the error term that is used to test all effects for which you do not explicitly specify an error term on the DESIGN subcommand. ERROR affects all terms in all subsequent designs, except terms for which you explicitly provide an error term.

WITHIN *Terms in the model are tested against the within-cell sum of squares.* This specification can be abbreviated to W. This setting is the default unless there is no variance within cells or a continuous variable is named on the DESIGN subcommand.

RESIDUAL *Terms in the model are tested against the residual sum of squares.* This specification can be abbreviated to R. This specification includes all terms not named on the DESIGN subcommand.

WITHIN+RESIDUAL	*Terms are tested against the pooled within-cells and residual sum of squares.* This specification can be abbreviated to WR or RW. This setting is the default for designs in which a continuous variable appears on the DESIGN subcommand.
error number	*Terms are tested against a numbered error term.* The error term must be defined on each DESIGN subcommand. For a discussion of error terms, see DESIGN Keyword on p. 997.

- If you specify ERROR=WITHIN+RESIDUAL and one of the components does not exist, MANOVA uses the other component alone.
- If you specify your own error term by number and a design does not have an error term with the specified number, MANOVA does not carry out significance tests. MANOVA will, however, display hypothesis sums of squares and, if requested, parameter estimates.

Example

```
MANOVA DEP BY A(1,2) B(1,4)
  /ERROR = 1
  /DESIGN = A, B, A BY B = 1 VS WITHIN
  /DESIGN = A, B.
```

- ERROR defines error term 1 as the default error term.
- In the first design, *A* by *B* is defined as error term 1 and is therefore used to test the *A* and *B* effects. The *A* by *B* effect itself is explicitly tested against the within-cells error.
- In the second design, no term is defined as error term 1, so no significance tests are carried out. Hypothesis sums of squares are displayed for *A* and *B*.

CONTRAST Subcommand

CONTRAST specifies the type of contrast that is desired among the levels of a factor. For a factor with *k* levels or values, the contrast type determines the meaning of its *k*−1 degrees of freedom. If the subcommand is omitted or is specified with no keyword, the default is DEVIATION for between-subjects factors.

- Specify the factor name in parentheses following the subcommand CONTRAST.
- You can specify only one factor per CONTRAST subcommand, but you can enter multiple CONTRAST subcommands.
- After closing the parentheses, enter an equals sign followed by one of the contrast keywords.
- To obtain *F* tests for individual degrees of freedom for the specified contrast, enter the factor name followed by a number in parentheses on the DESIGN subcommand. The number refers to a partition of the factor's degrees of freedom. If you do not use the PARTITION subcommand, each degree of freedom is a distinct partition.

The following contrast types are available:

DEVIATION *Deviations from the grand mean.* This setting is the default for between-subjects factors. Each level of the factor (except one level) is compared to the grand mean. One category (by default, the last category) must be omitted so that the effects will be independent of one another. To omit a category other than the last category, specify the number of the omitted category (which is not necessarily the same as its value) in parentheses after the keyword `DEVIATION`. An example is as follows:

```
MANOVA A BY B(2,4) /CONTRAST(B)=DEVIATION(1).
```

The specified contrast omits the first category, in which *B* has the value 2. Deviation contrasts are not orthogonal.

POLYNOMIAL *Polynomial contrasts.* This setting is the default for within-subjects factors. The first degree of freedom contains the linear effect across the levels of the factor, the second degree of freedom contains the quadratic effect, and so on. In a balanced design, polynomial contrasts are orthogonal. By default, the levels are assumed to be equally spaced; you can specify unequal spacing by entering a metric—consisting of one integer for each level of the factor—in parentheses after the keyword `POLYNOMIAL`. An example is as follows:

```
MANOVA RESPONSE BY STIMULUS (4,6) /CONTRAST(STIMULUS) =
POLYNOMIAL(1,2,4).
```

The specified contrast indicates that the three levels of *STIMULUS* are actually in the proportion 1:2:4. The default metric is always (1,2,...,*k*), where *k* levels are involved. Only the relative differences between the terms of the metric matter. (1,2,4) is the same metric as (2,3,5) or (20,30,50) because, in each instance, the difference between the second and third numbers is twice the difference between the first and second numbers.

DIFFERENCE *Difference or reverse Helmert contrasts.* Each level of the factor (except the first level) is compared to the mean of the previous levels. In a balanced design, difference contrasts are orthogonal.

HELMERT *Helmert contrasts.* Each level of the factor (except the last level) is compared to the mean of subsequent levels. In a balanced design, Helmert contrasts are orthogonal.

SIMPLE *Contrast where each level of the factor (except the last level) is compared to the last level.* To use a category (other than the last category) as the omitted reference category, specify its number (which is not necessarily the same as its value) in parentheses following the keyword `SIMPLE`. An example is as follows:

```
MANOVA A BY B(2,4) /CONTRAST(B)=SIMPLE(1).
```

The specified contrast compares the other levels to the first level of *B*, in which *B* has the value 2. Simple contrasts are not orthogonal.

REPEATED *Comparison of adjacent levels.* Each level of the factor (except the last level) is compared to the next level. Repeated contrasts are not orthogonal.

SPECIAL *A user-defined contrast.* After this keyword, enter a square matrix in parentheses with as many rows and columns as there are levels in the factor. The first row represents the mean effect of the factor and is generally a vector of 1's. The row represents a set of weights indicating how to collapse over the categories of this factor in estimating parameters for other factors. The other rows of the contrast matrix contain the special contrasts indicating the desired comparisons between levels of the factor. If the special contrasts are linear combinations of each other, `MANOVA` reports the linear dependency and stops processing.

Orthogonal contrasts are particularly useful. In a balanced design, contrasts are orthogonal if the sum of the coefficients in each contrast row is 0 and if, for any pair of contrast rows, the products of corresponding coefficients sum to 0. DIFFERENCE, HELMERT, and POLYNOMIAL contrasts always meet these criteria in balanced designs.

Example

```
MANOVA DEP BY FAC(1,5)
  /CONTRAST(FAC)=DIFFERENCE
  /DESIGN=FAC(1) FAC(2) FAC(3) FAC(4).
```

- The factor *FAC* has five categories and therefore four degrees of freedom.
- CONTRAST requests DIFFERENCE contrasts, which compare each level (except the first level) with the mean of the previous levels.
- Each of the four degrees of freedom is tested individually on the DESIGN subcommand.

PARTITION Subcommand

PARTITION subdivides the degrees of freedom that are associated with a factor. This process permits you to test the significance of the effect of a specific contrast or group of contrasts of the factor instead of the overall effect of all contrasts of the factor. The default is a single degree of freedom for each partition.

- Specify the factor name in parentheses following the PARTITION subcommand.
- Specify an integer list in parentheses after the optional equals sign to indicate the degrees of freedom for each partition.
- Each value in the partition list must be a positive integer, and the sum of the values cannot exceed the degrees of freedom for the factor.
- The degrees of freedom that are available for a factor are one less than the number of levels of the factor.
- The meaning of each degree of freedom depends on the contrast type for the factor. For example, with deviation contrasts (the default for between-subjects factors), each degree of freedom represents the deviation of the dependent variable in one level of the factor from its grand mean over all levels. With polynomial contrasts, the degrees of freedom represent the linear effect, the quadratic effect, and so on.
- If your list does not account for all the degrees of freedom, MANOVA adds one final partition containing the remaining degrees of freedom.
- You can use a repetition factor of the form *n** to specify a series of partitions with the same number of degrees of freedom.
- To specify a model that tests only the effect of a specific partition of a factor in your design, include the number of the partition in parentheses on the DESIGN subcommand (see the example below).
- If you want the default single degree-of-freedom partition, you can omit the PARTITION subcommand and simply enter the appropriate term on the DESIGN subcommand.

Example

```
MANOVA OUTCOME BY TREATMNT(1,12)
  /PARTITION(TREATMNT) = (3*2,4)
  /DESIGN TREATMNT(2).
```

- The factor *TREATMNT* has 12 categories (hence, 11 degrees of freedom).
- PARTITION divides the effect of *TREATMNT* into four partitions, containing, respectively, 2, 2, 2, and 4 degrees of freedom. A fifth partition is formed to contain the remaining 1 degree of freedom.
- DESIGN specifies a model in which only the second partition of *TREATMNT* is tested. This partition contains the third and fourth degrees of freedom.
- Because the default contrast type for between-subjects factors is DEVIATION, this second partition represents the deviation of the third and fourth levels of *TREATMNT* from the grand mean.

METHOD Subcommand

METHOD controls the computational aspects of the MANOVA analysis. You can specify one of two different methods for partitioning the sums of squares. The default is UNIQUE.

UNIQUE *Regression approach.* Each term is corrected for every other term in the model. With this approach, sums of squares for various components of the model do not add up to the total sum of squares unless the design is balanced. This is the default if the METHOD subcommand is omitted or if neither of the two keywords is specified.

SEQUENTIAL *Hierarchical decomposition of the sums of squares.* Each term is adjusted only for the terms that precede it on the DESIGN subcommand. This decomposition is an orthogonal decomposition, and the sums of squares in the model add up to the total sum of squares.

You can control how parameters are to be estimated by specifying one of the following two keywords that are available on MANOVA. The default is QR.

QR *Use modified Givens rotations.* QR bypasses the normal equations and the inaccuracies that can result from creating the cross-products matrix, and it generally results in extremely accurate parameter estimates. This setting is the default if the METHOD subcommand is omitted or if neither of the two keywords is specified.

CHOLESKY *Use Cholesky decomposition of the cross-products matrix.* This method is useful for large data sets with covariates entered on the DESIGN subcommand.

You can also control whether a constant term is included in all models. Two keywords are available on METHOD. The default is CONSTANT.

CONSTANT *All models include a constant (grand mean) term, even if none is explicitly specified on the DESIGN subcommand.* This setting is the default if neither of the two keywords is specified.

NOCONSTANT *Exclude constant terms from models that do not include the keyword CONSTANT on the DESIGN subcommand.*

Example

```
MANOVA DEP BY A B C (1,4)
  /METHOD=NOCONSTANT
  /DESIGN=A, B, C
  /METHOD=CONSTANT SEQUENTIAL
  /DESIGN.
```

- For the first design, a main-effects model, the METHOD subcommand requests the model to be fitted with no constant.
- The second design requests a full factorial model to be fitted with a constant and with a sequential decomposition of sums of squares.

PRINT and NOPRINT Subcommands

PRINT and NOPRINT control the display of optional output.

- Specifications on PRINT remain in effect for all subsequent designs.
- Some PRINT output, such as CELLINFO, applies to the entire MANOVA procedure and is displayed only once.
- You can turn off optional output that you have requested on PRINT by entering a NOPRINT subcommand with the specifications that were originally used on the PRINT subcommand.
- Additional output can be obtained on the PCOMPS, DISCRIM, OMEANS, PMEANS, PLOT, and RESIDUALS subcommands.
- Some optional output greatly increases the processing time. Request only the output that you want to see.

The following specifications are appropriate for univariate MANOVA analyses. For information about PRINT specifications that are appropriate for multivariate models, see PRINT and NOPRINT Subcommands on p. 1018. For information about PRINT specifications that are appropriate for repeated measures models, see PRINT Subcommand on p. 1033.

CELLINFO	*Basic information about each cell in the design.*
PARAMETERS	*Parameter estimates.*
HOMOGENEITY	*Tests of homogeneity of variance.*
DESIGN	*Design information.*
ERROR	*Error standard deviations.*

CELLINFO Keyword

You can request any of the following cell information by specifying the appropriate keyword(s) in parentheses after CELLINFO. The default is MEANS.

MEANS	*Cell means, standard deviations, and counts for the dependent variable and covariates.* Confidence intervals for the cell means are displayed if you have set a wide width. This setting is the default when CELLINFO is requested with no further specification.
SSCP	*Within-cell sum-of-squares and cross-products matrices for the dependent variable and covariates.*
COV	*Within-cell variance-covariance matrices for the dependent variable and covariates.*
COR	*Within-cell correlation matrices, with standard deviations on the diagonal, for the dependent variable and covariates.*
ALL	*MEANS, SSCP, COV, and COR.*

- Output from CELLINFO is displayed once before the analysis of any particular design. Specify CELLINFO only once.
- When you specify SSCP, COV, or COR, the cells are numbered for identification, beginning with cell 1.
- The levels vary most rapidly for the factor named last on the MANOVA variables specification.
- Empty cells are neither displayed nor numbered.
- At the beginning of MANOVA output, a table is displayed, showing the levels of each factor corresponding to each cell number.

Example

```
MANOVA DEP BY A(1,4) B(1,2) WITH COV
  /PRINT=CELLINFO(MEANS COV)
  /DESIGN.
```

- For each combination of levels of *A* and *B*, MANOVA displays separately the means and standard deviations of *DEP* and *COV*. Beginning with cell 1, MANOVA will then display the variance-covariance matrix of *DEP* and *COV* within each non-empty cell.
- A table of cell numbers will be displayed to show the factor levels corresponding to each cell.
- The keyword COV, as a parameter of CELLINFO, is not confused with the variable *COV*.

PARAMETERS Keyword

The keyword PARAMETERS displays information about the estimated size of the effects in the model. You can specify any of the following keywords in parentheses on PARAMETERS. The default is ESTIM.

ESTIM	*The estimated parameters themselves, along with their standard errors,* t *tests, and confidence intervals.* Only nonredundant parameters are displayed. This setting is the default if PARAMETERS is requested without further specification.
NEGSUM	*The negative of the sum of parameters for each effect.* For DEVIATION main effects, this value equals the parameter for the omitted (redundant) contrast. NEGSUM is displayed, along with the parameter estimates.
ORTHO	*The orthogonal estimates of parameters that are used to produce the sums of squares.*
COR	*Covariance factors and correlations among the parameter estimates.*
EFSIZE	*The effect size values.*
OPTIMAL	*Optimal Scheffé contrast coefficients.*
ALL	*ESTIM, NEGSUM, ORTHO, COR, EFSIZE, and OPTIMAL.*

SIGNIF Keyword

SIGNIF requests special significance tests, most of which apply to multivariate designs (see SIGNIF Keyword on p. 1019). The following specification is useful in univariate applications of MANOVA:

SINGLEDF	*Significance tests for each single degree of freedom making up each effect for analysis-of-variance tables.*

- When non-orthogonal contrasts are requested or when the design is unbalanced, the SINGLEDF effects will differ from single degree-of-freedom partitions. SINGLEDEF effects are orthogonal within an effect; single degree-of-freedom partitions are not orthogonal within an effect.

Example

```
MANOVA DEP BY FAC(1,5)
  /CONTRAST(FAC)=POLY
  /PRINT=SIGNIF(SINGLEDF)
  /DESIGN.
```

- POLYNOMIAL contrasts are applied to *FAC*, testing the linear, quadratic, cubic, and quartic components of its five levels. POLYNOMIAL contrasts are orthogonal in balanced designs.
- The SINGLEDF specification on SIGNIF requests significance tests for each of these four components.

HOMOGENEITY Keyword

HOMOGENEITY requests tests for the homogeneity of variance of the dependent variable across the cells of the design. You can specify one or more of the following specifications in parentheses. If HOMOGENEITY is requested without further specification, the default is ALL.

BARTLETT	*Bartlett-Box* F *test.*
COCHRAN	*Cochran's* C.
ALL	*Both BARTLETT and COCHRAN.* This setting is the default.

DESIGN Keyword

You can enter one or more of the following specifications in parentheses following the keyword DESIGN. If DESIGN is requested without further specification, the default is OVERALL.

The DECOMP and BIAS matrices can provide valuable information about the confounding of the effects and the estimability of the chosen contrasts. If two effects are confounded, the entry corresponding to them in the BIAS matrix will be nonzero; if the effects are orthogonal, the entry will be zero. This feature is particularly useful in designs with unpatterned empty cells. For further discussion of the matrices, see Bock (1985).

OVERALL	*The overall reduced-model design matrix (not the contrast matrix).* This setting is the default.
ONEWAY	*The one-way basis matrix (not the contrast matrix) for each factor.*
DECOMP	*The upper triangular QR/CHOLESKY decomposition of the design.*
BIAS	*Contamination coefficients displaying the bias that is present in the design.*
SOLUTION	*Coefficients of the linear combinations of the cell means that are used in significance testing.*
REDUNDANCY	*Exact linear combinations of parameters that form a redundancy.* This keyword displays a table only if QR (the default) is the estimation method.
COLLINEARITY	*Collinearity diagnostics for design matrices.* These diagnostics include the singular values of the normalized design matrix (which are the same as those values of the normalized decomposition matrix), condition indexes corresponding to each singular value, and the proportion of variance of the corresponding parameter accounted for by each principal component. For greatest accuracy, use the QR method of estimation whenever you request collinearity diagnostics.
ALL	*All available options.*

ERROR Keyword

Generally, the keyword ERROR on PRINT produces error matrices. In univariate analyses, the only valid specification for ERROR is STDDEV, which is the default if ERROR is specified by itself.

STDDEV	*The error standard deviation.* Normally, this deviation is the within-cells standard deviation of the dependent variable. If you specify multiple error terms on DESIGN, this specification will display the standard deviation for each term.

OMEANS Subcommand

OMEANS (observed means) displays tables of the means of continuous variables for levels or combinations of levels of the factors.

- Use the keywords VARIABLES and TABLES to indicate which observed means you want to display.
- With no specifications, the OMEANS subcommand is equivalent to requesting CELLINFO (MEANS) on PRINT.
- OMEANS displays confidence intervals for the cell means if you have set the width to 132.
- Output from OMEANS is displayed once before the analysis of any particular design. This subcommand should be specified only once.

VARIABLES *Continuous variables for which you want means.* Specify the variables in parentheses after the keyword VARIABLES. You can request means for the dependent variable or any covariates. If you omit the VARIABLES keyword, observed means are displayed for the dependent variable and all covariates. If you enter the keyword VARIABLES, you must also enter the keyword TABLES (discussed below).

TABLES *Factors for which you want the observed means displayed.* In parentheses, list the factors, or combinations of factors, separated with BY. Observed means are displayed for each level, or combination of levels, of the factors that are named (see the example below). Both weighted means and unweighted means (where all cells are weighted equally, regardless of the number of cases that they contain) are displayed. If you enter the keyword CONSTANT, the grand mean is displayed.

Example

```
MANOVA DEP BY A(1,3) B(1,2)
  /OMEANS=TABLES(A,B)
  /DESIGN.
```

- Because there is no VARIABLES specification on the OMEANS subcommand, observed means are displayed for all continuous variables. *DEP* is the only dependent variable here, and there are no covariates.
- The TABLES specification on the OMEANS subcommand requests tables of observed means for each of the three categories of *A* (collapsing over *B*) and for both categories of *B* (collapsing over *A*).
- MANOVA displays weighted means, in which all cases count equally, and displays unweighted means, in which all cells count equally.

PMEANS Subcommand

PMEANS (predicted means) displays a table of the predicted cell means of the dependent variable, adjusted for the effect of covariates in the cell and unadjusted for covariates. For comparison, PMEANS also displays the observed cell means.

- Output from PMEANS can be computationally expensive.

- PMEANS without any additional specifications displays a table showing, for each cell, the observed mean of the dependent variable, the predicted mean adjusted for the effect of covariates in that cell (*ADJ. MEAN*), the predicted mean unadjusted for covariates (*EST. MEAN*), and the raw and standardized residuals from the estimated means.
- Cells are numbered in output from PMEANS so that the levels vary most rapidly on the factor that is named last in the MANOVA variables specification. A table showing the levels of each factor corresponding to each cell number is displayed at the beginning of the MANOVA output.
- Predicted means are suppressed for any design in which the MUPLUS keyword appears.
- Covariates are not predicted.
- In designs with covariates and multiple error terms, use the ERROR subcommand to designate which error term's regression coefficients are to be used in calculating the standardized residuals.

For univariate analysis, the following keywords are available on the PMEANS subcommand:

TABLES *Additional tables showing adjusted predicted means for specified factors or combinations of factors.* Enter the names of factors or combinations of factors in parentheses after this keyword. For each factor or combination, MANOVA displays the predicted means (adjusted for covariates) collapsed over all other factors.

PLOT *A plot of the predicted means for each cell.*

Example

```
MANOVA DEP BY A(1,4) B(1,3)
  /PMEANS TABLES(A, B, A BY B)
  /DESIGN = A, B.
```

- PMEANS displays the default table of observed and predicted means for *DEP* and raw and standardized residuals in each of the 12 cells in the model.
- The TABLES specification on PMEANS displays tables of predicted means for *A* (collapsing over *B*), for *B* (collapsing over *A*), and for all combinations of *A* and *B*.
- Because *A* and *B* are the only factors in the model, the means for *A* by *B* in the TABLES specification come from every cell in the model. The means are identical to the adjusted predicted means in the default PMEANS table, which always includes all non-empty cells.
- Predicted means for *A* by *B* can be requested in the TABLES specification, even though the *A* by *B* effect is not in the design.

RESIDUALS Subcommand

Use RESIDUALS to display and plot casewise values and residuals for your models.

- Use the ERROR subcommand to specify an error term other than the default to be used to standardize the residuals.
- If a designated error term does not exist for a given design, no predicted values or residuals are calculated.
- If you specify RESIDUALS without any keyword, CASEWISE output is displayed.

The following keywords are available:

CASEWISE	*A case-by-case listing of the observed, predicted, residual, and standardized residual values for each dependent variable.*
PLOT	*A plot of observed values, predicted values, and case numbers versus the standardized residuals, plus normal and detrended normal probability plots for the standardized residuals (five plots in all).*

POWER Subcommand

POWER requests observed power values based on fixed-effect assumptions for all univariate and multivariate *F* tests and *t* tests. Both approximate and exact power values can be computed, although exact multivariate power is displayed only when there is one hypothesis degree of freedom. If POWER is specified by itself, with no keywords, MANOVA calculates the approximate observed power values of all *F* tests at 0.05 significance level.

The following keywords are available on the POWER subcommand:

APPROXIMATE	*Approximate power values.* This setting is the default if POWER is specified without any keyword. Approximate power values for univariate tests are derived from an Edgeworth-type normal approximation to the noncentral beta distribution. Approximate values are normally accurate to three decimal places and are much cheaper to compute than exact values.
EXACT	*Exact power values.* Exact power values for univariate tests are computed from the noncentral incomplete beta distribution.
F(a)	*Alpha level at which the power is to be calculated for* F *tests*. The default is 0.05. To change the default, specify a decimal number between 0 and 1 in parentheses after *F*. The numbers 0 and 1 themselves are not allowed. *F* test at 0.05 significance level is the default when POWER is omitted or specified without any keyword.
T(a)	*Alpha level at which the power is to be calculated for* t *tests.* The default is 0.05. To change the default, specify a decimal number between 0 and 1 in parentheses after *t*. The numbers 0 and 1 themselves are not allowed.

- For univariate *F* tests and *t* tests, MANOVA computes a measure of the effect size based on partial η^2:

  partial $\eta^2 = (ssh)/(ssh + sse)$

  where *ssh* is the hypothesis sum of squares and *sse* is the error sum of squares. The measure is an overestimate of the actual effect size. However, the measure is consistent and is applicable to all *F* tests and *t* tests. For a discussion of effect size measures, see (Cohen, 1977) or (Hays, 1981).

CINTERVAL Subcommand

CINTERVAL requests simultaneous confidence intervals for each parameter estimate and regression coefficient. MANOVA provides either individual or joint confidence intervals at any desired confidence level. You can compute joint confidence intervals that are using either Scheffé or Bonferroni intervals. Scheffé intervals are based on all possible contrasts, while Bonferroni intervals are based on the number of contrasts that are actually made. For a large number of

contrasts, Bonferroni intervals will be larger than Scheffé intervals. Timm (Timm, 1975) provides a good discussion of which intervals are best for certain situations. Both Scheffé and Bonferroni intervals are computed separately for each term in the design. You can request only one type of confidence interval per design.

The following keywords are available on the CINTERVAL subcommand. If the subcommand is specified without any keyword, CINTERVAL automatically displays individual univariate confidence intervals at the 0.95 level.

INDIVIDUAL(a) *Individual confidence intervals.* Specify the desired confidence level in parentheses following the keyword. The desired confidence level can be any decimal number between 0 and 1. When individual intervals are requested, BONFER and SCHEFFE have no effect.

JOINT(a) *Joint confidence intervals.* Specify the desired confidence level in parentheses after the keyword. The default is 0.95. The desired confidence level can be any decimal number between 0 and 1.

UNIVARIATE(type) *Univariate confidence interval.* Specify either SCHEFFE (for Scheffé intervals) or BONFER (for Bonferroni intervals) in parentheses after the keyword. The default specification is SCHEFFE.

PLOT Subcommand

MANOVA can display a variety of plots that are useful in checking the assumptions that are needed in the analysis. Plots are produced only once in the MANOVA procedure, regardless of how many DESIGN subcommands you enter. Use the following keywords on the PLOT subcommand to request plots. If the PLOT subcommand is specified by itself, the default is BOXPLOTS.

BOXPLOTS *Boxplots.* Plots are displayed for each continuous variable (dependent or covariate) that is named on the MANOVA variable list. Boxplots provide a simple graphical means of comparing the cells in terms of mean location and spread. The data must be stored in memory for these plots; if there is not enough memory, boxplots are not produced, and a warning message is issued. This setting is the default if the PLOT subcommand is specified without a keyword.

CELLPLOTS *Cell statistics, including a plot of cell means versus cell variances, a plot of cell means versus cell standard deviations, and a histogram of cell means.* Plots are produced for each continuous variable (dependent or covariate) that is named on the MANOVA variable list. The first two plots aid in detecting heteroscedasticity (nonhomogeneous variances) and aid in determining an appropriate data transformation (if a transformation is needed). The third plot gives distributional information for the cell means.

NORMAL *Normal and detrended normal plots.* Plots are produced for each continuous variable (dependent or covariate) that is named on the MANOVA variable list. MANOVA ranks the scores and then plots the ranks against the expected normal deviate, or detrended expected normal deviate, for that rank. These plots aid in detecting non-normality and outlying observations. All data must be held in memory to compute ranks. If not enough memory is available, MANOVA displays a warning and skips the plots.

- ZCORR, an additional plot that is available on the PLOT subcommand, is described in *MANOVA: Multivariate*.
- You can request other plots on PMEANS and RESIDUALS (see these respective subcommands).

MISSING Subcommand

By default, cases with missing values for any of the variables on the MANOVA variable list are excluded from the analysis. The MISSING subcommand allows you to include cases with user-missing values. If MISSING is not specified, the defaults are LISTWISE and EXCLUDE.

- The same missing-value treatment is used to process all designs in a single execution of MANOVA.
- If you enter more than one MISSING subcommand, the last subcommand that was entered will be in effect for the entire procedure, including designs that were specified before the last MISSING subcommand.
- Pairwise deletion of missing data is not available in MANOVA.
- Keywords INCLUDE and EXCLUDE are mutually exclusive; either keyword can be specified with LISTWISE.

LISTWISE	*Cases with missing values for any variable that is named on the MANOVA variable list are excluded from the analysis.* This process is always true in the MANOVA procedure.
EXCLUDE	*Both user-missing and system-missing values are excluded.* This setting is the default when MISSING is not specified.
INCLUDE	*User-missing values are treated as valid.* For factors, you must include the missing-value codes within the range that is specified on the MANOVA variable list. It may be necessary to recode these values so that they will be adjacent to the other factor values. System-missing values cannot be included in the analysis.

MATRIX Subcommand

MATRIX reads and writes matrix data files. MATRIX writes correlation matrices that can be read by subsequent MANOVA procedures.

- Either IN or OUT is required to specify the matrix file in parentheses. When both IN and OUT are used on the same MANOVA procedure, they can be specified on separate MATRIX subcommands or on the same subcommand.
- The matrix materials include the *N*, mean, and standard deviation. Documents from the file that form the matrix are not included in the matrix data file.
- MATRIX=IN cannot be used in place of GET or DATA LIST to begin a new command syntax file. MATRIX is a subcommand on MANOVA, and MANOVA cannot run before an active dataset is defined. To begin a new command file and immediately read a matrix, first use GET to retrieve the matrix file, and then specify IN(*) on MATRIX.
- Records in the matrix data file that is read by MANOVA can be in any order, with the following exceptions: The order of split-file groups cannot be violated, and all *CORR* vectors must appear contiguously within each split-file group.
- When MANOVA reads matrix materials, it ignores the record containing the total number of cases. In addition, MANOVA skips unrecognized records. MANOVA does not issue a warning when it skips records.

The following two keywords are available on the MATRIX subcommand:

OUT *Write a matrix data file.* Specify either a file or an asterisk, and enclose the specification in parentheses. If you specify a file, the file is stored on disk and can be retrieved at any time. If you specify an asterisk (*) or leave the parentheses empty, the matrix file replaces the active dataset but is not stored on disk unless you use SAVE or XSAVE.

IN *Read a matrix data file.* If the matrix file *is not* the current active dataset, specify a file in parentheses. If the matrix file *is* the current active dataset, specify an asterisk (*) or leave the parentheses empty.

Format of the Matrix Data File

The matrix data file includes two special variables: *ROWTYPE_* and *VARNAME_*.

- Variable *ROWTYPE_* is a short string variable having values *N*, *MEAN*, *CORR* (for Pearson correlation coefficients), and *STDDEV*.
- Variable *VARNAME_* is a short string variable whose values are the names of the variables and covariates that are used to form the correlation matrix. When *ROWTYPE_* is *CORR*, *VARNAME_* gives the variable that is associated with that row of the correlation matrix.
- Between *ROWTYPE_* and *VARNAME_* are the factor variables (if any) that are defined in the BY portion of the MANOVA variable list. (Factor variables receive the system-missing value on vectors that represent pooled values.)
- Remaining variables are the variables that are used to form the correlation matrix.

Split Files and Variable Order

- When split-file processing is in effect, the first variables in the matrix system file will be the split variables, followed by *ROWTYPE_*, the factor variable(s), *VARNAME_*, and then the variables that are used to form the correlation matrix.
- A full set of matrix materials is written for each subgroup that is defined by the split variable(s).
- A split variable cannot have the same variable name as any other variable that is written to the matrix data file.
- If a split file is in effect when a matrix is written, the same split file must be in effect when that matrix is read into another procedure.

Additional Statistics

In addition to the *CORR* values, MANOVA always includes the following with the matrix materials:

- The total weighted number of cases used to compute each correlation coefficient.
- A vector of *N*'s for each cell in the data.
- A vector of *MEAN*'s for each cell in the data.
- A vector of pooled standard deviations, *STDDEV*, which is the square root of the within-cells mean square error for each variable.

Example

```
GET FILE IRIS.
MANOVA SEPALLEN SEPALWID PETALLEN PETALWID BY TYPE(1,3)
  /MATRIX=OUT(MANMTX).
```

- MANOVA reads data from the SPSS data file *IRIS* and writes one set of matrix materials to the file *MANMTX*.
- The active dataset is still *IRIS*. Subsequent commands are executed on the file *IRIS*.

Example

```
GET FILE IRIS.
MANOVA SEPALLEN SEPALWID PETALLEN PETALWID BY TYPE(1,3)
  /MATRIX=OUT(*).
LIST.
```

- MANOVA writes the same matrix as in the example above. However, the matrix file replaces the active dataset. The LIST command is executed on the matrix file (not on the file *IRIS*).

Example

```
GET FILE=PRSNNL.
FREQUENCIES VARIABLE=AGE.

MANOVA SEPALLEN SEPALWID PETALLEN PETALWID BY TYPE(1,3)
  /MATRIX=IN(MANMTX).
```

- This example assumes that you want to perform a frequencies analysis on the file *PRSNNL* and then use MANOVA to read a different file. The file that you want to read is an existing matrix data file. The external matrix file *MANMTX* is specified in parentheses after IN on the MATRIX subcommand.
- *MANMTX* does not replace *PRSNNL* as the active dataset.

Example

```
GET FILE=MANMTX.
MANOVA SEPALLEN SEPALWID PETALLEN PETALWID BY TYPE(1,3)
  /MATRIX=IN(*).
```

- This example assumes that you are starting a new session and want to read an existing matrix data file. GET retrieves the matrix file *MANMTX*.
- An asterisk is specified in parentheses after IN on the MATRIX subcommand to read the active dataset. You can also leave the parentheses empty to indicate the default.
- If the GET command is omitted, an error message is issued.
- If you specify *MANMTX* in parentheses after IN, an error message is issued.

ANALYSIS Subcommand

ANALYSIS allows you to work with a subset of the continuous variables (dependent variable and covariates) that you named on the MANOVA variable list. In univariate analysis of variance, you can use ANALYSIS to allow factor-by-covariate interaction terms in your model (see the DESIGN

subcommand below). You can also use ANALYSIS to switch the roles of the dependent variable and a covariate.

- In general, ANALYSIS gives you complete control over which continuous variables are to be dependent variables, which continuous variables are to be covariates, and which continuous variables are to be neither.
- ANALYSIS specifications are like the MANOVA variables specification, except that factors are not named. Enter the dependent variable and, if there are covariates, the keyword WITH and the covariates.
- Only variables that are listed as dependent variables or covariates on the MANOVA variable list can be entered on the ANALYSIS subcommand.
- In a univariate analysis of variance, the most important use of ANALYSIS is to omit covariates from the analysis list, thereby making them available for inclusion on DESIGN (see the example below and the DESIGN subcommand examples).
- For more information about ANALYSIS, refer to *MANOVA: Multivariate*.

Example

```
MANOVA DEP BY FACTOR(1,3) WITH COV
  /ANALYSIS DEP
  /DESIGN FACTOR, COV, FACTOR BY COV.
```

- *COV*, a continuous variable, is included on the MANOVA variable list as a covariate.
- *COV* is not mentioned on ANALYSIS, so it will not be included in the model as a dependent variable or covariate. *COV* can, therefore, be explicitly included on the DESIGN subcommand.
- DESIGN includes the main effects of *FACTOR* and *COV* and the *FACTOR* by *COV* interaction.

DESIGN Subcommand

DESIGN specifies the effects that are included in a specific model. DESIGN must be the last subcommand entered for any model.

The cells in a design are defined by all of the possible combinations of levels of the factors in that design. The number of cells equals the product of the number of levels of all the factors. A design is *balanced* if each cell contains the same number of cases. MANOVA can analyze both balanced and unbalanced designs.

- Specify a list of terms to be included in the model, separated by spaces or commas.
- The default design, if the DESIGN subcommand is omitted or is specified by itself, is a full factorial model containing all main effects and all orders of factor-by-factor interaction.
- If the last subcommand that is specified is not DESIGN, a default full factorial design is estimated.
- To include a term for the main effect of a factor, enter the name of the factor on the DESIGN subcommand.
- To include a term for an interaction between factors, use the keyword BY to join the factors that are involved in the interaction.

- Terms are entered into the model in the order in which you list them on DESIGN. If you have specified SEQUENTIAL on the METHOD subcommand to partition the sums of squares in a hierarchical fashion, this order may affect the significance tests.
- You can specify other types of terms in the model, as described in the following sections.
- Multiple DESIGN subcommands are accepted. An analysis of one model is produced for each DESIGN subcommand.

Example

```
MANOVA Y BY A(1,2) B(1,2) C(1,3)
  /DESIGN
  /DESIGN A, B, C
  /DESIGN A, B, C, A BY B, A BY C.
```

- The first DESIGN produces the default full factorial design, with all main effects and interactions for factors *A*, *B*, and *C*.
- The second DESIGN produces an analysis with main effects only for *A*, *B*, and *C*.
- The third DESIGN produces an analysis with main effects and the interactions between *A* and the other two factors. The interaction between *B* and *C* is not in the design, nor is the interaction between all three factors.

Partitioned Effects: Number in Parentheses

You can specify a number in parentheses following a factor name on the DESIGN subcommand to identify individual degrees of freedom or partitions of the degrees of freedom that are associated with an effect.

- If you specify PARTITION, the number refers to a partition. Partitions can include more than one degree of freedom (see PARTITION Subcommand on p. 992). For example, if the first partition of *SEED* includes two degrees of freedom, the term SEED(1) on a DESIGN subcommand tests the two degrees of freedom.
- If you do not use PARTITION, the number refers to a single degree of freedom that is associated with the effect.
- The number refers to an individual level for a factor if that factor follows the keyword WITHIN or MWITHIN (see the sections about nested effects and pooled effects below).
- A factor has one less degree of freedom than it has levels or values.

Example

```
MANOVA YIELD BY SEED(1,4) WITH RAINFALL
  /PARTITION(SEED)=(2,1)
  /DESIGN=SEED(1) SEED(2).
```

- Factor *SEED* is subdivided into two partitions, one partition containing the first two degrees of freedom and the other partition containing the last degree of freedom.
- The two partitions of *SEED* are treated as independent effects.

Nested Effects: WITHIN Keyword

Use the `WITHIN` keyword (alias `W`) to nest the effects of one factor within the effects of another factor or an interaction term.

Example

```
MANOVA YIELD BY SEED(1,4) FERT(1,3) PLOT (1,4)
  /DESIGN = FERT WITHIN SEED BY PLOT.
```

- The three factors in this example are type of seed (*SEED*), type of fertilizer (*FERT*), and location of plots (*PLOT*).
- The `DESIGN` subcommand nests the effects of *FERT* within the interaction term of *SEED* by *PLOT*. The levels of *FERT* are considered distinct for each combination of levels of *SEED* and *PLOT*.

Simple Effects: WITHIN and MWITHIN Keywords

A factor can be nested within one specific level of another factor by indicating the level in parentheses. This process allows you to estimate simple effects or the effect of one factor within only one level of another factor. Simple effects can be obtained for higher-order interactions as well.

Use `WITHIN` to request simple effects of between-subjects factors.

Example

```
MANOVA YIELD BY SEED(2,4) FERT(1,3) PLOT (1,4)
  /DESIGN = FERT WITHIN SEED (1).
```

- This example requests the simple effect of *FERT* within the first level of *SEED*.
- The number (*n*) specified after a `WITHIN` factor refers to the level of that factor. The value is the ordinal position, which is not necessarily the value of that level. In this example, the first level is associated with value 2.
- The number does *not* refer to the number of partitioned effects (see PARTITION Subcommand on p. 992).

Example

```
MANOVA YIELD BY SEED(2,4) FERT(1,3) PLOT (3,5)
 /DESIGN = FERT WITHIN PLOT(1) WITHIN SEED(2)
```

- This example requests the effect of *FERT* within the second *SEED* level of the first *PLOT* level.
- The second *SEED* level is associated with value 3, and the first *PLOT* level is associated with value 3.

Use `MWITHIN` to request simple effects of within-subjects factors in repeated measures analysis (see MWITHIN Keyword for Simple Effects on p. 1031).

Pooled Effects: Plus Sign

To pool different effects for the purpose of significance testing, join the effects with a plus sign (+). A single test is made for the combined effect of the pooled terms.

- The keyword BY is evaluated before effects are pooled together.
- Parentheses are not allowed for changing the order of evaluation. For example, it is illegal to specify (A + B) BY C. You must specify /DESIGN=A BY C + B BY C.

Example

```
MANOVA Y BY A(1,3) B(1,4) WITH X
 /ANALYSIS=Y
 /DESIGN=A, B, A BY B, A BY X + B BY X + A BY B BY X.
```

- This example shows how to test homogeneity of regressions in a two-way analysis of variance.
- The + signs are used to produce a pooled test of all interactions involving the covariate *X*. If this test is significant, the assumption of homogeneity of variance is questionable.

MUPLUS Keyword

MUPLUS combines the constant term (μ) in the model with the term that is specified after it. The normal use of this specification is to obtain parameter estimates that represent weighted means for the levels of some factor. For example, MUPLUS SEED represents the constant, or overall, mean plus the effect for each level of *SEED*. The significance of such effects is usually uninteresting, but the parameter estimates represent the weighted means for each level of *SEED*, adjusted for any covariates in the model.

- MUPLUS cannot appear more than once on a given DESIGN subcommand.
- MUPLUS is the only way to get standard errors for the predicted mean for each level of the specified factor.
- Parameter estimates are not displayed by default; you must explicitly request them on the PRINT subcommand or via a CONTRAST subcommand.
- You can obtain the unweighted mean by specifying the full factorial model, excluding those terms that are contained by an effect, and prefixing the effect whose mean is to be found by MUPLUS.

Effects of Continuous Variables

Usually you name factors but not covariates on the DESIGN subcommand. The linear effects of covariates are removed from the dependent variable before the design is tested. However, the design can include variables that are measured at the interval level and originally named as covariates or as additional dependent variables.

- Continuous variables on a DESIGN subcommand must be named as dependents or covariates on the MANOVA variable list.

- Before you can name a continuous variable on a DESIGN subcommand, you must supply an ANALYSIS subcommand that does *not* name the variable. This action excludes it from the analysis as a dependent variable or covariate and makes it eligible for inclusion on DESIGN.
- You can use the keyword POOL(varlist) to pool more than one continuous variable into a single effect (provided that the continuous variables are all excluded on an ANALYSIS subcommand). For a single continuous variable, POOL(VAR) is equivalent to VAR.
- The TO convention in the variable list for POOL refers to the order of continuous variables (dependent variables and covariates) on the original MANOVA variable list, which is not necessarily their order on the active dataset. This use is the only allowable use of the keyword TO on a DESIGN subcommand.
- You can specify interaction terms between factors and continuous variables. If *FAC* is a factor and *COV* is a covariate that has been omitted from an ANALYSIS subcommand, FAC BY COV is a valid specification on a DESIGN statement.
- You cannot specify an interaction between two continuous variables. Use the COMPUTE command to create a variable representing the interaction prior to MANOVA.

Example

```
*  This example tests whether the regression of the dependent
   variable Y on the two variables X1 and X2 is the same across
   all the categories of the factors AGE and TREATMNT.

MANOVA Y BY AGE(1,5) TREATMNT(1,3) WITH X1, X2
  /ANALYSIS = Y
  /DESIGN = POOL(X1,X2),
            AGE, TREATMNT, AGE BY TREATMNT,
            POOL(X1,X2) BY AGE + POOL(X1,X2) BY TREATMNT
              + POOL(X1,X2) BY AGE BY TREATMNT.
```

- ANALYSIS excludes *X1* and *X2* from the standard treatment of covariates so that they can be used in the design.
- DESIGN includes five terms. POOL(X1,X2), the overall regression of the dependent variable on *X1* and *X2*, is entered first, followed by the two factors and their interaction.
- The last term is the test for equal regressions. It consists of three factor-by-continuous-variable interactions pooled together. POOL(X1,X2) BY AGE is the interaction between *AGE* and the combined effect of the continuous variables *X1* and *X2*. It is combined with similar interactions between *TREATMNT* and the continuous variables and between the *AGE* by *TREATMNT* interaction and the continuous variables.
- If the last term is not statistically significant, there is no evidence that the regression of *Y* on *X1* and *X2* is different across any combination of the categories of *AGE* and *TREATMNT*.

Error Terms for Individual Effects

The "error" sum of squares against which terms in the design are tested is specified on the ERROR subcommand. For any particular term on a DESIGN subcommand, you can specify a different error term to be used in the analysis of variance. To do so, name the term followed by the keyword VS (or AGAINST) and the error term keyword.

- To test a term against only the within-cells sum of squares, specify the term followed by VS WITHIN on the DESIGN subcommand. For example, GROUP VS WITHIN tests the effect of the factor *GROUP* against only the within-cells sum of squares. For most analyses, this term is the default error term.
- To test a term against only the residual sum of squares (the sum of squares for all terms that are not included in your DESIGN), specify the term followed by VS RESIDUAL.
- To test against the combined within-cells and residual sums of squares, specify the term followed by VS WITHIN+RESIDUAL.
- To test against any other sum of squares in the analysis of variance, include a term corresponding to the desired sum of squares in the design and assign it to an integer between 1 and 10. You can then test against the number of the error term. It is often convenient to test against the term before you define it. This process is perfectly acceptable as long as you define the error term on the same DESIGN subcommand.

Example

```
MANOVA DEP BY A, B, C (1,3)
  /DESIGN=A VS 1,
          B WITHIN A = 1 VS 2,
          C WITHIN B WITHIN A = 2 VS WITHIN.
```

- In this example, the factors *A*, *B*, and *C* are completely nested; levels of *C* occur within levels of *B*, which occur within levels of *A*. Each factor is tested against everything within it.
- *A*, the outermost factor, is tested against the *B* within *A* sum of squares, to see if it contributes anything beyond the effects of *B* within each of its levels. The *B* within *A* sum of squares is defined as error term number 1.
- *B* nested within *A*, in turn, is tested against error term number 2, which is defined as the *C* within *B* within *A* sum of squares.
- Finally, *C* nested within *B* nested within *A* is tested against the within-cells sum of squares.

User-defined error terms are specified by simply inserting = n after a term, where *n* is an integer from 1 to 10. The equals sign is required. Keywords that are used in building a design term, such as BY or WITHIN, are evaluated first. For example, error term number 2 in the above example consists of the entire term C WITHIN B WITHIN A. An error-term *number,* but not an error-term *definition,* can follow the keyword VS.

CONSTANT Keyword

By default, the constant (grand mean) term is included as the first term in the model.

- If you have specified NOCONSTANT on the METHOD subcommand, a constant term will not be included in any design unless you request it with the CONSTANT keyword on DESIGN.
- You can specify an error term for the constant.
- A factor named CONSTANT will not be recognized on the DESIGN subcommand.

* The DESIGN subcommand has the same syntax as is described in *MANOVA: Univariate*.

**Default if the subcommand or keyword is omitted.

Example

```
MANOVA SCORE1 TO SCORE4 BY METHOD(1,3).
```

Overview

This section discusses the subcommands that are used in multivariate analysis of variance and covariance designs with several interrelated dependent variables. The discussion focuses on subcommands and keywords that do not apply, or apply in different manners, to univariate analyses. It does not contain information on all of the subcommands you will need to specify the design. For subcommands not covered here, see *MANOVA: Univariate*.

Options

Dependent Variables and Covariates. You can specify subsets and reorder the dependent variables and covariates using the ANALYSIS subcommand. You can specify linear transformations of the dependent variables and covariates using the TRANSFORM subcommand. When transformations are performed, you can rename the variables using the RENAME subcommand and request the display of a transposed transformation matrix currently in effect using the PRINT subcommand.

Optional Output. You can request or suppress output on the PRINT and NOPRINT subcommands. Additional output appropriate to multivariate analysis includes error term matrices, Box's *M* statistic, multivariate and univariate *F* tests, and other significance analyses. You can also request predicted cell means for specific dependent variables on the PMEANS subcommand, produce a canonical discriminant analysis for each effect in your model with the DISCRIM subcommand, specify a principal components analysis of each error sum-of-squares and cross-product matrix in a multivariate analysis on the PCOMPS subcommand, display multivariate confidence intervals using the CINTERVAL subcommand, and generate a half-normal plot of the within-cells correlations among the dependent variables with the PLOT subcommand.

Basic Specification

- The basic specification is a variable list identifying the dependent variables, with the factors (if any) named after BY and the covariates (if any) named after WITH.
- By default, MANOVA produces multivariate and univariate *F* tests.

Subcommand Order

- The variable list must be specified first.
- Subcommands applicable to a specific design must be specified before that DESIGN subcommand. Otherwise, subcommands can be used in any order.

Syntax Rules

- All syntax rules applicable to univariate analysis also apply to multivariate analysis.
- If you enter one of the multivariate specifications in a univariate analysis, MANOVA ignores it.

Limitations

- Maximum of 20 factors.
- Memory requirements depend primarily on the number of cells in the design. For the default full factorial model, the number of cells equals the product of the number of levels or categories in each factor.

MANOVA Variable List

- Multivariate MANOVA calculates statistical tests that are valid for analyses of dependent variables that are correlated with one another. The dependent variables must be specified first.
- The factor and covariate lists follow the same rules as in univariate analyses.
- If the dependent variables are uncorrelated, the univariate significance tests have greater statistical power.

TRANSFORM Subcommand

TRANSFORM performs linear transformations of some or all of the continuous variables (dependent variables and covariates). Specifications on TRANSFORM include an optional list of variables to be transformed, optional keywords to describe how to generate a transformation matrix from the specified contrasts, and a required keyword specifying the transformation contrasts.

- Transformations apply to all subsequent designs unless replaced by another TRANSFORM subcommand.
- TRANSFORM subcommands are not cumulative. Only the transformation specified most recently is in effect at any time. You can restore the original variables in later designs by specifying SPECIAL with an identity matrix.
- You should not use TRANSFORM when you use the WSFACTORS subcommand to request repeated measures analysis; a transformation is automatically performed in repeated measures analysis (see *MANOVA: Repeated Measures* on p. 1025).
- Transformations are in effect for the duration of the MANOVA procedure only. After the procedure is complete, the original variables remain in the active dataset.
- By default, the transformation matrix is not displayed. Specify the keyword TRANSFORM on the PRINT subcommand to see the matrix generated by the TRANSFORM subcommand.
- If you do not use the RENAME subcommand with TRANSFORM, the variables specified on TRANSFORM are renamed temporarily (for the duration of the procedure) as *T1*, *T2*, and so on. Explicit use of RENAME is recommended.
- Subsequent references to transformed variables should use the new names. The only exception is when you supply a VARIABLES specification on the OMEANS subcommand after using TRANSFORM. In this case, specify the original names. OMEANS displays observed means of original variables. See OMEANS Subcommand on p. 998.

Variable Lists

- By default, MANOVA applies the transformation you request to all continuous variables (dependent variables and covariates).
- You can enter a variable list in parentheses following the TRANSFORM subcommand. If you do, only the listed variables are transformed.

- You can enter multiple variable lists, separated by slashes, within a single set of parentheses. Each list must have the same number of variables, and the lists must not overlap. The transformation is applied separately to the variables on each list.
- In designs with covariates, transform only the dependent variables, or, in some designs, apply the same transformation separately to the dependent variables and the covariates.

CONTRAST, BASIS, and ORTHONORM Keywords

You can control how the transformation matrix is to be generated from the specified contrasts. If none of these three keywords is specified on TRANSFORM, the default is CONTRAST.

CONTRAST *Generate the transformation matrix directly from the contrast matrix specified* (see CONTRAST Subcommand on p. 990). This is the default.

BASIS *Generate the transformation matrix from the one-way basis matrix corresponding to the specified contrast matrix.* BASIS makes a difference only if the transformation contrasts are not orthogonal.

ORTHONORM *Orthonormalize the transformation matrix by rows before use.* MANOVA eliminates redundant rows. By default, orthonormalization is not done.

- CONTRAST and BASIS are alternatives and are mutually exclusive.
- ORTHONORM is independent of the CONTRAST/BASIS choice; you can enter it before or after either of those keywords.

Transformation Methods

To specify a transformation method, use one of the following keywords available on the TRANSFORM subcommand. Note that these are identical to the keywords available for the CONTRAST subcommand (see CONTRAST Subcommand on p. 990). However, in univariate designs, they are applied to the different levels of a factor. Here they are applied to the continuous variables in the analysis. This reflects the fact that the different dependent variables in a multivariate MANOVA setup can often be thought of as corresponding to different levels of some factor.

- The transformation keyword (and its specifications, if any) must follow all other specifications on the TRANSFORM subcommand.

DEVIATION *Deviations from the mean of the variables being transformed.* The first transformed variable is the mean of all variables in the transformation. Other transformed variables represent deviations of individual variables from the mean. One of the original variables (by default, the last) is omitted as redundant. To omit a variable other than the last, specify the number of the variable to be omitted in parentheses after the DEVIATION keyword. For example,

```
/TRANSFORM (A B C) = DEVIATION(1)
```

omits *A* and creates variables representing the mean, the deviation of *B* from the mean, and the deviation of *C* from the mean. A DEVIATION transformation is not orthogonal.

DIFFERENCE *Difference or reverse Helmert transformation.* The first transformed variable is the mean of the original variables. Each of the original variables except the first is then transformed by subtracting the mean of those (original) variables that precede it. A DIFFERENCE transformation is orthogonal.

HELMERT *Helmert transformation.* The first transformed variable is the mean of the original variables. Each of the original variables except the last is then transformed by subtracting the mean of those (original) variables that follow it. A HELMERT transformation is orthogonal.

SIMPLE *Each original variable, except the last, is compared to the last of the original variables.* To use a variable other than the last as the omitted reference variable, specify its number in parentheses following the keyword SIMPLE. For example,

/TRANSFORM(A B C) = SIMPLE(2)

specifies the second variable, *B*, as the reference variable. The three transformed variables represent the mean of *A*, *B*, and *C*, the difference between *A* and *B*, and the difference between *C* and *B*. A SIMPLE transformation is not orthogonal.

POLYNOMIAL *Orthogonal polynomial transformation.* The first transformed variable represents the mean of the original variables. Other transformed variables represent the linear, quadratic, and higher-degree components. By default, values of the original variables are assumed to represent equally spaced points. You can specify unequal spacing by entering a metric consisting of one integer for each variable in parentheses after the keyword POLYNOMIAL. For example,

/TRANSFORM(RESP1 RESP2 RESP3) = POLYNOMIAL(1,2,4)

might indicate that three response variables correspond to levels of some stimulus that are in the proportion 1:2:4. The default metric is always (1,2,..., *k*), where *k* variables are involved. Only the relative differences between the terms of the metric matter: (1,2,4) is the same metric as (2,3,5) or (20,30,50) because in each instance the difference between the second and third numbers is twice the difference between the first and second.

REPEATED *Comparison of adjacent variables.* The first transformed variable is the mean of the original variables. Each additional transformed variable is the difference between one of the original variables and the original variable that followed it. Such transformed variables are often called *difference scores.* A REPEATED transformation is not orthogonal.

SPECIAL *A user-defined transformation.* After the keyword SPECIAL, enter a square matrix in parentheses with as many rows and columns as there are variables to transform. MANOVA multiplies this matrix by the vector of original variables to obtain the transformed variables (see the examples below).

Example

```
MANOVA X1 TO X3 BY A(1,4)
  /TRANSFORM(X1 X2 X3) = SPECIAL( 1  1  1,
                                  1  0 -1,
                                  2 -1 -1)
  /DESIGN.
```

- The given matrix will be post-multiplied by the three continuous variables (considered as a column vector) to yield the transformed variables. The first transformed variable will therefore equal *X1 + X2 + X3*, the second will equal *X1 − X3*, and the third will equal *2X1 − X2 − X3*.
- The variable list is optional in this example since all three interval-level variables are transformed.
- You do not need to enter the matrix one row at a time, as shown above. For example,

  /TRANSFORM = SPECIAL(1 1 1 1 0 -1 2 -1 -1)

is equivalent to the TRANSFORM specification in the above example.

- You can specify a repetition factor followed by an asterisk to indicate multiple consecutive elements of a SPECIAL transformation matrix. For example,

  /TRANSFORM = SPECIAL (4*1 0 -1 2 2*-1)

  is again equivalent to the TRANSFORM specification above.

Example

```
MANOVA X1 TO X3, Y1 TO Y3 BY A(1,4)
 /TRANSFORM (X1 X2 X3/Y1 Y2 Y3) = SPECIAL( 1  1  1,
                                           1  0 -1,
                                           2 -1 -1)
 /DESIGN.
```

- Here the same transformation shown in the previous example is applied to *X1*, *X2*, *X3* and to *Y1*, *Y2*, *Y3*.

RENAME Subcommand

Use RENAME to assign new names to transformed variables. Renaming variables after a transformation is strongly recommended. If you transform but do not rename the variables, the names *T1*, *T2*, ...,*Tn* are used as names for the transformed variables.

- Follow RENAME with a list of new variable names.
- You must enter a new name for each dependent variable and covariate on the MANOVA variable list.
- Enter the new names in the order in which the original variables appeared on the MANOVA variable list.
- To retain the original name for one or more of the interval variables, you can either enter an asterisk or reenter the old name as the new name.
- References to dependent variables and covariates on subcommands following RENAME must use the new names. The original names will not be recognized within the MANOVA procedure. The only exception is the OMEANS subcommand, which displays observed means of the original (untransformed) variables. Use the original names on OMEANS.
- The new names exist only during the MANOVA procedure that created them. They do not remain in the active dataset after the procedure is complete.

Example

```
MANOVA A, B, C, V4, V5 BY TREATMNT(1,3)
  /TRANSFORM(A, B, C) = REPEATED
  /RENAME = MEANABC, AMINUSB, BMINUSC, *, *
  /DESIGN.
```

- The REPEATED transformation produces three transformed variables, which are then assigned mnemonic names *MEANABC*, *AMINUSB*, and *BMINUSC*.
- *V4* and *V5* retain their original names.

Example

```
MANOVA WT1, WT2, WT3, WT4 BY TREATMNT(1,3) WITH COV
  /TRANSFORM (WT1 TO WT4) = POLYNOMIAL
  /RENAME = MEAN, LINEAR, QUAD, CUBIC, *
  /ANALYSIS = MEAN, LINEAR, QUAD WITH COV
  /DESIGN.
```

- After the polynomial transformation of the four *WT* variables, RENAME assigns appropriate names to the various trends.
- Even though only four variables were transformed, RENAME applies to all five continuous variables. An asterisk is required to retain the original name for *COV*.
- The ANALYSIS subcommand following RENAME refers to the interval variables by their new names.

PRINT and NOPRINT Subcommands

All of the PRINT specifications described in *MANOVA: Univariate* are available in multivariate analyses. The following additional output can be requested. To suppress any optional output, specify the appropriate keyword on NOPRINT.

ERROR	*Error matrices.* Three types of matrices are available.
SIGNIF	*Significance tests.*
TRANSFORM	*Transformation matrix.* It is available if you have transformed the dependent variables with the TRANSFORM subcommand.
HOMOGENEITY	*Test for homogeneity of variance.* BOXM is available for multivariate analyses.

ERROR Keyword

In multivariate analysis, error terms consist of entire matrices, not single values. You can display any of the following error matrices on a PRINT subcommand by requesting them in parentheses following the keyword ERROR. If you specify ERROR by itself, without further specifications, the default is to display COV and COR.

SSCP	*Error sums-of-squares and cross-products matrix.*
COV	*Error variance-covariance matrix.*
COR	*Error correlation matrix with standard deviations on the diagonal.* This also displays the determinant of the matrix and Bartlett's test of sphericity, a test of whether the error correlation matrix is significantly different from an identity matrix.

SIGNIF Keyword

You can request any of the optional output listed below by entering the appropriate specification in parentheses after the keyword SIGNIF on the PRINT subcommand. Further specifications for SIGNIF are described in *MANOVA: Repeated Measures*.

MULTIV	*Multivariate* F *tests for group differences.* MULTIV is always printed unless explicitly suppressed with the NOPRINT subcommand.
EIGEN	*Eigenvalues of the* $S_k S_e^{-1}$ *matrix*. This matrix is the product of the hypothesis sums-of-squares and cross-products (SSCP) matrix and the inverse of the error SSCP matrix. To print EIGEN, request it on the PRINT subcommand.
DIMENR	*A dimension-reduction analysis.* To print DIMENR, request it on the PRINT subcommand.
UNIV	*Univariate* F *tests.* UNIV is always printed except in repeated measures analysis. If the dependent variables are uncorrelated, univariate tests have greater statistical power. To suppress UNIV, use the NOPRINT subcommand.
HYPOTH	*The hypothesis SSCP matrix.* To print HYPOTH, request it on the PRINT subcommand.
STEPDOWN	*Roy-Bargmann stepdown* F *tests.* To print STEPDOWN, request it on the PRINT subcommand.
BRIEF	*Abbreviated multivariate output.* This is similar to a univariate analysis of variance table but with Wilks' multivariate *F* approximation (lambda) replacing the univariate *F*. BRIEF overrides any of the SIGNIF specifications listed above.
SINGLEDF	*Significance tests for the single degree of freedom making up each effect for ANOVA tables.* Results are displayed separately corresponding to each hypothesis degree of freedom. For more information, see SIGNIF Keyword on p. 996.

- If neither PRINT nor NOPRINT is specified, MANOVA displays the results corresponding to MULTIV and UNIV for a multivariate analysis not involving repeated measures.
- If you enter any specification except BRIEF or SINGLEDF for SIGNIF on the PRINT subcommand, the requested output is displayed in addition to the default.
- To suppress the default, specify the keyword(s) on the NOPRINT subcommand.

TRANSFORM Keyword

The keyword TRANSFORM specified on PRINT displays the transposed transformation matrix in use for each subsequent design. This matrix is helpful in interpreting a multivariate analysis in which the interval-level variables have been transformed with either TRANSFORM or WSFACTORS.

- The matrix displayed by this option is the transpose of the transformation matrix.
- Original variables correspond to the rows of the matrix, and transformed variables correspond to the columns.
- A **transformed variable** is a linear combination of the original variables using the coefficients displayed in the column corresponding to that transformed variable.

HOMOGENEITY Keyword

In addition to the BARTLETT and COCHRAN specifications described in *MANOVA: Univariate*, the following test for homogeneity is available for multivariate analyses:

BOXM *Box's* M *statistic.* BOXM requires at least two dependent variables. If there is only one dependent variable when BOXM is requested, MANOVA prints Bartlett-Box *F* test statistic and issues a note.

PLOT Subcommand

In addition to the plots described in *MANOVA: Univariate*, the following is available for multivariate analyses:

ZCORR *A half-normal plot of the within-cells correlations among the dependent variables.* MANOVA first transforms the correlations using Fisher's *Z* transformation. If errors for the dependent variables are uncorrelated, the plotted points should lie close to a straight line.

PCOMPS Subcommand

PCOMPS requests a principal components analysis of each error matrix in a multivariate analysis. You can display the principal components of the error correlation matrix, the error variance-covariance matrix, or both. These principal components are corrected for differences due to the factors and covariates in the MANOVA analysis. They tend to be more useful than principal components extracted from the raw correlation or covariance matrix when there are significant group differences between the levels of the factors or when a significant amount of error variance is accounted for by the covariates. You can specify any of the keywords listed below on PCOMPS.

COR *Principal components analysis of the error correlation matrix.*

COV *Principal components analysis of the error variance-covariance matrix.*

ROTATE *Rotate the principal components solution.* By default, no rotation is performed. Specify a rotation type (either VARIMAX, EQUAMAX, or QUARTIMAX) in parentheses after the keyword ROTATE. To cancel a rotation specified for a previous design, enter NOROTATE in the parentheses after ROTATE.

NCOMP(n) *The number of principal components to rotate.* Specify a number in parentheses. The default is the number of dependent variables.

MINEIGEN(n) *The minimum eigenvalue for principal component extraction.* Specify a cutoff value in parentheses. Components with eigenvalues below the cutoff will not be retained in the solution. The default is 0; all components (or the number specified on NCOMP) are extracted.

ALL *COR, COV, and ROTATE.*

- You must specify either COR or COV (or both). Otherwise, MANOVA will not produce any principal components.
- Both NCOMP and MINEIGEN limit the number of components that are rotated.

- If the number specified on NCOMP is less than two, two components are rotated provided that at least two components have eigenvalues greater than any value specified on MINEIGEN.
- Principal components analysis is computationally expensive if the number of dependent variables is large.

DISCRIM Subcommand

DISCRIM produces a canonical discriminant analysis for each effect in a design. (For covariates, DISCRIM produces a canonical correlation analysis.) These analyses aid in the interpretation of multivariate effects. You can request the following statistics by entering the appropriate keywords after the subcommand DISCRIM:

RAW	*Raw discriminant function coefficients.*
STAN	*Standardized discriminant function coefficients.*
ESTIM	*Effect estimates in discriminant function space.*
COR	*Correlations between the dependent variables and the canonical variables defined by the discriminant functions.*
ROTATE	*Rotation of the matrix of correlations between dependent and canonical variables.* Specify rotation type VARIMAX, EQUAMAX, or QUARTIMAX in parentheses after this keyword.
ALL	*RAW, STAN, ESTIM, COR, and ROTATE.*

By default, the significance level required for the extraction of a canonical variable is 0.25. You can change this value by specifying the keyword ALPHA and a value between 0 and 1 in parentheses:

ALPHA	*The significance level required before a canonical variable is extracted.* The default is 0.25. To change the default, specify a decimal number between 0 and 1 in parentheses after ALPHA.

- The correlations between dependent variables and canonical functions are not rotated unless at least two functions are significant at the level defined by ALPHA.
- If you set ALPHA to 1.0, all discriminant functions are reported (and rotated, if you so request).
- If you set ALPHA to 0, no discriminant functions are reported.

POWER Subcommand

The following specifications are available for POWER in multivariate analysis. For applications of POWER in univariate analysis, see *MANOVA: Univariate*.

APPROXIMATE	*Approximate power values.* This is the default. Approximate power values for multivariate tests are derived from procedures presented by Muller and Peterson (Muller and Peterson, 1984). Approximate values are normally accurate to three decimal places and are much cheaper to compute than exact values.
EXACT	*Exact power values.* Exact power values for multivariate tests are computed from the noncentral *F* distribution. Exact multivariate power values will be displayed only if there is one hypothesis degree of freedom, where all the multivariate criteria have identical power.

- For information on the multivariate generalizations of power and effect size, see (Muller et al., 1984), (Green, 1978), and (Huberty, 1972).

CINTERVAL Subcommand

In addition to the specifications described in MANOVA: Univariate, the keyword MULTIVARIATE is available for multivariate analysis. You can specify a type in parentheses after the MULTIVARIATE keyword. The following type keywords are available on MULTIVARIATE:

ROY	*Roy's largest root.* An approximation given by Pillai (Pillai, 1967) is used. This approximation is accurate for upper percentage points (0.95 to 1), but it is not as good for lower percentage points. Thus, for Roy intervals, the user is restricted to the range 0.95 to 1.
PILLAI	*Pillai's trace.* The intervals are computed by approximating the percentage points with percentage points of the *F* distribution.
WILKS	*Wilks' lambda.* The intervals are computed by approximating the percentage points with percentage points of the *F* distribution.
HOTELLING	*Hotelling's trace.* The intervals are computed by approximating the percentage points with percentage points of the *F* distribution.
BONFER	*Bonferroni intervals.* This approximation is based on Student's *t* distribution.

- The Wilks', Pillai's, and Hotelling's approximate confidence intervals are thought to match exact intervals across a wide range of alpha levels, especially for large sample sizes (Burns, 1984). Use of these intervals, however, has not been widely investigated.
- To obtain multivariate intervals separately for each parameter, choose individual multivariate intervals. For individual multivariate confidence intervals, the hypothesis degree of freedom is set to 1, in which case Hotelling's, Pillai's, Wilks', and Roy's intervals will be identical and equivalent to those computed from percentage points of Hotelling's T^2 distribution. Individual Bonferroni intervals will differ and, for a small number of dependent variables, will generally be shorter.
- If you specify MULTIVARIATE on CINTERVAL, you must specify a type keyword. If you specify CINTERVAL without any keyword, the default is the same as with univariate analysis—CINTERVAL displays individual-univariate confidence intervals at the 0.95 level.

ANALYSIS Subcommand

ANALYSIS is discussed in *MANOVA: Univariate* as a means of obtaining factor-by-covariate interaction terms. In multivariate analyses, it is considerably more useful.

- ANALYSIS specifies a subset of the continuous variables (dependent variables and covariates) listed on the MANOVA variable list and completely redefines which variables are dependent and which are covariates.
- All variables named on an ANALYSIS subcommand must have been named on the MANOVA variable list. It does not matter whether they were named as dependent variables or as covariates.
- Factors cannot be named on an ANALYSIS subcommand.
- After the keyword ANALYSIS, specify the names of one or more dependent variables and, optionally, the keyword WITH followed by one or more covariates.
- An ANALYSIS specification remains in effect for all designs until you enter another ANALYSIS subcommand.
- Continuous variables named on the MANOVA variable list but omitted from the ANALYSIS subcommand currently in effect can be specified on the DESIGN subcommand. For more information, see DESIGN Subcommand on p. 1005.
- You can use an ANALYSIS subcommand to request analyses of several groups of variables provided that the groups do not overlap. Separate the groups of variables with slashes and enclose the entire ANALYSIS specification in parentheses.

CONDITIONAL and UNCONDITIONAL Keywords

When several analysis groups are specified on a single ANALYSIS subcommand, you can control how each list is to be processed by specifying CONDITIONAL or UNCONDITIONAL in the parentheses immediately following the ANALYSIS subcommand. The default is UNCONDITIONAL.

UNCONDITIONAL	*Process each analysis group separately, without regard to other lists.* This is the default.
CONDITIONAL	*Use variables specified in one analysis group as covariates in subsequent analysis groups.*

- CONDITIONAL analysis is not carried over from one ANALYSIS subcommand to another.
- You can specify a final covariate list outside the parentheses. These covariates apply to every list within the parentheses, regardless of whether you specify CONDITIONAL or UNCONDITIONAL. The variables on this global covariate list must not be specified in any individual lists.

Example

```
MANOVA A B C BY FAC(1,4) WITH D, E
  /ANALYSIS = (A, B / C / D WITH E)
  /DESIGN.
```

- The first analysis uses *A* and *B* as dependent variables and uses no covariates.

- The second analysis uses *C* as a dependent variable and uses no covariates.
- The third analysis uses *D* as the dependent variable and uses *E* as a covariate.

Example

```
MANOVA A, B, C, D, E BY FAC(1,4) WITH F G
  /ANALYSIS = (A, B / C / D WITH E) WITH F G
  /DESIGN.
```

- A final covariate list `WITH F G` is specified outside the parentheses. The covariates apply to every list within the parentheses.
- The first analysis uses *A* and *B*, with *F* and *G* as covariates.
- The second analysis uses *C*, with *F* and *G* as covariates.
- The third analysis uses *D*, with *E*, *F*, and *G* as covariates.
- Factoring out *F* and *G* is the only way to use them as covariates in all three analyses, since no variable can be named more than once on an `ANALYSIS` subcommand.

Example

```
MANOVA A B C BY FAC(1,3)
  /ANALYSIS(CONDITIONAL) = (A WITH B / C)
  /DESIGN.
```

- In the first analysis, *A* is the dependent variable, *B* is a covariate, and *C* is not used.
- In the second analysis, *C* is the dependent variable, and both *A* and *B* are covariates.

MANOVA: Repeated Measures

MANOVA is available in the Advanced Models option.

```
MANOVA dependent varlist [BY factor list (min,max)[factor list...]
         [WITH [varying covariate list] [(constant covariate list)]]

  /WSFACTORS = varname (levels) [varname...]

 [/WSDESIGN = [effect effect...]

 [/MEASURE = newname newname...]

 [/RENAME = newname newname...]

 [/{PRINT   }=[SIGNIF({AVERF**}) (HF) (GG) (EFSIZE)]]
   {NOPRINT}          {AVONLY }

 [/DESIGN]*
```

* The DESIGN subcommand has the same syntax as is described in *MANOVA: Univariate*.

** Default if the subcommand or keyword is omitted.

Example

```
MANOVA Y1 TO Y4 BY GROUP(1,2)
  /WSFACTORS=YEAR(4).
```

Overview

This section discusses the subcommands that are used in repeated measures designs, in which the dependent variables represent measurements of the same variable (or variables) at different times. This section does not contain information on all subcommands you will need to specify the design. For some subcommands or keywords not covered here, such as DESIGN, see *MANOVA: Univariate*. For information on optional output and the multivariate significance tests available, see *MANOVA: Multivariate*.

- In a simple repeated measures analysis, all dependent variables represent different measurements of the same variable for different values (or levels) of a within-subjects factor. Between-subjects factors and covariates can also be included in the model, just as in analyses not involving repeated measures.
- A **within-subjects factor** is simply a factor that distinguishes measurements made on the same subject or case, rather than distinguishing different subjects or cases.
- MANOVA permits more complex analyses, in which the dependent variables represent levels of two or more within-subjects factors.
- MANOVA also permits analyses in which the dependent variables represent measurements of several variables for the different levels of the within-subjects factors. These are known as **doubly multivariate designs**.

- A repeated measures analysis includes a within-subjects design describing the model to be tested with the within-subjects factors, as well as the usual between-subjects design describing the effects to be tested with between-subjects factors. The default for both types of design is a full factorial model.
- MANOVA always performs an orthonormal transformation of the dependent variables in a repeated measures analysis. By default, MANOVA renames them as *T1*, *T2*, and so forth.

Basic Specification

- The basic specification is a variable list followed by the WSFACTORS subcommand.
- By default, MANOVA performs special repeated measures processing. Default output includes SIGNIF(AVERF) but not SIGNIF(UNIV). In addition, for any within-subjects effect involving more than one transformed variable, the Mauchly test of sphericity is displayed to test the assumption that the covariance matrix of the transformed variables is constant on the diagonal and zero off the diagonal. The Greenhouse-Geiser epsilon and the Huynh-Feldt epsilon are also displayed for use in correcting the significance tests in the event that the assumption of sphericity is violated.

Subcommand Order

- The list of dependent variables, factors, and covariates must be first.
- WSFACTORS must be the first subcommand used after the variable list.

Syntax Rules

- The WSFACTORS (within-subjects factors), WSDESIGN (within-subjects design), and MEASURE subcommands are used only in repeated measures analysis.
- WSFACTORS is required for any repeated measures analysis.
- If WSDESIGN is not specified, a full factorial within-subjects design consisting of all main effects and interactions among within-subjects factors is used by default.
- The MEASURE subcommand is used for doubly multivariate designs, in which the dependent variables represent repeated measurements of more than one variable.
- Do not use the TRANSFORM subcommand with the WSFACTORS subcommand because WSFACTORS automatically causes an orthonormal transformation of the dependent variables.

Limitations

- Maximum of 20 between-subjects factors. There is no limit on the number of measures for doubly multivariate designs.
- Memory requirements depend primarily on the number of cells in the design. For the default full factorial model, this equals the product of the number of levels or categories in each factor.

Example

```
MANOVA Y1 TO Y4 BY GROUP(1,2)
  /WSFACTORS=YEAR(4)
  /CONTRAST(YEAR)=POLYNOMIAL
  /RENAME=CONST, LINEAR, QUAD, CUBIC
  /PRINT=TRANSFORM PARAM(ESTIM)
```

```
/WSDESIGN=YEAR
/DESIGN=GROUP.
```

- WSFACTORS immediately follows the MANOVA variable list and specifies a repeated measures analysis in which the four dependent variables represent a single variable measured at four levels of the within-subjects factor. The within-subjects factor is called *YEAR* for the duration of the MANOVA procedure.
- CONTRAST requests polynomial contrasts for the levels of *YEAR*. Because the four variables, *Y1*, *Y2*, *Y3*, and *Y4*, in the active dataset represent the four levels of *YEAR*, the effect is to perform an orthonormal polynomial transformation of these variables.
- RENAME assigns names to the dependent variables to reflect the transformation.
- PRINT requests that the transformation matrix and the parameter estimates be displayed.
- WSDESIGN specifies a within-subjects design that includes only the effect of the *YEAR* within-subjects factor. Because *YEAR* is the only within-subjects factor specified, this is the default design, and WSDESIGN could have been omitted.
- DESIGN specifies a between-subjects design that includes only the effect of the *GROUP* between-subjects factor. This subcommand could have been omitted.

MANOVA Variable List

The list of dependent variables, factors, and covariates must be specified first.

- WSFACTORS determines how the dependent variables on the MANOVA variable list will be interpreted.
- The number of dependent variables on the MANOVA variable list must be a multiple of the number of cells in the within-subjects design. If there are six cells in the within-subjects design, each group of six dependent variables represents a single within-subjects variable that has been measured in each of the six cells.
- Normally, the number of dependent variables should equal the number of cells in the within-subjects design multiplied by the number of variables named on the MEASURE subcommand (if one is used). If you have more groups of dependent variables than are accounted for by the MEASURE subcommand, MANOVA will choose variable names to label the output, which may be difficult to interpret.
- Covariates are specified after the keyword WITH. You can specify either varying covariates or constant covariates, or both. **Varying covariates**, similar to dependent variables in a repeated measures analysis, represent measurements of the same variable (or variables) at different times while **constant covariates** represent variables whose values remain the same at each within-subjects measurement.
- If you use varying covariates, the number of covariates specified must be an integer multiple of the number of dependent variables.
- If you use constant covariates, you must specify them in parentheses. If you use both constant and varying covariates, constant variates must be specified after all varying covariates.

Example

```
MANOVA MATH1 TO MATH4 BY METHOD(1,2) WITH PHYS1 TO PHYS4 (SES)
```

```
  /WSFACTORS=SEMESTER(4).
```

- The four dependent variables represent a score measured four times (corresponding to the four levels of *SEMESTER*).
- The four varying covariates *PHYS1* to *PHYS4* represents four measurements of another score.
- *SES* is a constant covariate. Its value does not change over the time covered by the four levels of *SEMESTER*.
- The default contrast (POLYNOMIAL) is used.

WSFACTORS Subcommand

WSFACTORS names the within-subjects factors and specifies the number of levels for each.

- For repeated measures designs, WSFACTORS must be the first subcommand after the MANOVA variable list.
- Only one WSFACTORS subcommand is permitted per execution of MANOVA.
- Names for the within-subjects factors are specified on the WSFACTORS subcommand. Factor names must not duplicate any of the dependent variables, factors, or covariates named on the MANOVA variable list.
- If there are more than one within-subjects factors, they must be named in the order corresponding to the order of the dependent variables on the MANOVA variable list. MANOVA varies the levels of the last-named within-subjects factor most rapidly when assigning dependent variables to within-subjects cells (see the example below).
- Levels of the factors must be represented in the data by the dependent variables named on the MANOVA variable list.
- Enter a number in parentheses after each factor to indicate how many levels the factor has. If two or more adjacent factors have the same number of levels, you can enter the number of levels in parentheses after all of them.
- Enter only the number of levels for within-subjects factors, not a range of values.
- The number of cells in the within-subjects design is the product of the number of levels for all within-subjects factors.

Example

```
MANOVA X1Y1 X1Y2 X2Y1 X2Y2 X3Y1 X3Y2 BY TREATMNT(1,5) GROUP(1,2)
  /WSFACTORS=X(3) Y(2)
  /DESIGN.
```

- The MANOVA variable list names six dependent variables and two between-subjects factors, *TREATMNT* and *GROUP*.
- WSFACTORS identifies two within-subjects factors whose levels distinguish the six dependent variables. *X* has three levels and *Y* has two. Thus, there are $3 \times 2 = 6$ cells in the within-subjects design, corresponding to the six dependent variables.

- Variable *X1Y1* corresponds to levels 1,1 of the two within-subjects factors; variable *X1Y2* corresponds to levels 1,2; *X2Y1* to levels 2,1; and so on up to *X3Y2*, which corresponds to levels 3,2. The first within-subjects factor named, *X*, varies most slowly, and the last within-subjects factor named, *Y*, varies most rapidly on the list of dependent variables.
- Because there is no `WSDESIGN` subcommand, the within-subjects design will include all main effects and interactions: *X*, *Y*, and *X* by *Y*.
- Likewise, the between-subjects design includes all main effects and interactions: *TREATMNT*, *GROUP*, and *TREATMNT* by *GROUP*.
- In addition, a repeated measures analysis always includes interactions between the within-subjects factors and the between-subjects factors. There are three such interactions for each of the three within-subjects effects.

CONTRAST for WSFACTORS

The levels of a within-subjects factor are represented by different dependent variables. Therefore, contrasts between levels of such a factor compare these dependent variables. Specifying the type of contrast amounts to specifying a transformation to be performed on the dependent variables.

- An orthonormal transformation is automatically performed on the dependent variables in a repeated measures analysis.
- To specify the type of orthonormal transformation, use the `CONTRAST` subcommand for the within-subjects factors.
- Regardless of the contrast type you specify, the transformation matrix is orthonormalized before use.
- If you do not specify a contrast type for within-subjects factors, the default contrast type is orthogonal `POLYNOMIAL`. Intrinsically orthogonal contrast types are recommended for within-subjects factors if you wish to examine each degree-of-freedom test. Other orthogonal contrast types are `DIFFERENCE` and `HELMERT`. `MULTIV` and `AVERF` tests are identical, no matter what contrast was specified.
- To perform non-orthogonal contrasts, you must use the `TRANSFORM` subcommand instead of `CONTRAST`. The `TRANSFORM` subcommand is discussed in *MANOVA: Multivariate*.
- When you implicitly request a transformation of the dependent variables with `CONTRAST` for within-subjects factors, the same transformation is applied to any covariates in the analysis. The number of covariates must be an integer multiple of the number of dependent variables.
- You can display the transpose of the transformation matrix generated by your within-subjects contrast using the keyword `TRANSFORM` on the `PRINT` subcommand.

Example

```
MANOVA SCORE1 SCORE2 SCORE3 BY GROUP(1,4)
  /WSFACTORS=ROUND(3)
  /CONTRAST(ROUND)=DIFFERENCE
  /CONTRAST(GROUP)=DEVIATION
  /PRINT=TRANSFORM PARAM(ESTIM).
```

- This analysis has one between-subjects factor, *GROUP*, with levels 1, 2, 3, and 4, and one within-subjects factor, *ROUND*, with three levels that are represented by the three dependent variables.
- The first CONTRAST subcommand specifies difference contrasts for *ROUND*, the within-subjects factor.
- There is no WSDESIGN subcommand, so a default full factorial within-subjects design is assumed. This could also have been specified as WSDESIGN=ROUND, or simply WSDESIGN.
- The second CONTRAST subcommand specifies deviation contrasts for *GROUP*, the between-subjects factor. This subcommand could have been omitted because deviation contrasts are the default.
- PRINT requests the display of the transformation matrix generated by the within-subjects contrast and the parameter estimates for the model.
- There is no DESIGN subcommand, so a default full factorial between-subjects design is assumed. This could also have been specified as DESIGN=GROUP, or simply DESIGN.

PARTITION for WSFACTORS

The PARTITION subcommand also applies to factors named on WSFACTORS. For more information, see PARTITION Subcommand on p. 992.

WSDESIGN Subcommand

WSDESIGN specifies the design for within-subjects factors. Its specifications are like those of the DESIGN subcommand, but it uses the within-subjects factors rather than the between-subjects factors.

- The default WSDESIGN is a full factorial design, which includes all main effects and all interactions for within-subjects factors. The default is in effect whenever a design is processed without a preceding WSDESIGN or when the preceding WSDESIGN subcommand has no specifications.
- A WSDESIGN specification can include main effects, factor-by-factor interactions, nested terms (term within term), terms using the keyword MWITHIN, and pooled effects using the plus sign. The specification is the same as on the DESIGN subcommand but involves only within-subjects factors.
- A WSDESIGN specification cannot include between-subjects factors or terms based on them, nor does it accept interval-level variables, the keywords MUPLUS or CONSTANT, or error-term definitions or references.
- The WSDESIGN specification applies to all subsequent within-subjects designs until another WSDESIGN subcommand is encountered.

Example

```
MANOVA JANLO,JANHI,FEBLO,FEBHI,MARLO,MARHI BY SEX(1,2)
  /WSFACTORS MONTH(3) STIMULUS(2)
  /WSDESIGN MONTH, STIMULUS
  /WSDESIGN
  /DESIGN SEX.
```

- There are six dependent variables, corresponding to three months and two different levels of stimulus.
- The dependent variables are named on the MANOVA variable list in such an order that the level of stimulus varies more rapidly than the month. Thus, *STIMULUS* is named last on the WSFACTORS subcommand.
- The first WSDESIGN subcommand specifies only the main effects for within-subjects factors. There is no *MONTH* by *STIMULUS* interaction term.
- The second WSDESIGN subcommand has no specifications and, therefore, invokes the default within-subjects design, which includes the main effects and their interaction.

MWITHIN Keyword for Simple Effects

You can use MWITHIN on either the WSDESIGN or the DESIGN subcommand in a model with both between- and within-subjects factors to estimate simple effects for factors nested within factors of the opposite type.

Example

```
MANOVA WEIGHT1 WEIGHT2 BY TREAT(1,2)
 /WSFACTORS=WEIGHT(2)
 /DESIGN=MWITHIN TREAT(1) MWITHIN TREAT(2)
MANOVA WEIGHT1 WEIGHT2 BY TREAT(1,2)
 /WSFACTORS=WEIGHT(2)
 /WSDESIGN=MWITHIN WEIGHT(1) MWITHIN WEIGHT(2)
 /DESIGN.
```

- The first DESIGN tests the simple effects of *WEIGHT* within each level of *TREAT*.
- The second DESIGN tests the simple effects of *TREAT* within each level of *WEIGHT*.

MEASURE Subcommand

In a doubly multivariate analysis, the dependent variables represent multiple variables measured under the different levels of the within-subjects factors. Use MEASURE to assign names to the variables that you have measured for the different levels of within-subjects factors.

- Specify a list of one or more variable names to be used in labeling the averaged results. If no within-subjects factor has more than two levels, MEASURE has no effect.
- The number of dependent variables on the DESIGN subcommand should equal the product of the number of cells in the within-subjects design and the number of names on MEASURE.
- If you do not enter a MEASURE subcommand and there are more dependent variables than cells in the within-subjects design, MANOVA assigns names (normally *MEAS.1*, *MEAS.2*, and so on) to the different measures.
- All of the dependent variables corresponding to each measure should be listed together and ordered so that the within-subjects factor named last on the WSFACTORS subcommand varies most rapidly.

Example

```
MANOVA TEMP1 TO TEMP6, WEIGHT1 TO WEIGHT6 BY GROUP(1,2)
  /WSFACTORS=DAY(3) AMPM(2)
  /MEASURE=TEMP WEIGHT
  /WSDESIGN=DAY, AMPM, DAY BY AMPM
  /PRINT=SIGNIF(HYPOTH AVERF)
  /DESIGN.
```

- There are 12 dependent variables: six temperatures and six weights, corresponding to morning and afternoon measurements on three days.
- `WSFACTORS` identifies the two factors (*DAY* and *AMPM*) that distinguish the temperature and weight measurements for each subject. These factors define six within-subjects cells.
- `MEASURE` indicates that the first group of six dependent variables correspond to *TEMP* and the second group of six dependent variables correspond to *WEIGHT*.
- These labels, *TEMP* and *WEIGHT*, are used on the output requested by `PRINT`.
- `WSDESIGN` requests a full factorial within-subjects model. Because this is the default, `WSDESIGN` could have been omitted.

RENAME Subcommand

Because any repeated measures analysis involves a transformation of the dependent variables, it is always a good idea to rename the dependent variables. Choose appropriate names depending on the type of contrast specified for within-subjects factors. This is easier to do if you are using one of the orthogonal contrasts. The most reliable way to assign new names is to inspect the transformation matrix.

Example

```
MANOVA LOW1 LOW2 LOW3 HI1 HI2 HI3
  /WSFACTORS=LEVEL(2) TRIAL(3)
  /CONTRAST(TRIAL)=DIFFERENCE
  /RENAME=CONST LEVELDIF TRIAL21 TRIAL312 INTER1 INTER2
  /PRINT=TRANSFORM
  /DESIGN.
```

- This analysis has two within-subjects factors and no between-subjects factors.
- Difference contrasts are requested for *TRIAL*, which has three levels.
- Because all orthonormal contrasts produce the same *F* test for a factor with two levels, there is no point in specifying a contrast type for *LEVEL*.
- New names are assigned to the transformed variables based on the transformation matrix. These names correspond to the meaning of the transformed variables: the mean or constant, the average difference between levels, the average effect of trial 2 compared to 1, the average effect of trial 3 compared to 1 and 2; and the two interactions between *LEVEL* and *TRIAL*.
- The transformation matrix requested by the `PRINT` subcommand looks like the following table.

Table 120-1
Transformation matrix

	CONST	LEVELDIF	TRIAL1	TRIAL2	INTER1	INTER2
LOW1	0.408	0.408	-0.500	-0.289	-0.500	-0.289
LOW2	0.408	0.408	0.500	-0.289	0.500	-0.289
LOW3	0.408	0.408	0.000	0.577	0.000	0.577
HI1	0.408	-0.408	-0.500	-0.289	0.500	0.289
HI2	0.408	-0.408	0.500	-0.289	-0.500	0.289
HI3	0.408	-0.408	0.000	0.577	0.000	-0.577

PRINT Subcommand

The following additional specifications on `PRINT` are useful in repeated measures analysis:

SIGNIF(AVERF) *Averaged* F *tests for use with repeated measures.* This is the default display in repeated measures analysis. The averaged *F* tests in the multivariate setup for repeated measures are equivalent to the univariate (or split-plot or mixed-model) approach to repeated measures.

SIGNIF(AVONLY) *Only the averaged* F *test for repeated measures.* `AVONLY` produces the same output as `AVERF` and suppresses all other `SIGNIF` output.

SIGNIF(HF) *The Huynh-Feldt corrected significance values for averaged univariate* F *tests*.

SIGNIF(GG) *The Greenhouse-Geisser corrected significance values for averaged univariate* F *tests.*

SIGNIF(EFSIZE) *The effect size for the univariate* F *and* t *tests.*

- The keywords `AVERF` and `AVONLY` are mutually exclusive.
- When you request repeated measures analysis with the `WSFACTORS` subcommand, the default display includes `SIGNIF(AVERF)` but does not include the usual `SIGNIF(UNIV)`.
- The averaged *F* tests are appropriate in repeated measures because the dependent variables that are averaged actually represent contrasts of the `WSFACTOR` variables. When the analysis is not doubly multivariate, as discussed above, you can specify `PRINT=SIGNIF(UNIV)` to obtain significance tests for each degree of freedom, just as in univariate `MANOVA`.

MATCH FILES

```
MATCH FILES FILE={'savfile'|'dataset'}  [TABLE={'savfile'|'dataset'}]
                 {*                   }         {*                   }

 [/RENAME=(old varnames=new varnames)...]

 [/IN=varname]

 /FILE=...  [TABLE= ...]

 [/BY varlist]

 [/MAP]

 [/KEEP={ALL**  }] [/DROP=varlist]
        {varlist}

 [/FIRST=varname]  [/LAST=varname]
```

**Default if the subcommand is omitted.

Example

```
MATCH FILES FILE='/data/part1.sav'
  /FILE='/data/part2.sav'
  /FILE=*.
```

Overview

MATCH FILES combines variables from 2 up to 50 SPSS-format data files. MATCH FILES can make parallel or nonparallel matches between different files or perform table lookups. **Parallel matches** combine files sequentially by case (they are sometimes referred to as **sequential matches**). **Nonparallel matches** combine files according to the values of one or more key variables. In a table lookup, MATCH FILES looks up variables in one file and transfers those variables to a case file.

The files specified on MATCH FILES can be SPSS-format data files or open datasets in the current session. The combined file becomes the new active dataset. Statistical procedures following MATCH FILES use this combined file. You must use the SAVE or XSAVE commands if you want to save the combined file as an SPSS-format data file.

In general, MATCH FILES is used to combine files containing the same cases but different variables. To combine files containing the same variables but different cases, use ADD FILES. To update existing SPSS-format data files, use UPDATE.

Options

Variable Selection. You can specify which variables from each input file are included in the new active dataset using the DROP and KEEP subcommands.

Variable Names. You can rename variables in each input file before combining the files using the RENAME subcommand. This permits you to combine variables that are the same but whose names differ in different input files or to separate variables that are different but have the same name.

Variable Flag. You can create a variable that indicates whether a case came from a particular input file using IN. You can use the FIRST or LAST subcommands to create a variable that flags the first or last case of a group of cases with the same value for the key variable.

Variable Map. You can request a map showing all variables in the new active dataset, their order, and the input files from which they came using the MAP subcommand.

Basic Specification

The basic specification is two or more FILE subcommands, each of which specifies a file to be matched. In addition, BY is required to specify the key variables for nonparallel matches. Both BY and TABLE are required to match table-lookup files.

- All variables from all input files are included in the new active dataset unless DROP or KEEP is specified.

Subcommand Order

- RENAME and IN must immediately follow the FILE or TABLE subcommand to which they apply.
- Any BY, FIRST, LAST, KEEP, DROP, and MAP subcommands must follow all of the TABLE, FILE, RENAME, and IN subcommands.

Syntax Rules

- RENAME can be repeated after each FILE or TABLE subcommand and applies only to variables in the file named on the immediately preceding FILE or TABLE.
- IN can be used only for a nonparallel match or for a table lookup. (Thus, IN can be used only if BY is specified.)
- BY can be specified only once. However, multiple variables can be specified on BY. When BY is used, all files must be sorted in ascending order of the key variables named on BY.
- MAP can be repeated as often as desired.

Operations

- MATCH FILES reads all files named on FILE or TABLE and builds a new active dataset that replaces any active dataset created earlier in the session.
- The new active dataset contains complete dictionary information from the input files, including variable names, labels, print and write formats, and missing-value indicators. The new file also contains the documents from each of the input files. See DROP DOCUMENTS for information on deleting documents.
- Variables are copied in order from the first file specified, then from the second file specified, and so on.
- If the same variable name is used in more than one input file, data are taken from the file specified first. Dictionary information is taken from the first file containing value labels, missing values, or a variable label for the common variable. If the first file has no such information, MATCH FILES checks the second file, and so on, seeking dictionary information.

- All cases from all input files are included in the combined file. Cases that are absent from one of the input files will be assigned system-missing values for variables unique to that file.
- BY specifies that cases should be combined according to a common value on one or more key variables. All input files must be sorted in ascending order of the key variables.
- If BY is not used, the program performs a parallel (sequential) match, combining the first case from each file, then the second case from each file, and so on, without regard to any identifying values that may be present.
- If the active dataset is named as an input file, any N and SAMPLE commands that have been specified are applied to that file before files are matched.

Limitations

- Maximum 50 files can be combined on one MATCH FILES command.
- Maximum one BY subcommand. However, BY can specify multiple variables.
- The TEMPORARY command cannot be in effect if the active dataset is used as an input file.

Example

```
MATCH FILES FILE='/data/part1.sav'
  /FILE='/data/part2.sav'
  /FILE=*.
```

- MATCH FILES combines three files (the active dataset and two SPSS-format data files) in a parallel match. Cases are combined according to their order in each file.
- The new active dataset contains as many cases as are contained in the largest of the three input files.

Example

```
GET FILE='/examples/data/mydata.sav'.
SORT CASES BY ID.
DATASET NAME mydata.
GET DATA /TYPE=XLS
  /FILE='/examples/data/excelfile.xls'.
SORT CASES BY ID.
DATASET NAME excelfile.
GET DATA /TYPE=ODBC /CONNECT=
 'DSN=MS Access Database;DBQ=/examples/data/dm_demo.mdb;'+
 'DriverId=25;FIL=MS Access;MaxBufferSize=2048;PageTimeout=5;'
 /SQL='SELECT * FROM main'.
SORT CASES BY ID.
MATCH FILES
 /FILE='mydata'
 /FILE='excelfile'
 /FILE=*
 /BY ID.
```

- An SPSS data file is read and assigned the dataset name *mydata*. Since it has been assigned a dataset name, it remains available for subsequent use even after other data sources have been opened.
- An Excel file is then read and assigned the dataset name *exceldata*. Like the SPSS data file, since it has been assigned a dataset name, it remains available after other data sources have been opened.

- Then a table from a database is read. Since it is the most recently opened or activated dataset, it is the active dataset.
- The three datasets are then merged together with MATCH FILES command, using the dataset names on the FILE subcommands instead of file names.
- An asterisk (*) is used to specify the active dataset, which is the database table in this example.
- The files are merged together based on the value of the key variable *ID*, specified on the BY subcommand.
- Since all the files being merged need to be sorted in the same order of the key variable(s), SORT CASES is performed on each dataset.

FILE Subcommand

FILE identifies the files to be combined (except table files). At least one FILE subcommand is required on MATCH FILES. A separate FILE subcommand must be used for each input file.

- An asterisk can be specified on FILE to refer to the active dataset.
- Dataset names instead of filenames can be used to refer to currently open datasets.
- The order in which files are specified determines the order of variables in the new active dataset. In addition, if the same variable name occurs in more than one input file, the variable is taken from the file specified first.
- If the files have unequal numbers of cases, cases are generated from the longest file. Cases that do not exist in the shorter files have system-missing values for variables that are unique to those files.

Text Data Files

You can add variables from one or more text data files by reading the files into SPSS (with DATA LIST or GET DATA), defining dataset names for each file (DATASET NAME command), and then using MATCH FILES to add the cases from each file.

Example

```
DATA LIST FILE="/data/textdata1.txt"
  /id 1-3 var1 5-7 var2 9-12.
SORT CASES by ID.
DATASET NAME file1.
DATA LIST FILE="/data/textdata2.txt"
  /id 1-3 var3 5-9 var4 11-15.
SORT CASES BY ID.
DATASET NAME file2.
DATA LIST FILE="/data/textdata3.txt"
  /id 1-3 var5 5-6 var6 8-10.
DATASET NAME file3.
MATCH FILES FILE='file1'
  /FILE='file2'
  /FILE='file3'
  /BY id.
SAVE OUTFILE='/data/combined_data.sav'.
```

BY Subcommand

BY specifies one or more identification, or key, variables that determine which cases are to be combined. When BY is specified, cases from one file are matched only with cases from other files that have the same values for the key variables. BY is required unless all input files are to be matched sequentially according to the order of cases.

- BY must follow the FILE and TABLE subcommands and any associated RENAME and IN subcommands.
- BY specifies the names of one or more key variables. The key variables must exist in all input files. The key variables can be numeric or long or short strings.
- All input files must be sorted in ascending order of the key variables. If necessary, use SORT CASES before MATCH FILES.
- Missing values for key variables are handled like any other values.
- Unmatched cases are assigned system-missing values (for numeric variables) or blanks (for string variables) for variables from files that do not contain a match.

Duplicate Cases

Duplicate cases are those with the same values for the key variables named on the BY subcommand.

- Duplicate cases are permitted in any input files except table files.
- When there is no table file, the first duplicate case in each file is matched with the first matching case (if any) from the other files; the second duplicate case is matched with a second matching duplicate, if any; and so on. (In effect, a parallel match is performed within groups of duplicate cases.) Unmatched cases are assigned system-missing values (for numeric variables) or blanks (for string variables) for variables from files that do not contain a match.
- The program displays a warning if it encounters duplicate keys in one or more of the files being matched.

TABLE Subcommand

TABLE specifies a table lookup (or keyed table) file. A lookup file contributes variables but not cases to the new active dataset. Variables from the table file are added to all cases from other files that have matching values for the key variables. FILE specifies the files that supply the cases.

- A separate TABLE subcommand must be used to specify each lookup file, and a separate FILE subcommand must be used to specify each case file.
- The BY subcommand is required when TABLE is used.
- All specified files must be sorted in ascending order of the key variables. If necessary, use SORT CASES before MATCH FILES.
- A lookup file cannot contain duplicate cases (cases for which the key variable[s] named on BY have identical values).
- An asterisk on TABLE refers to the active dataset.
- Dataset names instead of file names can be used to refer to currently open datasets.

- Cases in a case file that do not have matches in a table file are assigned system-missing values (for numeric variables) or blanks (for string variables) for variables from that table file.
- Cases in a table file that do not match any cases in a case file are ignored.

Example

```
MATCH FILES FILE=*
  /TABLE='/data/master.sav'
  /BY EMP_ID.
```

- MATCH FILES combines variables from the SPSS-format data file *master.sav* with the active dataset, matching cases by the variable *EMP_ID*.
- No new cases are added to the active dataset as a result of the table lookup.
- Cases whose value for *EMP_ID* is not included in the *master.sav* file are assigned system-missing values for variables taken from the table.

RENAME Subcommand

RENAME renames variables on the input files *before* they are processed by MATCH FILES. RENAME must follow the FILE or TABLE subcommand that contains the variables to be renamed.

- RENAME applies only to the immediately preceding FILE or TABLE subcommand. To rename variables from more than one input file, specify a RENAME subcommand after each FILE or TABLE subcommand.
- Specifications for RENAME consist of a left parenthesis, a list of old variable names, an equals sign, a list of new variable names, and a right parenthesis. The two variable lists must name or imply the same number of variables. If only one variable is renamed, the parentheses are optional.
- More than one rename specification can be specified on a single RENAME subcommand, each enclosed in parentheses.
- The TO keyword can be used to refer to consecutive variables in the file and to generate new variable names.
- RENAME takes effect immediately. Any KEEP and DROP subcommands entered prior to a RENAME must use the old names, while KEEP and DROP subcommands entered after a RENAME must use the new names.
- All specifications within a single set of parentheses take effect simultaneously. For example, the specification RENAME (A,B = B,A) swaps the names of the two variables.
- Variables cannot be renamed to scratch variables.
- Input SPSS-format data files are not changed on disk; only the copy of the file being combined is affected.

Example

```
MATCH FILES FILE='/data/update.sav'
 /RENAME=(NEWID = ID)
 /FILE='/data/master.sav'
 /BY ID.
```

- MATCH FILES matches a master SPSS-format data file (*master.sav*) with an update data file (*update.sav*).
- The variable *NEWID* in the *update.sav* file is renamed *ID* so that it will have the same name as the identification variable in the master file and can be used on the BY subcommand.

DROP and KEEP Subcommands

DROP and KEEP are used to include a subset of variables in the new active dataset. DROP specifies a set of variables to exclude and KEEP specifies a set of variables to retain.

- DROP and KEEP do not affect the input files on disk.
- DROP and KEEP must follow all FILE, TABLE, and RENAME subcommands.
- DROP and KEEP must specify one or more variables. If RENAME is used to rename variables, specify the new names on DROP and KEEP.
- The keyword ALL can be specified on KEEP. ALL must be the last specification on KEEP, and it refers to all variables not previously named on KEEP.
- DROP cannot be used with variables created by the IN, FIRST, or LAST subcommands.
- KEEP can be used to change the order of variables in the resulting file. By default, MATCH FILES first copies the variables in order from the first file, then copies the variables in order from the second file, and so on. With KEEP, variables are kept in the order in which they are listed on the subcommand. If a variable is named more than once on KEEP, only the first mention of the variable is in effect; all subsequent references to that variable name are ignored.

Example

```
MATCH FILES FILE='/data/particle.sav'
  /RENAME=(PARTIC=POLLUTE1)
  /FILE='/data/gas.sav'
  /RENAME=(OZONE TO SULFUR=POLLUTE2 TO POLLUTE4)
  /DROP=POLLUTE4.
```

- The renamed variable *POLLUTE4* is dropped from the resulting file. DROP is specified after all of the FILE and RENAME subcommands, and it refers to the dropped variable by its new name.

IN Subcommand

IN creates a new variable in the resulting file that indicates whether a case came from the input file named on the preceding FILE subcommand. IN applies only to the file specified on the immediately preceding FILE subcommand.

- IN can be used only for a nonparallel match or table lookup.
- IN has only one specification—the name of the flag variable.
- The variable created by IN has the value 1 for every case that came from the associated input file and the value 0 if the case came from a different input file.
- Variables created by IN are automatically attached to the end of the resulting file and cannot be dropped. If FIRST or LAST is used, the variable created by IN precedes the variables created by FIRST or LAST.

Example

```
MATCH FILES  FILE='/data/week10.sav'
  /FILE='/data/week11.sav'
  /IN=INWEEK11
  /BY=EMPID.
```

- IN creates the variable *INWEEK11*, which has the value 1 for all cases in the resulting file that had values in the input file *week11.sav* and the value 0 for those cases that were not in file *week11.sav*.

FIRST and LAST Subcommands

FIRST and LAST create logical variables that flag the first or last case of a group of cases with the same value for the BY variables.

- FIRST and LAST must follow all TABLE and FILE subcommands and any associated RENAME and IN subcommands.
- FIRST and LAST have only one specification—the name of the flag variable.
- FIRST creates a variable with the value 1 for the first case of each group and the value 0 for all other cases.
- LAST creates a variable with the value 1 for the last case of each group and the value 0 for all other cases.
- Variables created by FIRST and LAST are automatically attached to the end of the resulting file and cannot be dropped.
- If one file has several cases with the same values for the key variables, FIRST or LAST can be used to create a variable that flags the first or last case of the group.

Example

```
MATCH FILES  TABLE='/data/house.sav'
 /FILE='/data/persons.sav'
 /BY=HOUSEID /FIRST=HEAD.
```

- The variable *HEAD* contains the value 1 for the first person in each household and the value 0 for all other persons. Assuming that the *persons.sav* file is sorted with the head of household as the first case for each household, the variable *HEAD* identifies the case for the head of household.

Example

```
* Using match files with only one file.

* This example flags the first of several cases with
  the same value for a key variable.

MATCH FILES  FILE='/data/persons.sav'
 /BY HOUSEID /FIRST=HEAD.
SELECT IF  (HEAD EQ 1).
CROSSTABS  JOBCAT BY SEX.
```

- MATCH FILES is used instead of GET to read the SPSS-format data file *persons.sav*. The BY subcommand identifies the key variable (*HOUSEID*), and FIRST creates the variable *HEAD* with the value 1 for the first case in each household and the value 0 for all other cases.
- SELECT IF selects only the cases with the value 1 for *HEAD*, and the CROSSTABS procedure is run on these cases.

MAP Subcommand

MAP produces a list of the variables that are in the new active dataset and the file or files from which they came. Variables are listed in the order in which they appear in the resulting file. MAP has no specifications and must be placed after all FILE, TABLE, and RENAME subcommands.

- Multiple MAP subcommands can be used. Each MAP shows the current status of the active dataset and reflects only the subcommands that precede the MAP subcommand.
- To obtain a map of the resulting file in its final state, specify MAP last.
- If a variable is renamed, its original and new names are listed. Variables created by IN, FIRST, and LAST are not included in the map, since they are automatically attached to the end of the file and cannot be dropped.

MATRIX-END MATRIX

This command is not available on all operating systems.

```
MATRIX
matrix statements
END MATRIX
```

The following matrix language statements can be used in a matrix program:

BREAK	DO IF	END LOOP	MSAVE	SAVE
CALL	ELSE	GET	PRINT	WRITE
COMPUTE	ELSE IF	LOOP	READ	
DISPLAY	END IF	MGET	RELEASE	

The following functions can be used in matrix language statements:

ABS	Absolute values of matrix elements
ALL	Test if all elements are positive
ANY	Test if any element is positive
ARSIN	Arcsines of matrix elements
ARTAN	Arctangents of matrix elements
BLOCK	Create block diagonal matrix
CDFNORM	Cumulative normal distribution function
CHICDF	Cumulative chi-squared distribution function
CHOL	Cholesky decomposition
CMAX	Column maxima
CMIN	Column minima
COS	Cosines of matrix elements
CSSQ	Column sums of squares
CSUM	Column sums
DESIGN	Create design matrix
DET	Determinant
DIAG	Diagonal of matrix
EOF	Check end of file
EVAL	Eigenvalues of symmetric matrix
EXP	Exponentials of matrix elements
FCDF	Cumulative *F* distribution function
GINV	Generalized inverse
GRADE	Rank elements in matrix, using sequential integers for ties

GSCH	Gram-Schmidt orthonormal basis
IDENT	Create identity matrix
INV	Inverse
KRONECKER	Kronecker product of two matrices
LG10	Logarithms to base 10 of matrix elements
LN	Logarithms to base *e* of matrix elements
MAGIC	Create magic square
MAKE	Create a matrix with all elements equal
MDIAG	Create a matrix with the given diagonal
MMAX	Maximum element in matrix
MMIN	Minimum element in matrix
MOD	Remainders after division
MSSQ	Matrix sum of squares
MSUM	Matrix sum
NCOL	Number of columns
NROW	Number of rows
RANK	Matrix rank
RESHAPE	Change shape of matrix
RMAX	Row maxima
RMIN	Row minima
RND	Round off matrix elements to nearest integer
RNKORDER	Rank elements in matrix, averaging ties
RSSQ	Row sums of squares
RSUM	Row sums
SIN	Sines of matrix elements
SOLVE	Solve systems of linear equations
SQRT	Square roots of matrix elements
SSCP	Sums of squares and cross-products
SVAL	Singular values
SWEEP	Perform sweep transformation
T	Synonym for TRANSPOS
TCDF	Cumulative normal *t* distribution function
TRACE	Calculate trace (sum of diagonal elements)
TRANSPOS	Transposition of matrix
TRUNC	Truncation of matrix elements to integer
UNIFORM	Create matrix of uniform random numbers

Example

```
MATRIX.
READ A /FILE=MATRDATA /SIZE={6,6} /FIELD=1 TO 60.
CALL EIGEN(A,EIGENVEC,EIGENVAL).
```

```
LOOP J=1 TO NROW(EIGENVAL).
+ DO IF (EIGENVAL(J) > 1.0).
+   PRINT EIGENVAL(J) / TITLE="Eigenvalue:" /SPACE=3.
+   PRINT T(EIGENVEC(:,J)) / TITLE="Eigenvector:" /SPACE=1.
+ END IF.
END LOOP.
END MATRIX.
```

Overview

The MATRIX and END MATRIX commands enclose statements that are executed by the matrix processor. Using matrix programs, you can write your own statistical routines in the compact language of matrix algebra. Matrix programs can include mathematical calculations, control structures, display of results, and reading and writing matrices as character files or SPSS data files.

As discussed below, a matrix program is for the most part independent of the rest of the session, although it can read and write SPSS data files, including the active dataset.

This section does not attempt to explain the rules of matrix algebra. Many textbooks teach the application of matrix methods to statistics.

The MATRIX procedure was originally developed at the Madison Academic Computing Center, University of Wisconsin.

Terminology

A variable within a matrix program represents a **matrix**, which is simply a set of values arranged in a rectangular array of rows and columns.

- An $n \times m$ (read "n by m") matrix is one that has n rows and m columns. The integers n and m are the dimensions of the matrix. An $n \times m$ matrix contains $n \times m$ elements, or data values.
- An $n \times 1$ matrix is sometimes called a **column vector**, and a $1 \times n$ matrix is sometimes called a **row vector**. A vector is a special case of a matrix.
- A 1×1 matrix, containing a single data value, is often called a **scalar**. A scalar is also a special case of a matrix.
- An **index** to a matrix or vector is an integer that identifies a specific row or column. Indexes normally appear in printed works as subscripts, as in A_{31}, but are specified in the matrix language within parentheses, as in $A(3,1)$. The row index for a matrix precedes the column index.
- The **main diagonal** of a matrix consists of the elements whose row index equals their column index. It begins at the top left corner of the matrix; in a square matrix, it runs to the bottom right corner.
- The **transpose** of a matrix is the matrix with rows and columns interchanged. The transpose of an $n \times m$ matrix is an $m \times n$ matrix.
- A **symmetric matrix** is a square matrix that is unchanged if you flip it about the main diagonal. That is, the element in row i, column j equals the element in row j, column i. A symmetric matrix equals its transpose.
- Matrices are always rectangular, although it is possible to read or write symmetric matrices in triangular form. Vectors and scalars are considered degenerate rectangles.
- It is an error to try to create a matrix whose rows have different numbers of elements.

A matrix program does not process individual cases unless you so specify, using the control structures of the matrix language. Unlike ordinary SPSS variables, matrix variables do not have distinct values for different cases. A matrix is a single entity.

Vectors in matrix processing should not be confused with the vectors temporarily created by the VECTOR command. The latter are shorthand for a list of SPSS variables and, like all ordinary SPSS variables, are unavailable during matrix processing.

Matrix Variables

A matrix variable is created by a matrix statement that assigns a value to a variable name.

- A matrix variable name follows the same rules as those applicable to an ordinary SPSS variable name.
- The names of matrix functions and procedures cannot be used as variable names within a matrix program. (In particular, the letter *T* cannot be used as a variable name because T is an alias for the TRANSPOS function.)
- The COMPUTE, READ, GET, MGET, and CALL statements create matrices. An index variable named on a LOOP statement creates a scalar with a value assigned to it.
- A variable name can be redefined within a matrix program without regard to the dimensions of the matrix it represents. The same name can represent scalars, vectors, and full matrices at different points in the matrix program.
- MATRIX-END MATRIX does not include any special processing for missing data. When reading a data matrix from an SPSS data file, you must therefore specify whether missing data are to be accepted as valid or excluded from the matrix.

String Variables in Matrix Programs

Matrix variables can contain short string data. Support for string variables is limited, however.

- MATRIX will attempt to carry out calculations with string variables if you so request. The results will not be meaningful.
- You must specify a format (such as A8) when you display a matrix that contains string data.

Syntax of Matrix Language

A matrix program consists of statements. Matrix statements must appear in a matrix program, between the MATRIX and END MATRIX commands. They are analogous to SPSS commands and follow the rules of the command language regarding the abbreviation of keywords; the equivalence of upper and lower case; the use of spaces, commas, and equals signs; and the splitting of statements across multiple lines. However, commas are required to separate arguments to matrix functions and procedures and to separate variable names on the RELEASE statement.

Matrix statements are composed of the following elements:

- Keywords, such as the names of matrix statements
- Variable names

- Explicitly written matrices, which are enclosed within braces ({})
- Arithmetic and logical operators
- Matrix functions
- The command terminator, which serves as a statement terminator within a matrix program

Comments in Matrix Programs

Within a matrix program, you can enter comments in any of the following forms: on lines beginning with the COMMENT command, on lines beginning with an asterisk, or between the characters /* and */ on a command line.

Matrix Notation

To write a matrix explicitly:

- Enclose the matrix within braces ({}).
- Separate the elements of each row by commas.
- Separate the rows by semicolons.
- String elements must be enclosed in either quotes, as is generally true in the command language.

Example

```
{1,2,3;4,5,6}
```

- The example represents the following matrix:

$$\begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \end{bmatrix}$$

Example

```
{1,2,3}
```

- This example represents a row vector:

$$\begin{bmatrix} 1 & 2 & 3 \end{bmatrix}$$

Example

```
{11;12;13}
```

- This example represents a column vector:

$$\begin{bmatrix} 11 \\ 12 \\ 13 \end{bmatrix}$$

Example

```
{3}
```

- This example represents a scalar. The braces are optional. You can specify the same scalar as 3.

Matrix Notation Shorthand

You can simplify the construction of matrices using notation shorthand.

Consecutive Integers. Use a colon to indicate a range of consecutive integers. For example, the vector `{1,2,3,4,5,6}` can be written as `{1:6}`.

Incremented Ranges of Integers. Use a second colon followed by an integer to indicate the increment. The matrix `{1,3,5,7;2,5,8,11}` can be written as `{1:7:2;2:11:3}`, where `1:7:2` indicates the integers from 1 to 7 incrementing by 2, and `2:11:3` indicates the integers from 2 to 11 incrementing by 3.

- You must use integers when specifying a range in either of these ways. Numbers with fractional parts are truncated to integers.
- If an arithmetic expression is used, it should be enclosed in parentheses.

Extraction of an Element, a Vector, or a Submatrix

You can use indexes in parentheses to extract an element from a vector or matrix, a vector from a matrix, or a submatrix from a matrix. In the following discussion, an **integer index** refers to an integer expression used as an index, which can be a scalar matrix with an integer value or an integer element extracted from a vector or matrix. Similarly, a **vector index** refers to a vector expression used as an index, which can be a vector matrix or a vector extracted from a matrix.

For example, if S is a scalar matrix, $S = [2]$, R is a row vector, $R = \begin{bmatrix} 1 & 3 & 5 \end{bmatrix}$, C is a column vector, $C = \begin{bmatrix} 2 \\ 3 \\ 4 \end{bmatrix}$, and A is a 5 × 5 matrix, $A = \begin{bmatrix} 11 & 12 & 13 & 14 & 15 \\ 21 & 22 & 23 & 24 & 25 \\ 31 & 32 & 33 & 34 & 35 \\ 41 & 42 & 43 & 44 & 45 \\ 51 & 52 & 53 & 54 & 55 \end{bmatrix}$, then:

$R(S) = R(2) = \{3\}$
$C(S) = C(2) = \{3\}$

- An integer index extracts an element from a vector matrix.
- The distinction between a row and a column vector does not matter when an integer index is used to extract an element from it.

  $A(2,3) = A(S,3) = \{23\}$
- Two integer indexes separated by a comma extract an element from a rectangular matrix.

  $A(R,2)=A(1:5:2,2)=\{12; 32; 52\}$

  $A(2,R)=A(2,1:5:2)=\{21, 23, 25\}$

  $A(C,2)=A(2:4,2)= \{22;32;42\}$

  $A(2,C)=A(2,2:4)= \{22,23,24\}$

- An integer and a vector index separated by a comma extract a vector from a matrix.
- The distinction between a row and a column vector does not matter when used as indexes in this way.

  $A(2,:)=A(S,:)$ = {21, 22, 23, 24, 25}

  $A(:,2)=A(:,S)$= {12; 22; 32; 42; 52}
- A colon by itself used as an index extracts an entire row or column vector from a matrix.

  $A(R,C)=A(R,2:4)=A(1:5:2,C)=A(1:5:2,2:4)$={12,13,14;32,33,34;52,53,54}

  $A(C,R)=A(C,1:5:2)=A(2:4,R)=A(2:4,1:5:2)$={21,23,25;31,33,35;41,43,45}
- Two vector indexes separated by a comma extract a submatrix from a matrix.
- The distinction between a row and a column vector does not matter when used as indexes in this way.

Construction of a Matrix from Other Matrices

You can use vector or rectangular matrices to construct a new matrix, separating row expressions by semicolons and components of row expressions by commas. If a column vector V_c has n elements and matrix M has the dimensions $n \times m$, then $\{M; V_c\}$ is an $n \times (m + 1)$ matrix. Similarly, if the row vector V_r has m elements and M is the same, then $\{M; V_r\}$ is an $(n + 1) \times m$ matrix. In fact, you can paste together any number of matrices and vectors this way.

- All of the components of each column expression must have the same number of actual rows, and all of the row expressions must have the same number of actual columns.
- The distinction between row vectors and column vectors must be observed carefully when constructing matrices in this way, so that the components will fit together properly.
- Several of the matrix functions are also useful in constructing matrices; see in particular the `MAKE`, `UNIFORM`, and `IDENT` functions in Matrix Functions on p. 1057.

Example

```
COMPUTE M={CORNER, COL3; ROW3}.
```

- This example constructs the matrix *M* from the matrix *CORNER*, the column vector *COL3*, and the row vector *ROW3*.
- *COL3* supplies new row components and is separated from *CORNER* by a comma.
- *ROW3* supplies column elements and is separated from previous expressions by a semicolon.
- *COL3* must have the same number of rows as *CORNER*.
- *ROW3* must have the same number of columns as the matrix resulting from the previous expressions.
- For example, if $CORNER = \begin{bmatrix} 11 & 12 \\ 21 & 22 \end{bmatrix}$, $COL3 = \begin{bmatrix} 13 \\ 23 \end{bmatrix}$, and $ROW3 = \begin{bmatrix} 31 & 32 & 33 \end{bmatrix}$, then:

  $M = \begin{bmatrix} 11 & 12 & 13 \\ 21 & 22 & 23 \\ 31 & 32 & 33 \end{bmatrix}$

Matrix Operations

You can perform matrix calculations according to the rules of matrix algebra and compare matrices using relational or logical operators.

Conformable Matrices

Many operations with matrices make sense only if the matrices involved have "suitable" dimensions. Most often, this means that they should be the same size, with the same number of rows and the same number of columns. Matrices that are the right size for an operation are said to be **conformable matrices**. If you attempt to do something in a matrix program with a matrix that is not conformable for that operation—a matrix that has the wrong dimensions—you will receive an error message, and the operation will not be performed. An important exception, where one of the matrices is a scalar, is discussed below.

Requirements for carrying out matrix operations include:

- Matrix addition and subtraction require that the two matrices be the same size.
- The relational and logical operations described below require that the two matrices be the same size.
- Matrix multiplication requires that the number of columns of the first matrix equal the number of rows of the second matrix.
- Raising a matrix to a power can be done only if the matrix is square. This includes the important operation of *inverting* a matrix, where the power is −1.
- Conformability requirements for matrix functions are noted in Matrix Functions on p. 1057 and in COMPUTE Statement on p. 1056.

Scalar Expansion

When one of the matrices involved in an operation is a scalar, the scalar is treated as a matrix of the correct size in order to carry out the operation. This internal scalar expansion is performed for the following operations:

- Addition and subtraction.
- Elementwise multiplication, division, and exponentiation. Note that multiplying a matrix elementwise by an expanded scalar is equivalent to ordinary scalar multiplication—each element of the matrix is multiplied by the scalar.
- All relational and logical operators.

Arithmetic Operators

You can add, subtract, multiply, or exponentiate matrices according to the rules of matrix algebra, or you can perform elementwise arithmetic, in which you multiply, divide, or exponentiate each element of a matrix separately. The arithmetic operators are listed below.

`Unary -`	*Sign reversal.* A minus sign placed in front of a matrix reverses the sign of each element. (The unary + is also accepted but has no effect.)
`+`	*Matrix addition.* Corresponding elements of the two matrices are added. The matrices must have the same dimensions, or one must be a scalar.
`-`	*Matrix subtraction.* Corresponding elements of the two matrices are subtracted. The matrices must have the same dimensions, or one must be a scalar.
`*`	*Multiplication.* There are two cases. First, *scalar multiplication*: if either of the matrices is a scalar, each element of the other matrix is multiplied by that scalar. Second, *matrix multiplication*: if A is an $m \times n$ matrix and B is an $n \times p$ matrix, $A*B$ is an $m \times p$ matrix in which the element in row i, column k, is equal to $\Sigma_{j=1}^{n} A(i,j) \times B(j,k)$
`/`	*Division.* The division operator performs elementwise division (described below). True matrix division, the inverse operation of matrix multiplication, is accomplished by taking the `INV` function (square matrices) or the `GINV` function (rectangular matrices) of the denominator and multiplying.
`**`	*Matrix exponentiation.* A matrix can be raised only to an integer power. The matrix, which must be square, is multiplied by itself as many times as the absolute value of the exponent. If the exponent is negative, the result is then inverted.
`&*`	*Elementwise multiplication.* Each element of the matrix is multiplied by the corresponding element of the second matrix. The matrices must have the same dimensions, or one must be a scalar.
`&/`	*Elementwise division.* Each element of the matrix is divided by the corresponding element of the second matrix. The matrices must have the same dimensions, or one must be a scalar.
`&**`	*Elementwise exponentiation.* Each element of the first matrix is raised to the power of the corresponding element of the second matrix. The matrices must have the same dimensions, or one must be a scalar.
`:`	*Sequential integers.* This operator creates a vector of consecutive integers from the value preceding the operator to the value following it. You can specify an optional increment following a second colon. See Matrix Notation Shorthand on p. 1049 for the principal use of this operator.

- Use these operators only with numeric matrices. The results are undefined when they are used with string matrices.

Relational Operators

The relational operators are used to compare two matrices, element by element. The result is a matrix of the same size as the (expanded) operands and containing either 1 or 0. The value of each element, 1 or 0, is determined by whether the comparison between the corresponding element of the first matrix with the corresponding element of the second matrix is true or false—1 for true and 0 for false. The matrices being compared must be of the same dimensions unless one of them is a scalar. The relational operators are listed in the following table.

Table 122-1
Relational operators in matrix programs

>	GT	Greater than
<	LT	Less than
<> or ~= (¬=)	NE	Not equal to
<=	LE	Less than or equal to
>=	GE	Greater than or equal to
=	EQ	Equal to

- The symbolic and alphabetic forms of these operators are equivalent.
- The symbols representing NE (~= or ¬=) are system dependent. In general, the tilde (~) is valid for ASCII systems, while the logical-not sign (¬), or whatever symbol is over the number 6 on the keyboard, is valid for IBM EBCDIC systems.
- Use these operators only with numeric matrices. The results are undefined when they are used with string matrices.

Logical Operators

Logical operators combine two matrices, normally containing values of 1 (true) or 0 (false). When used with other numerical matrices, they treat all positive values as true and all negative and 0 values as false. The logical operators are:

NOT	*Reverses the truth of the matrix that follows it.* Positive elements yield 0, and negative or 0 elements yield 1.
AND	*Both must be true.* The matrix *A* AND *B* is 1 where the corresponding elements of *A* and *B* are both positive and 0 elsewhere.
OR	*Either must be true.* The matrix *A* OR *B* is 1 where the corresponding element of either *A* or *B* is positive and 0 where both elements are negative or 0.
XOR	*Either must be true but not both.* The matrix *A* XOR *B* is 1 where one but not both of the corresponding elements of *A* and *B* is positive and 0 where both are positive or neither is positive.

Precedence of Operators

Parentheses can be used to control the order in which complex expressions are evaluated. When the order of evaluation is not specified by parentheses, operations are carried out in the order listed below. The operations higher on the list take precedence over the operations lower on the list.

+ − (unary)

:

** &**

* &* &/

+ − (addition and subtraction)

> >= < <= <>=

NOT

AND

OR XOR

Operations of equal precedence are performed left to right of the expressions.

Examples

```
COMPUTE A = {1,2,3;4,5,6}.
COMPUTE B = A + 4.
COMPUTE C = A &** 2.
COMPUTE D = 2 &** A.
COMPUTE E = A < 5.
COMPUTE F = (C &/ 2) < B.
```

- The results of these COMPUTE statements are:

$$A = \begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \end{bmatrix} \qquad B = \begin{bmatrix} 5 & 6 & 7 \\ 8 & 9 & 10 \end{bmatrix} \qquad C = \begin{bmatrix} 1 & 4 & 9 \\ 16 & 25 & 36 \end{bmatrix}$$

$$D = \begin{bmatrix} 2 & 4 & 8 \\ 16 & 32 & 64 \end{bmatrix} \qquad E = \begin{bmatrix} 1 & 1 & 1 \\ 1 & 0 & 0 \end{bmatrix} \qquad F = \begin{bmatrix} 1 & 1 & 1 \\ 0 & 0 & 0 \end{bmatrix}$$

MATRIX and Other Commands

A matrix program is a single procedure within a session.

- No active dataset is needed to run a matrix program. If one exists, it is ignored during matrix processing unless you specifically reference it (with an asterisk) on the GET, SAVE, MGET, or MSAVE statements.
- Variables defined in the active dataset are unavailable during matrix processing, except with the GET or MGET statements.
- Matrix variables are unavailable after the END MATRIX command unless you use SAVE or MSAVE to write them to the active dataset.
- You cannot run a matrix program from a syntax window if split-file processing is in effect. If you save the matrix program into a syntax file, however, you can use the INCLUDE command to run the program even if split-file processing is in effect.

Matrix Statements

The following table lists all of the statements that are accepted within a matrix program. Most of them have the same name as an analogous SPSS command and perform an exactly analogous function. Use only these statements between the MATRIX and END MATRIX commands. Any command not recognized as a valid matrix statement will be rejected by the matrix processor.

Table 122-2
Valid matrix statements

BREAK	ELSE IF	MSAVE
CALL	END IF	PRINT

COMPUTE	END LOOP	READ
DISPLAY	GET	RELEASE
DO IF	LOOP	SAVE*
ELSE	MGET	WRITE

*Maximum of 100 SAVE commands in amatrix program.

Exchanging Data with SPSS Data Files

Matrix programs can read and write SPSS data files.

- The GET and SAVE statements read and write ordinary (case-oriented) SPSS data files, treating each case as a row of a matrix and each ordinary variable as a column.

A matrix program cannot contain more than 100 SAVE commands.

- The MGET and MSAVE statements read and write matrix-format SPSS data files, respecting the structure defined by SPSS when it creates the file. These statements are discussed below.
- Case weighting in an SPSS data file is ignored when the file is read into a matrix program.

Using an Active Dataset

You can use the GET statement to read a case-oriented active dataset into a matrix variable. The result is a rectangular data matrix in which cases have become rows and variables have become columns. Special circumstances can affect the processing of this data matrix.

Split-File Processing. After a SPLIT FILE command, a matrix program executed with the INCLUDE command will read one split-file group with each execution of a GET statement. This enables you to process the subgroups separately within the matrix program.

Case Selection. When a subset of cases is selected for processing, as the result of a SELECT IF, SAMPLE, or N OF CASES command, only the selected cases will be read by the GET statement in a matrix program.

Temporary Transformations. The entire matrix program is treated as a single procedure. Temporary transformations—those preceded by the TEMPORARY command—entered immediately before a matrix program are in effect throughout that program (even if you GET the active dataset repeatedly) and are no longer in effect at the end of the matrix program.

Case Weighting. Case weighting in a active dataset is ignored when the file is read into a matrix program.

MATRIX and END MATRIX Commands

The MATRIX command, when encountered in a session, invokes the matrix processor, which reads matrix statements until the END MATRIX or FINISH command is encountered.

- MATRIX is a procedure and cannot be entered inside a transformation structure such as DO IF or LOOP.

- The MATRIX procedure does not require an active dataset.
- Comments are removed before subsequent lines are passed to the matrix processor.
- Macros are expanded before subsequent lines are passed to the matrix processor.

The END MATRIX command terminates matrix processing and returns control to the command processor.

- The contents of matrix variables are lost after an END MATRIX command.
- The active dataset, if present, becomes available again after an END MATRIX command.

COMPUTE Statement

The COMPUTE statement carries out most of the calculations in the matrix program. It closely resembles the COMPUTE command in the SPSS transformation language.

- The basic specification is the target variable, an equals sign, and the assignment expression. Values of the target variable are calculated according to the specification on the assignment expression.
- The target variable must be named first, and the equals sign is required. Only one target variable is allowed per COMPUTE statement.
- Expressions that extract portions of a matrix, such as *M*(1,:) or *M*(1:3,4), are allowed to assign values. (For more information, see Matrix Notation Shorthand on p. 1049.) The target variable must be specified as a variable.
- Matrix functions must specify at least one argument enclosed in parentheses. If an expression has two or more arguments, each argument must be separated by a comma. For a complete discussion of the functions and their arguments, see Matrix Functions on p. 1057.

String Values on COMPUTE Statements

Matrix variables, unlike those in the transformation language, are not checked for data type (numeric or string) when you use them in a COMPUTE statement.

- Numerical calculations with matrices containing string values will produce meaningless results.
- One or more elements of a matrix can be set equal to string constants by enclosing the string constants in quotes on a COMPUTE statement.
- String values can be copied from one matrix to another with the COMPUTE statement.
- There is no way to display a matrix that contains both numeric and string values, if you compute one for some reason.

Example

```
COMPUTE LABELS={"Observe", "Predict", "Error"}.
PRINT LABELS /FORMAT=A7.
```

- *LABELS* is a row vector containing three string values.

Arithmetic Operations and Comparisons

The expression on a COMPUTE statement can be formed from matrix constants and variables, combined with the arithmetic, relational, and logical operators discussed above. Matrix constructions and matrix functions are also allowed.

Examples

```
COMPUTE PI = 3.14159265.
COMPUTE RSQ = R * R.
COMPUTE FLAGS = EIGENVAL >= 1.
COMPUTE ESTIM = {OBS, PRED, ERR}.
```

- The first statement computes a scalar. Note that the braces are optional on a scalar constant.
- The second statement computes the square of the matrix *R*. *R* can be any square matrix, including a scalar.
- The third statement computes a vector named *FLAGS*, which has the same dimension as the existing vector *EIGENVAL*. Each element of *FLAGS* equals 1 if the corresponding element of *EIGENVAL* is greater than or equal to 1, and 0 if the corresponding element is less than 1.
- The fourth statement constructs a matrix *ESTIM* by concatenating the three vectors or matrices *OBS*, *PRED*, and *ERR*. The component matrices must have the same number of rows.

Matrix Functions

The following functions are available in the matrix program. Except where noted, each takes one or more numeric matrices as arguments and returns a matrix value as its result. The arguments must be enclosed in parentheses, and multiple arguments must be separated by commas.

On the following list, matrix arguments are represented by names beginning with *M*. Unless otherwise noted, these arguments can be vectors or scalars. Arguments that must be vectors are represented by names beginning with *V*, and arguments that must be scalars are represented by names beginning with *S*.

ABS(M) *Absolute value.* Takes a single argument. Returns a matrix having the same dimensions as the argument, containing the absolute values of its elements.

ALL(M) *Test for all elements nonzero.* Takes a single argument. Returns a scalar: 1 if all elements of the argument are nonzero and 0 if any element is zero.

ANY(M) *Test for any element nonzero.* Takes a single argument. Returns a scalar: 1 if any element of the argument is nonzero and 0 if all elements are zero.

ARSIN(M) *Inverse sine.* Takes a single argument, whose elements must be between −1 and 1. Returns a matrix having the same dimensions as the argument, containing the inverse sines (arcsines) of its elements. The results are in radians and are in the range from $-\pi/2$ to $\pi/2$.

ARTAN(M) *Inverse tangent.* Takes a single argument. Returns a matrix having the same dimensions as the argument, containing the inverse tangents (arctangents) of its elements, in radians. To convert radians to degrees, multiply by $180/\pi$, which you can compute as 45/ARTAN(1). For example, the statement `COMPUTE DEGREES=ARTAN(M)*45/ARTAN(1)` returns a matrix containing inverse tangents in degrees.

BLOCK(M1,M2,...) *Create a block diagonal matrix.* Takes any number of arguments. Returns a matrix with as many rows as the sum of the rows in all the arguments, and as many columns as the sum of the columns in all the arguments, with the argument matrices down the diagonal and zeros elsewhere. For example, if:

$$A = \begin{bmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix}, B = \begin{bmatrix} 2 & 2 \\ 2 & 2 \end{bmatrix}, C = \begin{bmatrix} 3 & 3 & 3 \\ 3 & 3 & 3 \\ 3 & 3 & 3 \\ 3 & 3 & 3 \end{bmatrix}, \text{and } D = \begin{bmatrix} 4 & 4 & 4 \end{bmatrix}$$

then:

$$BLOCK(A, B, C, D) = \begin{bmatrix} 1 & 1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 1 & 1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 2 & 2 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 2 & 2 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 3 & 3 & 3 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 3 & 3 & 3 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 3 & 3 & 3 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 3 & 3 & 3 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 4 & 4 & 4 \end{bmatrix}$$

CDFNORM(M) *Standard normal cumulative distribution function of elements.* Takes a single argument. Returns a matrix having the same dimensions as the argument, containing the values of the cumulative normal distribution function for each of its elements. If an element of the argument is *x*, the corresponding element of the result is a number between 0 and 1, giving the proportion of a normal distribution that is less than *x*. For example, `CDFNORM({-1.96,0,1.96})` results in, approximately, {.025,.5,.975}.

CHICDF(M,S) *Chi-square cumulative distribution function of elements.* Takes two arguments, a matrix of chi-square values and a scalar giving the degrees of freedom (which must be positive). Returns a matrix having the same dimensions as the first argument, containing the values of the cumulative chi-square distribution function for each of its elements. If an element of the first argument is *x* and the second argument is *S*, the corresponding element of the result is a number between 0 and 1, giving the proportion of a chi-square distribution with *S* degrees of freedom that is less than *x*. If *x* is not positive, the result is 0.

CHOL(M) *Cholesky decomposition.* Takes a single argument, which must be a symmetric positive-definite matrix (a square matrix, symmetric about the main diagonal, with positive eigenvalues). Returns a matrix having the same dimensions as the argument. If *M* is a symmetric positive-definite matrix and *B*=`CHOL`(*M*), then `T`(*B*)* *B*=*M*, where `T` is the transpose function defined below.

CMAX(M) *Column maxima.* Takes a single argument. Returns a row vector with the same number of columns as the argument. Each column of the result contains the maximum value of the corresponding column of the argument.

CMIN(M) *Column minima.* Takes a single argument. Returns a row vector with the same number of columns as the argument. Each column of the result contains the minimum value of the corresponding column of the argument.

COS(M) *Cosines.* Takes a single argument. Returns a matrix having the same dimensions as the argument, containing the cosines of the elements of the argument. Elements of the argument matrix are assumed to be measured in radians. To convert degrees to radians, multiply by π/180, which you can compute as ARTAN(1)/45. For example, the statement `COMPUTE COSINES=COS(DEGREES*ARTAN(1)/45)` returns cosines from a matrix containing elements measured in degrees.

CSSQ(M) *Column sums of squares.* Takes a single argument. Returns a row vector with the same number of columns as the argument. Each column of the result contains the sum of the squared values of the elements in the corresponding column of the argument.

CSUM(M) *Column sums.* Takes a single argument. Returns a row vector with the same number of columns as the argument. Each column of the result contains the sum of the elements in the corresponding column of the argument.

DESIGN(M) *Main-effects design matrix from the columns of a matrix.* Takes a single argument. Returns a matrix having the same number of rows as the argument, and as many columns as the sum of the numbers of unique values in each column of the argument. Constant columns in the argument are skipped with a warning message. The result contains 1 in the row(s) where the value in question occurs in the argument and 0 otherwise. For example, if:

$$A = \begin{bmatrix} 1 & 2 & 8 \\ 1 & 3 & 8 \\ 2 & 6 & 5 \\ 3 & 3 & 8 \\ 3 & 6 & 5 \end{bmatrix}, \text{ then:}$$

$$DESIGN(A) = \begin{bmatrix} 1 & 0 & 0 & 1 & 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 0 & 1 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 & 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 0 & 1 & 0 & 1 & 0 \\ 0 & 0 & 1 & 0 & 0 & 1 & 0 & 1 \end{bmatrix}$$

The first three columns of the result correspond to the three distinct values 1, 2, and 3 in the first column of *A*; the fourth through sixth columns of the result correspond to the three distinct values 2, 3, and 6 in the second column of *A*; and the last two columns of the result correspond to the two distinct values 8 and 5 in the third column of *A*.

DET(M) *Determinant.* Takes a single argument, which must be a square matrix. Returns a scalar, which is the determinant of the argument.

DIAG(M) *Diagonal of a matrix.* Takes a single argument. Returns a column vector with as many rows as the minimum of the number of rows and the number of columns in the argument. The *i*th element of the result is the value in row *i*, column *i* of the argument.

EOF(file) *End of file indicator.* Normally used after a `READ` statement. Takes a single argument, which must be either a filename in quotes, or a file handle defined on a `FILE HANDLE` command that precedes the matrix program. Returns a scalar equal to 1 if the last attempt to read that file encountered the last record in the file, and equal to 0 if the last attempt did not encounter the last record in the file. Calling the `EOF` function causes a `REREAD` specification on the `READ` statement to be ignored on the next attempt to read the file.

EVAL(M) *Eigenvalues of a symmetric matrix.* Takes a single argument, which must be a symmetric matrix. Returns a column vector with the same number of rows as the argument, containing the eigenvalues of the argument in decreasing numerical order.

EXP(M) *Exponentials of matrix elements.* Takes a single argument. Returns a matrix having the same dimensions as the argument, in which each element equals *e* raised to the power of the corresponding element in the argument matrix.

FCDF(M,S1,S2) *Cumulative* F *distribution function of elements.* Takes three arguments, a matrix of *F* values and two scalars giving the degrees of freedom (which must be positive). Returns a matrix having the same dimensions as the first argument *M*, containing the values of the cumulative *F* distribution function for each of its elements. If an element of the first argument is *x* and the second and third arguments are *S1* and *S2*, the corresponding element of the result is a number between 0 and 1, giving the proportion of an *F* distribution with *S1* and *S2* degrees of freedom that is less than *x*. If *x* is not positive, the result is 0.

GINV(M) *Moore-Penrose generalized inverse of a matrix.* Takes a single argument. Returns a matrix with the same dimensions as the transpose of the argument. If *A* is the generalized inverse of a matrix *M*, then *M*A*M=M* and *A*M*A=A*. Both *A*M* and *M*A* are symmetric.

GRADE(M) *Ranks elements in a matrix*. Takes a single argument. Uses sequential integers for ties.

GSCH(M) *Gram-Schmidt orthonormal basis for the space spanned by the column vectors of a matrix.* Takes a single argument, in which there must be as many linearly independent columns as there are rows. (That is, the rank of the argument must equal the number of rows.) Returns a square matrix with as many rows as the argument. The columns of the result form a basis for the space spanned by the columns of the argument.

IDENT(S1 [,S2]) *Create an identity matrix.* Takes either one or two arguments, which must be scalars. Returns a matrix with as many rows as the first argument and as many columns as the second argument, if any. If the second argument is omitted, the result is a square matrix. Elements on the main diagonal of the result equal 1, and all other elements equal 0.

INV(M) *Inverse of a matrix.* Takes a single argument, which must be square and nonsingular (that is, its determinant must not be 0). Returns a square matrix having the same dimensions as the argument. If *A* is the inverse of *M*, then *M*A=A*M=I*, where *I* is the identity matrix.

KRONEKER(M1,M2) *Kronecker product of two matrices.* Takes two arguments. Returns a matrix whose row dimension is the product of the row dimensions of the arguments and whose column dimension is the product of the column dimensions of the arguments. The Kronecker product of two matrices *A* and *B* takes the form of an array of scalar products:

A(1,1)**BA*(1,2)* *B* ... *A*(1,*N*)**B*

A(2,1)**BA*(2,2)* *B* ... *A*(2,*N*)* *B*

...

A(*M*,1)**BA*(*M*,2)**B* ... *A*(*M*, *N*)**B*

LG10(M) *Base 10 logarithms of the elements.* Takes a single argument, all of whose elements must be positive. Returns a matrix having the same dimensions as the argument, in which each element is the logarithm to base 10 of the corresponding element of the argument.

LN(M) *Natural logarithms of the elements.* Takes a single argument, all of whose elements must be positive. Returns a matrix having the same dimensions as the argument, in which each element is the logarithm to base *e* of the corresponding element of the argument.

MAGIC(S) *Magic square.* Takes a single scalar, which must be 3 or larger, as an argument. Returns a square matrix with *S* rows and *S* columns containing the integers from 1 through S^2. All of the row sums and all of the column sums are equal in the result matrix. (The result matrix is only one of several possible magic squares.)

MAKE(S1,S2,S3) *Create a matrix, all of whose elements equal a specified value.* Takes three scalars as arguments. Returns an $S1 \times S2$ matrix, all of whose elements equal *S*3.

MDIAG(V) *Create a square matrix with a specified main diagonal.* Takes a single vector as an argument. Returns a square matrix with as many rows and columns as the dimension of the vector. The elements of the vector appear on the main diagonal of the matrix, and the other matrix elements are all 0.

MMAX(M) *Maximum element in a matrix.* Takes a single argument. Returns a scalar equal to the numerically largest element in the argument *M*.

MMIN(M) *Minimum element in a matrix.* Takes a single argument. Returns a scalar equal to the numerically smallest element in the argument *M*.

MOD(M,S) *Remainders after division by a scalar.* Takes two arguments, a matrix and a scalar (which must not be 0). Returns a matrix having the same dimensions as *M*, each of whose elements is the remainder after the corresponding element of *M* is divided by *S*. The sign of each element of the result is the same as the sign of the corresponding element of the matrix argument *M*.

MSSQ(M) *Matrix sum of squares.* Takes a single argument. Returns a scalar that equals the sum of the squared values of all of the elements in the argument.

MSUM(M) *Matrix sum.* Takes a single argument. Returns a scalar that equals the sum of all of the elements in the argument.

NCOL(M) *Number of columns in a matrix.* Takes a single argument. Returns a scalar that equals the number of columns in the argument.

NROW(M) *Number of rows in a matrix.* Takes a single argument. Returns a scalar that equals the number of rows in the argument.

RANK(M) *Rank of a matrix.* Takes a single argument. Returns a scalar that equals the number of linearly independent rows or columns in the argument.

RESHAPE(M,S1,S2) *Matrix of different dimensions.* Takes three arguments, a matrix and two scalars, whose product must equal the number of elements in the matrix. Returns a matrix whose dimensions are given by the scalar arguments. For example, if *M* is any matrix with exactly 50 elements, then `RESHAPE(M, 5, 10)` is a matrix with 5 rows and 10 columns. Elements are assigned to the reshaped matrix in order by row.

RMAX(M) *Row maxima.* Takes a single argument. Returns a column vector with the same number of rows as the argument. Each row of the result contains the maximum value of the corresponding row of the argument.

RMIN(M) *Row minima.* Takes a single argument. Returns a column vector with the same number of rows as the argument. Each row of the result contains the minimum value of the corresponding row of the argument.

RND(M) *Elements rounded to the nearest integers.* Takes a single argument. Returns a matrix having the same dimensions as the argument. Each element of the result equals the corresponding element of the argument rounded to an integer.

RNKORDER(M) *Ranking of matrix elements in ascending order.* Takes a single argument. Returns a matrix having the same dimensions as the argument *M*. The smallest element of the argument corresponds to a result element of 1, and the largest element of the argument to a result element equal to the number of elements, except that ties (equal elements in *M*) are resolved by assigning a rank equal to the arithmetic mean of the applicable ranks. For example, if:

$$M = \begin{bmatrix} -1 & -21.7 & 8 \\ 0 & 3.91 & -21.7 \\ 8 & 9 & 10 \end{bmatrix}, \text{ then:}$$

$$RNKORDER(M) = \begin{bmatrix} 3 & 1.5 & 6.5 \\ 4 & 5 & 1.5 \\ 6.5 & 8 & 9 \end{bmatrix}$$

RSSQ(M) *Row sums of squares.* Takes a single argument. Returns a column vector having the same number of rows as the argument. Each row of the result contains the sum of the squared values of the elements in the corresponding row of the argument.

RSUM(M) *Row sums.* Takes a single argument. Returns a column vector having the same number of rows as the argument. Each row of the result contains the sum of the elements in the corresponding row of the argument.

SIN(M) *Sines.* Takes a single argument. Returns a matrix having the same dimensions as the argument, containing the sines of the elements of the argument. Elements of the argument matrix are assumed to be measured in radians. To convert degrees to radians, multiply by π/180, which you can compute as ARTAN(1)/45. For example, the statement `COMPUTE SINES=SIN(DEGREES*ARTAN(1)/45)` computes sines from a matrix containing elements measured in degrees.

SOLVE(M1,M2) *Solution of systems of linear equations.* Takes two arguments, the first of which must be square and nonsingular (its determinant must be nonzero), and the second of which must have the same number of rows as the first. Returns a matrix with the same dimensions as the second argument. If *M1***X*=*M2*, then *X*= `SOLVE`(*M1*, *M2*). In effect, this function sets its result *X* equal to `INV`(*M1*)**M2*.

SQRT(M) *Square roots of elements.* Takes a single argument whose elements must not be negative. Returns a matrix having the same dimensions as the arguments, whose elements are the positive square roots of the corresponding elements of the argument.

SSCP(M) *Sums of squares and cross-products.* Takes a single argument. Returns a square matrix having as many rows (and columns) as the argument has columns. `SSCP`*(M)* equals `T`*(M)***M*, where `T` is the transpose function defined below.

SVAL(M) *Singular values of a matrix.* Takes a single argument. Returns a column vector containing as many rows as the minimum of the numbers of rows and columns in the argument, containing the singular values of the argument in decreasing numerical order. The singular values of a matrix *M* are the square roots of the eigenvalues of `T`*(M)***M*, where `T` is the transpose function discussed below.

SWEEP(M,S) *Sweep transformation of a matrix.* Takes two arguments, a matrix and a scalar, which must be less than or equal to both the number of rows and the number of columns of the matrix. In other words, the pivot element of the matrix, which is *M*(*S*,*S*), must exist. Returns a matrix of the same dimensions as *M*. Suppose that *S*={ *k*} and *A*=`SWEEP`(*M*,*S*). If *M*(*k*,*k*) is not 0, then

$A(k,k) = 1/M(k,k)$

$A(i,k) = -M(i,k)/M(k,k)$, for i not equal to k

$A(k,j) = M(k,j)/M(k,k)$, for j not equal to k

$A(i,j) = (M(i,j)*M(k,k), - M(i,k)*M(k,j))/M(k,k)$, for i,j not equal to k

and if $M(k,k)$ equals 0, then

$A(i,k) = A(k,i) = 0$, for all i

$A(i,j) = M(i,j)$, for i,j not equal to k

TCDF(M,S) *Cumulative* t *distribution function of elements.* Takes two arguments, a matrix of *t* values and a scalar giving the degrees of freedom (which must be positive). Returns a matrix having the same dimensions as *M*, containing the values of the cumulative *t* distribution function for each of its elements. If an element of the first argument is *x* and the second argument is *S*, then the corresponding element of the result is a number between 0 and 1, giving the proportion of a *t* distribution with *S* degrees of freedom that is less than *x*.

TRACE(M) *Sum of the main diagonal elements.* Takes a single argument. Returns a scalar, which equals the sum of the elements on the main diagonal of the argument.

TRANSPOS(M) *Transpose of the matrix.* Takes a single argument. Returns the transpose of the argument. `TRANSPOS` can be shortened to `T`.

TRUNC(M) *Truncation of elements to integers.* Takes a single argument. Returns a matrix having the same dimensions as the argument, whose elements equal the corresponding elements of the argument truncated to integers.

UNIFORM(S1,S2) *Uniformly distributed pseudo-random numbers between 0 and 1.* Takes two scalars as arguments. Returns a matrix with the number of rows specified by the first argument and the number of columns specified by the second argument, containing pseudo-random numbers uniformly distributed between 0 and 1.

CALL Statement

Closely related to the matrix functions are the matrix procedures, which are invoked with the `CALL` statement. Procedures, similarly to functions, accept arguments enclosed in parentheses and separated by commas. They return their result in one or more of the arguments as noted in the individual descriptions below. They are implemented as procedures rather than as functions so

that they can return more than one value or (in the case of SETDIAG) modify a matrix without making a copy of it.

EIGEN(M,var1,var2)	*Eigenvectors and eigenvalues of a symmetric matrix.* Takes three arguments: a symmetric matrix and two valid variable names to which the results are assigned. If *M* is a symmetric matrix, the statement CALL EIGEN(M, A, B) will assign to *A* a matrix having the same dimensions as *M*, containing the eigenvectors of *M* as its columns, and will assign to *B* a column vector having as many rows as *M*, containing the eigenvalues of *M* in descending numerical order. The eigenvectors in *A* are ordered to correspond with the eigenvalues in *B*; thus, the first column corresponds to the largest eigenvalue, the second to the second largest, and so on.
SETDIAG(M,V)	*Set the main diagonal of a matrix.* Takes two arguments, a matrix and a vector. Elements on the main diagonal of *M* are set equal to the corresponding elements of *V*. If *V* is a scalar, all the diagonal elements are set equal to that scalar. Otherwise, if *V* has fewer elements than the main diagonal of *M*, remaining elements on the main diagonal are unchanged. If *V* has more elements than are needed, the extra elements are not used. See also the MDIAG matrix function.
SVD(M,var1,var2,var3)	*Singular value decomposition of a matrix.* Takes four arguments: a matrix and three valid variable names to which the results are assigned. If *M* is a matrix, the statement CALL SVD(M,U,Q,V) will assign to *Q* a diagonal matrix of the same dimensions as *M*, and to *U* and *V* unitary matrices (matrices whose inverses equal their transposes) of appropriate dimensions, such that *M*=*U***Q**T(*V*), where T is the transpose function defined above. The singular values of *M* are in the main diagonal of *Q*.

PRINT Statement

The PRINT statement displays matrices or matrix expressions. Its syntax is as follows:

```
PRINT [matrix expression]
      [/FORMAT="format descriptor"]
      [/TITLE="title"]
      [/SPACE={NEWPAGE}]
              {n      }
      [{/RLABELS=list of quoted names}]
       {/RNAMES=vector of names      }

      [{/CLABELS=list of quoted names}]
       {/CNAMES=vector of names      }
```

Matrix Expression

Matrix expression is a single matrix variable name or an expression that evaluates to a matrix. PRINT displays the specified matrix.

- The matrix specification must precede any other specifications on the PRINT statement. If no matrix is specified, no data will be displayed, but the TITLE and SPACE specifications will be honored.
- You can specify a matrix name, a matrix raised to a power, or a matrix function (with its arguments in parentheses) by itself, but you must enclose other matrix expressions in parentheses. For example, PRINT A, PRINT INV(A), and PRINT B**DET(T(C)*D) are all legal, but PRINT A+B is not. You must specify PRINT (A+B).

- Constant expressions are allowed.
- A matrix program can consist entirely of PRINT statements, without defining any matrix variables.

FORMAT Keyword

FORMAT specifies a single format descriptor for display of the matrix data.

- All matrix elements are displayed with the same format.
- You can use any printable numeric format (for numeric matrices) or string format (for string matrices) as defined in FORMATS.
- The matrix processor will choose a suitable numeric format if you omit the FORMAT specification, but a string format such as A8 is essential when displaying a matrix containing string data.
- String values exceeding the width of a string format are truncated.
- See Scaling Factor in Displays on p. 1066 for default formatting of matrices containing large or small values.

TITLE Keyword

TITLE specifies a title for the matrix displayed. The title must be enclosed in quotes. If it exceeds the maximum display width, it is truncated. The slash preceding TITLE is required, even if it is the only specification on the PRINT statement. If you omit the TITLE specification, the matrix name or expression from the PRINT statement is used as a default title.

SPACE Keyword

SPACE controls output spacing before printing the title and the matrix. You can specify either a positive number or the keyword NEWPAGE. The slash preceding SPACE is required, even if it is the only specification on the PRINT statement.

NEWPAGE	*Start a new page before printing the title.*
n	*Skip* n *lines before displaying the title.*

RLABELS Keyword

RLABELS allows you to supply row labels for the matrix.

- The labels must be separated by commas.
- Enclose individual labels in quotes if they contain embedded commas or if you want to preserve lowercase letters. Otherwise, quotes are optional.
- If too many names are supplied, the extras are ignored. If not enough names are supplied, the last rows remain unlabeled.

RNAMES Keyword

RNAMES allows you to supply the name of a vector or a vector expression containing row labels for the matrix.

- Either a row vector or a column vector can be used, but the vector must contain string data.
- If too many names are supplied, the extras are ignored. If not enough names are supplied, the last rows remain unlabeled.

CLABELS Keyword

CLABELS allows you to supply column labels for the matrix.

- The labels must be separated by commas.
- Enclose individual labels in quotes if they contain embedded commas or if you want to preserve lowercase letters. Otherwise, quotes are optional.
- If too many names are supplied, the extras are ignored. If not enough names are supplied, the last columns remain unlabeled.

CNAMES Keyword

CNAMES allows you to supply the name of a vector or a vector expression containing column labels for the matrix.

- Either a row vector or a column vector can be used, but the vector must contain string data.
- If too many names are supplied, the extras are ignored. If not enough names are supplied, the last columns remain unlabeled.

Scaling Factor in Displays

When a matrix contains very large or very small numbers, it may be necessary to use scientific notation to display the data. If you do not specify a display format, the matrix processor chooses a power-of-10 multiplier that will allow the largest value to be displayed, and it displays this multiplier on a heading line before the data. The multiplier is not displayed for each element in the matrix. The displayed values, multiplied by the power of 10 that is indicated in the heading, equal the actual values (possibly rounded).

- Values that are very small, relative to the multiplier, are displayed as 0.
- If you explicitly specify a scientific-notation format (Ew.d), each matrix element is displayed using that format. This permits you to display very large and very small numbers in the same matrix without losing precision.

Example

```
COMPUTE M = {.0000000001357, 2.468, 3690000000}.
PRINT M /TITLE "Default format".
```

```
PRINT M /FORMAT "E13" /TITLE "Explicit exponential format".
```

- The first PRINT subcommand uses the default format with 10^9 as the multiplier for each element of the matrix. This results in the following output:

Figure 122-1

```
Default format
  10 ** 9   X
    .000000000    .000000002   3.690000000
```

Note that the first element is displayed as 0 and the second is rounded to one significant digit.

- An explicitly specified exponential format on the second PRINT subcommand allows each element to be displayed with full precision, as the following output shows:

Figure 122-2

```
Explicit exponential format
       1.E-010       2.E+000       4.E+009
```

Matrix Control Structures

The matrix language includes two structures that allow you to alter the flow of control within a matrix program.

- The DO IF statement tests a logical expression to determine whether one or more subsequent matrix statements should be executed.
- The LOOP statement defines the beginning of a block of matrix statements that should be executed repeatedly until a termination criterion is satisfied or a BREAK statement is executed.

These statements closely resemble the DO IF and LOOP commands in the SPSS transformation language. In particular, these structures can be nested within one another as deeply as the available memory allows.

DO IF Structures

A DO IF structure in a matrix program affects the flow of control exactly as the analogous commands affect a transformation program, except that missing-value considerations do not arise in a matrix program. The syntax of the DO IF structure is as follows:

```
DO IF [(]logical expression[)]
  matrix statements
[ELSE IF [(]logical expression[)]]
  matrix statements
[ELSE IF...]
  .
  .
  .
[ELSE]
 matrix statements
END IF.
```

- The DO IF statement marks the beginning of the structure, and the END IF statement marks its end.
- The ELSE IF statement is optional and can be repeated as many times as desired within the structure.
- The ELSE statement is optional. It can be used only once and must follow any ELSE IF statements.
- The END IF statement must follow any ELSE IF and ELSE statements.
- The DO IF and ELSE IF statements must contain a logical expression, normally one involving the relational operators EQ, GT, and so on. However, the matrix language allows any expression that evaluates to a scalar to be used as the logical expression. Scalars greater than 0 are considered true, and scalars less than or equal to 0 are considered false.

A DO IF structure affects the flow of control within a matrix program as follows:

- If the logical expression on the DO IF statement is true, the statements immediately following the DO IF are executed up to the next ELSE IF or ELSE in the structure. Control then passes to the first statement following the END IF for that structure.
- If the expression on the DO IF statement is false, control passes to the first ELSE IF, where the logical expression is evaluated. If this expression is true, statements following the ELSE IF are executed up to the next ELSE IF or ELSE statement, and control passes to the first statement following the END IF for that structure.
- If the expressions on the DO IF and the first ELSE IF statements are both false, control passes to the next ELSE IF, where that logical expression is evaluated. If none of the expressions is true on any of the ELSE IF statements, statements following the ELSE statement are executed up to the END IF statement, and control falls out of the structure.
- If none of the expressions on the DO IF statement or the ELSE IF statements is true and there is no ELSE statement, control passes to the first statement following the END IF for that structure.

LOOP Structures

A LOOP structure in a matrix program affects the flow of control exactly as the analogous commands affect transformation program, except that missing-value considerations do not arise in a matrix program. Its syntax is as follows:

```
LOOP [varname=n TO m [BY k]] [IF [()]logical expression[)]
matrix statements
[BREAK]
matrix statements
END LOOP [IF [()]logical expression[)]]
```

The matrix statements specified between LOOP and END LOOP are executed repeatedly until one of the following conditions is met:

- A logical expression on the IF clause of the LOOP statement is evaluated as false.
- An index variable used on the LOOP statement passes beyond its terminal value.

- A logical expression on the IF clause of the END LOOP statement is evaluated as true.
- A BREAK statement is executed within the loop structure (but outside of any nested loop structures).

Note: Unlike the LOOP command (outside the matrix language), the index value of a matrix LOOP structure does not override the maximum number of loops controlled by SET MXLOOPS. You must explicitly set the MXLOOPS value to a value high enough to accommodate the index value. For more information, see MXLOOPS Subcommand on p. 1719.

Index Clause on the LOOP Statement

An index clause on a LOOP statement creates an index variable whose name is specified immediately after the keyword LOOP. The variable is assigned an initial value of *n*. Each time through the loop, the variable is tested against the terminal value *m* and incremented by the increment value *k* if *k* is specified or by 1 if *k* is not specified. When the index variable is greater than *m* for positive increments or less than *m* for negative increments, control passes to the statement after the END LOOP statement.

- Both the index clause and the IF clause are optional. If both are present, the index clause must appear first.
- The index variable must be scalar with a valid matrix variable name.
- The initial value, *n*, the terminal value, *m*, and the increment, *k* (if present), must be scalars or matrix expressions evaluating to scalars. Non-integer values are truncated to integers before use.
- If the keyword BY and the increment *k* are absent, an increment of 1 is used.

IF Clause on the LOOP Statement

The logical expression is evaluated before each iteration of the loop structure. If it is false, the loop terminates and control passes to the statement after END LOOP.

- The IF clause is optional. If both the index clause and the IF clause are present, the index clause must appear first.
- As in the DO IF structure, the logical expression of the IF clause is evaluated as scalar, with positive values being treated as true and 0 or negative values, as false.

IF Clause on the END LOOP Statement

When an IF clause is present on an END LOOP statement, the logical expression is evaluated after each iteration of the loop structure. If it is true, the loop terminates and control passes to the statement following the END LOOP statement.

- The IF clause is optional.
- As in the LOOP statement, the logical expression of the IF clause is evaluated as scalar, with positive values being treated as true and 0 or negative values, as false.

BREAK Statement

The BREAK statement within a loop structure transfers control immediately to the statement following the (next) END LOOP statement. It is normally placed within a DO IF structure inside the LOOP structure to exit the loop when the specified conditions are met.

Example

```
LOOP LOCATION = 1, NROW(VEC).
+  DO IF (VEC(LOCATION) = TARGET).
+     BREAK.

+  END IF.
END LOOP.
```

- This loop searches for the (first) location of a specific value, *TARGET*, in a vector, *VEC*.
- The DO IF statement checks whether the vector element indexed by *LOCATION* equals the target.
- If so, the BREAK statement transfers control out of the loop, leaving *LOCATION* as the index of *TARGET* in *VEC*.

READ Statement: Reading Character Data

The READ statement reads data into a matrix or submatrix from a character-format file—that is, a file containing ordinary numbers or words in readable form. The syntax for the READ statement is:

```
READ  variable reference
  [/FILE = file reference]
   /FIELD = c1 TO c2 [BY w]
  [/SIZE = size expression]
  [/MODE = {RECTANGULAR}]
           {SYMMETRIC  }
  [/REREAD]
  [/FORMAT = format descriptor]
```

- The file can contain values in freefield or fixed-column format. The data can appear in any of the field formats supported by DATA LIST.
- More than one matrix can be read from a single input record by rereading the record.
- If the end of the file is encountered during a READ operation (that is, fewer values are available than the number of elements required by the specified matrix size), a warning message is displayed and the contents of the unread elements of the matrix are unpredictable.

Variable Specification

The variable reference on the READ statement is a matrix variable name, with or without indexes.

For a name without indexes:

- READ creates the specified matrix variable.
- The matrix need not exist when READ is executed.

- If the matrix already exists, it is replaced by the matrix read from the file.
- You must specify the size of the matrix using the SIZE specification.

For an indexed name:

- READ creates a submatrix from an existing matrix.
- The matrix variable named must already exist.
- You can define any submatrix with indexes; for example, M(:,I). To define an entire existing matrix, specify M(:,:).
- The SIZE specification can be omitted. If specified, its value must match the size of the specified submatrix.

FILE Specification

FILE designates the character file containing the data. It can be an actual filename in quotes, or a file handle defined on a FILE HANDLE command that precedes the matrix program.

- The filename or handle must specify an existing file containing character data, not an SPSS data file or a specially formatted file of another kind, such as a spreadsheet file.
- The FILE specification is required on the first READ statement in a matrix program (first in order of appearance, not necessarily in order of execution). If you omit the FILE specification from a later READ statement, the statement uses the most recently named file (in order of appearance) on a READ statement in the same matrix program.

FIELD Specification

FIELD specifies the column positions of a fixed-format record where the data for matrix elements are located.

- The FIELD specification is required.
- Startcol is the number of the leftmost column of the input area.
- Endcol is the number of the rightmost column of the input area.
- Both startcol and endcol are required and both must be constants. For example, FIELD = 9 TO 72 specifies that values to be read appear between columns 9 and 72 (inclusive) of each input record.
- The BY clause, if present, indicates that each value appears within a fixed set of columns on the input record; that is, one value is separated from the next by its column position rather than by a space or comma. Width is the width of the area designated for each value. For example, FIELD = 1 TO 80 BY 10 indicates that there are eight possible values per record and that one will appear between columns 1 and 10 (inclusive), another between columns 11 and 20, and so on, up to columns 71 and 80. The BY value must evenly divide the length of the field. That is, endcol-startcol+1 must be a multiple of the width.
- You can use the FORMAT specification to supply the same information as the BY clause of the FIELD specification. If you omit the BY clause and do not specify a format on the FORMAT specification, READ assumes that values are separated by blanks or commas within the designated field.

SIZE Specification

The SIZE specification is a matrix expression that, when evaluated, specifies the size of the matrix to be read.

- The expression should evaluate to a two-element row or column vector. The first element designates the number of rows in the matrix to be read; the second element gives the number of columns.
- Values of the SIZE specification are truncated to integers if necessary.
- The size expression may be a constant, such as {5;5}, or a matrix variable name, such as MSIZE, or any valid expression, such as INFO(1,:).
- If you use a scalar as the size expression, a column vector containing that number of rows is read. Thus, SIZE=1 reads a scalar, and SIZE=3 reads a 3 × 1 column vector.

You must include a SIZE specification whenever you name an entire matrix (rather than a submatrix) on the READ statement. If you specify a submatrix, the SIZE specification is optional but, if included, must agree with the size of the specified submatrix.

MODE Specification

MODE specifies the format of the matrix to be read in. It can be either rectangular or symmetric. If the MODE specification is omitted, the default is RECTANGULAR.

RECTANGULAR	*Matrix is completely represented in file.* Each row begins on a new record, and all entries in that row are present on that and (possibly) succeeding records. This is the default if the MODE specification is omitted.
SYMMETRIC	*Elements of the matrix below the main diagonal are the same as those above it.* Only matrix elements on and below the main diagonal are read; elements above the diagonal are set equal to the corresponding symmetric elements below the diagonal. Each row is read beginning on a new record, although it may span more than one record. Only a single value is read from the first record, two values are read from the second, and so on.

- If SYMMETRIC is specified, the matrix processor first checks that the number of rows and the number of columns are the same. If the numbers, specified either on SIZE or on the variable reference, are not the same, an error message is displayed and the command is not executed.

REREAD Specification

The REREAD specification indicates that the current READ statement should begin with the last record read by a previous READ statement.

- REREAD has no further specifications.
- REREAD cannot be used on the first READ statement to read from a file.
- If you omit REREAD, the READ statement begins with the first record following the last one read by the previous READ statement.
- The REREAD specification is ignored on the first READ statement following a call to the EOF function for the same file.

FORMAT Specification

FORMAT specifies how the matrix processor should interpret the input data. The format descriptor can be any valid SPSS data format, such as F6, E12.2, or A6, or it can be a type code; for example, F, E, or A.

- If you omit the FORMAT specification, the default is F.
- You can specify the width of fixed-size data fields with either a FORMAT specification or a BY clause on a FIELD specification. You can include it in both places only if you specify the same value.
- If you do not include either a FORMAT or a BY clause on FIELD, READ expects values separated by blanks or commas.
- An additional way of specifying the width is to supply a repetition factor without a width (for example, 10F, 5COMMA, or 3E). The field width is then calculated by dividing the width of the whole input area on the FIELD specification by the repetition factor. A format with a digit for the repetition factor must be enclosed in quotes.
- Only one format can be specified. A specification such as FORMAT='5F2.0 3F3.0 F2.0' is invalid.

WRITE Statement: Writing Character Data

WRITE writes the value of a matrix expression to an external file. The syntax of the WRITE statement is:

```
WRITE  matrix expression
   [/OUTFILE = file reference]
    /FIELD = startcol TO endcol [BY width]
   [/MODE = {RECTANGULAR}]
            {TRIANGULAR }
   [/HOLD]
   [/FORMAT = format descriptor]
```

Matrix Expression Specification

Specify any matrix expression that evaluates to the value(s) to be written.

- The matrix specification must precede any other specifications on the WRITE statement.
- You can specify a matrix name, a matrix raised to a power, or a matrix function (with its arguments in parentheses) by itself, but you must enclose other matrix expressions in parentheses. For example, WRITE A, WRITE INV(A), or WRITE B**DET(T(C)*D) is legal, but WRITE A+B is not. You must specify WRITE (A+B).
- Constant expressions are allowed.

OUTFILE Specification

OUTFILE designates the character file to which the matrix expression is to be written. The file reference can be an actual filename in quotes or a file handle defined on a FILE HANDLE command that precedes the matrix program. The filename or file handle must be a valid file specification.

- The OUTFILE specification is required on the first WRITE statement in a matrix program (first in order of appearance, not necessarily in order of execution).
- If you omit the OUTFILE specification from a later WRITE statement, the statement uses the most recently named file (in order of appearance) on a WRITE statement in the same matrix program.

FIELD Specification

FIELD specifies the column positions of a fixed-format record to which the data should be written.

- The FIELD specification is required.
- The start column, *c1*, is the number of the leftmost column of the output area.
- The end column, *c2*, is the number of the rightmost column of the output area.
- Both *c1* and *c2* are required, and both must be constants. For example, FIELD = 9 TO 72 specifies that values should be written between columns 9 and 72 (inclusive) of each output record.
- The BY clause, if present, indicates how many characters should be allocated to the output value of a single matrix element. The value *w* is the width of the area designated for each value. For example, FIELD = 1 TO 80 BY 10 indicates that up to eight values should be written per record, and that one should go between columns 1 and 10 (inclusive), another between columns 11 and 20, and so on up to columns 71 and 80. The value on the BY clause must evenly divide the length of the field. That is, $c2 - c1 + 1$ must be a multiple of *w*.
- You can use the FORMAT specification (see below) to supply the same information as the BY clause. If you omit the BY clause from the FIELD specification and do not specify a format on the FORMAT specification, WRITE uses freefield format, separating matrix elements by single blank spaces.

MODE Specification

MODE specifies the format of the matrix to be written. If MODE is not specified, the default is RECTANGULAR.

RECTANGULAR	*Write the entire matrix*. Each row starts a new record, and all of the values in that row are present in that and (possibly) subsequent records. This is the default if the MODE specification is omitted.
TRIANGULAR	*Write only the lower triangular entries and the main diagonal*. Each row begins a new record and may span more than one record. This mode may save file space.

- A matrix written with MODE = TRIANGULAR must be square, but it need not be symmetric. If it is not, values in the upper triangle are not written.
- A matrix written with MODE = TRIANGULAR may be read with MODE = SYMMETRIC.

HOLD Specification

HOLD causes the last line written by the current WRITE statement to be held so that the next WRITE to that file will write on the same line. Use HOLD to write more than one matrix on a line.

FORMAT Specification

FORMAT indicates how the internal (binary) values of matrix elements should be converted to character format for output.

- The format descriptor is any valid SPSS data format, such as F6, E12.2, or A6, or it can be a format type code, such as F, E, or A. It specifies how the written data are encoded and, if a width is specified, how wide the fields containing the data are. (See FORMATS for valid formats.)
- If you omit the FORMAT specification, the default is F.
- The data field widths may be specified either here or after BY on the FIELD specification. You may specify the width in both places only if you give the same value.
- An additional way of specifying the width is to supply a repetition factor without a width (for example, 10F or 5COMMA). The field width is then calculated by dividing the width of the whole output area on the FIELD specification by the repetition factor. A format with a digit for the repetition factor must be enclosed in quotes.
- If the field width is not specified in any of these ways, then the freefield format is used—matrix values are written separated by one blank, and each value occupies as many positions as necessary to avoid the loss of precision. Each row of the matrix is written starting with a new output record.
- Only one format descriptor can be specified. Do *not* try to specify more than one format; for example, '5F2.0 3F3.0 F2.0' is invalid as a FORMAT specification on WRITE.

GET Statement: Reading SPSS Data Files

GET reads matrices from an external SPSS data file or from the active dataset. The syntax of GET is as follows:

```
GET variable reference
  [/FILE={file reference}]
         {*             }
  [/VARIABLES = variable list]
  [/NAMES = names vector]
  [/MISSING = {ACCEPT}]
              {OMIT  }
              {value }
  [/SYSMIS = {OMIT }]
             {value}
```

Variable Specification

The variable reference on the GET statement is a matrix variable name with or without indexes.

For a name without indexes:

- GET creates the specified matrix variable.

- The size of the matrix is determined by the amount of data read from the SPSS data file or the active dataset.
- If the matrix already exists, it is replaced by the matrix read from the file.

For an indexed name:

- GET creates a submatrix from an existing matrix.
- The matrix variable named must already exist.
- You can define any submatrix with indexes; for example, M(:,I). To define an entire existing matrix, specify M(:,:).
- The indexes, along with the size of the existing matrix, specify completely the size of the submatrix, which must agree with the dimensions of the data read from the SPSS data file.
- The specified submatrix is replaced by the matrix elements read from the SPSS data file.

FILE Specification

FILE designates the SPSS data file to be read. Use an asterisk, or simply omit the FILE specification, to designate the current active dataset.

- The file reference can be either a filename enclosed in quotes, or a file handle defined on a FILE HANDLE command that precedes the matrix program.
- If you omit the FILE specification, the active dataset is used.
- In a matrix program executed with the INCLUDE command, if a SPLIT FILE command is in effect, a GET statement that references the active dataset will read a single split-file group of cases. (A matrix program cannot be executed from a syntax window if a SPLIT FILE command is in effect.)

VARIABLES Specification

VARIABLES specifies a list of variables to be read from the SPSS data file.

- The keyword TO can be used to reference consecutive variables on the SPSS data file.
- The variable list can consist of the keyword ALL to get all the variables in the SPSS data file. ALL is the default if the VARIABLES specification is omitted.
- All variables read from the SPSS data file should be numeric. If a string variable is specified, a warning message is issued and the string variable is skipped.

Example

```
GET M /VARIABLES = AGE, RESIDE, INCOME TO HEALTH.
```

- The variables *AGE*, *RESIDE*, and *INCOME TO HEALTH* from the active dataset will form the columns of the matrix *M*.

NAMES Specification

NAMES specifies a vector to store the variable names from the SPSS data file.

- If you omit the NAMES specification, the variable names are not available to the MATRIX procedure.

MISSING Specification

MISSING specifies how missing values declared for the SPSS data file should be handled.

- The MISSING specification is required if the SPSS data file contains missing values for any variable being read.
- If you omit the MISSING specification and a missing value is encountered for a variable being read, an error message is displayed and the GET statement is not executed.

The following keywords are available on the MISSING specification. There is no default.

ACCEPT *Accept user-missing values for entry.* If the system-missing value exists for a variable to be read, you must specify SYSMIS to indicate how the system-missing value should be handled.

OMIT *Skip an entire observation when a variable with a missing value is encountered.*

value *Recode all missing values encountered (including the system-missing value) to the specified value for entry.* The replacement value can be any numeric constant.

SYSMIS Specification

SYSMIS specifies how system-missing values should be handled when you have specified ACCEPT on MISSING.

- The SYSMIS specification is ignored unless ACCEPT is specified on MISSING.
- If you specify ACCEPT on MISSING but omit the SYSMIS specification, and a system-missing value is encountered for a variable being read, an error message is displayed and the GET statement is not executed.

The following keywords are available on the SYSMIS specification. There is no default.

OMIT *Skip an entire observation when a variable with a system-missing value is encountered.*

value *Recode all system-missing values encountered to the specified value for entry.* The replacement value can be any numeric constant.

Example

```
GET SCORES
  /VARIABLES = TEST1,TEST2,TEST3
  /NAMES = VARNAMES
  /MISSING = ACCEPT
  /SYSMIS = -1.0.
```

- A matrix named *SCORES* is read from the active dataset.

- The variables *TEST1*, *TEST2*, and *TEST3* form the columns of the matrix, while the cases in the active dataset form the rows.
- A vector named *VARNAMES*, whose three elements contain the variable names *TEST1*, *TEST2*, and *TEST3*, is created.
- User-missing values defined in the active dataset are accepted into the matrix *SCORES*.
- System-missing values in the active dataset are converted to the value −1 in the matrix *SCORES*.

SAVE Statement: Writing SPSS Data Files

SAVE writes matrices to an SPSS data file or to the current active dataset. The rows of the matrix expression become cases, and the columns become variables. The syntax of the SAVE statement is as follows:

```
SAVE matrix expression
  [/OUTFILE = {file reference}]
              {*              }
  [/VARIABLES = variable list]
  [/NAMES = names vector]
  [/STRINGS = variable list]
```

Matrix Expression Specification

The matrix expression following the keyword SAVE is any matrix language expression that evaluates to the value(s) to be written to an SPSS data file.

- The matrix specification must precede any other specifications on the SAVE statement.
- You can specify a matrix name, a matrix raised to a power, or a matrix function (with its arguments in parentheses) by itself, but you must enclose other matrix expressions in parentheses. For example, SAVE A, SAVE INV(A), or SAVE B**DET(T(C)*D) is legal, but SAVE A+B is not. You must specify SAVE (A+B).
- Constant expressions are allowed.

OUTFILE Specification

OUTFILE designates the file to which the matrix expression is to be written. It can be an actual filename in quotes or a file handle defined on a FILE HANDLE command that precedes the matrix program. The filename or handle must be a valid file specification.

- To save a matrix expression as the active dataset, specify an asterisk (*). If there is no active dataset, one will be created; if there is one, it is replaced by the saved matrices.
- The OUTFILE specification is required on the first SAVE statement in a matrix program (first in order of appearance, not necessarily in order of execution). If you omit the OUTFILE specification from a later SAVE statement, the statement uses the most recently named file (in order of appearance) on a SAVE statement in the same matrix program.

- If more than one SAVE statement writes to the active dataset in a single matrix program, the dictionary of the new active dataset is written on the basis of the information given by the first such SAVE. All of the subsequently saved matrices are appended to the new active dataset as additional cases. If the number of columns differs, an error occurs.
- When you execute a matrix program with the INCLUDE command, the SAVE statement creates a new SPSS data file at the end of the matrix program's execution, so any attempt to GET the data file obtains the original data file, if any.
- When you execute a matrix program from a syntax window, SAVE creates a new SPSS data file immediately, but the file remains open, so you cannot GET it until after the END MATRIX statement.

VARIABLES Specification

You can provide variable names for the SPSS data file with the VARIABLES specification. The variable list is a list of valid variable names separated by commas.

- You can use the TO convention, as shown in the example below.
- You can also use the NAMES specification, discussed below, to provide variable names.

Example

```
SAVE {A,B,X,Y} /OUTFILE=*
  /VARIABLES = A,B,X1 TO X50,Y1,Y2.
```

- The matrix expression on the SAVE statement constructs a matrix from two column vectors *A* and *B* and two matrices *X* and *Y*. All four matrix variables must have the same number of rows so that this matrix construction will be valid.
- The VARIABLES specification provides descriptive names so that the variable names in the new active dataset will resemble the names used in the matrix program.

NAMES Specification

As an alternative to the explicit list on the VARIABLES specification, you can specify a name list with a vector containing string values. The elements of this vector are used as names for the variables.

- The NAMES specification on SAVE is designed to complement the NAMES specification on the GET statement. Names extracted from an SPSS data file can be used in a new data file by specifying the same vector name on both NAMES specifications.
- If you specify both VARIABLES and NAMES, a warning message is displayed and the VARIABLES specification is used.
- If you omit both the VARIABLES and NAMES specifications, or if you do not specify names for all columns of the matrix, the MATRIX procedure creates default names. The names have the form *COLn*, where *n* is the column number.

STRINGS Specification

The STRINGS specification provides the names of variables that contain short string data rather than numeric data.

- By default, all variables are assumed to be numeric.
- The variable list specification following STRINGS consists of a list of variable names separated by commas. The names must be among those used by SAVE.

MGET Statement: Reading Matrix Data Files

MGET reads a matrix-format data file. MGET puts the data it reads into separate matrix variables. It also names these new variables automatically. The syntax of MGET is as follows:

```
MGET [ [/] FILE = file reference]
  [/TYPE = {COV   }]
           {CORR  }
           {MEAN  }
           {STDDEV}
           {N     }
           {COUNT }
```

- Since MGET assigns names to the matrices it reads, do not specify matrix names on the MGET statement.

FILE Specification

FILE designates a matrix-format data file. See MATRIX DATA on p. 1087 for a discussion of matrix-format data files. To designate the active dataset (if it is a matrix-format data file), use an asterisk, or simply omit the FILE specification.

- The file reference can be either a filename enclosed in quotes or a file handle defined on a FILE HANDLE command that precedes the matrix program.
- The same matrix-format SPSS data file can be read more than once.
- If you omit the FILE specification, the current active dataset is used.
- MGET ignores the SPLIT FILE command when reading the active dataset. It does honor the split-file groups that were in effect when the matrix-format data file was created.
- The maximum number of split-file groups that can be read is 99.
- The maximum number of cells that can be read is 99.

TYPE Specification

TYPE specifies the rowtype(s) to read from the matrix-format data file.

- By default, records of all rowtypes are read.
- If the matrix-format data file does not contain rows of the requested type, an error occurs.

Valid keywords on the TYPE specification are:

COV	*A matrix of covariances.*
CORR	*A matrix of correlation coefficients.*
MEAN	*A vector of means.*
STDDEV	*A vector of standard deviations.*
N	*A vector of numbers of cases.*
COUNT	*A vector of counts.*

Names of Matrix Variables from MGET

- The MGET statement automatically creates matrix variable names for the matrices it reads.
- All new variables created by MGET are reported to the user.
- If a matrix variable already exists with the same name that MGET chose for a new variable, the new variable is not created and a warning is issued. The RELEASE statement can be used to get rid of a variable. A COMPUTE statement followed by RELEASE can be used to change the name of an existing matrix variable.

MGET constructs variable names in the following manner:

- The first two characters of the name identify the row type. If there are no cells and no split file groups, these two characters constitute the name:

CV	A covariance matrix (rowtype COV)
CR	A correlation matrix (rowtype CORR)
MN	A vector of means (rowtype MEAN)
SD	A vector of standard deviations (rowtype STDDEV)
NC	A vector of numbers of cases (rowtype N)
CN	A vector of counts (rowtype COUNT)

- Characters 3–5 of the variable name identify the cell number or the split-group number. Cell identifiers consist of the letter *F* and a two-digit cell number. Split-group identifiers consist of the letter *S* and a two-digit split-group number; for example, *MNF12* or *SDS22*.
- If there are both cells and split groups, characters 3–5 identify the cell and characters 6–8 identify the split group. The same convention for cell or split-file numbers is used; for example, *CRF12S21*.
- After the name is constructed as described above, any leading zeros are removed from the cell number and the split-group number; for example, *CNF2S99* or *CVF2S1*.

MSAVE Statement: Writing Matrix Data Files

The MSAVE statement writes matrix expressions to a matrix-format data file that can be used as matrix input to other procedures. (See MATRIX DATA on p. 1087 for a discussion of matrix-format data files.) The syntax of MSAVE is as follows:

```
MSAVE matrix expression
```

```
 /TYPE = {COV   }
         {CORR  }
         {MEAN  }
         {STDDEV}
         {N     }
         {COUNT }
[/OUTFILE = {file reference}]
            {*             }
[/VARIABLES = variable list]
[/SNAMES = variable list]
[/SPLIT = split vector]
[/FNAMES = variable list]
[/FACTOR = factor vector]
```

- Only one matrix-format data file can be saved in a single matrix program.
- Each MSAVE statement writes records of a single rowtype. Therefore, several MSAVE statements will normally be required to write a complete matrix-format data file.
- Most specifications are retained from one MSAVE statement to the next so that it is not necessary to repeat the same specifications on a series of MSAVE statements. The exception is the FACTOR specification, as noted below.

Example

```
MSAVE M /TYPE=MEAN /OUTFILE=CORRMAT /VARIABLES=V1 TO V8.
MSAVE S /TYPE STDDEV.
MSAVE MAKE(1,8,24) /TYPE N.
MSAVE C /TYPE CORR.
```

- The series of MSAVE statements save the matrix variables *M*, *S*, and *C*, which contain, respectively, vectors of means and standard deviations and a matrix of correlation coefficients. The matrix-format data file thus created is suitable for use in a procedure such as FACTOR.
- The first MSAVE statement saves *M* as a vector of means. This statement specifies OUTFILE, a previously defined file handle, and VARIABLES, a list of variable names to be used in the SPSS data file.
- The second MSAVE statement saves *S* as a vector of standard deviations. Note that the OUTFILE and VARIABLES specifications do not have to be repeated.
- The third MSAVE statement saves a vector of case counts. The matrix function MAKE constructs an eight-element vector with values equal to the case count (24 in this example).
- The last MSAVE statement saves *C*, an 8 × 8 matrix, as the correlation matrix.

Matrix Expression Specification

- The matrix expression must be specified first on the MSAVE statement.
- The matrix expression specification can be any matrix language expression that evaluates to the value(s) to be written to the matrix-format file.
- You can specify a matrix name, a matrix raised to a power, or a matrix function (with its arguments in parentheses) by itself, but you must enclose other matrix expressions in parentheses. For example, MSAVE A, SAVE INV(A), or MSAVE B**DET(T(C)*D) is legal, but MSAVE N * WT is not. You must specify MSAVE (N * WT).
- Constant expressions are allowed.

TYPE Specification

TYPE specifies the rowtype to write to the matrix-format data file. Only a single rowtype can be written by any one MSAVE statement.Valid keywords on the TYPE specification are:

COV	*A matrix of covariances.*
CORR	*A matrix of correlation coefficients.*
MEAN	*A vector of means.*
STDDEV	*A vector of standard deviations.*
N	*A vector of numbers of cases.*
COUNT	*A vector of counts.*

OUTFILE Specification

OUTFILE designates the matrix-format data file to which the matrices are to be written. It can be an asterisk, an actual filename in quotes, or a file handle defined on a FILE HANDLE command that precedes the matrix program. The filename or handle must be a valid file specification.

- The OUTFILE specification is required on the first MSAVE statement in a matrix program.
- To save a matrix expression as the active dataset (replacing any active dataset created before the matrix program), specify an asterisk (*).
- Since only one matrix-format data file can be written in a single matrix program, any OUTFILE specification on the second and later MSAVE statements in one matrix program must be the same as that on the first MSAVE statement.

VARIABLES Specification

You can provide variable names for the matrix-format data file with the VARIABLES specification. The variable list is a list of valid variable names separated by commas. You can use the TO convention.

- The VARIABLES specification names only the data variables in the matrix. Split-file variables and grouping or factor variables are named on the SNAMES and FNAMES specifications.
- The names in the VARIABLES specification become the values of the special variable *VARNAME_* in the matrix-format data file for rowtypes of CORR and COV.
- You cannot specify the reserved names *ROWTYPE_* and *VARNAME_* on the VARIABLES specification.
- If you omit the VARIABLES specification, the default names *COL1*, *COL2*, ..., etc., are used.

FACTOR Specification

To write a matrix-format data file with factor or group codes, you must use the FACTOR specification to provide a row matrix containing the values of each of the factors or group variables for the matrix expression being written by the current MSAVE statement.

- The factor vector must have the same number of columns as there are factors in the matrix data file being written. You can use a scalar when the groups are defined by a single variable. For example, FACTOR=1 indicates that the matrix data being written are for the value 1 of the factor variable.
- The values of the factor vector are written to the matrix-format data file as values of the factors in the file.
- To create a complete matrix-format data file with factors, you must execute an MSAVE statement for every combination of values of the factors or grouping variables (in other words, for every group). If split-file variables are also present, you must execute an MSAVE statement for every combination of factor codes within every combination of values of the split-file variables.

Example

```
MSAVE M11 /TYPE=MEAN /OUTFILE=CORRMAT /VARIABLES=V1 TO V8
    /FNAMES=SEX, GROUP /FACTOR={1,1}.
MSAVE S11 /TYPE STDDEV.
MSAVE MAKE(1,8,N(1,1)) /TYPE N.
MSAVE C11 /TYPE CORR.

MSAVE M12 /TYPE=MEAN /FACTOR={1,2}.
MSAVE S12 /TYPE STDDEV.
MSAVE MAKE(1,8,N(1,2)) /TYPE N.
MSAVE C12 /TYPE CORR.

MSAVE M21 /TYPE=MEAN /FACTOR={2,1}.
MSAVE S21 /TYPE STDDEV.
MSAVE MAKE(1,8,N(2,1)) /TYPE N.
MSAVE C21 /TYPE CORR.

MSAVE M22 /TYPE=MEAN /FACTOR={2,2}.
MSAVE S22 /TYPE STDDEV.
MSAVE MAKE(1,8,N(2,2)) /TYPE N.
MSAVE C22 /TYPE CORR.
```

- The first four MSAVE statements provide data for a group defined by the variables *SEX* and *GROUP*, with both factors having the value 1.
- The second, third, and fourth groups of four MSAVE statements provide the corresponding data for the other groups, in which *SEX* and *GROUP*, respectively, equal 1 and 2, 2 and 1, and 2 and 2.
- Within each group of MSAVE statements, a suitable number-of-cases vector is created with the matrix function MAKE.

FNAMES Specification

To write a matrix-format data file with factor or group codes, you can use the FNAMES specification to provide variable names for the grouping or factor variables.

- The variable list following the keyword FNAMES is a list of valid variable names, separated by commas.
- If you omit the FNAMES specification, the default names *FAC1*, *FAC2*, ..., etc., are used.

SPLIT Specification

To write a matrix-format data file with split-file groups, you must use the SPLIT specification to provide a row matrix containing the values of each of the split-file variables for the matrix expression being written by the current MSAVE statement.

- The split vector must have the same number of columns as there are split-file variables in the matrix data file being written. You can use a scalar when there is only one split-file variable. For example, SPLIT=3 indicates that the matrix data being written are for the value 3 of the split-file variable.
- The values of the split vector are written to the matrix-format data file as values of the split-file variable(s).
- To create a complete matrix-format data file with split-file variables, you must execute MSAVE statements for every combination of values of the split-file variables. (If factor variables are present, you must execute MSAVE statements for every combination of factor codes within every combination of values of the split-file variables.)

SNAMES Specification

To write a matrix-format data file with split-file groups, you can use the SNAMES specification to provide variable names for the split-file variables.

- The variable list following the keyword SNAMES is a list of valid variable names separated by commas.
- If you omit the SNAMES specification, the default names *SPL1*, *SPL2*, ..., etc., are used.

DISPLAY Statement

DISPLAY provides information on the matrix variables currently defined in a matrix program and on usage of internal memory by the matrix processor. Two keywords are available on DISPLAY:

DICTIONARY	*Display variable name and row and column dimensions for each matrix variable currently defined.*
STATUS	*Display the status and size of internal tables.* This display is intended as a debugging aid when writing large matrix programs that approach the memory limitations of your system.

If you enter the DISPLAY statement with no specifications, both DICTIONARY and STATUS information is displayed.

RELEASE Statement

Use the RELEASE statement to release the work areas in memory assigned to matrix variables that are no longer needed.

- Specify a list of currently defined matrix variables. Variable names on the list must be separated by commas.
- RELEASE discards the contents of the named matrix variables. Releasing a large matrix when it is no longer needed makes memory available for additional matrix variables.
- All matrix variables are released when the END MATRIX statement is encountered.

Macros Using the Matrix Language

Macro expansion (see DEFINE-!ENDDEFINE on p. 545) occurs before command lines are passed to the matrix processor. Therefore, previously defined macro names can be used within a matrix program. If the macro name expands to one or more valid matrix statements, the matrix processor will execute those statements. Similarly, you can define an entire matrix program, including the MATRIX and END MATRIX commands, as a macro, but you cannot define a macro within a matrix program, since DEFINE and END DEFINE are not valid matrix statements.

MATRIX DATA

```
MATRIX DATA VARIABLES=varlist   [/FILE={INLINE**}]
                                       {file    }

 [/FORMAT=[{LIST**}]  [{LOWER**}]  [{DIAGONAL**}]]
           {FREE  }    {UPPER  }    {NODIAGONAL}
                       {FULL   }

 [/SPLIT=varlist]    [/FACTORS=varlist]

 [/CELLS=number of cells]    [/N=sample size]

 [/CONTENTS= [CORR**]  [COV]  [MAT]  [MSE]  [DFE]  [MEAN]  [PROX]

             [{STDDEV}]  [N_SCALAR]  [{N_VECTOR}]  [N_MATRIX]  [COUNT]]
              {SD    }                {N        }
```

**Default if the subcommand is omitted.

Example

```
MATRIX DATA VARIABLES=ROWTYPE_ SAVINGS POP15 POP75 INCOME GROWTH.
BEGIN DATA
MEAN 9.6710 35.0896 2.2930 1106.7784 3.7576
STDDEV 4.4804 9.1517 1.2907 990.8511 2.8699
N 50 50 50 50 50
CORR 1
CORR -.4555 1
CORR .3165 -.9085 1
CORR .2203 -.7562 .7870 1
CORR .3048 -.0478 .0253 -.1295  1
END DATA.
```

Overview

MATRIX DATA reads raw matrix materials and converts them to a matrix data file that can be read by procedures that handle matrix materials. The data can include vector statistics, such as means and standard deviations, as well as matrices.

MATRIX DATA is similar to a DATA LIST command: it defines variable names and their order in a raw data file. However, MATRIX DATA can read only data that conform to the general format of matrix data files.

Matrix Files

Like the matrix data files created by procedures, the file that MATRIX DATA creates contains the following variables in the indicated order. If the variables are in a different order in the raw data file, MATRIX DATA rearranges them in the active dataset.

- *Split-file variables.* These optional variables define split files. There can be up to eight split variables, and they must have numeric values. Split-file variables will appear in the order in which they are specified on the SPLIT subcommand.

- *ROWTYPE_*. This is a string variable with A8 format. Its values define the data type for each record. For example, it might identify a row of values as means, standard deviations, or correlation coefficients. Every matrix data file has a *ROWTYPE_* variable.
- *Factor variables.* There can be any number of factors. They occur only if the data include within-cells information, such as the within-cells means. Factors have the system-missing value on records that define pooled information. Factor variables appear in the order in which they are specified on the FACTORS subcommand.
- *VARNAME_*. This is a string variable with A8 format. MATRIX DATA automatically generates *VARNAME_* and its values based on the variables named on VARIABLES. You never enter values for *VARNAME_*. Values for *VARNAME_* are blank for records that define vector information. Every matrix in the program has a *VARNAME_* variable.
- *Continuous variables.* These are the variables that were used to generate the correlation coefficients or other aggregated data. There can be any number of them. Continuous variables appear in the order in which they are specified on VARIABLES.

Options

Data Files. You can define both inline data and data in an external file.

Data Format. By default, data are assumed to be entered in freefield format with each vector or row beginning on a new record (the keyword LIST on the FORMAT subcommand). If each vector or row does not begin on a new record, use the keyword FREE. You can also use FORMAT to indicate whether matrices are entered in upper or lower triangular or full square or rectangular format and whether or not they include diagonal values.

Variable Types. You can specify split-file and factor variables using the SPLIT and FACTORS subcommands. You can identify record types by specifying ROWTYPE_ on the VARIABLES subcommand if *ROWTYPE_* values are included in the data or by implying *ROWTYPE_* values on CONTENTS.

Basic Specification

The basic specification is VARIABLES and a list of variables. Additional specifications are required as follows:

- FILE is required to specify the data file if the data are not inline.
- If data are in any format other than lower triangular with diagonal values included, FORMAT is required.
- If the data contain values in addition to matrix coefficients, such as the mean and standard deviation, either the variable *ROWTYPE_* must be specified on VARIABLES and *ROWTYPE_* values must be included in the data or CONTENTS must be used to describe the data.
- If the data include split-file variables, SPLIT is required. If there are factors, FACTORS is required.

Specifications on most MATRIX DATA subcommands depend on whether *ROWTYPE_* is included in the data and specified on VARIABLES or whether it is implied using CONTENTS.

Table 123-1
*Subcommand requirements in relation to ROWTYPE_*

Subcommand	Implicit ROWTYPE_ using CONTENTS	Explicit ROWTYPE_ on VARIABLES
FILE	Defaults to INLINE	Defaults to INLINE
VARIABLES	Required	Required
FORMAT	Defaults to LOWER DIAG	Defaults to LOWER DIAG
SPLIT	Required if split files*	Required if split files
FACTORS	Required if factors	Required if factors
CELLS	Required if factors	Inapplicable
CONTENTS	Defaults to CORR	Optional
N	Optional	Optional

* If the data do not contain values for the split-file variables, this subcommand can specify a single variable, which is not specified on the VARIABLES subcommand.

Subcommand Order

- SPLIT and FACTORS, when used, must follow VARIABLES.
- The remaining subcommands can be specified in any order.

Syntax Rules

- No commands can be specified between MATRIX DATA and BEGIN DATA, not even a VARIABLE LABELS or FORMAT command. Data transformations cannot be used until after MATRIX DATA is executed.

Examples

Reading a Correlation Matrix

```
MATRIX DATA
    VARIABLES=ROWTYPE_ SAVINGS POP15 POP75 INCOME GROWTH.
BEGIN DATA
MEAN 9.6710 35.0896 2.2930 1106.7784 3.7576
STDDEV 4.4804 9.1517 1.2907 990.8511 2.8699
N 50 50 50 50 50
CORR 1
CORR -.4555 1
CORR .3165 -.9085 1
CORR .2203 -.7562 .7870 1
CORR .3048 -.0478 .0253 -.1295  1
END DATA.
```

- The variable *ROWTYPE_* is specified on VARIABLES. *ROWTYPE_* values are included in the data.
- No other specifications are required.

MATRIX DATA with DISCRIMINANT

```
MATRIX DATA VARIABLES=WORLD ROWTYPE_ FOOD APPL SERVICE RENT
  /FACTORS=WORLD.
BEGIN DATA
1 N      25 25 25 25
1 MEAN   76.64 77.32 81.52 101.40
2 N      7 7 7 7
2 MEAN   76.1428571 85.2857143 60.8571429 249.571429
3 N      13 13 13 13
3 MEAN   55.5384615 76 63.4615385 86.3076923
. SD     16.4634139 22.5509310 16.8086768 77.1085326
. CORR   1
. CORR   .1425366 1
. CORR   .5644693 .2762615 1
. CORR   .2133413 -.0499003 .0417468 1
END DATA.

DISCRIMINANT GROUPS=WORLD(1,3)
  /VARIABLES=FOOD APPL SERVICE RENT /METHOD=WILKS /MATRIX=IN(*).
```

- MATRIX DATA is used to generate a active dataset that DISCRIMINANT can read. DISCRIMINANT reads the mean, count (unweighted *N*), and *N* (weighted *N*) for each cell in the data, as well as the pooled values for the standard deviation and correlation coefficients. If count equals *N*, only *N* needs to be supplied.
- *ROWTYPE_* is specified on VARIABLES to identify record types in the data. Though CONTENTS and CELLS can be used to identify record types and distinguish between within-cells data and pooled values, it is usually easier to specify *ROWTYPE_* on VARIABLES and enter the *ROWTYPE_* values in the data.
- Because factors are present in the data, the continuous variables (*FOOD, APPL, SERVICE,* and *RENT*) must be specified last on VARIABLES and must be last in the data.
- The FACTORS subcommand identifies *WORLD* as the factor variable.
- BEGIN DATA immediately follows MATRIX DATA.
- *N* and *MEAN* values for each cell are entered in the data.
- *ROWTYPE_* values for the pooled records are *SD* and *COR*. MATRIX DATA assigns the values *STDDEV* and *CORR* to the corresponding vectors in the matrix. Records with pooled information have the system-missing value (.) for the factors.
- The DISCRIMINANT procedure reads the data matrix. An asterisk (*) is specified as the input file on the MATRIX subcommand because the data are in the active dataset.

MATRIX DATA with REGRESSION

```
MATRIX DATA VARIABLES=SAVINGS POP15 POP75 INCOME GROWTH
  /CONTENTS=MEAN SD N CORR /FORMAT=UPPER NODIAGONAL.

BEGIN DATA
9.6710 35.0896 2.2930 1106.7784 3.7576
4.4804 9.1517 1.2908 990.8511 2.8699
50 50 50 50 50
-.4555 .3165 .2203 .3048
-.9085 -.7562 -.0478
 .7870 .0253
-.1295
END DATA.
```

```
REGRESSION MATRIX=IN(*) /VARIABLES=SAVINGS TO GROWTH
  /DEP=SAVINGS /ENTER.
```

- `MATRIX DATA` is used to generate a matrix that `REGRESSION` can read. `REGRESSION` reads and writes matrices that always contain the mean, standard deviation, *N*, and Pearson correlation coefficients. Data in this example do not have *ROWTYPE_* values, and the correlation values are from the upper triangle of the matrix without the diagonal values.
- *ROWTYPE_* is not specified on `VARIABLES` because its values are not included in the data.
- Because there are no *ROWTYPE_* values, `CONTENTS` is required to define the record types and the order of the records in the file.
- By default, `MATRIX DATA` reads values from the lower triangle of the matrix, including the diagonal values. `FORMAT` is required in this example to indicate that the data are in the upper triangle and do not include diagonal values.
- `BEGIN DATA` immediately follows the `MATRIX DATA` command.
- The `REGRESSION` procedure reads the data matrix. An asterisk (*) is specified as the input file on the `MATRIX` subcommand because the data are in the active dataset. Since there is a single vector of *N*'s in the data, missing values are handled listwise (the default for `REGRESSION`).

MATRIX DATA with ONEWAY

```
MATRIX DATA VARIABLES=EDUC ROWTYPE_ WELL /FACTORS=EDUC.
BEGIN DATA
1 N 65
2 N 95
3 N 181
4 N 82
5 N 40
6 N 37
1 MEAN 2.6462
2 MEAN 2.7737
3 MEAN 4.1796
4 MEAN 4.5610
5 MEAN 4.6625
6 MEAN 5.2297
. MSE 6.2699
. DFE 494
END DATA.

ONEWAY WELL BY EDUC(1,6) /MATRIX=IN(*)
```

- One of the two types of matrices that the `ONEWAY` procedure reads includes a vector of frequencies for each factor level, a vector of means for each factor level, a record containing the pooled variance (within-group mean square error), and the degrees of freedom for the mean square error. `MATRIX DATA` is used to generate an active dataset containing this type of matrix data for the `ONEWAY` procedure.
- *ROWTYPE_* is explicit on `VARIABLES` and identifies record types.
- Because factors are present in the data, the continuous variables (*WELL*) must be specified last on `VARIABLES` and must be last in the data.
- The `FACTORS` subcommand identifies *EDUC* as the factor variable.
- *MSE* is entered in the data as the *ROWTYPE_* value for the vector of square pooled standard deviations.

- *DFE* is entered in the data as the *ROWTYPE_* value for the vector of degrees of freedom.
- Records with pooled information have the system-missing value (.) for the factors.

Operations

- MATRIX DATA defines and writes data in one step.
- MATRIX DATA clears the active dataset and defines a new active dataset.
- If CONTENTS is not specified and *ROWTYPE_* is not specified on VARIABLES, MATRIX DATA assumes that the data contain only CORR values and issues warning messages to alert you to its assumptions.
- With the default format, data values, including diagonal values, must be in the lower triangle of the matrix. If MATRIX DATA encounters values in the upper triangle, it ignores those values and issues a series of warnings.
- With the default format, if any matrix rows span records in the data file, MATRIX DATA cannot form the matrix properly.
- MATRIX DATA does not allow format specifications for matrix materials. The procedure assigns the formats shown in the following table. To change data formats, execute MATRIX DATA and then assign new formats with the FORMATS, PRINT FORMATS, or WRITE FORMATS command.

Table 123-2
Print and write formats for matrix variables

Variable type	Format
*ROWTYPE_, VARNAME_*	A8
Split-file variables	F4.0
Factors	F4.0
Continuous variables	F10.4

Format of the Raw Matrix Data File

- If LIST is in effect on the FORMAT subcommand, the data are entered in freefield format, with blanks and commas used as separators and each scalar, vector, or row of the matrix beginning on a new record. Unlike LIST format with DATA LIST, a vector or row of the matrix can be contained on multiple records. The continuation records do not have a value for *ROWTYPE_*.
- *ROWTYPE_* values can be enclosed in quotes.
- The order of variables in the raw data file must match the order in which they are specified on VARIABLES. However, this order does not have to correspond to the order of variables in the resulting matrix data file.
- The way records are entered for pooled vectors or matrices when factors are present depends upon whether *ROWTYPE_* is specified on the VARIABLES subcommand. For more information, see FACTORS Subcommand on p. 1098.
- MATRIX DATA recognizes plus and minus signs as field separators when they are not preceded by the letter *D* or *E*. This allows MATRIX DATA to read scientific notation as well as correlation matrices written by FORTRAN in F10.8 format. A plus sign preceded by a *D* or *E* is read as part of the number in scientific notation.

VARIABLES Subcommand

VARIABLES specifies the names of the variables in the raw data and the order in which they occur.

- VARIABLES is required.
- There is no limit to the number of variables that can be specified.
- If *ROWTYPE_* is specified on VARIABLES, the continuous variables must be the last variables specified on the subcommand and must be last in the data.
- If split-file variables are present, they must also be specified on SPLIT.
- If factor variables are present, they must also be specified on FACTORS.

When either of the following is true, the only variables that must be specified on VARIABLES are the continuous variables:

1. The data contain only correlation coefficients. There can be no additional information, such as the mean and standard deviation, and no factor information or split-file variables. MATRIX DATA assigns the record type *CORR* to all records.

2. CONTENTS is used to define all record types. The data can then contain information such as the mean and standard deviation, but no factor, split-file, or *ROWTYPE_* variables. MATRIX DATA assigns the record types defined on the CONTENTS subcommand.

Variable VARNAME_

*VARNAME_* cannot be specified on the VARIABLES subcommand or anywhere on MATRIX DATA, and its values cannot be included in the data. The MATRIX DATA command generates the variable *VARNAME_* automatically.

Variable ROWTYPE_

- *ROWTYPE_* is a string variable with A8 format. Its values define the data types. All matrix data files contain a *ROWTYPE_* variable.
- If *ROWTYPE_* is specified on VARIABLES and its values are entered in the data, MATRIX DATA is primarily used to define the names and order of the variables in the raw data file.
- *ROWTYPE_* must precede the continuous variables.
- Valid values for *ROWTYPE_* are *CORR*, *COV*, *MAT*, *MSE*, *DFE*, *MEAN*, *STDDEV* (or *SD*), *N_VECTOR* (or *N*), *N_SCALAR*, *N_MATRIX*, *COUNT*, or *PROX*. For definitions of these values. For more information, see CONTENTS Subcommand on p. 1100. Three-character abbreviations for these values are permitted. These values can also be enclosed in quotation marks or apostrophes.
- If *ROWTYPE_* is not specified on VARIABLES, CONTENTS must be used to define the order in which the records occur within the file. MATRIX DATA follows these specifications strictly and generates a *ROWTYPE_* variable according to the CONTENTS specifications. A data-entry error, especially skipping a record, can cause the procedure to assign the wrong values to the wrong records.

Example

```
* ROWTYPE_ is specified on VARIABLES.

MATRIX DATA
     VARIABLES=ROWTYPE_ SAVINGS POP15 POP75 INCOME GROWTH.
BEGIN DATA
MEAN 9.6710 35.0896 2.2930 1106.7784 3.7576
STDDEV 4.4804 9.1517 1.2907 990.8511 2.8699
N 50 50 50 50 50
CORR 1
CORR -.4555 1
CORR .3165 -.9085 1
CORR .2203 -.7562 .7870 1
CORR .3048 -.0478 .0253 -.1295  1
END DATA.
```

- *ROWTYPE_* is specified on VARIABLES. *ROWTYPE_* values in the data identify each record type.
- Note that *VARNAME_* is not specified on VARIABLES, and its values are not entered in the data.

Example

```
* ROWTYPE_ is specified on VARIABLES.

MATRIX DATA
     VARIABLES=ROWTYPE_ SAVINGS POP15 POP75 INCOME GROWTH.
BEGIN DATA
'MEAN    ' 9.6710 35.0896 2.2930 1106.7784 3.7576
'SD      ' 4.4804 9.1517 1.2907 990.8511 2.8699
'N       ' 50 50 50 50 50
"CORR    " 1
"CORR    " -.4555 1
"CORR    " .3165 -.9085 1
"CORR    " .2203 -.7562 .7870 1
"CORR    " .3048 -.0478 .0253 -.1295  1
END DATA.
```

- *ROWTYPE_* values for the mean, standard deviation, *N*, and Pearson correlation coefficients are abbreviated and enclosed in quotes.

Example

```
* ROWTYPE_ is not specified on VARIABLES.

MATRIX DATA VARIABLES=SAVINGS POP15 POP75 INCOME GROWTH
  /CONTENTS=MEAN SD N CORR.
BEGIN DATA
9.6710 35.0896 2.2930 1106.7784 3.7576
4.4804 9.1517 1.2907 990.8511 2.8699
50 50 50 50 50
 1
-.4555 1
 .3165 -.9085 1
 .2203 -.7562 .7870 1
 .3048 -.0478 .0253 -.1295 1
END DATA.
```

- *ROWTYPE_* is not specified on VARIABLES, and its values are not included in the data.
- CONTENTS is required to define the record types and the order of the records in the file.

FILE Subcommand

FILE specifies the matrix file containing the data. The default specification is INLINE, which indicates that the data are included within the command sequence between the BEGIN DATA and END DATA commands.

- If the data are in an external file, FILE must specify the file.
- If the FILE subcommand is omitted, the data must be inline.

Example

```
MATRIX DATA FILE=RAWMTX /VARIABLES=varlist.
```

- FILE indicates that the data are in the file *RAWMTX*.

FORMAT Subcommand

FORMAT indicates how the matrix data are formatted. It applies only to matrix values in the data, not to vector values, such as the mean and standard deviation.

- FORMAT can specify up to three keywords: one to specify the data-entry format, one to specify matrix shape, and one to specify whether the data include diagonal values.
- The minimum specification is a single keyword.
- Default settings remain in effect unless explicitly overridden.

Data-Entry Format

FORMAT has two keywords that specify the data-entry format:

LIST	*Each scalar, vector, and matrix row must begin on a new record.* A vector or row of the matrix may be continued on multiple records. This is the default.
FREE	*Matrix rows do not need to begin on a new record.* Any item can begin in the middle of a record.

Matrix Shape

FORMAT has three keywords that specify the matrix shape. With either triangular shape, no values—not even missing indicators—are entered for the implied values in the matrix.

LOWER	*Read data values from the lower triangle.* This is the default.
UPPER	*Read data values from the upper triangle.*
FULL	*Read the full square matrix of data values.* FULL cannot be specified with NODIAGONAL.

Diagonal Values

FORMAT has two keywords that refer to the diagonal values:

DIAGONAL *Data include the diagonal values.* This is the default.

NODIAGONAL *Data do not include diagonal values.* The diagonal value is set to the system-missing value for all matrices except the correlation matrices. For correlation matrices, the diagonal value is set to 1. NODIAGONAL cannot be specified with FULL.

The following table shows how data might be entered for each combination of FORMAT settings that govern matrix shape and diagonal values. With UPPER NODIAGONAL and LOWER NODIAGONAL, you do not enter the matrix row that has blank values for the continuous variables. If you enter that row, MATRIX DATA cannot properly form the matrix.

Table 123-3
Various FORMAT settings

FULL	UPPER DIAGONAL	UPPER NODIAGONAL	LOWER DIAGONAL	LOWER NODIAGONAL
MEAN 5 4 3	MEAN 5 4 3	MEAN 5 4 3	MEAN 5 4 3	MEAN 5 4 3
SD 3 2 1	SD 3 2 1	SD 3 2 1	SD 3 2 1	SD 3 2 1
N 9 9 9	N 9 9 9	N 9 9 9	N 9 9 9	N 9 9 9
CORR 1 .6 .7	CORR 1 .6 .7	CORR .6 .7	CORR 1	CORR .6
CORR .6 1 .8	CORR 1 .8	CORR .8	CORR .6 1	CORR .7 .8
CORR .7 .8 1	CORR 1		CORR .7 .8 1	

Example

```
MATRIX DATA VARIABLES=ROWTYPE_ V1 TO V3
   /FORMAT=UPPER NODIAGONAL.
BEGIN DATA
MEAN    5  4  3
SD      3  2  1
N       9  9  9
CORR      .6 .7
CORR         .8
END DATA.
LIST.
```

- FORMAT specifies the upper-triangle format with no diagonal values. The default LIST is in effect for the data-entry format.

Example

```
MATRIX DATA VARIABLES=ROWTYPE_ V1 TO V3
   /FORMAT=UPPER NODIAGONAL.
BEGIN DATA
MEAN 5 4 3
SD 3 2 1
N 9 9 9
CORR .6 .7
CORR .8
END DATA.
```

```
LIST.
```

- This example is identical to the previous example. It shows that data do not have to be aligned in columns. Data throughout this section are aligned in columns to emphasize the matrix format.

SPLIT Subcommand

SPLIT specifies the variables whose values define the split files. SPLIT must follow the VARIABLES subcommand.

- SPLIT can specify a subset of up to eight of the variables named on VARIABLES. All split variables must be numeric. The keyword TO can be used to imply variables in the order in which they are named on VARIABLES.
- A separate matrix must be included in the data for each value of each split variable. MATRIX DATA generates a complete set of matrix materials for each.
- If the data contain neither *ROWTYPE_* nor split-file variables, a single split-file variable can be specified on SPLIT. This variable is *not* specified on the VARIABLES subcommand. MATRIX DATA generates a complete set of matrix materials for each set of matrix materials in the data and assigns values 1, 2, 3, etc., to the split variable until the end of the data is encountered.

Example

```
MATRIX DATA  VARIABLES=S1 ROWTYPE_ V1 TO V3 /SPLIT=S1.
BEGIN DATA
0 MEAN   5  4  3
0 SD     1  2  3
0 N      9  9  9
0 CORR   1
0 CORR  .6  1
0 CORR  .7 .8  1
1 MEAN   9  8  7
1 SD     5  6  7
1 N      9  9  9
1 CORR   1
1 CORR  .4  1
1 CORR  .3 .2  1
END DATA.
LIST.
```

- The split variable *S1* has two values: 0 and 1. Two separate matrices are entered in the data, one for each value *S1*.
- *S1* must be specified on both VARIABLES and SPLIT.

Example

```
MATRIX DATA VARIABLES=V1 TO V3 /CONTENTS=MEAN SD N CORR
   /SPLIT=SPL.
BEGIN DATA
  5  4  3
  1  2  3
  9  9  9
  1
 .6  1
 .7 .8  1
```

```
  9  8  7
  5  6  7
  9  9  9
  1
 .4  1
 .3 .2  1
END DATA.
LIST.
```

- The split variable *SPL* is not specified on VARIABLES, and values for *SPL* are not included in the data.
- Two sets of matrix materials are included in the data. MATRIX DATA therefore assigns values 1 and 2 to variable *SPL* and generates two matrices in the matrix data file.

FACTORS Subcommand

FACTORS specifies the variables whose values define the cells represented by the within-cells data. FACTORS must follow the VARIABLES subcommand.

- FACTORS specifies a subset of the variables named on the VARIABLES subcommand. The keyword TO can be used to imply variables in the order in which they are named on VARIABLES.
- If *ROWTYPE_* is explicit on VARIABLES and its values are included in the data, records that represent pooled information have the system-missing value (indicated by a period) for the factors, since the values of *ROWTYPE_* are ambiguous.
- If *ROWTYPE_* is not specified on VARIABLES and its values are not in the data, enter data values for the factors only for records that represent within-cells information. Enter nothing for the factors for records that represent pooled information. CELLS must be specified to indicate the number of within-cells records, and CONTENTS must be specified to indicate which record types have within-cells data.

Example

```
* Rowtype is explicit.

MATRIX DATA VARIABLES=ROWTYPE_ F1 F2  VAR1 TO VAR3
  /FACTORS=F1 F2.
BEGIN DATA
MEAN 1 1  1  2  3
SD   1 1  5  4  3
N    1 1  9  9  9
MEAN 1 2  4  5  6
SD   1 2  6  5  4
N    1 2  9  9  9
MEAN 2 1  7  8  9
SD   2 1  7  6  5
N    2 1  9  9  9
MEAN 2 2  9  8  7
SD   2 2  8  7  6
N    2 2  9  9  9
CORR . . .1
CORR . . .6  1
CORR . . .7 .8  1
END DATA.
```

- *ROWTYPE_* is specified on VARIABLES.

- Factor variables must be specified on both VARIABLES and FACTORS.
- Periods in the data represent missing values for the *CORR* factor values.

Example

```
* Rowtype is implicit.

MATRIX DATA VARIABLES=F1 F2  VAR1 TO VAR3
  /FACTORS=F1 F2 /CONTENTS=(MEAN SD N) CORR /CELLS=4.
BEGIN DATA
1 1  1  2  3
1 1  5  4  3
1 1  9  9  9
1 2  4  5  6
1 2  6  5  4
1 2  9  9  9
2 1  7  8  9
2 1  7  6  5
2 1  9  9  9
2 2  9  8  7
2 2  8  7  6
2 2  9  9  9
     1
    .6  1
    .7 .8 1
END DATA.
```

- *ROWTYPE_* is not specified on VARIABLES.
- Nothing is entered for the *CORR* factor values because the records contain pooled information.
- CELLS is required because there are factors in the data and *ROWTYPE_* is implicit.
- CONTENTS is required to define the record types and to differentiate between the within-cells and pooled types.

CELLS Subcommand

CELLS specifies the number of within-cells records in the data. The only valid specification for CELLS is a single integer, which indicates the number of sets of within-cells information that MATRIX DATA must read.

- CELLS is required when there are factors in the data and *ROWTYPE_* is implicit.
- If CELLS is used when *ROWTYPE_* is specified on VARIABLES, MATRIX DATA issues a warning and ignores the CELLS subcommand.

Example

```
MATRIX DATA VARIABLES=F1 VAR1 TO VAR3 /FACTORS=F1 /CELLS=2
  /CONTENTS=(MEAN SD N) CORR.
BEGIN DATA
1  5  4  3
1  3  2  1
1  9  9  9
2  8  7  6
2  6  7  8
2  9  9  9
   1
  .6  1
```

```
  .7 .8  1
END DATA.
```

- The specification for CELLS is 2 because the factor variable *F1* has two values (1 and 2) and there are therefore two sets of within-cells information.
- If there were two factor variables, *F1* and *F2*, and each had two values, 1 and 2, CELLS would equal 4 to account for all four possible factor combinations (assuming all that 4 combinations are present in the data).

CONTENTS Subcommand

CONTENTS defines the record types when *ROWTYPE_* is not included in the data. The minimum specification is a single keyword indicating a type of record. The default is CORR.

- CONTENTS is required to define record types and record order whenever *ROWTYPE_* is not specified on VARIABLES and its values are not in the data. The only exception to this rule is the rare situation in which all data values represent pooled correlation records and there are no factors. In that case, MATRIX DATA reads the data values and assigns the default *ROWTYPE_* of *CORR* to all records.
- The order in which keywords are specified on CONTENTS must correspond to the order in which records appear in the data. If the keywords on CONTENTS are in the wrong order, MATRIX DATA will incorrectly assign values.

CORR *Matrix of correlation coefficients.* This is the default. If *ROWTYPE_* is not specified on the VARIABLES subcommand and you omit the CONTENTS subcommand, MATRIX DATA assigns the *ROWTYPE_* value *CORR* to all matrix rows.

COV *Matrix of covariance coefficients.*

MAT *Generic square matrix.*

MSE *Vector of mean squared errors.*

DFE *Vector of degrees of freedom.*

MEAN *Vector of means.*

STDDEV *Vector of standard deviations.* SD is a synonym for STDDEV. MATRIX DATA assigns the *ROWTYPE_* value STDDEV to the record if either STDDEV or SD is specified.

N_VECTOR *Vector of counts. N* is a synonym for N_VECTOR. MATRIX DATA assigns the *ROWTYPE_* value *N* to the record.

N_SCALAR *Count.* Scalars are a shorthand mechanism for representing vectors in which all elements have the same value, such as when a vector of *N*'s is calculated using listwise deletion of missing values. Enter N_SCALAR as the *ROWTYPE_* value in the data and then the N_SCALAR value for the first continuous variable only. MATRIX DATA assigns the *ROWTYPE_* value *N* to the record and copies the specified N_SCALAR value across all of the continuous variables.

N_MATRIX *Square matrix of counts.* Enter N_MATRIX as the *ROWTYPE_* value for each row of counts in the data. MATRIX DATA assigns the *ROWTYPE_* value *N* to each of those rows.

COUNT	*Count vector accepted by procedure DISCRIMINANT.* This contains unweighted *N*'s.
PROX	*Matrix produced by PROXIMITIES.* Any proximity matrix can be used with PROXIMITIES or CLUSTER. A value label of *SIMILARITY* or *DISSIMILARITY* should be specified for PROX by using the VALUE LABELS command after END DATA.

Example

```
MATRIX DATA VARIABLES=V1 TO V3 /CONTENTS=MEAN SD N_SCALAR CORR.
BEGIN DATA
  5  4  3
  3  2  1
  9
  1
 .6  1
 .7 .8  1
END DATA.
LIST.
```

- *ROWTYPE_* is not specified on VARIABLES, and *ROWTYPE_* values are not in the data. CONTENTS is therefore required to identify record types.
- CONTENTS indicates that the matrix records are in the following order: mean, standard deviation, *N*, and correlation coefficients.
- The *N_SCALAR* value is entered for the first continuous variable only.

Example

```
MATRIX DATA VARIABLES=V1 TO V3 /CONTENTS=PROX.
BEGIN DATA

data records

END DATA.
VALUE LABELS ROWTYPE_ 'PROX' 'DISSIMILARITY'.
```

- CONTENTS specifies PROX to read a raw matrix and create a matrix data file in the same format as one produced by procedure PROXIMITIES. PROX is assigned the value label *DISSIMILARITY*.

Within-Cells Record Definition

When the data include factors and *ROWTYPE_* is not specified, CONTENTS distinguishes between within-cells and pooled records by enclosing the keywords for within-cells records in parentheses.

- If the records associated with the within-cells keywords appear together for each set of factor values, enclose the keywords together within a single set of parentheses.
- If the records associated with each within-cells keyword are grouped together across factor values, enclose the keyword within its own parentheses.

Example

```
MATRIX DATA VARIABLES=F1 VAR1 TO VAR3 /FACTORS=F1 /CELLS=2
  /CONTENTS=(MEAN SD N) CORR.
```

- MEAN, SD, and N contain within-cells information and are therefore specified within parentheses. CORR is outside the parentheses because it identifies pooled records.
- CELLS is required because there is a factor specified and *ROWTYPE_* is implicit.

Example

```
MATRIX DATA VARIABLES=F1 VAR1 TO VAR3 /FACTORS=F1 /CELLS=2
  /CONTENTS=(MEAN SD N) CORR.
BEGIN DATA
1  5  4  3
1  3  2  1
1  9  9  9
2  4  5  6
2  6  5  4
2  9  9  9
   1
  .6  1
  .7 .8  1
END DATA.
```

- The parentheses around the CONTENTS keywords indicate that the mean, standard deviation, and *N* for value 1 of factor *F1* are together, followed by the mean, standard deviation, and *N* for value 2 of factor *F1*.

Example

```
MATRIX DATA VARIABLES=F1 VAR1 TO VAR3 /FACTORS=F1 /CELLS=2
  /CONTENTS=(MEAN) (SD) (N) CORR.
BEGIN DATA
1  5  4  3
2  4  5  6
1  3  2  1
2  6  5  4
1  9  9  9
2  9  9  9
   1
  .6  1
  .7 .8  1
END DATA.
```

- The parentheses around each CONTENTS keyword indicate that the data include the means for all cells, followed by the standard deviations for all cells, followed by the *N* values for all cells.

Example

```
MATRIX DATA VARIABLES=F1 VAR1 TO VAR3 /FACTORS=F1 /CELLS=2
  /CONTENTS=(MEAN SD) (N) CORR.
BEGIN DATA
1  5  4  3
1  3  2  1
2  4  5  6
2  6  5  4
1  9  9  9
2  9  9  9
   1
  .6  1
  .7 .8  1
```

```
END DATA.
```

- The parentheses around the CONTENTS keywords indicate that the data include the mean and standard deviation for value 1 of *F1*, followed by the mean and standard deviation for value 2 of *F1*, followed by the *N* values for all cells.

Optional Specification When ROWTYPE_ Is Explicit

When *ROWTYPE_* is explicitly named on VARIABLES, MATRIX DATA uses *ROWTYPE_* values to determine record types.

- When *ROWTYPE_* is explicitly named on VARIABLES, CONTENTS can be used for informational purposes. However, *ROWTYPE_* values in the data determine record types.
- If MATRIX DATA reads values for *ROWTYPE_* that are not specified on CONTENTS, it issues a warning.
- Missing values for factors are entered as periods, even though CONTENTS is specified. For more information, see FACTORS Subcommand on p. 1098.

Example

```
MATRIX DATA VARIABLES=ROWTYPE_ F1 F2 VAR1 TO VAR3
  /FACTORS=F1 F2 /CONTENTS=(MEAN SD N) CORR.
BEGIN DATA
MEAN 1 1  1  2  3
SD   1 1  5  4  3
N    1 1  9  9  9
MEAN 1 2  4  5  6
SD   1 2  6  5  4
N    1 2  9  9  9
CORR . .  1
CORR . . .6  1
CORR . . .7 .8  1
END DATA.
```

- *ROWTYPE_* is specified on VARIABLES. MATRIX DATA therefore uses *ROWTYPE_* values in the data to identify record types.
- Because *ROWTYPE_* is specified on VARIABLES, CONTENTS is optional. However, CONTENTS is specified for informational purposes. This is most useful when data are in an external file and the *ROWTYPE_* values cannot be seen in the data.
- Missing values for factors are entered as periods, even though CONTENTS is specified.

N Subcommand

N specifies the population *N* when the data do not include it. The only valid specification is an integer, which indicates the population *N*.

- MATRIX DATA generates one record with a *ROWTYPE_* of *N* for each split file, and it uses the specified *N* value for each continuous variable.

Example

```
MATRIX DATA VARIABLES=V1 TO V3 /CONTENTS=MEAN SD CORR
```

```
   /N=99.
BEGIN DATA
  5  4  3
  3  4  5
  1
 .6  1
 .7 .8  1
END DATA.
```

- `MATRIX DATA` uses 99 as the *N* value for all continuous variables.

MCONVERT

```
MCONVERT [[/MATRIX=] [IN({*   })] [OUT({*   })]]
                        {file}        {file}
         [{/REPLACE}]
          {/APPEND }
```

Example

```
MCONVERT MATRIX=OUT(CORMTX) /APPEND.
```

Overview

MCONVERT converts covariance matrix materials to correlation matrix materials, or vice versa. For MCONVERT to convert a correlation matrix, the matrix data must contain *CORR* values (Pearson correlation coefficients) and a vector of standard deviations (*STDDEV*). For MCONVERT to convert a covariance matrix, only *COV* values are required in the data.

Options

Matrix Files. MCONVERT can read matrix materials from an external matrix data file, and it can write converted matrix materials to an external file.

Matrix Materials. MCONVERT can write the converted matrix only or both the converted matrix and the original matrix to the resulting matrix data file.

Basic Specification

The minimum specification is the command itself. By default, MCONVERT reads the original matrix from the active dataset and then replaces it with the converted matrix.

Syntax Rules

- The keywords IN and OUT cannot specify the same external file.
- The APPEND and REPLACE subcommands cannot be specified on the same MCONVERT command.

Operations

- If the data are covariance matrix materials, MCONVERT converts them to a correlation matrix plus a vector of standard deviations.
- If the data are a correlation matrix and vector of standard deviations, MCONVERT converts them to a covariance matrix.
- If there are multiple *CORR* or *COV* matrices (for example, one for each grouping (factor) or one for each split variable), each will be converted to a separate matrix, preserving the values of any factor or split variables.

- All cases with *ROWTYPE_* values other than *CORR* or *COV*, such as *MEAN*, *N*, and *STDDEV*, are always copied into the new matrix data file.
- MCONVERT cannot read raw matrix values. If your data are raw values, use the MATRIXDATA command.
- Split variables (if any) must occur first in the file that MCONVERT reads, followed by the variable *ROWTYPE_*, the grouping variables (if any), and the variable *VARNAME_*. All variables following *VARNAME_* are the variables for which a matrix will be read and created.

Limitations

- The total number of split variables plus grouping variables cannot exceed eight.

Examples

```
MATRIX DATA VARIABLES=ROWTYPE_ SAVINGS POP15 POP75 INCOME GROWTH
  /FORMAT=FULL.
BEGIN DATA
COV    20.0740459  -18.678638    1.8304990  978.181242 3.9190106
COV   -18.678638    83.7541100 -10.731666 -6856.9888  -1.2561071
COV     1.8304990  -10.731666    1.6660908 1006.52742   .0937992
COV   978.181242 -6856.9888   1006.52742 981785.907 -368.18652
COV     3.9190106   -1.2561071    .0937992 -368.18652  8.2361574
END DATA.
MCONVERT.
```

- MATRIX DATA defines the variables in the file and creates a active dataset of matrix materials. The values for the variable *ROWTYPE_* are *COV*, indicating that the matrix contains covariance coefficients. The FORMAT subcommand indicates that data are in full square format.
- MCONVERT converts the covariance matrix to a correlation matrix plus a vector of standard deviations. By default, the converted matrix is written to the active dataset.

MATRIX Subcommand

The MATRIX subcommand specifies the file for the matrix materials. By default, MATRIX reads the original matrix from the active dataset and replaces the active dataset with the converted matrix.

- MATRIX has two keywords, IN and OUT. The specification on both IN and OUT is the name of an external file in parentheses or an asterisk (*) to refer to the active dataset (the default).
- The actual keyword MATRIX is optional.
- IN and OUT cannot specify the same external file.
- MATRIX=IN cannot be specified unless an active dataset has already been defined. To convert an existing matrix at the beginning of a session, use GET to retrieve the matrix file and then specify IN(*) on MATRIX.

IN *The matrix file to read.*

OUT *The matrix file to write.*

Example

```
GET FILE=COVMTX.
MCONVERT MATRIX=OUT(CORMTX).
```

- GET retrieves the SPSS-format matrix data file *COVMTX*. *COVMTX* becomes the active dataset.
- By default, MCONVERT reads the original matrix from the active dataset. IN(*) can be specified to make the default explicit.
- The keyword OUT on MATRIX writes the converted matrix to file *CORMTX*.

REPLACE and APPEND Subcommands

By default, MCONVERT writes only the converted matrix to the resulting matrix file. Use APPEND to copy both the original matrix and the converted matrix.

- The only specification is the keyword REPLACE or APPEND.
- REPLACE and APPEND are alternatives.
- REPLACE and APPEND affect the resulting matrix file only. The original matrix materials, whether in the active dataset or in an external file, remain intact.

APPEND *Write the original matrix followed by the converted matrix to the matrix file.* If there are multiple sets of matrix materials, APPEND appends each converted matrix to the end of a copy of its original matrix.

REPLACE *Write the original matrix followed by the covariance matrix to the matrix file.*

Example

```
MCONVERT MATRIX=OUT(COVMTX) /APPEND.
```

- MCONVERT reads matrix materials from the active dataset.
- The APPEND subcommand copies original matrix materials, appends each converted matrix to the end of the copy of its original matrix, and writes both sets to the file *COVMTX*.

MEANS

```
MEANS [TABLES=]{varlist} [BY varlist] [BY...] [/varlist...]
              {ALL    }

 [/MISSING={TABLE     }]
           {INCLUDE  }
           {DEPENDENT}

 [/CELLS= [MEAN**  ] [COUNT**  ]  [STDDEV**]
          [MEDIAN] [GMEDIAN] [SEMEAN]  [SUM ]
          [MIN] [MAX] [RANGE] [VARIANCE]
          [KURT] [SEKURT] [SKEW] [SESKEW]
          [FIRST] [LAST]
          [NPCT] [SPCT] [NPCT(var)] [SPCT(var)]
          [HARMONIC] [GEOMETRIC]
          [DEFAULT]
          [ALL] [NONE]  ]

 [/STATISTICS=[ANOVA] [{LINEARITY}]  [NONE**]]
                      {ALL      }
```

**Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
MEANS TABLES=V1 TO V5 BY GROUP.
```

Overview

By default, MEANS (alias BREAKDOWN) displays means, standard deviations, and group counts for a numeric dependent variable and group counts for a string variable within groups defined by one or more control (independent) variables. Other procedures that display univariate statistics are SUMMARIZE, FREQUENCIES, and DESCRIPTIVES.

Options

Cell Contents. By default, MEANS displays means, standard deviations, and cell counts for a dependent variable across groups defined by one or more control variables. You can also display sums and variances using the CELLS subcommand.

Statistics. In addition to the statistics displayed for each cell of the table, you can obtain a one-way analysis of variance and test of linearity using the STATISTICS subcommand.

Basic Specification

The basic specification is TABLES with a table list. The actual keyword TABLES can be omitted.

- The minimum table list specifies a dependent variable.
- By default, MEANS displays means, standard deviations, and number of cases.

Subcommand Order

The table list must be first if the keyword TABLES is omitted. If the keyword TABLES is explicitly used, subcommands can be specified in any order.

Operations

- MEANS displays the number and percentage of the processed and missing cases in the Case Process Summary table.
- MEANS displays univariate statistics for the population as a whole and for each value of each successive control variable defined by the BY keyword on the TABLE subcommand in the Group Statistics table.
- ANOVA and linearity statistics, if requested, are displayed in the ANOVA and Measures of Association tables.
- If a string variable is specified as a dependent variable on any table lists, the MEANS procedure produces limited statistics (COUNT, FIRST, and LAST).

Limitations

- Each TABLES subcommand can contain a maximum of 10 BY variable lists.
- There is a maximum of 30 TABLES subcommands for each MEANS command.

Examples

Specifying a Range of Dependent Variables

```
MEANS TABLES=V1 TO V5 BY GROUP
   /STATISTICS=ANOVA.
```

- TABLES specifies that *V1* through *V5* are the dependent variables. *GROUP* is the control variable.
- Assuming that variables *V2, V3,* and *V4* lie between *V1* and *V5* in the active dataset, five tables are produced: *V1* by *GROUP*, *V2* by *GROUP*, *V3* by *GROUP*, and so on.
- STATISTICS requests one-way analysis-of-variance tables of *V1* through *V5* by *GROUP*.

Creating Analyses for Two Separate Sets of Dependent Variables

```
MEANS VARA BY VARB BY VARC/V1 V2 BY V3 V4 BY V5.
```

- This command contains two TABLES subcommands that omit the optional TABLES keyword.
- The first table list produces a Group Statistics table for *VARA* within groups defined by each combination of values as well as the totals of *VARB* and *VARC*.
- The second table list produces a Group Statistics table displaying statistics for *V1* by *V3* by *V5*, *V1* by *V4* by *V5*, *V2* by *V3* by *V5*, and *V2* by *V4* by *V5*.

TABLES Subcommand

TABLES specifies the table list.

- You can specify multiple TABLES subcommands on a single MEANS command (up to a maximum of 30). The slash between the subcommands is required. You can also name multiple table lists separated by slashes on one TABLES subcommand.
- The dependent variable is specified first. If the dependent variable is a string variable, MEANS produces only limited statistics (COUNT, FIRST, and LAST). The control (independent) variables follow the BY keyword and can be numeric (integer or noninteger) or string.
- Each use of the keyword BY in a table list adds a dimension to the table requested. Statistics are displayed for each dependent variable by each combination of values and the totals of the control variables across dimensions. There is a maximum of 10 BY variable lists for each TABLES subcommand.
- The order in which control variables are displayed is the same as the order in which they are specified on TABLES. The values of the first control variable defined for the table appear in the leftmost column of the table and change the most slowly in the definition of groups.
- More than one dependent variable can be specified in a table list, and more than one control variable can be specified in each dimension of a table list.

CELLS Subcommand

By default, MEANS displays the means, standard deviations, and cell counts in each cell. Use CELLS to modify cell information.

- If CELLS is specified without keywords, MEANS displays the default statistics.
- If any keywords are specified on CELLS, only the requested information is displayed.
- MEDIAN and GMEDIAN are expensive in terms of computer resources and time. Requesting these statistics (via these keywords or ALL) may slow down performance.

DEFAULT	*Means, standard deviations, and cell counts.* This is the default if CELLS is omitted.
MEAN	*Cell means.*
STDDEV	*Cell standard deviations.*
COUNT	*Cell counts.*
MEDIAN	*Cell median.*
GMEDIAN	*Grouped median.*
SEMEAN	*Standard error of cell mean.*
SUM	*Cell sums.*
MIN	*Cell minimum.*
MAX	*Cell maximum.*
RANGE	*Cell range.*
VARIANCE	*Variances.*
KURT	*Cell kurtosis.*
SEKURT	*Standard error of cell kurtosis.*

SKEW	*Cell skewness.*
SESKEW	*Standard error of cell skewness.*
FIRST	*First value.*
LAST	*Last value.*
NPCT	*Percentage of the total number of cases.*
SPCT	*Percentage of the total sum.*
NPCT(var)	*Percentage of the total number of cases within the specified variable.* The specified variable must be one of the control variables.
SPCT(var)	*Percentage of the total sum within the specified variable.* The specified variable must be one of the control variables.
HARMONIC	*Harmonic mean.*
GEOMETRIC	*Geometric mean.*
ALL	*All cell information.*

STATISTICS Subcommand

Use STATISTICS to request a one-way analysis of variance and a test of linearity for each TABLE list.

- Statistics requested on STATISTICS are computed in addition to the statistics displayed in the Group Statistics table.
- If STATISTICS is specified without keywords, MEANS computes ANOVA.
- If two or more dimensions are specified, the second and subsequent dimensions are ignored in the analysis-of-variance table. To obtain a two-way and higher analysis of variance, use the ANOVA or MANOVA procedure. The ONEWAY procedure calculates a one-way analysis of variance with multiple comparison tests.

ANOVA	*Analysis of variance.* ANOVA displays a standard analysis-of-variance table and calculates eta and eta squared (displayed in the Measures of Association table). This is the default if STATISTICS is specified without keywords.
LINEARITY	*Test of linearity.* LINEARITY (alias ALL) displays additional statistics to the tables created by the ANOVA keyword: the sums of squares, degrees of freedom, and mean square associated with linear and nonlinear components, the *F* ratio, and significance level for the ANOVA table and Pearson's *r* and r^2 for the Measures of Association table. LINEARITY is ignored if the control variable is a string.
NONE	*No additional statistics.* This is the default if STATISTICS is omitted.

Example

```
MEANS TABLES=INCOME BY SEX BY RACE
  /STATISTICS=ANOVA.
```

- MEANS produces a Group Statistics table of *INCOME* by *RACE* within *SEX* and computes an analysis of variance only for *INCOME* by *SEX*.

MISSING Subcommand

MISSING controls the treatment of missing values. If no MISSING subcommand is specified, each combination of a dependent variable and control variables is handled separately.

TABLE	*Delete cases with missing values on a tablewise basis.* A case with a missing value for any variable specified for a table is not used. Thus, every case contained in a table has a complete set of nonmissing values for all variables in that table. When you separate table requests with a slash, missing values are handled separately for each list. Any MISSING specification will result in tablewise treatment of missing values.
INCLUDE	*Include user-missing values.* This option treats user-missing values as valid values.
DEPENDENT	*Exclude user-missing values for dependent variables only.* DEPENDENT treats user-missing values for all control variables as valid.

References

Hays, W. L. 1981. *Statistics for the social sciences*, 3rd ed. New York: Holt, Rinehart, and Winston.

MISSING VALUES

```
MISSING VALUES {varlist}(value list) [[/]{varlist} ...]
               {ALL    }               {ALL    }
```

Keywords for numeric value lists:

```
LO, LOWEST, HI, HIGHEST, THRU
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Example

```
MISSING VALUES V1 (8,9) V2 V3 (0) V4 ('X') V5 TO V9 ('    ').
```

Overview

MISSING VALUES declares values user-missing. These values can then receive special treatment in data transformations, statistical calculations, and case selection. By default, user-missing values are treated the same as the system-missing values. System-missing values are automatically assigned by the program when no legal value can be produced, such as when an alphabetical character is encountered in the data for a numeric variable, or when an illegal calculation, such as division by 0, is requested in a data transformation.

Basic Specification

The basic specification is a single variable followed by the user-missing value or values in parentheses. Each specified value for the variable is treated as user-missing for any analysis.

Syntax Rules

- Each variable can have a maximum of three individual user-missing values. A space or comma must separate each value. For numeric variables, you can also specify a range of missing values. For more information, see Specifying Ranges of Missing Values on p. 1115.
- The missing-value specification must correspond to the variable type (numeric or string).
- The same values can be declared missing for more than one variable by specifying a variable list followed by the values in parentheses. Variable lists must have either all numeric or all string variables.
- Different values can be declared missing for different variables by specifying separate values for each variable. An optional slash can be used to separate specifications.
- Missing values for string variables must be enclosed in single or double quotes. The value specifications must include any leading or trailing blanks. For more information, see String Values in Command Specifications on p. 35.

- For date format variables (for example, DATE, ADATE), missing values expressed in date formats must be enclosed in single or double quotes, and values must be expressed in the same date format as the defined date format for the variable.
- A variable list followed by an empty set of parentheses ( ) deletes any user-missing specifications for those variables.
- The keyword ALL can be used to refer to all user-defined variables in the active dataset, provided the variables are either all numeric or all string. ALL can refer to both numeric and string variables if it is followed by an empty set of parentheses. This will delete all user-missing specifications in the active dataset.
- More than one MISSING VALUES command can be specified per session.

Operations

- Unlike most transformations, MISSING VALUES takes effect as soon as it is encountered. Special attention should be paid to its position among commands. For more information, see Command Order on p. 36.
- Missing-value specifications can be changed between procedures. New specifications replace previous ones. If a variable is mentioned more than once on one or more MISSING VALUES commands before a procedure, only the last specification is used.
- Missing-value specifications are saved in SPSS-format data files (see SAVE) and portable files (see EXPORT).

Limitations

Missing values for string variables cannot exceed 8 bytes. (There is no limit on the defined width of the string variable, but defined missing values cannot exceed 8 bytes.)

Examples

Declaring Missing Values for Multiple Variables

```
MISSING VALUES V1 (8,9) V2 V3 (0) V4 ('X') V5 TO V9 ('    ').
```

- The values 8 and 9 are declared missing for the numeric variable *V1*.
- The value 0 is declared missing for the numeric variables *V2* and *V3*.
- The value X is declared missing for the string variable *V4*.
- Blanks are declared missing for the string variables between and including *V5* and *V9*. All of these variables must have a width of four columns.

Clearing Missing Values for Selected Variables

```
MISSING VALUES V1 ().
```

- Any previously declared missing values for *V1* are deleted.

Declaring Missing Values for All Variables

```
MISSING VALUES ALL (9).
```

- The value 9 is declared missing for all variables in the active dataset; the variables must all be numeric. All previous user-missing specifications are overridden.

Clearing Missing Values for All Variables

```
MISSING VALUES ALL ().
```

- All previously declared user-missing values for all variables in the active dataset are deleted. The variables in the active dataset can be both numeric and string.

Specifying Ranges of Missing Values

A range of values can be specified as missing for numeric variables but *not* for string variables.

- The keyword `THRU` indicates an inclusive list of values. Values must be separated from `THRU` by at least one blank space.
- The keywords `HIGHEST` and `LOWEST` with `THRU` indicate the highest and lowest values of a variable. `HIGHEST` and `LOWEST` can be abbreviated to `HI` and `LO`.
- Only one `THRU` specification can be used for each variable or variable list. Each `THRU` specification can be combined with one additional missing value.

Example

```
MISSING VALUES  V1 (LOWEST THRU 0).
```

- All negative values and 0 are declared missing for the variable *V1*.

Example

```
MISSING VALUES  V1 (0 THRU 1.5).
```

- Values from 0 through and including 1.5 are declared missing.

Example

```
MISSING VALUES V1 (LO THRU 0, 999).
```

- All negative values, 0, and 999 are declared missing for the variable *V1*.

MIXED

MIXED is available in the Advanced Models option.

```
MIXED dependent varname [BY factor list] [WITH covariate list]

[/CRITERIA = [CIN({95** })] [HCONVERGE({0**  } {ABSOLUTE**})
                 {value}              {value} {RELATIVE  }

             [LCONVERGE({0**  } {ABSOLUTE**})] [MXITER({100**})]
                        {value} {RELATIVE  }           {n    }

             [MXSTEP({5**})] [PCONVERGE({1E-6**},{ABSOLUTE**})] [SCORING({1**})]
                     {n  }              {value } {RELATIVE  }            {n  }

             [SINGULAR({1E-12**})] ]
                       {value  }

[/EMMEANS = TABLES ({OVERALL          })]
                    {factor           }
                    {factor*factor ...}
            [WITH (covariate=value [covariate = value ...])
            [COMPARE [({factor})] [REFCAT({value})] [ADJ({LSD**     })] ]
                                          {FIRST}        {BONFERRONI}
                                          {LAST }        {SIDAK     }

[/FIXED = [effect [effect ...]] [| [NOINT] [SSTYPE({1  })] ] ]
                                                 {3**}

[/METHOD = {ML    }]
           {REML**}

[/MISSING = {EXCLUDE**}]
            {INCLUDE  }

[/PRINT = [CORB] [COVB] [CPS] [DESCRIPTIVES] [G] [HISTORY(1**)] [LMATRIX] [R]
                                                        (n  )
          [SOLUTION] [TESTCOV]]

[/RANDOM = effect [effect ...]
           [| [SUBJECT(varname[*varname[*...]])] [COVTYPE({VC**      })]]]
                                                  {covstruct+}

[/REGWGT = varname]

[/REPEATED = varname[*varname[*...]] | SUBJECT(varname[*varname[*...]])
             [COVTYPE({DIAG**    })]]
                      {covstruct†}

[/SAVE = [tempvar [(name)] [tempvar [(name)]] ...]

[/TEST[(valuelist)] =
    ['label']  effect valuelist ... [| effect valuelist ...] [divisor=value]]
    [; effect valuelist ... [| effect valuelist ...] [divisor=value]]

[/TEST[(valuelist)] = ['label'] ALL list [| list] [divisor=value]]
                      [; ALL list [| list] [divisor=value]]
```

** Default if the subcommand is omitted.

† covstruct can take the following values: AD1, AR1, ARH1, ARMA11, CS, CSH, CSR, DIAG, FA1, FAH1, HF, ID, TP, TPH, UN, UNR, VC.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
MIXED Y.
```

Overview

The MIXED procedure fits a variety of mixed linear models. The mixed linear model expands the general linear model used in the GLM procedure in that the data are permitted to exhibit correlation and non-constant variability. The mixed linear model, therefore, provides the flexibility of modeling not only the means of the data but also their variances and covariances.

The MIXED procedure is also a flexible tool for fitting other models that can be formulated as mixed linear models. Such models include multilevel models, hierarchical linear models, and random coefficient models.

Important Changes to MIXED Compared to Previous Versions

Independence of random effects. Prior to version 11.5, random effects were assumed to be independent. If you are using MIXED syntax jobs from a version prior to 11.5, be aware that the interpretation of the covariance structure may have changed. For more information, see Interpretation of Random Effect Covariance Structures on p. 1134.

Default covariance structures. Prior to version 11.5, the default covariance structure for random effects was ID, and the default covariance structure for repeated effects was VC.

Interpretation of VC covariance structure. Prior to version 11.5, the variance components (VC) structure was a diagonal matrix with heterogenous variances. Now, when the variance components structure is specified on a RANDOM subcommand, a scaled identity (ID) structure is assigned to each of the effects specified on the subcommand. If the variance components structure is specified on the REPEATED subcommand, it will be replaced by the diagonal (DIAG) structure. Note that the diagonal structure has the same interpretation as the variance components structure in versions prior to 11.5.

Basic Features

Covariance structures. Various structures are available. Use multiple RANDOM subcommands to model a different covariance structure for each random effect.

Standard errors. Appropriate standard errors will be automatically calculated for all hypothesis tests on the fixed effects, and specified estimable linear combinations of fixed and random effects.

Subject blocking. Complete independence can be assumed across subject blocks.

Choice of estimation method. Two estimation methods for the covariance parameters are available.

Tuning the algorithm. You can control the values of algorithm-tuning parameters with the CRITERIA subcommand.

Optional output. You can request additional output through the PRINT subcommand. The SAVE subcommand allows you to save various casewise statistics back to the active dataset.

Basic Specification

- The basic specification is a variable list identifying the dependent variable, the factors (if any) and the covariates (if any).
- By default, MIXED adopts the model that consists of the intercept term as the only fixed effect and the residual term as the only random effect.

Subcommand Order

- The variable list must be specified first.
- Subcommands can be specified in any order.

Syntax Rules

- For many analyses, the MIXED variable list, the FIXED subcommand, and the RANDOM subcommand are the only specifications needed.
- A dependent variable must be specified.
- Empty subcommands are silently ignored.
- Multiple RANDOM subcommands are allowed. However, if an effect with the same subject specification appears in multiple RANDOM subcommands, only the last specification will be used.
- Multiple TEST subcommands are allowed.
- All subcommands, except the RANDOM and the TEST subcommands, should be specified only once. If a subcommand is repeated, only the last specification will be used.
- The following words are reserved as keywords in the MIXED procedure: BY, WITH, and WITHIN.

Examples

The following are examples of models that can be specified using MIXED:

Model 1: Fixed-Effects ANOVA Model

Suppose that *TREAT* is the treatment factor and *BLOCK* is the blocking factor.

```
MIXED Y BY TREAT BLOCK
  /FIXED = TREAT BLOCK.
```

Model 2: Randomized Complete Blocks Design

Suppose that *TREAT* is the treatment factor and *BLOCK* is the blocking factor.

```
MIXED Y BY TREAT BLOCK
  /FIXED = TREAT
  /RANDOM = BLOCK.
```

Model 3: Split-Plot Design

An experiment consists of two factors, *A* and *B*. The experiment unit with respect to *A* is *C*. The experiment unit with respect to *B* is the individual subject, a subdivision of the factor *C*. Thus, *C* is the whole-plot unit, and the individual subject is the split-plot unit.

```
MIXED Y BY A B C
  /FIXED = A B A*B
  /RANDOM = C(A).
```

Model 4: Purely Random-Effects Model

Suppose that *A*, *B*, and *C* are random factors.

```
MIXED Y BY A B C
  /FIXED = | NOINT
  /RANDOM  = INTERCEPT A B C A*B A*C B*C | COVTYPE(CS).
```

The MIXED procedure allows effects specified on the same RANDOM subcommand to be correlated. Thus, in the model above, the parameters of a compound symmetry covariance matrix are computed across all levels of the random effects. In order to specify independent random effects, you need to specify separate RANDOM subcommands. For example:

```
MIXED Y BY A B C
  /FIXED = | NOINT
  /RANDOM  = INTERCEPT | COVTYPE(ID)
  /RANDOM  = A | COVTYPE(CS)
  /RANDOM  = B | COVTYPE(CS)
  /RANDOM  = C | COVTYPE(CS)
  /RANDOM  = A*B | COVTYPE(CS)
  /RANDOM  = A*C | COVTYPE(CS)
  /RANDOM  = B*C | COVTYPE(CS).
```

Here, the parameters of compound symmetry matrices are computed separately for each random effect.

Model 5: Random Coefficient Model

Suppose that the dependent variable *Y* is regressed on the independent variable *X* for each level of *A*.

```
MIXED Y BY A WITH X
  /FIXED = X
  /RANDOM = INTERCEPT X | SUBJECT(A) COVTYPE(ID).
```

Model 6: Multilevel Analysis

Suppose that *SCORE* is the score of a particular achievement test given over *TIME*. *STUDENT* is nested within *CLASS*, and *CLASS* is nested within *SCHOOL*.

```
MIXED SCORE WITH TIME
  /FIXED = TIME
  /RANDOM = INTERCEPT TIME | SUBJECT(SCHOOL) COVTYPE(ID)
  /RANDOM = INTERCEPT TIME | SUBJECT(SCHOOL*CLASS) COVTYPE(ID)
  /RANDOM = INTERCEPT TIME | SUBJECT(SCHOOL*CLASS*STUDENT) COVTYPE(ID).
```

Model 7: Unconditional Linear Growth Model

Suppose that *SUBJ* is the individual's identification and *Y* is the response of an individual observed over *TIME*. The covariance structure is unspecified.

```
MIXED Y WITH TIME
  /FIXED = TIME
  /RANDOM = INTERCEPT TIME | SUBJECT(SUBJ) COVTYPE(ID).
```

Model 8: Linear Growth Model with a Person-Level Covariate

Suppose that *PCOVAR* is the person-level covariate.

```
MIXED Y WITH TIME PCOVAR
  /FIXED = TIME PCOVAR TIME*PCOVAR
  /RANDOM = INTERCEPT TIME | SUBJECT(SUBJ) COVTYPE(ID).
```

Model 9: Repeated Measures Analysis

Suppose that *SUBJ* is the individual's identification and *Y* is the response of an individual observed over several *STAGE*s. The covariance structure is compound symmetry.

```
MIXED Y BY STAGE
  /FIXED = STAGE
  /REPEATED = STAGE | SUBJECT(SUBJ) COVTYPE(CS).
```

Model 10: Repeated Measures Analysis with Time-Dependent Covariate

Suppose that *SUBJ* is the individual's identification and *Y* is the response of an individual observed over several *STAGE*s. *X* is an individual-level covariate that also measures over several *STAGE*s. The residual covariance matrix structure is *AR(1)*.

```
MIXED Y BY STAGE WITH X
  /FIXED = X STAGE
  /REPEATED = STAGE | SUBJECT(SUBJ) COVTYPE(AR1).
```

Case Frequency

- If a `WEIGHT` variable is specified, its values are used as frequency weights by the `MIXED` procedure.
- Cases with missing weights or weights less than 0.5 are not used in the analyses.
- The weight values are rounded to the nearest whole numbers before use. For example, 0.5 is rounded to 1, and 2.4 is rounded to 2.

Covariance Structure List

The following is the list of covariance structures being offered by the MIXED procedure. Unless otherwise implied or stated, the structures are not constrained to be non-negative definite in order to avoid nonlinear constraints and to reduce the optimization complexity. However, the variances are restricted to be non-negative.

- Separate covariance matrices are computed for each random effect; that is, while levels of a given random effect are allowed to co-vary, they are considered independent of the levels of other random effects.

AD1 *First-order ante-dependence.* The constraint $|\rho_k| \leq 1$ is imposed for stationarity.

$$\begin{bmatrix} \sigma_1^2 & \sigma_2\sigma_1\rho_1 & \sigma_3\sigma_1\rho_1\rho_2 & \sigma_4\sigma_1\rho_1\rho_2\rho_3 \\ \sigma_2\sigma_1\rho_1 & \sigma_2^2 & \sigma_3\sigma_2\rho_2 & \sigma_4\sigma_2\rho_2\rho_3 \\ \sigma_3\sigma_1\rho_1\rho_2 & \sigma_3\sigma_2\rho_2 & \sigma_3^2 & \sigma_4\sigma_3\rho_3 \\ \sigma_4\sigma_1\rho_1\rho_2\rho_3 & \sigma_4\sigma_2\rho_2\rho_3 & \sigma_4\sigma_3\rho_3 & \sigma_4^2 \end{bmatrix}$$

AR1 *First-order autoregressive.* The constraint $|\rho| \leq 1$ is imposed for stationarity.

$$\sigma^2 \begin{bmatrix} 1 & \rho & \rho^2 & \rho^3 \\ \rho & 1 & \rho & \rho^2 \\ \rho^2 & \rho & 1 & \rho \\ \rho^3 & \rho^2 & \rho & 1 \end{bmatrix}$$

ARH1 *Heterogenous first-order autoregressive.* The constraint $|\rho_k| \leq 1$ is imposed for stationarity.

$$\begin{bmatrix} \sigma_1^2 & \sigma_2\sigma_1\rho & \sigma_3\sigma_1\rho^2 & \sigma_4\sigma_1\rho^3 \\ \sigma_2\sigma_1\rho & \sigma_2^2 & \sigma_3\sigma_2\rho & \sigma_4\sigma_2\rho^2 \\ \sigma_3\sigma_1\rho^2 & \sigma_3\sigma_2\rho & \sigma_3^2 & \sigma_4\sigma_3\rho \\ \sigma_4\sigma_1\rho^3 & \sigma_4\sigma_2\rho^2 & \sigma_4\sigma_3\rho & \sigma_4^2 \end{bmatrix}$$

ARMA1 *Autoregressive moving average (1,1).* The constraints $|\varphi| \leq 1$ and $|\rho| \leq 1$ are imposed for stationarity.

$$\sigma^2 \begin{bmatrix} 1 & \phi\rho & \phi\rho^2 & \phi\rho^3 \\ \phi\rho & 1 & \phi\rho & \phi\rho^2 \\ \phi\rho^2 & \phi\rho & 1 & \phi\rho \\ \phi\rho^3 & \phi\rho^2 & \phi\rho & 1 \end{bmatrix}$$

CS *Compound symmetry.* This structure has constant variance and constant covariance.

$$\begin{bmatrix} \sigma^2+\sigma_1^2 & \sigma_1 & \sigma_1 & \sigma_1 \\ \sigma_1 & \sigma^2+\sigma_1^2 & \sigma_1 & \sigma_1 \\ \sigma_1 & \sigma_1 & \sigma^2+\sigma_1^2 & \sigma_1 \\ \sigma_1 & \sigma_1 & \sigma_1 & \sigma^2+\sigma_1^2 \end{bmatrix}$$

CSH *Heterogenous compound symmetry.* This structure has non-constant variance and constant correlation.

$$\begin{bmatrix} \sigma_1^2 & \sigma_2\sigma_1\rho & \sigma_3\sigma_1\rho & \sigma_4\sigma_1\rho \\ \sigma_2\sigma_1\rho & \sigma_2^2 & \sigma_3\sigma_2\rho & \sigma_4\sigma_2\rho \\ \sigma_3\sigma_1\rho & \sigma_3\sigma_2\rho & \sigma_3^2 & \sigma_4\sigma_3\rho \\ \sigma_4\sigma_1\rho & \sigma_4\sigma_2\rho & \sigma_4\sigma_3\rho & \sigma_4^2 \end{bmatrix}$$

CSR *Compound symmetry with correlation parameterization.* This structure has constant variance and constant covariance.

$$\sigma^2 \begin{bmatrix} 1 & \rho & \rho & \rho \\ \rho & 1 & \rho & \rho \\ \rho & \rho & 1 & \rho \\ \rho & \rho & \rho & 1 \end{bmatrix}$$

DIAG *Diagonal.* This is a diagonal structure with heterogenous variance. This is the default covariance structure for repeated effects.

$$\begin{bmatrix} \sigma_1^2 & 0 & 0 & 0 \\ 0 & \sigma_2^2 & 0 & 0 \\ 0 & 0 & \sigma_3^2 & 0 \\ 0 & 0 & 0 & \sigma_4^2 \end{bmatrix}$$

FA1 *First-order factor analytic with constant diagonal offset* ($d \geq 0$).

$$\begin{bmatrix} \lambda_1^2 + d & \lambda_2\lambda_1 & \lambda_3\lambda_1 & \lambda_4\lambda_1 \\ \lambda_2\lambda_1 & \lambda_2^2 + d & \lambda_3\lambda_2 & \lambda_4\lambda_2 \\ \lambda_3\lambda_1 & \lambda_3\lambda_2 & \lambda_3^2 + d & \lambda_4\lambda_3 \\ \lambda_4\lambda_1 & \lambda_4\lambda_2 & \lambda_4\lambda_3 & \lambda_4^2 + d \end{bmatrix}$$

FAH1 *First-order factor analytic with heterogenous diagonal offsets* ($d_k \geq 0$).

$$\begin{bmatrix} \lambda_1^2 + d_1 & \lambda_2\lambda_1 & \lambda_3\lambda_1 & \lambda_4\lambda_1 \\ \lambda_2\lambda_1 & \lambda_2^2 + d_2 & \lambda_3\lambda_2 & \lambda_4\lambda_2 \\ \lambda_3\lambda_1 & \lambda_3\lambda_2 & \lambda_3^2 + d_3 & \lambda_4\lambda_3 \\ \lambda_4\lambda_1 & \lambda_4\lambda_2 & \lambda_4\lambda_3 & \lambda_4^2 + d_4 \end{bmatrix}$$

HF *Huynh-Feldt.* This is a circular matrix that satisfies the condition $\sigma_i^2 + \sigma_j^2 - 2\sigma_{ij} = 2\lambda$.

$$\begin{bmatrix} \sigma_1^2 & \frac{\sigma_1^2+\sigma_2^2}{2} - \lambda & \frac{\sigma_1^2+\sigma_3^2}{2} - \lambda & \frac{\sigma_1^2+\sigma_4^2}{2} - \lambda \\ \frac{\sigma_1^2+\sigma_2^2}{2} - \lambda & \sigma_2^2 & \frac{\sigma_2^2+\sigma_3^2}{2} - \lambda & \frac{\sigma_2^2+\sigma_4^2}{2} - \lambda \\ \frac{\sigma_1^2+\sigma_3^2}{2} - \lambda & \frac{\sigma_2^2+\sigma_3^2}{2} - \lambda & \sigma_3^2 & \frac{\sigma_3^2+\sigma_4^2}{2} - \lambda \\ \frac{\sigma_1^2+\sigma_4^2}{2} - \lambda & \frac{\sigma_2^2+\sigma_4^2}{2} - \lambda & \frac{\sigma_3^2+\sigma_4^2}{2} - \lambda & \sigma_4^2 \end{bmatrix}$$

ID *Identity.* This is a scaled identity matrix.

$$\sigma^2 \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

TP *Toeplitz* ($|\rho_k| \leq 1$).

$$\sigma^2 \begin{bmatrix} 1 & \rho_1 & \rho_2 & \rho_3 \\ \rho_1 & 1 & \rho_1 & \rho_2 \\ \rho_2 & \rho_1 & 1 & \rho_1 \\ \rho_3 & \rho_2 & \rho_1 & 1 \end{bmatrix}$$

TPH *Heterogenous Toeplitz* ($|\rho_k| \leq 1$).

$$\begin{bmatrix} \sigma_1^2 & \sigma_2\sigma_1\rho_1 & \sigma_3\sigma_1\rho_2 & \sigma_4\sigma_1\rho_3 \\ \sigma_2\sigma_1\rho_1 & \sigma_2^2 & \sigma_3\sigma_2\rho_1 & \sigma_4\sigma_2\rho_2 \\ \sigma_3\sigma_1\rho_2 & \sigma_3\sigma_2\rho_1 & \sigma_3^2 & \sigma_4\sigma_3\rho_1 \\ \sigma_4\sigma_1\rho_3 & \sigma_4\sigma_2\rho_2 & \sigma_4\sigma_3\rho_1 & \sigma_4^2 \end{bmatrix}$$

UN *Unstructured.* This is a completely general covariance matrix.

$$\begin{bmatrix} \sigma_1^2 & \sigma_{21} & \sigma_{31} & \sigma_{41} \\ \sigma_{21} & \sigma_2^2 & \sigma_{32} & \sigma_{42} \\ \sigma_{31} & \sigma_{32} & \sigma_3^2 & \sigma_{43} \\ \sigma_{41} & \sigma_{42} & \sigma_{43} & \sigma_4^2 \end{bmatrix}$$

UNR *Unstructured correlations* ($|\rho_{jk}| \leq 1$).

$$\begin{bmatrix} \sigma_1^2 & \sigma_2\sigma_1\rho_{21} & \sigma_3\sigma_1\rho_{31} & \sigma_4\sigma_1\rho_{41} \\ \sigma_2\sigma_1\rho_{21} & \sigma_2^2 & \sigma_3\sigma_2\rho_{32} & \sigma_4\sigma_2\rho_{42} \\ \sigma_3\sigma_1\rho_{31} & \sigma_3\sigma_2\rho_{32} & \sigma_3^2 & \sigma_4\sigma_3\rho_{43} \\ \sigma_4\sigma_1\rho_{41} & \sigma_4\sigma_2\rho_{42} & \sigma_4\sigma_3\rho_{43} & \sigma_4^2 \end{bmatrix}$$

VC *Variance components.* This is the default covariance structure for random effects. When the variance components structure is specified on a `RANDOM` subcommand, a scaled identity (`ID`) structure is assigned to each of the effects specified on the subcommand. If the variance components structure is specified on the `REPEATED` subcommand, it is replaced by the diagonal (`DIAG`) structure.

Variable List

The variable list specifies the dependent variable, the factors, and the covariates in the model.

- The dependent variable must be the first specification on `MIXED`.
- The names of the factors, if any, must be preceded by the keyword `BY`.
- The names of the covariates, if any, must be preceded by the keyword `WITH`.
- The dependent variable and the covariates must be numeric.
- The factor variables can be of any type (numeric and string).
- Only cases with no missing values in all of the variables specified will be used.

CRITERIA Subcommand

The `CRITERIA` subcommand controls the iterative algorithm used in the estimation and specifies numerical tolerance for checking singularity.

CIN(value) *Confidence interval level.* This value is used whenever a confidence interval is constructed. Specify a value greater than or equal to 0 and less than 100. The default value is 95.

HCONVERGE(value, type) *Hessian convergence criterion.* Convergence is assumed if $g'_k H_k^{-1} g_k$ is less than a multiplier of *value*. The multiplier is 1 for `ABSOLUTE` type and is the absolute value of the current log-likelihood function for `RELATIVE` type. The criterion is not used if *value* equals 0. This criterion is not used by default. Specify a non-negative value and a measure type of convergence.

LCONVERGE(value, type) *Log-likelihood function convergence criterion.* Convergence is assumed if the ABSOLUTE or RELATIVE change in the log-likelihood function is less than *value*. The criterion is not used if *a* equals 0. This criterion is not used by default. Specify a non-negative value and a measure type of convergence.

MXITER(n) *Maximum number of iterations.* Specify a non-negative integer. The default value is 100.

PCONVERGE(value, type) *Parameter estimates convergence criterion.* Convergence is assumed if the maximum ABSOLUTE or maximum RELATIVE change in the parameter estimates is less than *value*. The criterion is not used if *a* equals 0. Specify a non-negative value and a measure type of convergence. The default value for *a* is 10^{-6}.

MXSTEP(n) *Maximum step-halving allowed.* At each iteration, the step size is reduced by a factor of 0.5 until the log-likelihood increases or maximum step-halving is reached. Specify a positive integer. The default value is 5.

SCORING(n) *Apply scoring algorithm.* Requests to use the Fisher scoring algorithm up to iteration number *n*. Specify a positive integer. The default is 1.

SINGULAR(value) *Value used as tolerance in checking singularity.* Specify a positive value. The default value is 10^{-12}.

Example

```
MIXED SCORE BY SCHOOL CLASS WITH AGE
/CRITERIA = CIN(90) LCONVERGE(0) MXITER(50) PCONVERGE(1E-5 RELATIVE)
/FIXED = AGE
/RANDOM = SCHOOL CLASS.
```

- The CRITERIA subcommand requests that a 90% confidence interval be calculated whenever appropriate.
- The log-likelihood convergence criterion is not used. Convergence is attained when the maximum relative change in parameter estimates is less than 0.00001 and number of iterations is less than 50.

Example

```
MIXED SCORE BY SCHOOL CLASS WITH AGE
  /CRITERIA = MXITER(100) SCORING(100)
  /FIXED = AGE
  /RANDOM = SCHOOL CLASS.
```

- The Fisher scoring algorithm is used for all iterations.

EMMEANS Subcommand

EMMEANS displays estimated marginal means of the dependent variable in the cells and their standard errors for the specified factors. Note that these are predicted, not observed, means.

- The TABLES keyword, followed by an option in parentheses, is required. COMPARE is optional; if specified, it must follow TABLES.
- Multiple EMMEANS subcommands are allowed. Each is treated independently.

- If identical EMMEANS subcommands are specified, only the last identical subcommand is in effect. EMMEANS subcommands that are redundant but not identical (for example, crossed factor combinations such as *A*B* and *B*A*) are all processed.

TABLES(option)

Table specification. Valid options are the keyword OVERALL, factors appearing on the factor list, and crossed factors constructed of factors on the factor list. Crossed factors can be specified by using an asterisk (*) or the keyword BY. All factors in a crossed factor specification must be unique.

If OVERALL is specified, the estimated marginal means of the dependent variable are displayed, collapsing over all factors.

If a factor, or a crossing factor, is specified on the TABLES keyword, MIXED will compute the estimated marginal mean for each level combination of the specified factor(s), collapsing over all other factors not specified with TABLES.

WITH (option)

Covariate values. Valid options are covariates appearing on the covariate list on the VARIABLES subcommand. Each covariate must be followed by a numeric value or the keyword MEAN.

If a numeric value is used, the estimated marginal mean will be computed by holding the specified covariate at the supplied value.

When the keyword MEAN is used, the estimated marginal mean will be computed by holding the covariate at its overall mean. If a covariate is not specified in the WITH option, its overall mean will be used in estimated marginal mean calculations.

COMPARE(factor)
REFCAT(value)
ADJ(method)

Main- or simple-main-effects omnibus tests and pairwise comparisons of the dependent variable. This option gives the mean difference, standard error, degrees of freedom, significance, and confidence intervals for each pair of levels for the effect specified in the COMPARE keyword, and an omnibus test for that effect. If only one factor is specified on TABLES, COMPARE can be specified by itself; otherwise, the factor specification is required. In this case, levels of the specified factor are compared with each other for each level of the other factors in the interaction.

The optional ADJ keyword allows you to apply an adjustment to the confidence intervals and significance values to account for multiple comparisons. Methods available are LSD (no adjustment), BONFERRONI, or SIDAK.

By default, all pairwise comparisons of the specified factor will be constructed. Optionally, comparisons can be made to a reference category by specifying the value of that category after the REFCAT keyword. If the compare factor is a string variable, the category value must be a quoted string. If the compare factor is a numeric variable, the category value should be specified as an unquoted numeric value. Alternatively, the keywords FIRST or LAST can be used to specify whether the first or the last category will be used as a reference category.

Example

```
MIXED Y BY A B WITH X
  /FIXED A B X
  /EMMEANS TABLES(A*B) WITH(X=0.23) COMPARE(A) ADJ(SIDAK)
  /EMMEANS TABLES(A*B) WITH(X=MEAN) COMPARE(A) REFCAT(LAST) ADJ(LSD).
```

- In the example, the first EMMEANS subcommand will compute estimated marginal means for all level combinations of *A*B* by fixing the covariate *X* at 0.23. Then for each level of *B*, all pairwise comparisons on *A* will be performed using SIDAK adjustment.
- In the second EMMEANS subcommand, the estimated marginal means will be computed by fixing the covariate *X* at its mean. Since REFCAT(LAST) is specified, comparison will be made to the last category of factor *A* using LSD adjustment.

FIXED Subcommand

The FIXED subcommand specifies the fixed effects in the mixed model.

- Specify a list of terms to be included in the model, separated by commas or spaces.
- The intercept term is included by default.
- The default model is generated if the FIXED subcommand is omitted or empty. The default model consists of only the intercept term (if included).
- To explicitly include the intercept term, specify the keyword INTERCEPT on the FIXED subcommand. The INTERCEPT term must be specified first on the FIXED subcommand.
- To include a main-effect term, enter the name of the factor on the FIXED subcommand.
- To include an interaction-effect term among factors, use the keyword BY or the asterisk (*) to connect factors involved in the interaction. For example, A*B*C means a three-way interaction effect of the factors *A, B,* and *C*. The expression A BY B BY C is equivalent to A*B*C. Factors inside an interaction effect must be distinct. Expressions such as A*C*A and A*A are invalid.
- To include a nested-effect term, use the keyword WITHIN or a pair of parentheses on the FIXED subcommand. For example, A(B) means that *A* is nested within *B*, where *A* and *B* are factors. The expression A WITHIN B is equivalent to A(B). Factors inside a nested effect must be distinct. Expressions such as A(A) and A(B*A) are invalid.
- Multiple-level nesting is supported. For example, A(B(C)) means that *B* is nested within *C*, and *A* is nested within *B(C)*. When more than one pair of parentheses is present, each pair of parentheses must be enclosed or nested within another pair of parentheses. Thus, A(B)(C) is invalid.
- Nesting within an interaction effect is valid. For example, A(B*C) means that *A* is nested within *B*C*.
- Interactions among nested effects are allowed. The correct syntax is the interaction followed by the common nested effect inside the parentheses. For example, the interaction between *A* and *B* within levels of *C* should be specified as A*B(C) instead of A(C)*B(C).
- To include a covariate term in the model, enter the name of the covariate on the FIXED subcommand.
- Covariates can be connected using the keyword BY or the asterisk (*). For example, X*X is the product of *X* and itself. This is equivalent to entering a covariate whose values are the squared values of *X*.
- Factor and covariate effects can be connected in many ways. Suppose that *A* and *B* are factors and *X* and *Y* are covariates. Examples of valid combinations of factor and covariate effects are A*X, A*B*X, X(A), X(A*B), X*A(B), X*Y(A*B), and A*B*X*Y.

- No effects can be nested within a covariate effect. Suppose that *A* and *B* are factors and *X* and *Y* are covariates. The effects `A(X)`, `A(B*Y)`, `X(Y)`, and `X(B*Y)` are invalid.
- The following options, which are specific for the fixed effects, can be entered after the effects. Use the vertical bar (|) to precede the options.

NOINT	*No intercept.* The intercept terms are excluded from the fixed effects.
SSTYPE(n)	*Type of sum of squares.* Specify the methods for partitioning the sums of squares. Specify *n* = 1 for Type I sum of squares or *n* = 3 for Type III sum of squares. The default is Type III sum of squares.

Example

```
MIXED  SCORE BY SCHOOL CLASS WITH AGE PRETEST
  /FIXED = AGE(SCHOOL) AGE*PRETEST(SCHOOL)
  /RANDOM = CLASS.
```

- In this example, the fixed-effects design consists of the default `INTERCEPT`, a nested effect *AGE* within *SCHOOL*, and another nested effect of the product of *AGE* and *PRETEST* within *SCHOOL*.

Example

```
MIXED SCORE BY SCHOOL CLASS
  /FIXED = | NOINT
  /RANDOM = SCHOOL CLASS.
```

- In this example, a purely random-effects model is fitted. The random effects are *SCHOOL* and *CLASS*. The fixed-effects design is empty because the implicit intercept term is removed by the `NOINT` keyword.
- You can explicitly insert the `INTERCEPT` effect as `/FIXED = INTERCEPT | NOINT`. But the specification will be identical to `/FIXED = | NOINT`.

METHOD Subcommand

The `METHOD` subcommand specifies the estimation method.

- If this subcommand is not specified, the default is `REML`.
- The keywords `ML` and `REML` are mutually exclusive. Only one of them can be specified once.

ML	*Maximum likelihood.*
REML	*Restricted maximum likelihood.* This is the default.

MISSING Subcommand

The `MISSING` subcommand specifies the way to handle cases with user-missing values.

- If this subcommand is not specified, the default is `EXCLUDE`.

- Cases, which contain system-missing values in one of the variables, are always deleted.
- The keywords EXCLUDE and INCLUDE are mutually exclusive. Only one of them can be specified at once.

EXCLUDE *Exclude both user-missing and system-missing values.* This is the default.

INCLUDE *User-missing values are treated as valid.* System-missing values cannot be included in the analysis.

PRINT Subcommand

The PRINT subcommand specifies additional output. If no PRINT subcommand is specified, the default output includes:

- A model dimension summary table
- A covariance parameter estimates table
- A model fit summary table
- A test of fixed effects table

CORB *Asymptotic correlation matrix of the fixed-effects parameter estimates.*

COVB *Asymptotic covariance matrix of the fixed-effects parameter estimates.*

CPS *Case processing summary.* Displays the sorted values of the factors, the repeated measure variables, the repeated measure subjects, the random-effects subjects, and their frequencies.

DESCRIPTIVES *Descriptive statistics.* Displays the sample sizes, the means, and the standard deviations of the dependent variable, and covariates (if specified). These statistics are displayed for each distinct combination of the factors.

G *Estimated covariance matrix of random effects.* This keyword is accepted only when at least one RANDOM subcommand is specified. Otherwise, it will be ignored. If a SUBJECT variable is specified for a random effect, then the common block is displayed.

HISTORY(n) *Iteration history.* The table contains the log-likelihood function value and parameter estimates for every *n* iterations beginning with the 0*th* iteration (the initial estimates). The default is to print every iteration (*n* = 1). If HISTORY is specified, the last iteration is always printed regardless of the value of *n*.

LMATRIX *Estimable functions.* Displays the estimable functions used for testing the fixed effects and for testing the custom hypothesis.

R *Estimated covariance matrix of residual.* This keyword is accepted only when a REPEATED subcommand is specified. Otherwise, it will be ignored. If a SUBJECT variable is specified, the common block is displayed.

SOLUTION *A solution for the fixed-effects and the random-effects parameters.* The fixed-effects and the random-effects parameter estimates are displayed. Their approximate standard errors are also displayed.

TESTCOV *Tests for the covariance parameters.* Displays the asymptotic standard errors and Wald tests for the covariance parameters.

RANDOM Subcommand

The RANDOM subcommand specifies the random effects in the mixed model.

- Depending on the covariance type specified, random effects specified in one RANDOM subcommand may be correlated.
- One covariance G matrix will be constructed for each RANDOM subcommand. The dimension of the random effect covariance G matrix is equal to the sum of the levels of all random effects in the subcommand.
- When the variance components (VC) structure is specified, a scaled identity (ID) structure will be assigned to each of the effects specified. This is the default covariance type for the RANDOM subcommand.
- Note that the RANDOM subcommand in the MIXED procedure is different in syntax from the RANDOM subcommand in the GLM and VARCOMP procedures.
- Use a separate RANDOM subcommand when a different covariance structure is assumed for a list of random effects. If the same effect is listed on more than one RANDOM subcommand, it must be associated with a different SUBJECT combination.
- Specify a list of terms to be included in the model, separated by commas or spaces.
- No random effects are included in the mixed model unless a RANDOM subcommand is specified correctly.
- Specify the keyword INTERCEPT to include the intercept as a random effect. The MIXED procedure does not include the intercept in the RANDOM subcommand by default. The INTERCEPT term must be specified first on the RANDOM subcommand.
- To include a main-effect term, enter the name of the factor on the RANDOM subcommand.
- To include an interaction-effect term among factors, use the keyword BY or the asterisk (*) to join factors involved in the interaction. For example, A*B*C means a three-way interaction effect of *A*, *B*, and *C*, where *A*, *B*, and *C* are factors. The expression A BY B BY C is equivalent to A*B*C. Factors inside an interaction effect must be distinct. Expressions such as A*C*A and A*A are invalid.
- To include a nested-effect term, use the keyword WITHIN or a pair of parentheses on the RANDOM subcommand. For example, A(B) means that *A* is nested within *B*, where *A* and *B* are factors. The expression A WITHIN B is equivalent to A(B). Factors inside a nested effect must be distinct. Expressions such as A(A) and A(B*A) are invalid.
- Multiple-level nesting is supported. For example, A(B(C)) means that *B* is nested within *C*, and *A* is nested within *B(C)*. When more than one pair of parentheses is present, each pair of parentheses must be enclosed or nested within another pair of parentheses. Thus, A(B)(C) is invalid.
- Nesting within an interaction effect is valid. For example, A(B*C) means that *A* is nested within *B*C*.
- Interactions among nested effects are allowed. The correct syntax is the interaction followed by the common nested effect inside the parentheses. For example, the interaction between *A* and *B* within levels of *C* should be specified as A*B(C) instead of A(C)*B(C).
- To include a covariate term in the model, enter the name of the covariate on the FIXED subcommand.
- Covariates can be connected using the keyword BY or the asterisk (*). For example, X*X is the product of *X* and itself. This is equivalent to entering a covariate whose values are the squared values of *X*.

- Factor and covariate effects can be connected in many ways. Suppose that *A* and *B* are factors and *X* and *Y* are covariates. Examples of valid combinations of factor and covariate effects are `A*X`, `A*B*X`, `X(A)`, `X(A*B)`, `X*A(B)`, `X*Y(A*B)`, and `A*B*X*Y`.
- No effects can be nested within a covariate effect. Suppose that *A* and *B* are factors and *X* and *Y* are covariates. The effects `A(X)`, `A(B*Y)`, `X(Y)`, and `X(B*Y)` are invalid.
- The following options, which are specific for the random effects, can be entered after the effects. Use the vertical bar (|) to precede the options.

SUBJECT(varname*varname*…) *Identify the subjects.* Complete independence is assumed across subjects, thus producing a block-diagonal structure in the covariance matrix of the random effect with identical blocks. Specify a list of variable names (of any type) connected by asterisks. The number of subjects is equal to the number of distinct combinations of values of the variables. A case will not be used if it contains a missing value on any of the subject variables.

COVTYPE(type) *Covariance structure.* Specify the covariance structure of the identical blocks for the random effects (see Covariance Structure List on p. 1121). The default covariance structure for random effects is `VC`.

- If the `REPEATED` subcommand is specified, the variables in the `RANDOM` subject list must be a subset of the variables in the `REPEATED` subject list.
- Random effects are considered independent of each other, and a separate covariance matrix is computed for each effect.

Example

```
MIXED  SCORE BY SCHOOL CLASS
  /RANDOM = INTERCEPT SCHOOL CLASS.
```

REGWGT Subcommand

The `REGWGT` subcommand specifies the name of a variable containing the regression weights.

- Specify a numeric variable name following the `REGWGT` subcommand.
- Cases with missing or non-positive weights are not used in the analyses.
- The regression weights will be applied only to the covariance matrix of the residual term.

REPEATED Subcommand

The `REPEATED` subcommand specifies the residual covariance matrix in the mixed-effects model. If no `REPEATED` subcommand is specified, the residual covariance matrix assumes the form of a scaled identity matrix with the scale being the usual residual variance.

- Specify a list of variable names (of any type) connected by asterisks (repeated measure) following the `REPEATED` subcommand.

- Distinct combinations of values of the variables are used simply to identify the repeated observations. Order of the values will determine the order of occurrence of the repeated observations. Therefore, the lowest values of the variables associate with the first repeated observation, and the highest values associate with the last repeated observation.
- The VC covariance structure is obsolete in the REPEATED subcommand. If it is specified, it will be replaced with the DIAG covariance structure. An annotation will be made in the output to indicate this change.
- The default covariance type for repeated effects is DIAG.
- The following keywords, which are specific for the REPEATED subcommand, can be entered after the effects. Use the vertical bar (|) to precede the options.

SUBJECT(varname*varname*…)	*Identify the subjects.* Complete independence is assumed across subjects, thus producing a block-diagonal structure in the residual covariance matrix with identical blocks. The number of subjects is equal to the number of distinct combinations of values of the variables. A case will not be used if it contains a missing value on any of the subject variables.
COVTYPE(type)	*Covariance structure.* Specify the covariance structure of the identical blocks for the residual covariance matrix (see Covariance Structure List on p. 1121). The default structure for repeated effects is DIAG.

- The SUBJECT keyword must be specified to identify the subjects in a repeated measurement analysis. The analysis will not be performed if this keyword is omitted.
- The list of subject variables must contain all of the subject variables specified in all RANDOM subcommands.
- Any variable used in the repeated measure list must not be used in the repeated subject specification.

Example

```
MIXED  SCORE BY CLASS
  /RANDOM = CLASS | SUBJECT(SCHOOL)
  /REPEATED = FLOOR | SUBJECT(SCHOOL*STUDENT).
```

However, the syntax in each of the following examples is invalid:

```
MIXED  SCORE BY CLASS
  /RANDOM = CLASS | SUBJECT(SCHOOL)
  /REPEATED = FLOOR | SUBJECT(STUDENT).
```

```
MIXED  SCORE BY CLASS
  /RANDOM = CLASS | SUBJECT(SCHOOL*STUDENT)
  /REPEATED = FLOOR | SUBJECT(STUDENT).
```

```
MIXED  SCORE BY CLASS
  /RANDOM = CLASS | SUBJECT(SCHOOL)
  /REPEATED = STUDENT | SUBJECT(STUDENT*SCHOOL).
```

- In the first two examples, the RANDOM subject list contains a variable not on the REPEATED subject list.
- In the third example, the REPEATED subject list contains a variable on the REPEATED variable list.

SAVE Subcommand

Use the SAVE subcommand to save one or more casewise statistics to the active dataset.

- Specify one or more temporary variables, each followed by an optional new name in parentheses.
- If new names are not specified, default names are generated.

FIXPRED	*Fixed predicted values.* The regression means without the random effects.
PRED	*Predicted values.* The model fitted value.
RESID	*Residuals.* The data value minus the predicted value.
SEFIXP	*Standard error of fixed predicted values.* These are the standard error estimates for the fixed effects predicted values obtained by the keyword FIXPRED.
SEPRED	*Standard error of predicted values.* These are the standard error estimates for the overall predicted values obtained by the keyword PRED.
DFFIXP	*Degrees of freedom of fixed predicted values.* These are the Satterthwaite degrees of freedom for the fixed effects predicted values obtained by the keyword FIXPRED.
DFPRED	*Degrees of freedom of predicted values.* These are the Satterthwaite degrees of freedom for the fixed effects predicted values obtained by the keyword PRED.

Example

```
MIXED  SCORE BY SCHOOL CLASS WITH AGE
  /FIXED = AGE
  /RANDOM = SCHOOL CLASS(SCHOOL)
  /SAVE = FIXPRED(BLUE) PRED(BLUP) SEFIXP(SEBLUE) SEPRED(SEBLUP).
```

- The SAVE subcommand appends four variables to the active dataset: *BLUE*, containing the fixed predicted values, *BLUP*, containing the predicted values, *SEBLUE*, containing the standard error of *BLUE*, and *SEBLUP*, containing the standard error of *BLUP*.

TEST Subcommand

The TEST subcommand allows you to customize your hypotheses tests by directly specifying null hypotheses as linear combinations of parameters.

- Multiple TEST subcommands are allowed. Each is handled independently.
- The basic format for the TEST subcommand is an optional list of values enclosed in a pair of parentheses, an optional label in quotes, an effect name or the keyword ALL, and a list of values.
- When multiple linear combinations are specified within the same TEST subcommand, a semicolon (;) terminates each linear combination except the last one.

- At the end of a contrast coefficients row, you can use the option DIVISOR=value to specify a denominator for coefficients in that row. When specified, the contrast coefficients in that row will be divided by the given value. Note that the equals sign is required.
- The value list preceding the first effect or the keyword ALL contains the constants, to which the linear combinations are equated under the null hypotheses. If this value list is omitted, the constants are assumed to be zeros.
- The optional label is a string with a maximum length of 255 bytes. Only one label per TEST subcommand can be specified.
- The effect list is divided into two parts. The first part is for the fixed effects, and the second part is for the random effects. Both parts have the same syntax structure.
- Effects specified in the fixed-effect list should have already been specified or implied on the FIXED subcommand.
- Effects specified in the random-effect list should have already been specified on the RANDOM subcommand.
- To specify the coefficient for the intercept, use the keyword INTERCEPT. Only one value is expected to follow INTERCEPT.
- The number of values following an effect name must be equal to the number of parameters (including the redundant ones) corresponding to that effect. For example, if the effect *A*B* takes up to six parameters, then exactly six values must follow *A*B*.
- A number can be specified as a fraction with a positive denominator. For example, 1/3 or –1/3 are valid, but 1/–3 is invalid.
- When ALL is specified, only a list of values can follow. The number of values must be equal to the number of parameters (including the redundant ones) in the model.
- Effects appearing or implied on the FIXED and RANDOM subcommands but not specified on TEST are assumed to take the value 0 for all of their parameters.
- If ALL is specified for the first row in a TEST matrix, then all subsequent rows should begin with the ALL keyword.
- If effects are specified for the first row in a TEST matrix, then all subsequent rows should use the effect name (thus ALL is not allowed).
- When SUBJECT( ) is specified on a RANDOM subcommand, the coefficients given in the TEST subcommand will be divided by the number of subjects of that random effect automatically.

Example

```
MIXED Y BY A B C
  /FIX = A
  /RANDOM = B C
  /TEST = 'Contrasts of A' A 1/3 1/3 1/3; A 1 -1 0; A 1 -1/2 -1/2
  /TEST(1) = 'Contrast of B' | B 1 -1
  /TEST = 'BLUP at First Level of A'
          ALL 0 1 0 0 | 1 0 1 0;
          ALL         | 1 0 0 1;
          ALL 0 1 0 0;
          ALL 0 1 0 0 | 0 1 0 1.
```

Suppose that factor *A* has three levels and factors *B* and *C* each have two levels.

- The first TEST is labeled *Contrasts of A*. It performs three contrasts among levels of *A*. The first is technically not a contrast but the mean of level 1, level 2, and level 3 of *A*, the second is between level 1 and level 2 of *A*, and the third is between level 1 and the mean of level 2 and level 3 of *A*.
- The second TEST is labeled *Contrast of B*. Coefficients for *B* are preceded by the vertical bar (|) because *B* is a random effect. This contrast computes the difference between level 1 and level 2 of *B*, and tests if the difference equals 1.
- The third TEST is labeled *BLUP at First Level of A*. There are four parameters for the fixed effects (intercept and *A*), and there are four parameters for the random effects (*B* and *C*). Coefficients for the fixed-effect parameters are separated from those for the random-effect parameters by the vertical bar (|). The coefficients correspond to the parameter estimates in the order in which the parameter estimates are listed in the output.

Example

Suppose that factor *A* has three levels and factor *B* has four levels.

```
MIXED Y BY A B
  /FIXED = A B
  /TEST = 'test example' A 1 -1 0 DIVISOR=3;
                  B 0 0 1 -1 DIVISOR=4.
```

- For effect *A*, all contrast coefficients will be divided by 3; therefore, the actual coefficients are (1/3,–1/3,0).
- For effect *B*, all contrast coefficients will be divided by 4; therefore, the actual coefficients are (0,0,1/4,–1/4).

Interpretation of Random Effect Covariance Structures

This section is intended to provide some insight into the specification random effects and how their covariance structures differ from versions prior to 11.5. Throughout the examples, let *A* and *B* be factors with three levels, and let *X* and *Y* be covariates.

Example (Variance Component Models)

Random effect covariance matrix of *A:*

$$G_A = \sigma_A^2 I_3$$

Random effect covariance matrix of *B:*

$$G_B = \sigma_B^2 I_3$$

Overall random effect covariance matrix:

$$G = \begin{bmatrix} G_A & 0 \\ 0 & G_B \end{bmatrix}_{6\times 6}$$

Prior to version 11.5, this model could be specified by:

```
/RANDOM = A B | COVTYPE(ID)
```

or

```
/RANDOM = A | COVTYPE(ID)
/RANDOM = B | COVTYPE(ID)
```

with or without the explicit specification of the covariance structure.

As of version 11.5, this model could be specified by:

```
/RANDOM = A B | COVTYPE(VC)
```

or

```
/RANDOM = A | COVTYPE(VC)
/RANDOM = B | COVTYPE(VC)
```

with or without the explicit specification of the covariance structure.

or

```
/RANDOM = A | COVTYPE(ID)
/RANDOM = B | COVTYPE(ID)
```

with the explicit specification of the covariance structure.

Example (Independent Random Effects with Heterogeneous Variances)

Random effect covariance matrix of *A:*

$$G_A = \begin{bmatrix} \sigma_{A1}^2 & 0 & 0 \\ 0 & \sigma_{A2}^2 & 0 \\ 0 & 0 & \sigma_{A3}^2 \end{bmatrix}$$

Random effect covariance matrix of *B*:

$$G_B = \begin{bmatrix} \sigma_{B1}^2 & 0 & 0 \\ 0 & \sigma_{B2}^2 & 0 \\ 0 & 0 & \sigma_{B3}^2 \end{bmatrix}$$

Overall random effect covariance matrix:

$$G = \begin{bmatrix} G_A & 0 \\ 0 & G_B \end{bmatrix}_{6\times 6}$$

Prior to version 11.5, this model could be specified by:

```
/RANDOM = A B | COVTYPE(VC)
```

or

```
/RANDOM = A | COVTYPE(VC)
/RANDOM = B | COVTYPE(VC)
```

As of version 11.5, this model could be specified by:

```
/RANDOM = A B | COVTYPE(DIAG)
```

or

```
/RANDOM = A | COVTYPE(DIAG)
/RANDOM = B | COVTYPE(DIAG)
```

Example (Correlated Random Effects)

Overall random effect covariance matrix; one column belongs to *X* and one column belongs to Y.

$$G = \begin{bmatrix} \sigma^2 & \sigma^2\rho \\ \sigma^2\rho & \sigma^2 \end{bmatrix}$$

Prior to version 11.5, it was impossible to specify this model.

As of version 11.5, this model could be specified by:

```
/RANDOM = A B | COVTYPE(CSR)
```

MLP

Release History

Release 16.0

- Command introduced.

Example

```
MLP dep_var BY A B C WITH X Y Z.
```

Overview

Neural networks are a data mining tool for finding unknown patterns in databases. Neural networks can be used to make business decisions by forecasting demand for a product as a function of price and other variables or by categorizing customers based on buying habits and demographic characteristics. The MLP procedure fits a particular kind of neural network called a multilayer perceptron. The multilayer perceptron uses a feedforward architecture and can have multiple hidden layers. It is one of the most commonly used neural network architectures.

Options

Prediction or classification. One or more dependent variables may be specified, and they may be scale, categorical, or a combination. If a dependent variable has a scale measurement level, then the neural network predicts continuous values that approximate the “true” value of some continuous function of the input data. If a dependent variable is categorical, then the neural network is used to classify cases into the “best” category based on the input predictors.

Rescaling. MLP optionally rescales covariates or scale dependent variables before training the neural network. There are three rescaling options: standardization, normalization, and adjusted normalization.

Training, testing, and holdout data. MLP optionally divides the dataset into training, testing, and holdout data. The neural network is trained using the training data. The training data or testing data, or both, can be used to track errors across steps and determine when to stop training. The holdout data is completely excluded from the training process and is used for independent assessment of the final network.

Architecture selection. MLP can perform automatic architecture selection, or it can build a neural network based on user specifications. Automatic architecture selection creates a neural network with one hidden layer and finds the "best" number of hidden units. Alternatively, you can specify one or two hidden layers and define the number of hidden units in each layer.

Activation functions. Units in the hidden layers can use the hyperbolic or sigmoid activation functions. Units in the output layer can use the hyperbolic, sigmoid, identity, or softmax activation functions.

Training methods. The neural network can be built using batch, online, or mini-batch training. Gradient descent and scaled conjugate gradient optimization algorithms are available.

Missing Values. The MLP procedure has an option for treating user-missing values of categorical variables as valid. User-missing values of scale variables are always treated as invalid.

Output. MLP displays pivot table output but offers an option for suppressing most such output. Graphical output includes a network diagram (default) and a number of optional charts: predicted-by-observed values, residual-by-predicted values, ROC (Receiver Operating Characteristic) curves, cumulative gains, lift, and independent variable importance. The procedure also optionally saves predicted values in the active dataset. Synaptic weight estimates can be saved in SPSS or XML files also.

Basic Specification

The basic specification is the MLP command followed by one or more dependent variables, the BY keyword and one or more factors, and the WITH keyword and one or more covariates. By default, the MLP procedure standardizes covariates and selects a training sample before training the neural network. Automatic architecture selection is used to find the "best" neural network architecture. User-missing values are excluded, and default pivot table output is displayed.

Syntax Rules

- All subcommands are optional.
- Subcommands may be specified in any order.
- Only a single instance of each subcommand is allowed.
- An error occurs if a keyword is specified more than once within a subcommand.
- Parentheses, equals signs, and slashes shown in the syntax chart are required.
- The command name, subcommand names, and keywords must be spelled in full.
- Empty subcommands are not allowed.
- Any split variable defined on the SPLIT FILE command may not be used as a dependent variable, factor, covariate, or partition variable.

Limitations

The WEIGHT setting is ignored with a warning by the MLP procedure.

Categorical Variables

Although the MLP procedure accepts categorical variables as predictors or as the dependent variable, the user should be cautious when using a categorical variable with a very large number of categories.

The MLP procedure temporarily recodes categorical predictors and dependent variables using one-of-*c* coding for the duration of the procedure. If there are *c* categories of a variable, then the variable is stored as *c* vectors, with the first category denoted (1,0,...,0), the next category (0,1,0,...,0), ..., and the final category (0,0,...,0,1).

This coding scheme increases the number of synaptic weights. In particular, the total number of input units is the number of scale predictors plus the number of categories across all categorical predictors. As a result, this coding scheme can lead to slower training, but more "compact" coding methods usually lead to poorly fit neural networks. If your network training is proceeding very slowly, you might try reducing the number of categories in your categorical predictors by combining similar categories or dropping cases that have extremely rare categories before running the MLP procedure.

All one-of-*c* coding is based on the training data, even if a testing or holdout sample is defined (see PARTITION Subcommand). Thus, if the testing or holdout samples contain cases with predictor categories that are not present in the training data, then those cases are not used by the procedure or in scoring. If the testing or holdout samples contain cases with dependent variable categories that are not present in the training data, then those cases are not used by the procedure but they may be scored.

Replicating results

The MLP procedure uses random number generation during random assignment of partitions, random subsampling for initialization of synaptic weights, random subsampling for automatic architecture selection, and the simulated annealing algorithm used in weight initialization and automatic architecture selection. To reproduce the same randomized results in the future, use the SET command to set the initialization value for the random number generator before each run of the MLP procedure.

MLP results are also dependent on data order. The online and mini-batch training methods are explicitly dependent upon data order; however, even batch training is dependent upon data order because initialization of synaptic weights involves subsampling from the dataset. See the CRITERIA subcommand TRAINING keyword for more information about the training methods.

To minimize data order effects, randomly order the cases before running the MLP procedure. To verify the stability of a given solution, you may want to obtain several different solutions with cases sorted in different random orders. In situations with extremely large file sizes, multiple runs can be performed with a sample of cases sorted in different random orders.

Finally, MLP results may be influenced by the variable order on the command line due to the different pattern of initial values assigned when the command line variable order is changed. As with data order effects, you might try different command line variable orders to assess the stability of a given solution.

In summary, if you want to exactly replicate MLP results in the future, use the same initialization value for the random number generator, the same data order, and the same command line variable order, in addition to using the same MLP procedure settings.

Examples

Basic specification with default neural network settings

```
MLP DepVar BY A B C WITH X Y Z.
```

- The MLP procedure treats *DepVar* as the dependent variable.
- Predictors *A*, *B*, and *C* are factors, and *X*, *Y*, and *Z* are covariates.
- By default, covariates are standardized before training. Also, the active dataset is partitioned into training and testing data samples, with 70% going to the training data and 30% to the testing data sample.
- Automatic architecture selection is used to find the "best" neural network architecture.
- User-missing values are excluded and default output is displayed.

User-specified neural network with two hidden layers

```
MLP DepVar BY A B C WITH X Y Z
  /PARTITION
     TRAINING=100 TESTING=0
  /ARCHITECTURE
     AUTOMATIC=NO
     HIDDENLAYERS=2 (NUMUNITS=25,10)
     OUTPUTFUNCTION=SIGMOID.
```

- The MLP procedure treats *DepVar* as the dependent variable. Predictors *A*, *B*, and *C* are factors, and *X*, *Y*, and *Z* are covariates.
- By default, covariates are standardized before training. The PARTITION subcommand overrides the default partitioning of the active dataset into training and testing data and treats all cases as training data.
- The ARCHITECTURE subcommand turns off automatic architecture selection (AUTOMATIC = NO) and specifies a neural network with two hidden layers. There are 25 hidden units in the first hidden layer and 10 hidden units in the second hidden layer. The sigmoid activation function is used for units in the output layer.
- User-missing values are excluded and default output is displayed.

Automatic architecture with partitions specified by variable

```
*Multilayer Perceptron Network.
MLP default (MLEVEL=N) BY ed WITH age employ address income debtinc
    creddebt othdebt
```

```
  /RESCALE COVARIATE=STANDARDIZED
  /PARTITION  VARIABLE=partition
  /ARCHITECTURE   AUTOMATIC=YES (MINUNITS=1 MAXUNITS=50)
  /CRITERIA TRAINING=BATCH OPTIMIZATION=SCALEDCONJUGATE LAMBDAINITIAL=0.0000005
    SIGMAINITIAL=0.00005 INTERVALCENTER=0 INTERVALOFFSET=0.5
  /PRINT CPS NETWORKINFO SUMMARY CLASSIFICATION IMPORTANCE
  /PLOT ROC GAIN LIFT PREDICTED
  /STOPPINGRULES ERRORSTEPS= 1 (DATA=AUTO) TRAININGTIMER=ON (MAXTIME=15)
    MAXEPOCHS=AUTO ERRORCHANGE=1.0E-4 ERRORRATIO=0.0010
  /MISSING USERMISSING=EXCLUDE .
```

- The procedure builds a network for the nominal-level variable *default*, based upon the factor *ed* and covariates *age* through *othdebt*.
- Cases are assigned to training, testing, and holdout samples based on the values of *partition*.
- In addition to the default tabular output, a sensitivity analysis to compute the importance of each predictor is requested.
- The default graphical output (the network diagram) is not requested, but an ROC curve, cumulative gains chart, lift chart, and predicted by observed chart will be produced.
- All other options are set to their default values.

Multiple dependent variables; two hidden layers with automatic numbers of units selection

```
*Multilayer Perceptron Network.
MLP los (MLEVEL=S) cost (MLEVEL=S) BY agecat gender diabetes bp smoker choles
    active obesity angina mi nitro anticlot time doa ekg cpk tropt clotsolv
    bleed magnes digi betablk der proc comp
  /RESCALE DEPENDENT=ADJNORMALIZED (CORRECTION=0.02)
  /PARTITION  TRAINING=7  TESTING=2  HOLDOUT=1
  /ARCHITECTURE   AUTOMATIC=NO HIDDENLAYERS=2 (NUMUNITS=AUTO)
    HIDDENFUNCTION=TANH OUTPUTFUNCTION=TANH
  /CRITERIA TRAINING=ONLINE OPTIMIZATION=GRADIENTDESCENT LEARNINGINITIAL= 0.4
  LEARNINGLOWER= 0.001 LEARNINGEPOCHS= 10 MOMENTUM= 0.9 INTERVALCENTER=0
  INTERVALOFFSET=0.5 MEMSIZE=1000
  /PRINT CPS NETWORKINFO SUMMARY IMPORTANCE
  /PLOT PREDICTED RESIDUAL
  /SAVE PREDVAL
  /STOPPINGRULES ERRORSTEPS= 1 (DATA=AUTO) TRAININGTIMER=ON (MAXTIME=15)
    MAXEPOCHS=AUTO ERRORCHANGE=1.0E-4 ERRORRATIO=0.0010
  /MISSING USERMISSING=INCLUDE .
```

- The procedure has fit a network to the scale variables *los* and *cost*, using *agecat* through *anticlot* and *time* through *comp* as factors.
- The `RESCALE` subcommand specifies that dependent variables are rescaled using the adjusted normalized method.
- The `PARTITION` subcommand requests that cases be assigned to the training, testing, and holdout samples in a 7:2:1 ratio.
- The `ARCHITECTURE` subcommand specifies a custom architecture with two hidden layers and the hyperbolic tangent as the activation function for the output layer.
- The `CRITERIA` subcommand specifies that online training will be used to estimate the network parameters, using the default settings for the gradient descent algorithm.
- The `PRINT` subcommand requests a sensitivity analysis to compute the importance of each predictor, in addition to the default output.

- The PLOT subcommand does not request default graphical output (the network diagram), but predicted-by-observed and residuals-by-predicted charts will be produced.
- The SAVE subcommand requests that predicted values be saved to the active dataset.
- The MISSING subcommand specifies that user-missing values of factors and categorical dependents be included in the analysis.
- All other options are set to their default values.

Variable Lists

The command line variable lists specify the dependent variables, any categorical predictors (also known as factors), and any scale predictors (also known as covariates).

Dependent Variables

- A list of one or more dependent variables must be the first specification on the MLP command.
- Each dependent variable may be followed by the measurement level specification, which contains, in parentheses, the MLEVEL keyword followed by an equals sign and then S for scale, O for ordinal, or N for nominal. MLP treats ordinal and nominal dependent variables equivalently as categorical.
- If a measurement level is specified, then it temporarily overrides a dependent variable's setting in the data dictionary.
- If no measurement level is specified, then MLP defaults to the dictionary setting.
- If a measurement level is not specified and no setting is recorded in the data dictionary, then a numeric variable is treated as scale and a string variable is treated as categorical.
- Dependent variables can be numeric or string.
- A string variable may be defined as ordinal or nominal only.

Predictor Variables

- The names of the factors, if any, must be preceded by the keyword BY.
- If keyword BY is specified with no factors, then a warning is issued and BY is ignored.
- The names of the covariates, if any, must be preceded by the keyword WITH.
- If keyword WITH is specified with no covariates, then a warning is issued and WITH is ignored.
- A dependent variable may not be specified within a factor or covariate list. If a dependent variable is specified within one of these lists, then an error is issued.
- All variables specified within a factor or covariate list must be unique. If duplicate variables are specified within a list, then the duplicates are ignored.
- If duplicate variables are specified across the factor and covariate lists, then an error is issued.
- The universal keywords TO and ALL may be specified in the factor and covariate lists.
- Factor variables can be numeric or string.
- Covariates must be numeric.

- If no predictors at all are specified, then the procedure fits an input layer containing only the bias unit—that is, the constant-only input layer.
- At least one predictor must be specified.

EXCEPT Subcommand

The EXCEPT subcommand lists any variables that the MLP procedure should exclude from the factor or covariate lists on the command line. This subcommand is useful if the factor or covariate lists contain a large number of variables—specified using the TO or ALL keyword, for example—but there are a few variables (for example, Case ID) that should be excluded.

The EXCEPT subcommand is introduced strictly for the purpose of simplifying syntax. Missing values on factors or covariates specified on EXCEPT do not affect whether a case is included in the analysis. For example, the following two MLP commands are equivalent. In both commands, listwise deletion is based on the dependent variable and factors *A*, *B*, and *C*.

```
MLP DepVar BY A B C.

MLP DepVar BY A B C D   /EXCEPT VARIABLES=D.
```

- The EXCEPT subcommand ignores duplicate variables and variables that are not specified on the command line's factor or covariate lists.
- There is no default variable list on the EXCEPT subcommand.

RESCALE Subcommand

The RESCALE subcommand is used to rescale covariates or scale dependent variables.

All rescaling is performed based on the training data, even if a testing or holdout sample is defined (see PARTITION Subcommand). That is, depending on the type of rescaling, the mean, standard deviation, minimum value, or maximum value of a covariate or dependent variable are computed using only the training data. It is important that these covariates or dependent variables have similar distributions across the training, testing, and holdout samples. If the data are partitioned by specifying percentages on the PARTITION subcommand, then the MLP procedure attempts to ensure this similarity by random assignment. However, if you use the PARTITION subcommand VARIABLE keyword to assign cases to the training, testing, and holdout samples, then we recommend that you confirm the distributions are similar across samples before running the MLP procedure.

COVARIATE Keyword

The COVARIATE keyword specifies the rescaling method to use for covariates specified following WITH on the command line. If no covariates are specified on the command line, then the COVARIATE keyword is ignored.

STANDARDIZED	*Subtract the mean and divide by the standard deviation, (x−mean)/s.* This is the default rescaling method for covariates.
NORMALIZED	*Subtract the minimum and divide by the range, (x−min)/(max−min).*

ADJNORMALIZED *Adjusted version of subtract the minimum and divide by the range, [2*(x−min)/(max−min)]−1 .*

NONE *No rescaling of covariates.*

DEPENDENT Keyword

The DEPENDENT keyword specifies the rescaling method to use for scale dependent variables.

- This keyword applies only to scale dependent variables—that is, either MLEVEL=S is specified on the command line or the variable has a scale measurement level based on its data dictionary setting. If a dependent variable is not scale, then the DEPENDENT keyword is ignored for that variable.
- The availability of these rescaling methods for scale dependent variables depends on the output layer activation function in effect.
- If the identity activation function is in effect, then any of the rescaling methods, including NONE, may be requested. If the sigmoid activation function is in effect, then NORMALIZED is required. If the hyperbolic tangent activation function is in effect, then ADJNORMALIZED is required.
- If automatic architecture selection is in effect (/ARCHITECTURE AUTOMATIC=YES), then the default output layer activation function (identity if there are any scale dependent variables) is always used. In this case, the default rescaling method (STANDARDIZED) is also used and the DEPENDENT keyword is ignored.

STANDARDIZED *Subtract the mean and divide by the standard deviation, (x−mean)/s.* This is the default rescaling method for scale dependent variables if the output layer uses the identity activation function. This rescaling method may not be specified if the output layer uses the sigmoid or hyperbolic tangent activation function.

NORMALIZED *Subtract the minimum and divide by the range, (x−min)/(max−min).* This is the required rescaling method for scale dependent variables if the output layer uses the sigmoid activation function. This rescaling method may not be specified if the output layer uses the hyperbolic tangent activation function.

The NORMALIZED keyword may be followed by the CORRECTION option, which specifies a number ε that is applied as a correction to the rescaling formula. In particular, the corrected formula is [x−(min−ε)]/[(max+ε)−(min−ε)]. This correction ensures that all rescaled dependent variable values will be within the range of the activation function. A real number greater than or equal to 0 must be specified. The default is 0.02.

ADJNORMALIZED *Adjusted version of subtract the minimum and divide by the range, [2*(x−min)/(max−min)]−1 .* This is the required rescaling method for scale dependent variables if the output layer uses the hyperbolic tangent activation function. This rescaling method may not be specified if the output layer uses the sigmoid activation function.

The ADJNORMALIZED keyword may be followed by the CORRECTION option, which specifies a number ε that is applied as a correction to the rescaling formula. In particular, the corrected formula is {2*[(x−(min−ε))/((max+ε)−(min−ε))]}−1. This correction ensures that all rescaled dependent variable values will be within the range of the activation function. A real number greater than or equal to 0 must be specified. The default is 0.02.

NONE *No rescaling of scale dependent variables.*

PARTITION Subcommand

The PARTITION subcommand specifies the method of partitioning the active dataset into training, testing, and holdout samples. The training sample comprises the data records used to train the neural network. The testing sample is an independent set of data records used to track prediction error during training in order to prevent overtraining. The holdout sample is another independent set of data records used to assess the final neural network.

- The partition can be defined by specifying the ratio of cases randomly assigned to each sample (training, testing, and holdout) or by a variable that assigns each case to the training, testing, or holdout sample.
- If the PARTITION subcommand is not specified, then the default partition randomly assigns 70% of the cases to the training sample, 30% to the testing sample, and 0% to the holdout sample. If you want to specify a different random assignment, then you must specify new values for the TRAINING, TESTING, and HOLDOUT keywords. The value specified on each keyword gives the relative number of cases in the active dataset to assign to each sample. For example, /PARTITION TRAINING = 50 TESTING = 30 HOLDOUT = 20 is equivalent to /PARTITION TRAINING = 5 TESTING = 3 HOLDOUT = 2; both subcommands randomly assign 50% of the cases to the training sample, 30% to the testing sample, and 20% to the holdout sample.
- If you want to be able to reproduce results based on the TRAINING, TESTING, and HOLDOUT keywords later, use the SET command to set the initialization value for the random number generator before running the MLP procedure.
- Be aware of the relationship between rescaling and partitioning. For more information, see RESCALE Subcommand on p. 1144.
- All partitioning is performed after listwise deletion of any cases with invalid data for any variable used by the procedure. See MISSING Subcommand for details about valid and invalid data.

TRAINING Keyword

The TRAINING keyword specifies the relative number of cases in the active dataset to randomly assign to the training sample. The value must be an integer greater than 0. The default (if the PARTITION subcommand is not specified) is 70.

TESTING Keyword

The TESTING keyword specifies the relative number of cases in the active dataset to randomly assign to the testing sample. The value must be an integer greater than 0. The default (if the PARTITION subcommand is not specified) is 30.

HOLDOUT Keyword

The HOLDOUT keyword specifies the relative number of cases in the active dataset to randomly assign to the holdout sample. The value must be an integer greater than 0. The default (if the PARTITION subcommand is not specified) is 0.

VARIABLE Keyword

The VARIABLE keyword specifies a variable that assigns each case in the active dataset to the training, testing, or holdout sample. Cases with a positive value on the variable are assigned to the training sample, cases with a value of 0 to the testing sample, and cases with a negative value to the holdout sample. Cases with a system-missing value are excluded from the analysis. (Any user-missing values for the partition variable are always treated as valid.)

The variable may not be the dependent variable or any variable specified on the command line factor or covariate lists. The variable must be numeric.

ARCHITECTURE Subcommand

The ARCHITECTURE subcommand is used to specify the neural network architecture. By default, automatic architecture selection is used to build the network. However, you have the option of overriding automatic architecture selection and building a more specific structure.

AUTOMATIC Keyword

The AUTOMATIC keyword indicates whether to use automatic architecture selection to build the neural network. Automatic architecture selection builds a network with one hidden layer. Using a prespecified range defining the minimum and maximum number of hidden units, automatic architecture selection computes the “best” number of units in the hidden layer. Automatic architecture selection uses the default activation functions for the hidden and output layers.

If automatic architecture selection is used, then a random sample from the total dataset (excluding any data records included in the holdout sample as defined on the PARTITION subcommand) is taken and split into training (70%) and testing (30%) samples. This random sample is used to find the architecture and fit the network. Then, the network is retrained using the entire dataset (taking into account the training, testing, and holdout samples defined on the PARTITION subcommand), with the synaptic weights obtained from the random sample used as the initial weights.

The size of the random sample N = min(1000, memsize), where memsize is the user-specified maximum number of cases to store in memory (see the MEMSIZE keyword in CRITERIA Subcommand). If the total dataset (excluding holdout cases) has less than N cases, then all cases (excluding holdout cases) are used. If you want to be able to reproduce results based on the

AUTOMATIC keyword later, use the SET command to set the initialization value for the random number generator before running the MLP procedure.

YES *Use automatic architecture selection to build the network.* This is the default.

The YES keyword may be followed by parentheses containing the MINUNITS and MAXUNITS options, which specify the minimum and maximum number of units, respectively, that automatic architecture selection will consider in determining the "best" number of units. It is invalid to specify only one option; you must specify both or neither. The options may be specified in any order and must be separated by a comma or space character. Both numbers must be integers greater than 0, with MINUNITS less than MAXUNITS. The defaults are MINUNITS=1, MAXUNITS=50.

If AUTOMATIC=YES is specified, then all other ARCHITECTURE subcommand keywords are invalid.

NO *Do not use automatic architecture selection to build the network.* All other ARCHITECTURE subcommand keywords are valid only if AUTOMATIC=NO is specified.

HIDDENLAYERS Keyword

The HIDDENLAYERS keyword specifies the number of hidden layers in the neural network.

This keyword is honored only if automatic architecture selection is not used—that is, if AUTOMATIC=NO. If automatic architecture selection is in effect, then the HIDDENLAYERS keyword is ignored.

1 *One hidden layer.* This is the default. The HIDDENLAYERS=1 specification may be followed by the NUMUNITS option, which gives the number of units in the first hidden layer, excluding the bias unit. Specify AUTO to automatically compute the number of units based on the number of input and output units. Alternatively, specify an integer greater than or equal to 1 to request a particular number of hidden units. The default is AUTO.

2 *Two hidden layers.* The HIDDENLAYERS=2 specification may be followed by the NUMUNITS option, which gives the number of units in the first and second hidden layers, excluding the bias unit in each layer. Specify AUTO to automatically compute the numbers of units based on the number of input and output units. Alternatively, specify two integers greater than or equal to 1 to request particular numbers of hidden units in the first and second hidden layers, respectively. The default is AUTO.

HIDDENFUNCTION Keyword

The HIDDENFUNCTION keyword specifies the activation function to use for all units in the hidden layers. This keyword is honored only if automatic architecture selection is not used—that is, if AUTOMATIC=NO. If automatic architecture selection is in effect, then the HIDDENFUNCTION keyword is ignored.

TANH *Hyperbolic tangent.* This function has form: $\gamma(c) = \tanh(c) = (e^{c}-e^{-c})/(e^{c}+e^{-c})$. It takes real-valued arguments and transforms them to the range (–1, 1). This is the default activation function for all units in the hidden layers.

SIGMOID *Sigmoid.* This function has form: $\gamma(c) = 1/(1+e^{-c})$. It takes real-valued arguments and transforms them to the range (0, 1).

OUTPUTFUNCTION Keyword

The OUTPUTFUNCTION keyword specifies the activation function to use for all units in the output layer.

The activation function used in the output layer has a special relationship with the error function, which is the measure that the neural network is trying to minimize. In particular, the error function is automatically assigned based on the activation function for the output layer. Sum-of-squares error, the sum of the squared deviations between the observed dependent variable values and the model-predicted values, is used when the identity, sigmoid, or hyperbolic tangent activation function is applied to the output layer. Cross-entropy error is used when the softmax activation function is applied to the output layer.

The OUTPUTFUNCTION keyword is honored only if automatic architecture selection is not used—that is, if AUTOMATIC=NO. If automatic architecture selection is in effect, then OUTPUTFUNCTION is ignored.

IDENTITY *Identity.* This function has form: $\gamma(c) = c$. It takes real-valued arguments and returns them unchanged. This is the default activation function for units in the output layer if there are any scale dependent variables.

SIGMOID *Sigmoid.* This function has form: $\gamma(c) = 1/(1+e^{-c})$. It takes real-valued arguments and transforms them to the range (0, 1).

TANH *Hyperbolic tangent.* This function has form: $\gamma(c) = \tanh(c) = (e^{c}-e^{-c})/(e^{c}+e^{-c})$. It takes real-valued arguments and transforms them to the range (–1, 1).

SOFTMAX *Softmax.* This function has form: $\gamma(c_k) = \exp(c_k)/\Sigma_j\exp(c_j)$. It takes a vector of real-valued arguments and transforms it to a vector whose elements fall in the range (0, 1) and sum to 1. Softmax is available only if all dependent variables are categorical; if SOFTMAX is specified and there are any scale dependent variables, then an error is issued. This is the default activation function for units in the output layer if all dependent variables are categorical.

CRITERIA Subcommand

The CRITERIA subcommand specifies computational and resource settings for the MLP procedure.

TRAINING Keyword

The TRAINING keyword specifies the training type, which determines how the neural network processes training data records.

The online and mini-batch training methods are explicitly dependent upon data order; however, even batch training is dependent upon data order because initialization of synaptic weights involves subsampling from the dataset. To minimize data order effects, randomly order the cases before running the MLP procedure.

BATCH *Batch training.* Updates the synaptic weights only after passing all training data records—that is, batch training uses information from all records in the training dataset. Batch training is often preferred because it directly minimizes the total prediction error. However, batch training may need to update the weights many times until one of the stopping rules is met and, hence, may need many data passes. It is most useful for smaller datasets. This is the default training type.

ONLINE *Online training.* Updates the synaptic weights after every single training data record—that is, online training uses information from one record at a time. Online training continuously gets a record and updates the weights until one of the stopping rules is met. If all the records are used once and none of the stopping rules is met, then the process continues by recycling the data records. Online training is superior to batch only for larger datasets with associated predictors. If there are many records and many inputs, and their values are not independent of each other, then online training can more quickly obtain a reasonable answer than batch training.

MINIBATCH *Mini-batch training.* Divides the training data records into *K* groups of approximately equal size, then updates the synaptic weights after passing one group—that is, mini-batch training uses information from a group of records. The process then recycles the data group if necessary. The number of training records per mini-batch is determined by the MINIBATCHSIZE keyword. Mini-batch training offers a compromise between batch and online training, and it may be best for "medium-size" datasets.

MINIBATCHSIZE Keyword

The MINIBATCHSIZE keyword specifies the number of training records per mini-batch.

- Specify AUTO to automatically compute the number of records per mini-batch as $R = \min(\max(M/10,2),memsize)$, where M is the number of training records and *memsize* is the maximum number of cases to store in memory (see the MEMSIZE keyword below). If the remainder of M/R is r, then when the end of the data is reached, the process places the final r records in the same mini-batch with the first $R-r$ records of the next data pass. This "wrapping" of mini-batches will place different cases in the mini-batches with each data pass unless R divides M with no remainder.
- Alternatively, specify an integer greater than or equal to 2 and less than or equal to *memsize* to request a particular number of records. If the number of training records turns out to be less than the specified MINIBATCHSIZE, the number of training records is used instead.
- The default is AUTO.
- This keyword is ignored if TRAINING = MINIBATCH is not in effect.

MEMSIZE Keyword

The MEMSIZE keyword specifies the maximum number of cases to store in memory when automatic architecture selection and/or mini-batch training is in effect.

- Specify an integer greater than or equal to 2. The default is 1000.
- This keyword is ignored if neither /ARCHITECTURE AUTOMATIC = YES nor /CRITERIA TRAINING = MINIBATCH is in effect.

OPTIMIZATION Keyword

The OPTIMIZATION keyword specifies the optimization algorithm used to determine the synaptic weights.

GRADIENTDESCENT

Gradient descent. Gradient descent is the required optimization algorithm for online and mini-batch training. It is optional for batch training. When gradient descent is used with online and mini-batch training, the algorithm's user-specified parameters are the initial learning rate, lower bound for the learning rate, momentum, and number of data passes (see the LEARNINGINITIAL, LEARNINGLOWER, MOMENTUM, and LEARNINGEPOCHS keywords, respectively). With batch training, the user-specified parameters are the initial learning rate and the momentum.

SCALEDCONJUGATE

Scaled conjugate gradient. Scaled conjugate gradient is the default for batch training. The assumptions that justify the use of conjugate gradient methods do not apply to the online and mini-batch training, so this method may not be used if TRAINING = ONLINE or MINIBATCH. The user-specified parameters are the initial lambda and sigma (see the LAMBDAINITIAL and SIGMAINITIAL keywords).

LEARNINGINITIAL Keyword

The LEARNINGINITIAL keyword specifies the initial learning rate η_0 for the gradient descent optimization algorithm.

- Specify a number greater than 0. The default is 0.4.
- This keyword is ignored if OPTIMIZATION = GRADIENTDESCENT is not in effect.

LEARNINGLOWER Keyword

The LEARNINGLOWER keyword specifies the lower boundary for the learning rate η_{low} when gradient descent is used with online or mini-batch training.

- Specify a number greater than 0 and less than the initial learning rate (see the LEARNINGINITIAL keyword). The default is 0.001.
- This keyword is ignored if TRAINING = ONLINE or MINIBATCH and OPTIMIZATION = GRADIENTDESCENT are not in effect.

MOMENTUM Keyword

The MOMENTUM keyword specifies the initial momentum rate α for the gradient descent optimization algorithm.

- Specify a number greater than 0. The default is 0.9.
- This keyword is ignored if OPTIMIZATION = GRADIENTDESCENT is not in effect.

LEARNINGEPOCHS Keyword

The LEARNINGEPOCHS keyword specifies the number of epochs (data passes of the training set) p to reduce the learning rate when gradient descent is used with online or mini-batch training. You can control the learning rate decay factor β by specifying the number of epochs it takes for the learning rate to decrease from η_0 to η_{low}. This corresponds to $\beta = (1/pK)*\ln(\eta_0/\eta_{low})$, where K is the total number of mini-batches in the training dataset. For online training, $K = M$, where M is the number of training records.

- Specify an integer greater than 0. The default is 10.
- This keyword is ignored if TRAINING = ONLINE or MINIBATCH and OPTIMIZATION = GRADIENTDESCENT are not in effect.

LAMBDAINITIAL Keyword

The LAMBDAINITIAL keyword specifies the initial lambda, λ_0, for the scaled conjugate gradient optimization algorithm.

- Specify a number greater than 0 and less than 10^{-6}. The default is 0.0000005.
- This keyword is ignored if OPTIMIZATION = SCALEDCONJUGATE is not in effect.

SIGMAINITIAL Keyword

The SIGMAINITIAL keyword specifies the initial sigma, σ_0, for the scaled conjugate gradient optimization algorithm.

- Specify a number greater than 0 and less than 10^{-4}. The default is 0.00005.
- This keyword is ignored if OPTIMIZATION = SCALEDCONJUGATE is not in effect.

INTERVALCENTER and INTERVALOFFSET Keywords

The INTERVALCENTER and INTERVALOFFSET keywords specify the interval $[a_0-a, a_0+a]$ in which weight vectors are randomly generated when simulated annealing is used. INTERVALCENTER corresponds to a_0 and INTERVALOFFSET corresponds to a.

- Simulated annealing is used to break out of a local minimum, with the goal of finding the global minimum, during the optimization algorithm. This approach is used in weight initialization and automatic architecture selection.
- Specify a number for INTERVALCENTER. The INTERVALCENTER default is 0. Specify a number greater than 0 for INTERVALOFFSET. The INTERVALOFFSET default is 0.5. The default interval is [−0.5, 0.5].

STOPPINGRULES Subcommand

The STOPPINGRULES subcommand specifies the rules that determine when to stop training the neural network. Training proceeds through at least one data pass. Training can then be stopped according to the following criteria, which are listed as STOPPINGRULES keywords. Stopping rules are checked in the listed order. (In the keyword descriptions, a step is a data pass for the online and mini-batch methods, an iteration for the batch method.)

Note: After each complete data pass, online and mini-batch training require an extra data pass in order to compute the training error. This extra data pass can slow training considerably, so if you use online or mini-batch training, we recommend specifying a testing dataset. Then, if you use only the testing set in the ERRORSTEPS criterion, the ERRORCHANGE and ERRORRATIO criteria will not be checked.

ERRORSTEPS Keyword

The ERRORSTEPS keyword specifies the number of steps, *n*, to allow before checking for a decrease in error. If there is no decrease in error after *n* steps, then training stops.

- Any integer greater than or equal to 1 may be specified. The default is 1.
- The DATA option following ERRORSTEPS specifies how to compute error.

(DATA=AUTO)

Compute error using the testing sample if it exists or using the training sample otherwise. If the error at any step does not decrease below the current minimum error (based on preceding steps) over the next *n* steps, then training stops.

For online and mini-batch training, if there is no testing sample, then the procedure computes error using the training sample. Batch training, on the other hand, guarantees a decrease in the training sample error after each data pass, thus this option is ignored if batch training is in effect and there is no testing sample.

DATA = AUTO is the default option.

(DATA=BOTH)

Compute errors using the testing sample and the training sample. If neither the testing sample error nor the training sample error decreases below its current minimum error over the next *n* steps, then training stops.

For batch training, which guarantees a decrease in the training sample error after each data pass, this option is the same as DATA= AUTO.

DATA = BOTH may be specified only if testing data are defined—that is, /PARTITION TESTING is specified with a number greater than zero or /PARTITION VARIABLE is used. If DATA = BOTH is specified when /PARTITION TESTING = 0, or when /PARTITION VARIABLE is used but no testing data exist in the active dataset, then an error is issued.

TRAININGTIMER Keyword

The TRAININGTIMER keyword specifies whether the training timer is turned on or off.

- If TRAININGTIMER = ON, then the MAXTIME option gives the maximum number of minutes allowed for training. Training stops if the algorithm exceeds the maximum allotted time.
- If TRAININGTIMER = OFF, then the MAXTIME option is ignored.

- TRAININGTIMER may be specified with keyword ON or OFF. The default is ON.
- The MAXTIME option may be specified with any number greater than 0. The default is 15.

MAXEPOCHS Keyword

The MAXEPOCHS keyword specifies the maximum number of epochs (data passes) allowed for the training data. If the maximum number of epochs is exceeded, then training stops.

- Specify AUTO to automatically compute the maximum number of epochs as max(2*N*+1, 100), where *N* is the number of synaptic weights in the neural network.
- Alternatively, specify an integer greater than 0 to request a particular maximum number of epochs.
- The default is AUTO.

ERRORCHANGE Keyword

The ERRORCHANGE keyword specifies the relative change in training error criterion. Training stops if the relative change in the training error compared to the previous step is less than the criterion value.

- Any number greater than 0 may be specified. The default is 0.0001.
- For online and mini-batch training, this criterion is ignored if the ERRORSTEPS criterion uses only testing data.

ERRORRATIO Keyword

The ERRORRATIO keyword specifies the training error ratio criterion. Training stops if the ratio of the training error to the error of the null model is less than the criterion value. The null model predicts the average value for all dependent variables.

- Any number greater than 0 may be specified. The default is 0.001.
- For online and mini-batch training, this criterion is ignored if the ERRORSTEPS criterion uses only testing data.

MISSING Subcommand

The MISSING subcommand is used to control whether user-missing values for categorical variables—that is, factors and categorical dependent variables—are treated as valid values. By default, user-missing values for categorical variables are treated as invalid.

- User-missing values for scale variables are always treated as invalid.
- System-missing values for any variables are always treated as invalid.

USERMISSING=EXCLUDE

User-missing values for categorical variables are treated as invalid. This is the default.

USERMISSING=INCLUDE

User-missing values for categorical variables are treated as valid values.

PRINT Subcommand

The PRINT subcommand indicates the tabular output to display and can be used to request a sensitivity analysis. If PRINT is not specified, then the default tables are displayed. If PRINT is specified, then only the requested PRINT output is displayed.

CPS Keyword

The CPS keyword displays the case processing summary table, which summarizes the number of cases included and excluded in the analysis, in total and by training, testing, and holdout samples. This table is shown by default.

NETWORKINFO Keyword

The NETWORKINFO keyword displays information about the neural network, including the dependent variables, number of input and output units, number of hidden layers and units, and activation functions. This table is shown by default.

SUMMARY Keyword

The SUMMARY keyword displays a summary of the neural network results, including the error, the relative error or percent of incorrect predictions, the stopping rule used to stop training, and the training time.

- The error is the sum-of-squares error when the identity, sigmoid, or hyperbolic tangent activation function is applied to the output layer. It is the cross-entropy error when the softmax activation function is applied to the output layer.
- In addition, relative errors or percents of incorrect predictions are displayed, depending on the dependent variable measurement levels. If any dependent variable has a scale measurement level, then the average overall relative error (relative to the mean model) is displayed. If all dependent variables are categorical, then the average percent of incorrect predictions is displayed. Relative errors or percents of incorrect predictions are also displayed for individual dependent variables.
- Summary results are given for the training data and for testing and hold-out data if they exist.
- This table is shown by default.

CLASSIFICATION Keyword

The CLASSIFICATION keyword displays a classification table for each categorical dependent variable. The table gives the number of cases classified correctly and incorrectly for each dependent variable category.

- In addition to classification tables, the CLASSIFICATION keyword reports the percent of the total cases that were correctly classified. A case is correctly classified if its highest predicted probabilities correspond to the observed categories for that case.
- Classification results are given for the training data and for testing and holdout data if they exist.

- Classification results are shown by default.
- The CLASSIFICATION keyword is ignored for scale dependent variables.

SOLUTION Keyword

The SOLUTION keyword displays the synaptic weights—that is, the coefficient estimates, from layer $i-1$ unit j to layer i unit k. The synaptic weights are based on the training sample even if the active dataset is partitioned into training, testing, and holdout data.

This table is not shown by default because the number of synaptic weights may be extremely large, and these weights are generally not used for interpreting network results.

IMPORTANCE Keyword

The IMPORTANCE keyword performs a sensitivity analysis, which computes the importance of each predictor in determining the neural network. The analysis is based on the combined training and testing samples or only the training sample if there is no testing sample. This keyword creates a table and a chart displaying importance and normalized importance for each predictor.

Sensitivity analysis is not performed by default because it is computationally expensive and time-consuming if there are a large number of predictors or cases.

NONE Keyword

The NONE keyword suppresses all PRINT output except the Notes table and any warnings. This keyword may not be specified with any other PRINT keywords.

PLOT Subcommand

The PLOT subcommand indicates the chart output to display. If PLOT is not specified, then the default chart (the network diagram) is displayed. If PLOT is specified, then only the requested PLOT output is displayed.

NETWORK Keyword

The NETWORK keyword displays the network diagram. This chart is shown by default.

PREDICTED Keyword

The PREDICTED keyword displays a predicted-by-observed value chart for each dependent variable. For categorical dependent variables, a boxplot of predicted pseudo-probabilities is displayed. For scale dependent variables, a scatterplot is displayed.

- Predicted-by-observed value charts are based on the combined training and testing samples or only the training sample if there is no testing sample.

RESIDUAL Keyword

The RESIDUAL keyword displays a residual-by-predicted value chart for each scale dependent variable. This chart is available only for scale dependent variables. The RESIDUAL keyword is ignored for categorical dependent variables.

- Residual-by-predicted value charts are based on the combined training and testing samples or only the training sample if there is no testing sample.

ROC Keyword

The ROC keyword displays an ROC (Receiver Operating Characteristic) chart for each categorical dependent variable. It also displays a table giving the area under each curve in the chart.

- For a given dependent variable, the ROC chart displays one curve for each category. If the dependent variable has two categories, then each curve treats the category at issue as the positive state versus the other category. If the dependent variable has more than two categories, then each curve treats the category at issue as the positive state versus the aggregate of all other categories.
- This chart is available only for categorical dependent variables. The ROC keyword is ignored for scale dependent variables.
- ROC charts and area computations are based on the combined training and testing samples or only the training sample if there is no testing sample.

GAIN Keyword

The GAIN keyword displays a cumulative gains chart for each categorical dependent variable.

- The display of one curve for each dependent variable category is the same as for the ROC keyword.
- This chart is available only for categorical dependent variables. The GAIN keyword is ignored for scale dependent variables.
- Cumulative gains charts are based on the combined training and testing samples or only the training sample if there is no testing sample.

LIFT Keyword

The LIFT keyword displays a lift chart for each categorical dependent variable.

- The display of one curve for each dependent variable category is the same as for the ROC keyword.
- This chart is available only for categorical dependent variables. The LIFT keyword is ignored for scale dependent variables.
- Lift charts are based on the combined training and testing samples or only the training sample if there is no testing sample.

NONE Keyword

The NONE keyword suppresses all PLOT output. This keyword may not be specified with any other PLOT keywords.

SAVE Subcommand

The SAVE subcommand writes optional temporary variables to the active dataset.

PREDVAL(varname varname…)

Predicted value or category. This saves the predicted value for scale dependent variables and the predicted category for categorical dependent variables.

Specify one or more unique, valid variable names. There should be as many variable names specified as there are dependent variables, and the names should be listed in the order of the dependent variables on the command line. If you do not specify enough variable names, then default names are used for any remaining variables. If you specify too many variable names, then any remaining names are ignored.

If there is only one dependent variable, then the default variable name is *MLP_PredictedValue*. If there are multiple dependent variables, then the default variable names are *MLP_PredictedValue_1*, *MLP_PredictedValue_2*, etc., corresponding to the order of the dependent variables on the command line.

PSEUDOPROB(rootname:n rootname…)

Predicted pseudo-probability. If a dependent variable is categorical, then this keyword saves the predicted pseudo-probabilities of the first *n* categories of that dependent variable.

Specify one or more unique, valid variable names. There should be as many variable names specified as there are categorical dependent variables, and the names should be listed in the order of the categorical dependent variables on the command line. The specified names are treated as rootnames. Suffixes are added to each rootname to get a group of variable names corresponding to the categories for a given dependent variable. If you do not specify enough variable names, then default names are used for any remaining categorical dependent variables. If you specify too many variable names, then any remaining names are ignored.

A colon and a positive integer giving the number of probabilities to save for a dependent variable can follow the rootname.

If there is only one dependent variable, then the default rootname is *MLP_PseudoProbability*. If there are multiple dependent variables, then the default rootnames are *MLP_PseudoProbability_1*, *MLP_PseudoProbability_2*, etc., corresponding to the order of the categorical dependent variables on the command line and taking into account the position of any scale dependent variables.

The default *n* is 25.

This keyword is ignored for scale dependent variables.

Probabilities and Pseudo-probabilities

Categorical dependent variables with softmax activation and cross-entropy error will have a predicted value for each category, where each predicted value is the probability that the case belongs to the category.

Categorical dependent variables with sum-of-squares error will have a predicted value for each category, but the predicted values cannot be interpreted as probabilities. The SAVE subcommand saves these predicted pseudo-probabilities even if any are less than zero or greater than one or the sum for a given dependent variable is not 1.

The ROC, cumulative gains, and lift charts (see /PLOT ROC, GAIN, and LIFT, respectively) are created based on pseudo-probabilities. In the event that any of the pseudo-probabilities are less than zero or greater than one or the sum for a given variable is not 1, they are first rescaled to be between zero and one and to sum to 1. The SAVE subcommand saves the original pseudo-probabilities, but the charts are based on rescaled pseudo-probabilities.

Pseudo-probabilities are rescaled by dividing by their sum. For example, if a case has predicted pseudo-probabilities of 0.50, 0.60, and 0.40 for a three-category dependent variable, then each pseudo-probability is divided by the sum 1.50 to get 0.33, 0.40, and 0.27.

If any of the pseudo-probabilities are negative, then the absolute value of the lowest is added to all pseudo-probabilities before the above rescaling. For example, if the pseudo-probabilities are -0.30, 0.50, and 1.30, then first add 0.30 to each value to get 0.00, 0.80, and 1.60. Next, divide each new value by the sum 2.40 to get 0.00, 0.33, and 0.67.

OUTFILE Subcommand

The OUTFILE subcommand saves XML-format (PMML) files containing the synaptic weights. SmartScore and SPSS Server (a separate product) can use this file to apply the model information to other data files for scoring purposes.

- Filenames must be specified in full. MLP does not supply extensions.
- The MODEL keyword is not honored if split-file processing is in effect (see SPLIT FILE). If this keyword is specified when split-file processing is on, a warning is displayed.

MODEL = 'file' 'file'…

Writes the synaptic weights to XML (PMML) files. Specify one or more unique, valid filenames. There should be as many filenames as there are dependent variables, and the names should be listed in the order of the dependent variables on the command line. If you do not specify enough filenames, then an error is issued. If you specify too many filenames, then any remaining names are ignored.

If any 'file' specification refers to an existing file, then the file is overwritten. If any 'file' specifications refer to the same file, then only the last instance of this 'file' specification is honored.

MODEL CLOSE

MODEL CLOSE is available in SPSS Server.

```
MODEL CLOSE NAME={handlelist}
                 {ALL       }
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Release History

Release 13.0

- Command introduced.

Example

```
MODEL CLOSE NAME=discrimmod1 twostep1.

MODEL CLOSE NAME=ALL.
```

Overview

The MODEL CLOSE command is available only if you have access to SPSS Server. MODEL CLOSE is used to discard cached models and their associated model handle names (see MODEL HANDLE on p. 1161).

Basic Specification

The basic specification is NAME followed by a list of model handles. Each model handle name should match the name specified on the MODEL HANDLE command. The keyword ALL specifies that all model handles are to be closed.

MODEL HANDLE

MODEL HANDLE is available in SPSS Server.

```
MODEL HANDLE NAME=handle FILE='file specification'
 [/OPTIONS  [MISSING=[{SUBSTITUTE**}]] ]
                      {SYSMIS      }

 [/MAP  VARIABLES=varlist MODELVARIABLES=varlist  ]
```

**Default if the keyword is omitted.

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Release History

Release 13.0

- Command introduced.

Example

```
MODEL HANDLE NAME=discrimmod1 FILE='/modelfiles/discrim1.mml'.
```

Overview

The MODEL HANDLE command is available only if you have access to SPSS Server.

MODEL HANDLE reads an external XML file containing specifications for a predictive model. It caches the model specifications and associates a unique name (handle) with the cached model. The model can then be used by the APPLYMODEL and STRAPPLYMODEL transformation functions to calculate scores and other results (see Scoring Expressions (SPSS Server) on p. 111). The MODEL CLOSE command is used to discard a cached model from memory.

Different models can be applied to the same data by using separate MODEL HANDLE commands for each of the models.

MODEL HANDLE can read XML model specifications produced by:

- REGRESSION, DISCRIMINANT, and TWOSTEP CLUSTER in the Base system
- LOGISTIC REGRESSION and NOMREG in the Regression Models option
- TREE in the Classification Trees option
- All Clementine models that support export to PMML except Sequence Detection
- AnswerTree and Predictive Analytic Components

Options

Variable Mapping. You can map any or all of the variables in the original model to different variables in the current active dataset. By default, the model is applied to variables in the current active dataset with the same names as the variables in the original model.

Handling Missing Values. You can choose how to handle cases with missing values. By default, an attempt is made to substitute a sensible value for a missing value, but you can choose to treat missing values as system-missing.

Basic Specification

The basic specification is NAME and FILE. NAME specifies the model handle name to be used when referring to this model. FILE specifies the external file containing the model specifications.

Subcommand Order

- Subcommands can be specified in any order.

Syntax Rules

- When using the MAP subcommand, you must specify both the VARIABLES and MODELVARIABLES keywords.
- Multiple MAP subcommands are allowed. Each MAP subcommand should provide the mappings for a distinct subset of the variables. Subsequent mappings of a given variable override any previous mappings of that same variable.

Operations

- A model handle is used only during the current working session. The handle is not saved as part of an SPSS-format data file.
- Issuing a SET LOCALE command that changes the server's code page requires closing any existing model handles (using MODEL CLOSE) and reopening the models (using MODEL HANDLE) before proceeding with scoring.

NAME Subcommand

NAME specifies the model handle name. The rules for valid model handle names are the same as for SPSS variable names with the addition of the $ character as an allowed first character. The model handle name should be unique for each model.

FILE Keyword

The FILE keyword is used to specify the external model file that you want to refer to by the model handle.

- File specifications should be enclosed in quotation marks.
- Fully qualified paths are recommended to avoid ambiguity.

OPTIONS Subcommand

Use OPTIONS to control the treatment of missing data.

MISSING Keyword

The MISSING keyword controls the treatment of missing values, encountered during the scoring process, for the predictor variables defined in the model. A missing value in the context of scoring refers to one of the following:

- A predictor variable contains no value. For numeric variables, this means the system-missing value. For string variables, this means a null string.
- The value has been defined as user-missing, in the model, for the given predictor. Values defined as user-missing in the active dataset, but not in the model, are not treated as missing values in the scoring process.
- The predictor variable is categorical and the value is not one of the categories defined in the model.

SYSMIS	*Return the system-missing value when scoring a case with a missing value.*
SUBSTITUTE	*Use value substitution when scoring cases with missing values.* This is the default.

The method for determining a value to substitute for a missing value depends on the type of predictive model:

- **SPSS models.** For independent variables in linear regression (REGRESSION command) and discriminant (DISCRIMINANT command) models, if mean value substitution for missing values was specified when building and saving the model, then this mean value is used in place of the missing value in the scoring computation, and scoring proceeds. If the mean value is not available, then APPLYMODEL and STRAPPLYMODEL return the system-missing value.
- **AnswerTree models & TREE command models.** For the CHAID and Exhaustive CHAID algorithms, the biggest child node is selected for a missing split variable. The biggest child node is determined by the algorithm to be the one with the largest population among the child nodes using learning sample cases. For C&RT and QUEST algorithms, surrogate split variables (if any) are used first. (Surrogate splits are splits that attempt to match the original split as closely as possible using alternate predictors.) If no surrogate splits are specified or all surrogate split variables are missing, the biggest child node is used.
- **Clementine models.** Linear regression models are handled as described under SPSS models. Logistic regression models are handled as described under Logistic Regression models. C&R Tree models are handled as described for C&RT models under AnswerTree models.
- **Logistic Regression models.** For covariates in logistic regression models, if a mean value of the predictor was included as part of the saved model, then this mean value is used in place of the missing value in the scoring computation, and scoring proceeds. If the predictor is categorical (for example, a factor in a logistic regression model), or if the mean value is not available, then APPLYMODEL and STRAPPLYMODEL return the system-missing value.

Example

```
MODEL HANDLE NAME=twostep1 FILE='twostep1.mml'
   /OPTIONS MISSING=SYSMIS.
```

- In this example, missing values encountered during scoring give rise to system-missing results.

MAP Subcommand

Use MAP to map a set of variable names from the input model to a different set of variable names in the active dataset. Both the VARIABLES and MODELVARIABLES keywords must be included. MODELVARIABLES is used to specify the list of variable names from the model that are to be mapped. VARIABLES is used to specify the list of target variable names in the active dataset.

- Both variable lists must contain the same number of names.
- No validation is performed against the current active file dictionary when the MODEL HANDLE command is processed. Errors associated with incorrect target variable names or variable data type mismatch are signaled when an APPLYMODEL or STRAPPLYMODEL transformation is processed.

Example

```
MODEL HANDLE NAME=creditmod1 FILE='credit1.mml'
   /MAP VARIABLES=agecat curdebt
        MODELVARIABLES=age debt.
```

- In this example, the variable *age* from the model file is mapped to the variable *agecat* in the active dataset. Likewise, the variable *debt* from the model file is mapped to the variable *curdebt* in the active dataset.

MODEL LIST

MODEL LIST is available in SPSS Server.

```
MODEL LIST
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Release History

Release 13.0

- Command introduced.

Example

```
MODEL LIST.
```

Overview

The MODEL LIST command is available only if you have access to SPSS Server. MODEL LIST produces a list, in pivot table format, of the existing model handles (see MODEL HANDLE on p. 1161). The listing includes the handle name, the type of predictive model (for example, NOMREG) associated with the model handle, the external XML model file associated with the model handle, and the method (specified on the MODEL HANDLE command) for handling cases with missing values.

Basic Specification

The basic specification is simply MODEL LIST. There are no additional specifications.

Operations

- The MODEL LIST command lists only the handles created in the current working session.

MODEL NAME

```
MODEL NAME [model name] ['model label']
```

Example

```
MODEL NAME PLOTA1 'PLOT OF THE OBSERVED SERIES'.
```

Overview

MODEL NAME specifies a model name and label for the next procedure in the session.

Basic Specification

The specification on MODEL NAME is a name, a label, or both.

- The default model name is *MOD_n*, where *n* increments by 1 each time an unnamed model is created. This default is in effect if it is not changed on the MODEL NAME command, or if the command is not specified. There is no default label.

Syntax Rules

- If both a name and label are specified, the name must be specified first.
- Only one model name and label can be specified on the command.
- The model name must be unique. The name can contain up to eight characters and must begin with a letter (*A–Z*).
- The model label can contain up to 60 characters and must be specified in quotes.

Operations

- MODEL NAME is executed at the next model-generating procedure.
- If the MODEL NAME command is used more than once before a procedure, the last command is in effect.
- If a duplicate model name is specified, the default *MOD_n* name will be used instead.
- *MOD_n* reinitializes at the start of every session and when the READ MODEL command is specified (see READ MODEL). If any models in the active dataset are already named *MOD_n*, those numbers are skipped when new *MOD_n* names are assigned.
- The following procedures can generate models that can be named with the MODEL NAME command: AREG, ARIMA, EXSMOOTH, SEASON, and SPECTRA in the Trends add-on module; ACF, CASEPLOT, CCF, CURVEFIT, PACF, PPLOT, and TSPLOT in the Base system; and WLS and 2SLS in Regression Models.

Example

```
MODEL NAME CURVE1 'First CURVEFIT model'.
```

```
CURVEFIT Y1.
CURVEFIT Y2.
CURVEFIT Y3
   /APPLY 'CURVE1'.
```

- In this example, the model name *CURVE1* and the label *First CURVEFIT model* are assigned to the first CURVEFIT command.
- The second CURVEFIT command has no MODEL NAME command before it, so it is assigned the name *MOD_n*, where *n* is the next unused integer in the sequence.
- The third CURVEFIT command applies the model named *CURVE1* to the series *Y3*. This model is named *MOD_m*, where $m = n + 1$.

MRSETS

```
MRSETS

 /MDGROUP NAME= setname  {LABEL= 'label'      }
                         {LABELSOURCE=VARLABEL}
  CATEGORYLABELS={VARLABELS    }
                 {COUNTEDVALUES}
  VARIABLES= varlist
  VALUE= {value  }
         {'chars'}

 /MCGROUP NAME= setname  LABEL= 'label'
    VARIABLES= varlist

 /DELETE NAME= {[setlist]}
               {ALL      }

 /DISPLAY NAME= {[setlist]}
                {ALL      }
```

The set name must begin with a $ and follow SPSS variable naming conventions.

Square brackets shown in the DELETE and DISPLAY subcommands are required if one or more set names is specified, but not with the keyword ALL.

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Release History

Release 14.0

- LABELSOURCE keyword introduced on MDGROUP subcommand.
- CATEGORYLABELS keyword introduced on MDGROUP subcommand.

Example

```
MRSETS
  /MDGROUP NAME=$mltnews LABEL='News sources'
   VARIABLES=news5 news4 news3 news2 news1
   VALUE=1
  /DISPLAY NAME=[$mltnews].

MRSETS
  /MCGROUP NAME=$mltcars
   LABEL='Car maker, most recent car'
   VARIABLES=car1 car2 car3
  /DISPLAY NAME=[$mltcars].
```

Overview

The MRSETS command defines and manages multiple response sets. The set definitions are saved in the SPSS data file, so they are available whenever the file is in use. Multiple response sets can be used in the GGRAPH and CTABLES (Tables option) commands. Two types of multiple response sets can be defined:

- Multiple dichotomy (MD) groups combine variables so that each variable becomes a category in the group. For example, take five variables that ask for *yes*/*no* responses to the questions: Do you get news from the Internet? Do you get news from the radio? Do you get news from television? Do you get news from news magazines? Do you get news from newspapers? These variables are coded 1 for *yes* and 0 for *no*. A multiple dichotomy group combines the five variables into a single variable with five categories in which a respondent could be counted zero to five times, depending on how many of the five elementary variables contain a 1 for that respondent. It is not required that the elementary variables be dichotomous. If the five elementary variables had the values 1 for *regularly*, 2 for *occasionally*, and 3 for *never*, it would still be possible to create a multiple dichotomy group that counts the variables with 1's and ignores the other responses.
- Multiple category (MC) groups combine variables that have identical categories. For example, suppose that instead of having five *yes*/*no* questions for the five news sources, there are three variables, each coded 1 = *Internet*, 2 = *radio*, 3 = *television*, 4 = *magazines*, and 5 = *newspapers*. For each variable, a respondent could select one of these values. In a multiple category group based on these variables, a respondent could be counted zero to three times, once for each variable for which he or she selected a news source. For this sort of multiple response group, it is important that all of the source variables have the same set of values and value labels and the same missing values.

The MRSETS command also allows you to delete sets and to display information about the sets in the data file.

Syntax Conventions

The following conventions apply to the MRSETS command:

- All subcommands are optional, but at least one must be specified.
- Subcommands can be issued more than once in any order.
- Within a subcommand, attributes can be specified in any order. If an attribute is specified more than once, the last instance is honored.
- Equals signs are required where shown in the syntax diagram.
- Square brackets are required where shown in the syntax diagram.
- The TO convention and the ALL keyword are honored in variable lists.

MDGROUP Subcommand

```
/MDGROUP NAME= setname  {LABEL= 'label'      }
                        {LABELSOURCE=VARLABEL}
  CATEGORYLABELS={VARLABELS    }
                 {COUNTEDVALUES}
  VARIABLES= varlist
```

```
  VALUE= {value  }
         {'chars'}
```

The MDGROUP subcommand defines or modifies a multiple dichotomy set. A name, variable list, and value must be specified. Optionally, you can control assignment of set and category labels.

NAME *The name of the multiple dichotomy set.* The name must follow SPSS variable naming conventions and begin with a $. If the name refers to an existing set, the set definition is overwritten.

LABEL *The label for the set.* The label must be quoted and cannot be wider than the limit for variable labels. By default, the set is unlabeled. LABEL and LABELSOURCE are mutually exclusive.

LABELSOURCE *Use the variable label for the first variable in the set with a defined variable label as the set label.* If none of the variables in the set have defined variable labels, the name of the first variable in the set is used as the set label. LABELSOURCE is an alternative to LABEL an is only available with CATEGORYLABELS=COUNTEDVALUES.

CATEGORYLABELS = [VARLABELS|COUNTEDVALUES]

Use variable labels or value labels of the counted values as category labels for the set. VARLABELS uses the defined variable labels (or variable names for variables without defined variable labels) as the set category labels. This is the default. COUNTEDVALUES uses the defined value labels of the counted values as the set category labels. The counted value for each variable must have a defined value label and the labels must be unique (the value label for the counted value must be different for each variable).

VARIABLES *The list of elementary variables that define the set*. Variables must be of the same type (numeric or string). At least two variables must be specified.

VALUE *The value that indicates presence of a response.* This is also referred to as the "counted" value. If the set type is numeric, the counted value must be an integer. If the set type is string, the counted value, after trimming trailing blanks, cannot be wider than the narrowest elementary variable.

Elementary variables need not have variable labels, but because variable labels are used as value labels for categories of the MD variable, a warning is issued if two or more variables of an MD set have the same variable label. A warning is also issued if two or more elementary variables use different labels for the counted value—for example, if it is labeled *Yes* for Q1 and *No* for Q2. When checking for label conflicts, case is ignored.

MCGROUP Subcommand

```
/MCGROUP NAME= setname  LABEL= 'label'
    VARIABLES= varlist
```

The MCGROUP subcommand defines or modifies a multiple category group. A name and variable list must be specified. Optionally, a label can be specified for the set.

NAME	*The name of the multiple category set.* The name must follow SPSS variable naming conventions and begin with a $. If the name refers to an existing set, the set definition is overwritten.
LABEL	*The label for the set.* The label must be quoted and cannot be wider than the limit for variable labels. By default, the set is unlabeled.
VARIABLES	*The list of elementary variables that define the set*. Variables must be of the same type (numeric or string). At least two variables must be specified.

The elementary variables need not have value labels, but a warning is issued if two or more elementary variables have different labels for the same value. When checking for label conflicts, case is ignored.

DELETE Subcommand

```
/DELETE NAME= {[setlist]}
              {ALL      }
```

The DELETE subcommand deletes one or more set definitions. If one or more set names is given, the list must be enclosed in square brackets. ALL can be used to delete all sets; it is not enclosed in brackets.

DISPLAY Subcommand

```
/DISPLAY NAME= {[setlist]}
               {ALL      }
```

The DISPLAY subcommand creates a table of information about one or more sets. If one or more set names is given, the list must be enclosed in square brackets. ALL can be used to refer to all sets; it is not enclosed in brackets.

MULT RESPONSE

```
MULT RESPONSE†

 {/GROUPS=groupname['label'](varlist ({value1,value2}))}
                                      {value        }
      ...[groupname...]

 {/VARIABLES=varlist(min,max)  [varlist...]            }

 {/FREQUENCIES=varlist                                }

 {/TABLES=varlist BY varlist... [BY varlist] [(PAIRED)]}
        [/varlist BY...]

 [/MISSING=[{TABLE**}] [INCLUDE]]
           {MDGROUP}
           {MRGROUP}

 [/FORMAT={LABELS**}  {TABLE** }  [DOUBLE]]
          {NOLABELS}  {CONDENSE}
                      {ONEPAGE }

 [/BASE={CASES**  }]
        {RESPONSES}

 [/CELLS=[COUNT**] [ROW] [COLUMN] [TOTAL] [ALL]]
```

†A minimum of two subcommands must be used: at least one from the pair GROUPS or VARIABLES and one from the pair FREQUENCIES or TABLES.

**Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
MULT RESPONSE  GROUPS=MAGS (TIME TO STONE (2))
   /FREQUENCIES=MAGS.
```

Overview

MULT RESPONSE displays frequencies and optional percentages for multiple-response items in univariate tables and multivariate crosstabulations. Another procedure that analyzes multiple-response items is TABLES, which has most, but not all, of the capabilities of MULT RESPONSE. TABLES has special formatting capabilities that make it useful for presentations.

Multiple-response items are questions that can have more than one value for each case. For example, the respondent may have been asked to circle all magazines read within the last month in a list of magazines. You can organize multiple-response data in one of two ways for use in the program. For each possible response, you can create a variable that can have one of two values, such as 1 for *no* and 2 for *yes*; this is the multiple-dichotomy method. Alternatively, you can estimate the maximum number of possible answers from a respondent and create that number of variables, each of which can have a value representing one of the possible answers, such as 1 for

Time, 2 for *Newsweek*, and 3 for *PC Week*. If an individual did not give the maximum number of answers, the extra variables receive a missing-value code. This is the multiple-response or multiple-category method of coding answers.

To analyze the data entered by either method, you combine variables into groups. The technique depends on whether you have defined multiple-dichotomy or multiple-response variables. When you create a multiple-dichotomy group, each component variable with at least one *yes* value across cases becomes a category of the group variable. When you create a multiple-response group, each value becomes a category and the program calculates the frequency for a particular value by adding the frequencies of all component variables with that value. Both multiple-dichotomy and multiple-response groups can be crosstabulated with other variables in MULT RESPONSE.

Options

Cell Counts and Percentages. By default, crosstabulations include only counts and no percentages. You can request row, column, and total table percentages using the CELLS subcommand. You can also base percentages on responses instead of respondents using BASE.

Format. You can suppress the display of value labels and request condensed format for frequency tables using the FORMAT subcommand.

Basic Specification

The subcommands required for the basic specification fall into two groups: GROUPS and VARIABLES name the elements to be included in the analysis; FREQUENCIES and TABLES specify the type of table display to be used for tabulation. The basic specification requires at least one subcommand from each group:

- GROUPS defines groups of multiple-response items to be analyzed and specifies how the component variables will be combined.
- VARIABLES identifies all individual variables to be analyzed.
- FREQUENCIES requests frequency tables for the groups and/or individual variables specified on GROUPS and VARIABLES.
- TABLES requests crosstabulations of groups and/or individual variables specified on GROUPS and VARIABLES.

Subcommand Order

- The basic subcommands must be used in the following order: GROUPS, VARIABLES, FREQUENCIES, and TABLES. Only one set of basic subcommands can be specified.
- All basic subcommands must precede all optional subcommands. Optional subcommands can be used in any order.

Operations

- Empty categories are not displayed in either frequency tables or crosstabulations.
- If you define a multiple-response group with a very wide range, the tables require substantial amounts of workspace. If the component variables are sparsely distributed, you should recode them to minimize the workspace required.

- MULT RESPONSE stores category labels in the workspace. If there is insufficient space to store the labels after the tables are built, the labels are not displayed.

Limitations

- The component variables must have integer values. Non-integer values are truncated.
- A maximum of 100 existing variables named or implied by GROUPS and VARIABLES together.
- A maximum of 20 groups defined on GROUPS.
- A maximum of 32,767 categories for a multiple-response group or an individual variable.
- A maximum of 10 table lists on TABLES.
- A maximum of 5 dimensions per table.
- A maximum of 100 groups and variables named or implied on FREQUENCIES and TABLES together.
- A maximum of 200 non-empty rows and 200 non-empty columns in a single table.

GROUPS Subcommand

GROUPS defines both multiple-dichotomy and multiple-response groups.

- Specify a name for the group and an optional label, followed by a list of the component variables and the value or values to be used in the tabulation.
- Enclose the variable list in parentheses and enclose the values in an inner set of parentheses following the last variable in the list.
- The label for the group is optional and can be up to 40 characters in length, including imbedded blanks. Quotes around the label are not required.
- To define a multiple-dichotomy group, specify only one tabulating value (the value that represents *yes*) following the variable list. Each component variable becomes a value of the group variable, and the number of cases that have the tabulating value becomes the frequency. If there are no cases with the tabulating value for a given component variable, that variable does not appear in the tabulation.
- To define a multiple-response group, specify two values following the variable list. These are the minimum and maximum values of the component variables. The group variable will have the same range of values. The frequency for each value is tabulated across all component variables in the list.
- You can use any valid variable name for the group except the name of an existing variable specified on the same MULT RESPONSE command. However, you can reuse a group name on another MULT RESPONSE command.
- The group names and labels exist only during MULT RESPONSE and disappear once MULT RESPONSE has been executed. If group names are referred to in other procedures, an error results.
- For a multiple-dichotomy group, the category labels come from the variable labels defined for the component variables.

- For a multiple-response group, the category labels come from the value labels for the first component variable in the group. If categories are missing for the first variable but are present for other variables in the group, you must define value labels for the missing categories. (You can use the ADD VALUE LABELS command to define extra value labels.)

Example

```
MULT RESPONSE  GROUPS=MAGS 'MAGAZINES READ' (TIME TO STONE (2))
   /FREQUENCIES=MAGS.
```

- The GROUPS subcommand creates a multiple-dichotomy group named *MAGS*. The variables between and including *TIME* and *STONE* become categories of *MAGS*, and the frequencies are cases with the value 2 (indicating *yes, read the magazine*) for the component variables.
- The group label is *MAGAZINES READ*.

Example

```
MULT RESPONSE  GROUPS=PROBS 'PERCEIVED NATIONAL PROBLEMS'
   (PROB1 TO PROB3 (1,9))
   /FREQUENCIES=PROBS.
```

- The GROUPS subcommand creates the multiple-response group *PROBS*. The component variables are the existing variables between and including *PROB1* and *PROB3*, and the frequencies are tabulated for the values 1 through 9.
- The frequency for a given value is the number of cases that have that value in any of the variables *PROB1* to *PROB3*.

VARIABLES Subcommand

VARIABLES specifies existing variables to be used in frequency tables and crosstabulations. Each variable is followed by parentheses enclosing a minimum and a maximum value, which are used to allocate cells for the tables for that variable.

- You can specify any numeric variable on VARIABLES, but non-integer values are truncated.
- If GROUPS is also specified, VARIABLES follows GROUPS.
- To provide the same minimum and maximum for each of a set of variables, specify a variable list followed by a range specification.
- The component variables specified on GROUPS can be used in frequency tables and crosstabulations, but you must specify them again on VARIABLES, along with a range for the values. You do not have to respecify the component variables if they will not be used as individual variables in any tables.

Example

```
MULT RESPONSE  GROUPS=MAGS 'MAGAZINES READ' (TIME TO STONE (2))
   /VARIABLES SEX(1,2) EDUC(1,3)
   /FREQUENCIES=MAGS SEX EDUC.
```

- The VARIABLES subcommand names the variables *SEX* and *EDUC* so that they can be used in a frequencies table.

Example

```
MULT RESPONSE  GROUPS=MAGS 'MAGAZINES READ' (TIME TO STONE (2))
   /VARIABLES=EDUC (1,3) TIME (1,2).
   /TABLES=MAGS BY EDUC TIME.
```

- The variable *TIME* is used in a group and also in a table.

FREQUENCIES Subcommand

FREQUENCIES requests frequency tables for groups and individual variables. By default, a frequency table contains the count for each value, the percentage of responses, and the percentage of cases. For another method of producing frequency tables for individual variables, see the FREQUENCIES procedure.

- All groups must be created by GROUPS, and all individual variables to be tabulated must be named on VARIABLES.
- You can use the keyword TO to imply a set of group or individual variables. TO refers to the order in which variables are specified on the GROUPS or VARIABLES subcommand.

Example

```
MULT RESPONSE  GROUPS=MAGS 'MAGAZINES READ' (TIME TO STONE (2))
   /FREQUENCIES=MAGS.
```

- The FREQUENCIES subcommand requests a frequency table for the multiple-dichotomy group *MAGS*, tabulating the frequency of the value 2 for each of the component variables *TIME* to *STONE*.

Example

```
MULT RESPONSE
 GROUPS=MAGS 'MAGAZINES READ' (TIME TO STONE (2))
      PROBS 'PERCEIVED NATIONAL PROBLEMS' (PROB1 TO PROB3 (1,9))
      MEMS 'SOCIAL ORGANIZATION MEMBERSHIPS' (VFW AMLEG ELKS (1))
 /VARIABLES SEX(1,2) EDUC(1,3)
 /FREQUENCIES=MAGS TO MEMS SEX EDUC.
```

- The FREQUENCIES subcommand requests frequency tables for *MAGS, PROBS, MEMS, SEX*, and *EDUC*.
- You cannot specify MAGS TO EDUC because *SEX* and *EDUC* are individual variables, and *MAGS*, *PROBS*, and *MEMS* are group variables.

TABLES Subcommand

TABLES specifies the crosstabulations to be produced by MULT RESPONSE. Both individual variables and group variables can be tabulated together.

- The first list defines the rows of the tables; the next list (following BY) defines the columns. Subsequent lists following BY keywords define control variables, which produce subtables. Use the keyword BY to separate the dimensions. You can specify up to five dimensions (four BY keywords) for a table.
- To produce more than one table, name one or more variables for each dimension of the tables. You can also specify multiple table lists separated by a slash. If you use the keyword TO to imply a set of group or individual variables, TO refers to the order in which groups or variables are specified on the GROUPS or VARIABLES subcommand.
- If FREQUENCIES is also specified, TABLES follows FREQUENCIES.
- The value labels for columns are displayed on three lines with eight characters per line. To avoid splitting words, reverse the row and column variables, or redefine the variable or value labels (depending on whether the variables are multiple-dichotomy or multiple-response variables).

Example

```
MULT RESPONSE  GROUPS=MAGS 'MAGAZINES READ' (TIME TO STONE (2))
   /VARIABLES=EDUC (1,3)/TABLES=EDUC BY MAGS.
```

- The TABLES subcommand requests a crosstabulation of variable *EDUC* by the multiple-dichotomy group *MAGS*.

Example

```
MULT RESPONSE  GROUPS=MAGS 'MAGAZINES READ' (TIME TO STONE (2))
   MEMS 'SOCIAL ORGANIZATION MEMBERSHIPS' (VFW AMLEG ELKS (1))
   /VARIABLES EDUC (1,3)/TABLES=MEMS MAGS BY EDUC.
```

- The TABLES subcommand specifies two crosstabulations—*MEMS* by *EDUC* and *MAGS* by *EDUC*.

Example

```
MULT RESPONSE  GROUPS=MAGS 'MAGAZINES READ' (TIME TO STONE (2))
   /VARIABLES SEX (1,2) EDUC (1,3)
   /TABLES=MAGS BY EDUC SEX/EDUC BY SEX/MAGS BY EDUC BY SEX.
```

- The TABLES subcommand uses slashes to separate three table lists. It produces two tables from the first table list (*MAGS* by *EDUC* and *MAGS* by *SEX*) and one table from the second table list (*EDUC* by *SEX*). The third table list produces separate tables for each sex (*MAGS* by *EDUC* for male and for female).

Example

```
MULT RESPONSE  GROUPS=MAGS 'MAGAZINES READ' (TIME TO STONE (2))
   PROBS 'NATIONAL PROBLEMS MENTIONED' (PROB1 TO PROB3 (1,9))
   /TABLES=MAGS BY PROBS.
```

- The TABLES subcommand requests a crosstabulation of the multiple-dichotomy group *MAGS* with the multiple-response group *PROBS*.

PAIRED Keyword

When MULT RESPONSE crosstabulates two multiple-response groups, by default it tabulates each variable in the first group with each variable in the second group and sums the counts for each cell. Thus, some responses can appear more than once in the table. Use PAIRED to pair the first variable in the first group with the first variable in the second group, the second variable in the first group with the second variable in the second group, and so on.

- The keyword PAIRED is specified in parentheses on the TABLES subcommand following the last variable named for a specific table list.
- When you request paired crosstabulations, the order of the component variables on the GROUPS subcommand determines the construction of the table.
- Although the tables can contain individual variables and multiple-dichotomy groups in a paired table request, only variables within multiple-response groups are paired.
- PAIRED also applies to a multiple-response group used as a control variable in a three-way or higher-order table.
- Paired tables are identified in the output by the label *PAIRED GROUP*.
- Percentages in paired tables are always based on responses rather than cases.

Example

```
MULT RESPONSE GROUPS=PSEX 'SEX OF CHILD'(P1SEX P2SEX P3SEX (1,2))
   /PAGE 'AGE OF ONSET OF PREGNANCY' (P1AGE P2AGE P3AGE (1,4))
   /TABLES=PSEX BY PAGE (PAIRED).
```

- The PAIRED keyword produces a paired crosstabulation of *PSEX* by *PAGE*, which is a combination of the tables *P1SEX* by *P1AGE*, *P2SEX* by *P2AGE*, and *P3SEX* by *P3AGE*.

Example

```
MULT RESPONSE GROUPS=PSEX 'SEX OF CHILD'(P1SEX P2SEX P3SEX (1,2))
   PAGE 'AGE OF ONSET OF PREGNANCY' (P1AGE P2AGE P3AGE (1,4))
   /VARIABLES=EDUC (1,3)
   /TABLES=PSEX BY PAGE BY EDUC (PAIRED).
```

- The TABLES subcommand pairs only *PSEX* with *PAGE*. *EDUC* is not paired because it is an individual variable, not a multiple-response group.

CELLS Subcommand

By default, MULT RESPONSE displays cell counts but not percentages in crosstabulations. CELLS requests percentages for crosstabulations.

- If you specify one or more keywords on CELLS, MULT RESPONSE displays cell counts plus the percentages you request. The count cannot be eliminated from the table cells.

COUNT	*Cell counts.* This is the default if you omit the CELLS subcommand.
ROW	*Row percentages.*

COLUMN	*Column percentages.*
TOTAL	*Two-way table total percentages.*
ALL	*Cell counts, row percentages, column percentages, and two-way table total percentages.* This is the default if you specify the CELLS subcommand without keywords.

Example

```
MULT RESPONSE  GROUPS=MAGS 'MAGAZINES READ' (TIME TO STONE (2))
  /VARIABLES=SEX (1,2) (EDUC (1,3)
  /TABLES=MAGS BY EDUC SEX
  /CELLS=ROW COLUMN.
```

- The CELLS subcommand requests row and column percentages in addition to counts.

BASE Subcommand

BASE lets you obtain cell percentages and marginal frequencies based on responses rather than respondents. Specify one of two keywords:

CASES	*Base cell percentages on cases.* This is the default if you omit the BASE subcommand and do not request paired tables. You cannot use this specification if you specify PAIRED on TABLE.
RESPONSES	*Base cell percentages on responses.* This is the default if you request paired tables.

Example

```
MULT RESPONSE  GROUPS=PROBS 'NATIONAL PROBLEMS MENTIONED'
   (PROB1 TO PROB3 (1,9))/VARIABLES=EDUC (1,3)
   /TABLES=EDUC BY PROBS
   /CELLS=ROW COLUMN
   /BASE=RESPONSES.
```

- The BASE subcommand requests marginal frequencies and cell percentages based on responses.

MISSING Subcommand

MISSING controls missing values. Its minimum specification is a single keyword.

- By default, MULT RESPONSE deletes cases with missing values on a table-by-table basis for both individual variables and groups. In addition, values falling outside the specified range are not tabulated and are included in the missing category. Thus, specifying a range that excludes missing values is equivalent to the default missing-value treatment.
- For a multiple-dichotomy group, a case is considered missing by default if none of the component variables contains the tabulating value for that case. The keyword MDGROUP overrides the default and specifies listwise deletion for multiple-dichotomy groups.
- For a multiple-response group, a case is considered missing by default if none of the components has valid values falling within the tabulating range for that case. Thus, cases with missing or excluded values on some (but not all) of the components of a group are included in

tabulations of the group variable. The keyword MRGROUP overrides the default and specifies listwise deletion for multiple-response groups.

- You can use INCLUDE with MDGROUP, MRGROUP, or TABLE. The user-missing value is tabulated if it is included in the range specification.

TABLE	*Exclude missing values on a table-by-table basis.* Missing values are excluded on a table-by-table basis for both component variables and groups. This is the default if you omit the MISSING subcommand.
MDGROUP	*Exclude missing values listwise for multiple-dichotomy groups.* Cases with missing values for any component dichotomy variable are excluded from the tabulation of the multiple-dichotomy group.
MRGROUP	*Exclude missing values listwise for multiple-response groups.* Cases with missing values for any component variable are excluded from the tabulation of the multiple-response group.
INCLUDE	*Include user-missing values*. User-missing values are treated as valid values if they are included in the range specification on the GROUPS or VARIABLES subcommands.

Example

```
MULT RESPONSE  GROUPS=FINANCL 'FINANCIAL PROBLEMS MENTIONED'
   (FINPROB1 TO FINPROB3 (1,3))
   SOCIAL 'SOCIAL PROBLEMS MENTIONED'(SOCPROB1 TO SOCPROB4 (4,9))
   /VARIABLES=EDUC (1,3)
   /TABLES=EDUC BY FINANCL SOCIAL
   /MISSING=MRGROUP.
```

- The MISSING subcommand indicates that a case will be excluded from counts in the first table if any of the variables in the group *FINPROB1* to *FINPROB3* has a missing value or a value outside the range 1 to 3. A case is excluded from the second table if any of the variables in the group *SOCPROB1* to *SOCPROB4* has a missing value or value outside the range 4 to 9.

FORMAT Subcommand

FORMAT controls table formats. The minimum specification on FORMAT is a single keyword.

Labels are controlled by two keywords:

LABELS	*Display value labels in frequency tables and crosstabulations.* This is the default.
NOLABELS	*Suppress value labels in frequency tables and crosstabulations for multiple-response variables and individual variables.* You cannot suppress the display of variable labels used as value labels for multiple-dichotomy groups.

The following keywords apply to the format of frequency tables:

DOUBLE	*Double spacing for frequency tables.* By default, MULT RESPONSE uses single spacing.
TABLE	*One-column format for frequency tables.* This is the default if you omit the FORMAT subcommand.

CONDENSE *Condensed format for frequency tables.* This option uses a three-column condensed format for frequency tables for all multiple-response groups and individual variables. Labels are suppressed. This option does not apply to multiple-dichotomy groups.

ONEPAGE *Conditional condensed format for frequency tables.* Three-column condensed format is used if the resulting table would not fit on a page. This option does not apply to multiple-dichotomy groups.

Example

```
MULT RESPONSE  GROUPS=PROBS 'NATIONAL PROBLEMS MENTIONED'
   (PROB1 TO PROB3 (1,9))/VARIABLES=EDUC (1,3)
   /FREQUENCIES=EDUC PROBS
   /FORMAT=CONDENSE.
```

- The `FORMAT` subcommand specifies condensed format, which eliminates category labels and displays the categories in three parallel sets of columns, each set containing one or more rows of categories (rather than displaying one set of columns aligned vertically down the page).

MULTIPLE CORRESPONDENCE

MULTIPLE CORRESPONDENCE is available in the Categories option.

```
MULTIPLE CORRESPONDENCE [/VARIABLES =] varlist

  /ANALYSIS = varlist [([WEIGHT={1**}]
                                {n  }

 [/DISCRETIZATION = [varlist [([{GROUPING   }] [{NCAT={7}  }] [DISTR={NORMAL }])]]]
                                                    {n}            {UNIFORM}
                                                {EQINTV={n}}
                                {RANKING    }
                                {MULTIPLYING}

 [/MISSING = [{varlist} ([{PASSIVE**}] [{MODEIMPU**}])]]
              {ALL**  }                 {EXTRACAT  }
                           {ACTIVE   }  {MODEIMPU**}
                                        {EXTRACAT  }
                                        {LISTWISE  }

 [/SUPPLEMENTARY = [OBJECT(objlist)] [VARIABLE(varlist)]]

 [/CONFIGURATION = [{INITIAL}]('filename')]
                    {FIXED  }

 [/DIMENSION = {2**}]
               {n  }

 [/NORMALIZATION = {VPRINCIPAL**}]
                   {OPRINCIPAL  }
                   {SYMMETRICAL }
                   {INDEPENDENT }
                   {n           }

 [/MAXITER = {100**}]
             {n    }

 [/CRITITER = {.00001**}]
              {value   }

 [/PRINT = [CORR**] [DESCRIP**[(varlist)]] [HISTORY][DISCRIM**] [NONE]
           [OBJECT[([(varname)]varlist)]] [OCORR] [QUANT[(varlist)]]

 [/PLOT = [BIPLOT[((varlist))][(varlist)][(n)]]
          [CATEGORY (varlist)[(n)]]
          [JOINTCAT[(varlist)][(n)]]
          [DISCRIM**[(varlist)][(n)]]
          [NONE]
          [OBJECT**[(varlist)][(n)]]
          [RESID(varlist[({1**})])[(n)]]
                        {n  }
          [TRANS(varlist[({1**})])[(n)]]
                        {n  }
          [NDIM(value,value)]

 [/SAVE = [TRDATA[({TRA     }[(n)])]] [OBJECT[({OBSCO   }[(n)])]] ]
                   {rootname}                  {rootname}

[/OUTFILE = {DISCRDATA('filename')} {OBJECT('filename')} {TRDATA('filename')}]
```

** Default if subcommand is omitted

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Release History

Release 13.0

- Command introduced.

Overview

MULTIPLE CORRESPONDENCE (Multiple Correspondence Analysis; also known as homogeneity analysis) quantifies nominal (categorical) data by assigning numerical values to the cases (objects) and categories, such that in the low-dimensional representation of the data, objects within the same category are close together and objects in different categories are far apart. Each object is as close as possible to the category points of categories that apply to the object. In this way, the categories divide the objects into homogeneous subgroups. Variables are considered homogeneous when they classify objects in the same categories into the same subgroups.

Basic Specification

The basic specification is the command MULTIPLE CORRESPONDENCE with the VARIABLES and ANALYSIS subcommands.

Syntax Rules

- The VARIABLES and ANALYSIS subcommands always must appear.
- All subcommands can appear in any order.
- For the first subcommand after the procedure name, a slash is accepted, but not required.
- Variables specified in the ANALYSIS subcommand must be found in the VARIABLES subcommand.
- Variables specified in the SUPPLEMENTARY subcommand must be found in the ANALYSIS subcommand.

Operations

- If the same subcommand is repeated, it causes a syntax error and the procedure terminates.

Limitations

- MULTIPLE CORRESPONDENCE operates on category indicator variables. The category indicators should be positive integers. You can use the DISCRETIZATION subcommand to convert fractional value variables and string variables into positive integers. If DISCRETIZATION is not specified, fractional value variables are automatically converted into positive integers by grouping them into seven categories (or into the number of distinct values of the variable if this number is less than seven) with a close-to-normal distribution, and string variables are automatically converted into positive integers by ranking.
- In addition to system-missing values and user-defined missing values, MULTIPLE CORRESPONDENCE treats category indicator values less than 1 as missing. If one of the values of a categorical variable has been coded 0 or some negative value and you want to treat it as a valid category, use the COMPUTE command to add a constant to the values of that

variable such that the lowest value will be 1. You can also use the RANKING option of the DISCRETIZATION subcommand for this purpose, except for variables you want to treat as numerical, since the spacing of the categories will not be maintained.

- There must be at least three valid cases.
- Split-File has no implications for MULTIPLE CORRESPONDENCE.

Example

```
MULTIPLE CORRESPONDENCE /VARIABLES = TEST1 TEST2 TEST3 TO TEST6 TEST7 TEST8
  /ANALYSIS = TEST1 TO TEST2(WEIGHT=2)
              TEST3 TO TEST5
              TEST6 TEST7
              TEST8
  /DISCRETIZATION = TEST1(GROUPING NCAT=5 DISTR=UNIFORM)
                    TEST6(GROUPING) TEST8(MULTIPLYING)
  /MISSING = TEST5(ACTIVE) TEST6(ACTIVE EXTRACAT) TEST8(LISTWISE)
  /SUPPLEMENTARY = OBJECT(1 3) VARIABLE(TEST1)
  /CONFIGURATION = ('iniconf.sav')
  /DIMENSION = 2
  /NORMALIZATION = VPRINCIPAL
  /MAXITER = 150
  /CRITITER = .000001
  /PRINT =  DESCRIP DISCRIM CORR QUANT(TEST1 TO TEST3) OBJECT
  /PLOT = TRANS(TEST2 TO TEST5) OBJECT(TEST2 TEST3)
  /SAVE = TRDATA OBJECT
  /OUTFILE = TRDATA('/data/trans.sav')  OBJECT('/data/obs.sav').
```

- VARIABLES defines variables. The keyword TO refers to the order of the variables in the working data file.
- The ANALYSIS subcommand defines variables used in the analysis. It is specified that *TEST1* and *TEST2* have a weight of 2 (for the other variables, WEIGHT is not specified and thus they have the default weight value of 1).
- DISCRETIZATION specifies that *TEST6* and *TEST8*, which are fractional value variables, are discretized: *TEST6* by recoding into seven categories with a normal distribution (default because unspecified) and *TEST8* by "multiplying". *TEST1*, which is a categorical variable, is recoded into five categories with a close to uniform distribution.
- MISSING specifies that objects with missing values on *TEST5* and *TEST6* are included in the analysis: missing values on *TEST5* are replaced with the mode (default if not specified) and missing values on *TEST6* are treated as an extra category. Objects with a missing value on *TEST8* are excluded from the analysis. For all other variables, the default is in effect; that is, missing values (not objects) are excluded from the analysis.
- CONFIGURATION specifies *iniconf.sav* as the file containing the coordinates of a configuration that is to be used as the initial configuration (default because unspecified).
- DIMENSION specifies the number of dimensions to be 2. This is the default, so this subcommand could be omitted here.
- The NORMALIZATION subcommand specifies optimization of the association between variables. This is the default, so this subcommand could be omitted here.
- MAXITER specifies the maximum number of iterations to be 150 instead of the default value of 100.
- CRITITER sets the convergence criterion to a value smaller than the default value.

- PRINT specifies descriptives, discrimination measures, and correlations (all default), and quantifications for *TEST1* to *TEST3*, and the object scores.
- PLOT is used to request transformation plots for the variables *TEST2* to *TEST5*, an object points plot labeled with the categories of *TEST2*, and an object points plot labeled with the categories of *TEST3*.
- The SAVE subcommand adds the transformed variables and the object scores to the working data file.
- The OUTFILE subcommand writes the transformed data to a data file called *trans.sav* and the object scores to a data file called *obs.sav*, both in the directory */data*.

Options

Discretization. You can use the DISCRETIZATION subcommand to discretize fractional value variables or to recode categorical variables.

Missing data. You can specify the treatment of missing data per variable with the MISSING subcommand.

Supplementary objects and variables. You can specify objects and variables that you want to treat as supplementary.

Read configuration. MULTIPLE CORRESPONDENCE can read a configuration from a file through the CONFIGURATION subcommand. This configuration can be used as the initial configuration or as a fixed configuration in which to fit variables.

Number of dimensions. You can specify how many dimensions MULTIPLE CORRESPONDENCE should compute.

Normalization. You can specify one of five different options for normalizing the objects and variables.

Tuning the algorithm. You can control the values of algorithm-tuning parameters with the MAXITER and CRITITER subcommands.

Optional output. You can request optional output through the PRINT subcommand.

Optional plots. You can request a plot of object points, transformation plots per variable, plots of category points per variable, or a joint plot of category points for specified variables. Other plot options include residuals plots, a biplot, and a plot of discrimination measures.

Writing discretized data, transformed data, and object scores. You can write the discretized data, the transformed data, and the object scores to outfiles for use in further analyses.

Saving transformed data and object scores. You can save the transformed variables and the object scores in the working data file.

VARIABLES Subcommand

VARIABLES specifies the variables that may be analyzed in the current MULTIPLE CORRESPONDENCE procedure.

- The VARIABLES subcommand is required. The actual keyword VARIABLES can be omitted.

- At least two variables must be specified, except if the CONFIGURATION subcommand with the FIXED keyword is used.
- The keyword TO on the VARIABLES subcommand refers to the order of variables in the working data file. (Note that this behavior of TO is different from that in the varlist in the ANALYSIS subcommand.)

ANALYSIS Subcommand

ANALYSIS specifies the variables to be used in the computations, and the variable weight for each variable or variable list. ANALYSIS also specifies supplementary variables; no weight can be specified for supplementary variables.

- At least two variables must be specified, except if the CONFIGURATION subcommand with the FIXED keyword is used.
- All the variables on ANALYSIS must be specified on the VARIABLES subcommand.
- The ANALYSIS subcommand is required.
- The keyword TO in the variable list honors the order of variables in the VARIABLES subcommand.
- Variable weights are indicated by the keyword WEIGHT in parentheses following the variable or variable list.

WEIGHT *Specifies the variable weight.* The default value is 1. If WEIGHT is specified for supplementary variables, this is ignored (but with a syntax warning).

DISCRETIZATION Subcommand

DISCRETIZATION specifies fractional value variables you want to discretize. Also, you can use DISCRETIZATION for ranking or for two ways of recoding categorical variables.

- A string variable's values are always converted into positive integers, by assigning category indicators according to the ascending alphanumeric order. DISCRETIZATION for string variables applies to these integers.
- When the DISCRETIZATION subcommand is omitted, or when the DISCRETIZATION subcommand is used without a varlist, fractional value variables are converted into positive integers by grouping them into seven categories (or into the number of distinct values of the variable if this number is less than seven) with a close-to-normal distribution.
- When no specification is given for variables in a varlist following DISCRETIZATION, these variables are grouped into seven categories (or into the number of distinct values of the variable if this number is less than seven) with a close-to-normal distribution.
- In MULTIPLE CORRESPONDENCE a system-missing value, user-defined missing values, and values less than 1 are considered to be missing values (see next section). However, in discretizing a variable, values less than 1 are considered to be valid values and are thus

included in the discretization process. System-missing values and user-defined missing values are excluded.

GROUPING *Recode into the specified number of categories or recode intervals of equal size into categories.*

RANKING *Rank cases.* Rank 1 is assigned to the case with the smallest value on the variable.

MULTIPLYING *Multiplying the standardized values (z-scores) of a fractional value variable by 10, rounding, and adding a value such that the lowest value is 1.*

GROUPING Keyword

NCAT *Recode into ncat categories.* When NCAT is not specified, the number of categories is set to seven (or the number of distinct values of the variable if this number is less than seven).

EQINTV *Recode intervals of equal size into categories.* The interval size must be specified (there is no default value). The resulting number of categories depends on the interval size.

NCAT Keyword

NCAT has the keyword DISTR, which has the following keywords:

NORMAL *Normal distribution.* This is the default when DISTR is not specified.

UNIFORM *Uniform distribution.*

MISSING Subcommand

In MULTIPLE CORRESPONDENCE, system-missing values, user-defined missing values, and values less than 1 are treated as missing values. However, in discretizing a variable, values less than 1 are considered as valid values. The MISSING subcommand allows you to indicate how to handle missing values for each variable.

PASSIVE *Exclude missing values on a variable from analysis.* This is the default applicable to all variables, when the MISSING subcommand is omitted or specified without variable names or keywords. Also, any variable which is not included in the subcommand gets this specification. Passive treatment of missing values means that, in optimizing the quantification of a variable, only objects with non-missing values on the variable are involved and that only the non-missing values of variables contribute to the solution. Thus, when PASSIVE is specified, missing values do not affect the analysis. If an object has only missing values, and for all variables the MISSING option is passive, the object will be handled as a supplementary object. If on the PRINT subcommand, correlations are requested and passive treatment of missing values is specified for a variable, the missing values have to be imputed. For the correlations of the original variables, missing values on a variable are imputed with the most frequent category (mode) of the variable.

ACTIVE *Impute missing values.* You can choose to use mode imputation, or to consider objects with missing values on a variable as belonging to the same category and impute missing values with an extra category indicator.

LISTWISE *Exclude cases with missing values on the specified variable(s).* The cases used in the analysis are cases without missing values on the variable(s) specified. Also, any variable that is not included in the subcommand gets this specification.

- The ALL keyword may be used to indicate all variables. If it is used, it must be the only variable specification.
- A mode or extracat imputation is done before listwise deletion.

PASSIVE Keyword

MODEIMPU *Impute missing values on a variable with the mode of the quantified variable.* This is the default.

EXTRACAT *Impute missing values on a variable with the quantification of an extra category.* This implies that objects with a missing value are considered to belong to the same (extra) category.

Note: With passive treatment of missing values, imputation only applies to correlations and is done afterwards. Thus the imputation has no effect on the quantification or the solution.

ACTIVE Keyword

MODEIMPU *Impute missing values on a variable with the most frequent category (mode)*. When there are multiple modes, the smallest category indicator is used. This is the default.

EXTRACAT *Impute missing values on a variable with an extra category indicator.* This implies that objects with a missing value are considered to belong to the same (extra) category.

Note: With active treatment of missing values, imputation is done before the analysis starts, and thus will affect the quantification and the solution.

SUPPLEMENTARY Subcommand

The SUPPLEMENTARY subcommand specifies the objects or/and variables that you want to treat as supplementary. Supplementary variables must be found in the ANALYSIS subcommand. You can not weight supplementary objects and variables (specified weights are ignored). For supplementary variables, all options on the MISSING subcommand can be specified except LISTWISE.

OBJECT *Objects you want to treat as supplementary are indicated with an object number list in parentheses following OBJECT.* The keyword TO is allowed. The OBJECT specification is not allowed when CONFIGURATION = FIXED.

VARIABLE *Variables you want to treat as supplementary are indicated with a variable list in parentheses following VARIABLE.* The keyword TO is allowed and honors the order of variables in the VARIABLES subcommand. The VARIABLE specification is ignored when CONFIGURATION = FIXED, for in that case all the variables in the ANALYSIS subcommand are automatically treated as supplementary variables.

CONFIGURATION Subcommand

The CONFIGURATION subcommand allows you to read data from a file containing the coordinates of a configuration. The first variable in this file should contain the coordinates for the first dimension, the second variable should contain the coordinates for the second dimension, and so forth.

INITIAL('filename')	Use the configuration in the specified file as the starting point of the analysis.
FIXED('filename')	*Fit variables in the fixed configuration found in the specified file.* The variables to fit in should be specified on the ANALYSIS subcommand but will be treated as supplementary variables. The SUPPLEMENTARY subcommand will be ignored. Also, variable weights will be ignored.

DIMENSION Subcommand

DIMENSION specifies the number of dimensions you want MULTIPLE CORRESPONDENCE to compute.

- If you do not specify the DIMENSION subcommand, MULTIPLE CORRESPONDENCE computes a two dimensional solution.
- DIMENSION is followed by an integer indicating the number of dimensions.
- The maximum number of dimensions is the smaller of a) the number of observations minus 1 and b) the total number of valid variable levels (categories) minus the number of variables if there are no variables with missing values to be treated as passive. If there are variables with missing values to be treated as passive, the maximum number of dimensions is the smaller of a) the number of observations minus 1 and b) the total number of valid variable levels (categories) minus the larger of c) 1 and d) the number of variables without missing values to be treated as passive.
- The maximum number of dimensions is the smaller of the number of observations minus 1 and the total number of valid variable levels (categories) minus the number of variables without missing values.
- MULTIPLE CORRESPONDENCE adjusts the number of dimensions to the maximum if the specified value is too large.
- The minimum number of dimensions is 1.

NORMALIZATION Subcommand

The NORMALIZATION subcommand specifies one of five options for normalizing the object scores and the variables.

- Only one normalization method can be used in a given analysis.

VPRINCIPAL	*Optimize the association between variables.* With VPRINCIPAL, the categories are in the centroid of the objects in the particular categories. VPRINCIPAL is the default if the NORMALIZATION subcommand is not specified. This is useful when you are primarily interested in the association between the variables.
OPRINCIPAL	*Optimize distances between objects.* This is useful when you are primarily interested in differences or similarities between the objects.
SYMMETRICAL	*Use this normalization option if you are primarily interested in the relation between objects and variables.*
INDEPENDENT	*Use this normalization option if you want to examine distances between objects and associations between variables separately.*

The fifth method allows the user to specify any real value in the closed interval [–1, 1]. A value of 1 is equal to the OPRINCIPAL method, a value of 0 is equal to the SYMMETRICAL method, and a value of –1 is equal to the VPRINCIPAL method. By specifying a value greater than –1 and less than 1, the user can spread the eigenvalue over both objects and variables. This method is useful for making a tailor-made biplot. If the user specifies a value outside of this interval, the procedure issues a syntax error message and terminates.

MAXITER Subcommand

MAXITER specifies the maximum number of iterations MULTIPLE CORRESPONDENCE can go through in its computations.

- If MAXITER is not specified, the maximum number of iterations is 100.
- The specification on MAXITER is a positive integer indicating the maximum number of iterations. There is no uniquely predetermined (that is, hard-coded) maximum for the value that can be used.

CRITITER Subcommand

CRITITER specifies a convergence criterion value. MULTIPLE CORRESPONDENCE stops iterating if the difference in fit between the last two iterations is less than the CRITITER value.

- If CRITITER is not specified, the convergence value is 0.00001.
- The specification on CRITITER is any positive value.

PRINT Subcommand

The Model Summary statistics (Cronbach's alpha and the variance accounted for) and the HISTORY statistics (the variance accounted for, the loss, and the increase in variance accounted for) for the last iteration are always displayed. That is, they cannot be controlled by the PRINT

subcommand. The PRINT subcommand controls the display of optional additional output. The output of the MULTIPLE CORRESPONDENCE procedure is always based on the transformed variables. However, the correlations of the original variables can be requested as well by the keyword OCORR.

The default keywords are DESCRIP, DISCRIM, and CORR. That is, the three keywords are in effect when the PRINT subcommand is omitted or when the PRINT subcommand is given without any keywords. Note that when some keywords are specified, the default is nullified and only the keywords specified become in effect. If a keyword that cannot be followed by a varlist is duplicated or if a contradicting keyword is encountered, then the later one silently becomes effective (in case of a contradicting use of NONE, only the keywords following NONE are effective). For example,

```
/PRINT <=> /PRINT = DESCRIP DISCRIM CORR

/PRINT = DISCRIM DISCRIM <=> /PRINT = DISCRIM

/PRINT = DISCRIM NONE CORR <=> /PRINT = CORR
```

If a keyword that can be followed by a varlist is duplicated, it will cause a syntax error and the procedure will terminate. For example, /PRINT = QUANT QUANT is a syntax error.

The following keywords can be specified:

DESCRIP(varlist) *Descriptive statistics (frequencies, missing values, and mode).* The variables in the varlist must be specified on the VARIABLES subcommand, but need not appear on the ANALYSIS subcommand. If DESCRIP is not followed by a varlist, Descriptives tables are displayed for all the variables in the varlist on the ANALYSIS subcommand.

DISCRIM *Discrimination measures per variable and per dimension.*

QUANT(varlist) *Category quantifications (centroid coordinates), mass, inertia of the categories, contribution of the categories to the inertia of the dimensions, and contribution of the dimensions to the inertia of the categories.* Any variable in the ANALYSIS subcommand may be specified in parentheses after QUANT. If QUANT is not followed by a varlist, Quantification tables are displayed for all variables in the varlist on the ANALYSIS subcommand.

HISTORY *History of iterations.* For each iteration, the variance accounted for, the loss, and the increase in variance accounted for are shown.

CORR *Correlations of the transformed variables, and the eigenvalues of this correlation matrix.* Correlation tables are displayed for each set of quantifications, thus there are *ndim* (the number of dimensions in the analysis) correlation tables; the *i*th table contains the correlations of the quantifications of dimension *i*, *i* = 1, ..., *ndim*. For variables with missing values specified to be treated as PASSIVE on the MISSING subcommand, the missing values are imputed according to the specification on the PASSIVE keyword (if nothing is specified, mode imputation is used).

OCORR *Correlations of the original variables, and the eigenvalues of this correlation matrix.* For variables with missing values specified to be treated as PASSIVE on the MISSING subcommand, the missing values are imputed with the variable mode.

OBJECT((varname)varlist) *Object scores (component scores) and, in separate table, mass, inertia of the objects, contribution of the objects to the inertia of the dimensions, and contribution of the dimensions to the inertia of the objects.* Following the keyword, a `varlist` can be given in parentheses to display variables (category indicators) along with the object scores. If you want to use a variable to label the objects, this variable must occur in parenthesis as the first variable in the `varlist`. If no labeling variable is specified, the objects are labeled with case numbers. The variables to display along with the object scores and the variable to label the objects must be specified on the `VARIABLES` subcommand but need not appear on the `ANALYSIS` subcommand. If no `varlist` is given, only the object scores are displayed.

NONE *No optional output is displayed.* The only output shown is the Model Summary and the `HISTORY` statistics for the last iteration.

The keyword `TO` in a variable list can only be used with variables that are in the `ANALYSIS` subcommand, and `TO` applies only to the order of the variables in the `ANALYSIS` subcommand. For variables that are in the `VARIABLES` subcommand but not in the `ANALYSIS` subcommand, the keyword `TO` cannot be used. For example, if `/VARIABLES = v1 TO v5` and the `ANALYSIS` subcommand has `/ANALYSIS v2 v1 v4`, then `/PLOT OBJECT(v1 TO v4)` will give two object plots, one labeled with *v1* and one labeled with *v4*. (`/PLOT OBJECT(v1 TO v4 v2 v3 v5)` will give objects plots labeled with *v1*, *v2*, *v3*, *v4*, and *v5*).

PLOT Subcommand

The `PLOT` subcommand controls the display of plots. The default keywords are `OBJECT` and `DISCRIM`. That is, the two keywords are in effect when the `PLOT` subcommand is omitted, or when the `PLOT` subcommand is given without any keyword. If a keyword is duplicated (for example, `/PLOT = RESID RESID`), then it will cause a syntax error and the procedure will terminate. If the keyword `NONE` is used together with other keywords (for example, `/PLOT = RESID NONE DISCRIM`), then only the keywords following `NONE` are effective. That is, when keywords contradict, the later one overwrites the earlier ones.

- All the variables to be plotted must be specified in the `ANALYSIS` subcommand.
- If the variable list following the keywords `CATEGORIES`, `TRANS`, and `RESID` is empty, then it will cause a syntax error and the procedure will terminate.
- The variables in the `varlist` for labeling the object points following `OBJECT` and `BIPLOT` must be specified on the `VARIABLES` subcommand but need not appear on the `ANALYSIS` subcommand. This means that variables not included in the analysis can still be used to label plots.
- The keyword `TO` in a variable list can only be used with variables that are in the `ANALYSIS` subcommand, and `TO` applies only to the order of the variables in the `ANALYSIS` subcommand For variables that are in the `VARIABLES` subcommand but not in the `ANALYSIS` subcommand, the keyword `TO` cannot be used. For example, if `/VARIABLES = v1 TO v5` and `/ANALYSIS` is `v2 v1 v4`, then `/PLOT OBJECT(v1 TO v4)` will give two object plots, one

labeled with *v1* and one labeled with *v4*. (`/PLOT OBJECT(v1 TO v4 v2 v3 v5)` will give objects plots labeled with *v1*, *v2*, *v3*, *v4*, and *v5*).

- For multidimensional plots, all of the dimensions in the solution are produced in a matrix scatterplot if the number of dimensions in the solution is greater than two and the `NDIM` keyword is not specified; if the specified number of dimensions is 2, a scatterplot is produced.

The following keywords can be specified:

OBJECT (varlist)(n)	*Plots of the object points.* Following the keyword, a list of variables in parentheses can be given to indicate that plots of object points labeled with the categories of the variables should be produced (one plot for each variable). If the variable list is omitted, a plot labeled with case numbers is produced.
CATEGORY(varlist)(n)	*Plots of the category points (centroid coordinates).* A list of variables must be given in parentheses following the keyword. Categories are in the centroids of the objects in the particular categories.
DISCRIM(varlist)(n)	*Plot of the discrimination measures.* `DISCRIM` can be followed by a `varlist` to select the variables to include in the plot. If the variable list is omitted, a plot including all variables is produced.
TRANS(varlist(n))	*Transformation plots per variable (optimal category quantifications against category indicators).* Following the keyword, a list of variables in parentheses must be given. Each variable can be followed by a number of dimensions in parentheses to indicate you want to display *p* residual plots, one for each of the first *p* dimensions. If the number of dimensions is not specified, a plot for the first dimension is produced.
RESID(varlist(n))(n)	*Plot of residuals per variable (approximation against optimal category quantifications).* Following the keyword, a list of variables in parentheses must be given. Each variable can be followed by a number of dimensions in parentheses to indicate you want to display *p* residual plots, one for each of the first *p* dimensions. If the number of dimensions is not specified, a plot for the first dimension is produced.
BI-PLOT((varlist))(varlist)(n)	*Plot of objects and variables (centroids).* When `NORMALIZATION = INDEPENDENT`, this plot is incorrect and therefore not available. `BIPLOT` can be followed by a `varlist` in double parentheses to select the variables to include in the plot. If this variable list is omitted, a plot including all variables is produced. Following `BIPLOT` or `BIPLOT((varlist))`, a list of variables in single parentheses can be given to indicate that plots with objects labeled with the categories of the variables should be produced (one plot for each variable). If this variable list is omitted, a plot with objects labeled with case numbers is produced.
JOINTCAT(varlist)(n)	*Joint plot of the category points for the variables in the varlist.* If no `varlist` is given, the category points for all variables are displayed.
NONE	*No plots.*

- For all of the keywords except `TRANS` and `NONE`, the user can specify an optional parameter *l* in parentheses after the variable list in order to control the global upper boundary of variable name/label and value label lengths in the plot. Note that this boundary is applied uniformly to all variables in the list. The label length parameter *l* can take any non-negative integer less than or equal to the applicable maximum length (64 for variable names, 255 for variable labels, and 60 for value labels). If *l* = 0, names/values instead of variable/value labels are displayed to indicate variables/categories. If *l* is not specified, `MULTIPLE CORRESPONDENCE` assumes that each variable name/label and value label at its full length is displayed. If *l* is an integer larger than the applicable maximum, then we reset it to the applicable maximum but do

not issue a warning. If a positive value of *l* is given but if some or all of the variables/category values do not have labels, then for those variables/values the names/values themselves are used as the labels.

In addition to the plot keywords, the following can be specified:

NDIM(value,value) *Dimension pairs to be plotted.* NDIM is followed by a pair of values in parentheses. If NDIM is not specified or if NDIM is specified without parameter values, a matrix scatterplot including all dimensions is produced.

- The first value (an integer that can range from 1 to the number of dimensions in the solution minus 1) indicates the dimension that is plotted against higher dimensions.
- The second value (an integer that can range from 2 to the number of dimensions in the solution) indicates the highest dimension to be used in plotting the dimension pairs.
- The NDIM specification applies to all requested multidimensional plots.

SAVE Subcommand

The SAVE subcommand is used to add the transformed variables (category indicators replaced with optimal quantifications) and the object scores to the working data file.

- Excluded cases are represented by a dot (the sysmis symbol) on every saved variable.

TRDATA *Transformed variables.* Missing values specified to be treated as passive are represented by a dot. Following TRDATA, a rootname, and the number of dimensions to be saved can be specified in parentheses (if the number of dimensions is not specified, all dimensions are saved).

OBJECT *Object scores.*

MULTIPLE CORRESPONDENCE adds three numbers. The first number uniquely identifies the source variable names, the middle number corresponds to the dimension number, and the last number uniquely identifies the MULTIPLE CORRESPONDENCE procedures with the successfully executed SAVE subcommands. Only one rootname can be specified and it can contain up to three characters. If more than one rootname is specified, the first rootname is used; if a rootname contains more than three characters, the first three characters are used at most.

- If a rootname is not specified for TRDATA, rootname *TRA* is used to automatically generate unique variable names. The formula is *ROOTNAMEk_m_n*, where *k* increments from 1 to identify the source variable names by using the source variables' position numbers in the ANALYSIS subcommand, *m* increments from 1 to identify the dimension number, and *n* increments from 1 to identify the MULTIPLE CORRESPONDENCE procedures with the successfully executed SAVE subcommands for a given data file in a continuous session. For example, with two variables specified on ANALYSIS and 2 dimensions to save, the first set of default names, if they do not exist in the data file, would be *TRA1_1_1*, *TRA1_2_1*, *TRA2_1_1*, *TRA2_2_1*. The next set of default names, if they do not exist in the data file, would be *TRA1_1_2*, *TRA1_2_2*, *TRA2_1_2*, *TRA2_2_2*. However, if, for example, *TRA1_1_2* already exists in the data file, then the default names should be attempted as *TRA1_1_3*, *TRA1_2_3*, *TRA2_1_3*, *TRA2_2_3*. That is, the last number increments to the next available integer.

- Following OBJECT, a rootname and the number of dimensions can be specified in parentheses (if the number of dimensions is not specified, all dimensions are saved), to which MULTIPLE CORRESPONDENCE adds two numbers separated by the underscore symbol (_). The first number corresponds to the dimension number. The second number uniquely identifies the MULTIPLE CORRESPONDENCE procedures with the successfully executed SAVE subcommands. Only one rootname can be specified, and it can contain up to five characters. If more than one rootname is specified, the first rootname is used; if a rootname contains more than five characters, the first five characters are used at most.
- If a rootname is not specified for OBJECT, the rootname *OBSCO* is used to automatically generate unique variable names. The formula is *ROOTNAMEm_n*, where *m* increments from 1 to identify the dimension number and *n* increments from 1 to identify the MULTIPLE CORRESPONDENCE procedures with the successfully executed SAVE subcommands for a given data file in a continuous session. For example, if 2 dimensions are specified following OBJECT, the first set of default names, if they do not exist in the data file, would be *OBSCO1_1*, *OBSCO2_1*. The next set of default names, if they do not exist in the data file, would be *OBSCO1_2*, *OBSCO2_2*. However, if, for example, *OBSCO2_2* already exists in the data file, then the default names should be attempted as *OBSCO1_3*, *OBSCO2_3*. That is, the second number increments to the next available integer.
- Variable labels are created automatically. They are shown in the Notes table and can also be displayed in the Data Editor window.
- If the number of dimensions is not specified, the SAVE subcommand saves all dimensions.

OUTFILE Subcommand

The OUTFILE subcommand is used to write the discretized data, transformed data (category indicators replaced with optimal quantifications), and the object scores to an SPSS data file or previously declared dataset. Excluded cases are represented by a dot (the sysmis symbol) on every saved variable.

DISCRDATA ('savfile'|'dataset')	*Discretized data.*
TRDATA ('savfile'|'dataset')	*Transformed variables.* Missing values specified to be treated as passive are represented by a dot.
OBJECT ('savfile'|'dataset')	*Object scores.*

Filenames should be enclosed in quotes and are stored in the working directory unless a path is included as part of the file specification. datasets are available during the current session but are not available in subsequent sessions unless you explicitly save them as data files. The names should be different for each of the keywords.

- The active dataset, in principle, should not be replaced by this subcommand, and the asterisk (*) file specification is not supported. This strategy also helps prevent OUTFILE interference with the SAVE subcommand.

MVA

MVA is available in the Missing Values Analysis option.

```
MVA VARIABLES= {varlist}
               {ALL    }

```

Overview

MVA (Missing Value Analysis) describes the missing value patterns in a data file (data matrix). It can estimate the means, the covariance matrix, and the correlation matrix by using listwise, pairwise, regression, and EM estimation methods. Missing values themselves can be estimated (imputed), and you can then save the new data file.

Options

Categorical variables. String variables are automatically defined as categorical. For a long string variable, only the first eight characters are used to define categories. Quantitative variables can be designated as categorical by using the CATEGORICAL subcommand.

MAXCAT specifies the maximum number of categories for any categorical variable. If any categorical variable has more than the specified number of distinct values, MVA is not executed.

Analyzing Patterns. For each quantitative variable, the TTEST subcommand produces a series of *t* tests. Values of the quantitative variable are divided into two groups, based on the presence or absence of other variables. These pairs of groups are compared using the *t* test.

Crosstabulating Categorical Variables. The CROSSTAB subcommand produces a table for each categorical variable, showing, for each category, how many nonmissing values are in the other variables and the percentages of each type of missing value.

Displaying Patterns. DPATTERN displays a case-by-case data pattern with codes for system-missing, user-missing, and extreme values. MPATTERN displays only the cases that have missing values and sorts by the pattern that is formed by missing values. TPATTERN tabulates the cases that have a common pattern of missing values. The pattern tables have sorting options. Also, descriptive variables can be specified.

Labeling Cases. For pattern tables, an ID variable can be specified to label cases.

Suppression of Rows. To shorten tables, the PERCENT keyword suppresses missing-value patterns that occur relatively infrequently.

Statistics. Displays of univariate, listwise, and pairwise statistics are available.

Estimation. EM and REGRESSION use different algorithms to supply estimates of missing values, which are used in calculating estimates of the mean vector, the covariance matrix, and the correlation matrix of dependent variables. The estimates can be saved as replacements for missing values in a new data file.

Basic Specification

The basic specification depends on whether you want to describe the missing data pattern or estimate statistics. Often, description is done first, and then, considering the results, an estimation is done. Alternatively, both description and estimation can be done by using the same MVA command.

Descriptive Analysis. A basic descriptive specification includes a list of variables and a statistics or pattern subcommand. For example, a list of variables and the subcommand DPATTERN would show missing value patterns for all cases with respect to the list of variables.

Estimation. A basic estimation specification includes a variable list and an estimation method. For example, if the EM method is specified, the following are estimated: the mean vector, the covariance matrix, and the correlation matrix of quantitative variables with missing values.

Syntax Rules

- A variables specification is required directly after the command name. The specification can be either a variable list or the keyword ALL.
- The CATEGORICAL, MAXCAT, and ID subcommands, if used, must be placed after the variables list and before any other subcommand. These three subcommands can be in any order.
- Any combination of description and estimation subcommands can be specified. For example, both the EM and REGRESSION subcommands can be specified in one MVA command.
- Univariate statistics are displayed unless the NOUNIVARIATE subcommand is specified. Thus, if only a list of variables is specified, with no description or estimation subcommands, univariate statistics are displayed.
- If a subcommand is specified more than once, only the last subcommand is honored.
- The following words are reserved as keywords or internal commands in the MVA procedure: VARIABLES, SORT, NOSORT, DESCRIBE, and WITH. They cannot be used as variable names in MVA.
- The tables *Summary of Estimated Means* and *Summary of Estimated Standard Deviations* are produced if you specify more than one way to estimate means and standard deviations. The methods include univariate (default), listwise, pairwise, EM, and regression. For example, these tables are produced when you specify both LISTWISE and EM.

Symbols

The symbols that are displayed in the DPATTERN and MPATTERN table cells are:

+	Extremely high value
−	Extremely low value
S	System-missing value
A	First type of user-missing value
B	Second type of user-missing value
C	Third type of user-missing value

- An extremely high value is more than 1.5 times the interquartile range above the 75th percentile, if (number of variables) × $n \log n \leq 150000$, where n is the number of cases.
- An extremely low value is more than 1.5 times the interquartile range below the 25th percentile, if (number of variables) × $n \log n \leq 150000$, where n is the number of cases.
- For larger files—that is, (number of variables) × $n \log n > 150000$—extreme values are two standard deviations from the mean.

Missing Indicator Variables

For each variable in the variables list, a binary indicator variable is formed (internal to MVA), indicating whether a value is present or missing.

VARIABLES Subcommand

A list of variables or the keyword ALL is required.

- The order in which the variables are listed determines the default order in the output.
- If the keyword ALL is used, the default order is the order of variables in the active dataset.
- String variables that are specified in the variable list, whether short or long, are automatically defined as categorical. For a long string variable, only the first eight characters of the values are used to distinguish categories.
- The list of variables must precede all other subcommands.
- Multiple lists of variables are not allowed.

CATEGORICAL Subcommand

The MVA procedure automatically treats all string variables in the variables list as categorical. You can designate numeric variables as categorical by listing them on the CATEGORICAL subcommand. If a variable is designated categorical, it will be ignored if listed as a dependent or independent variable on the REGRESSION or EM subcommand.

MAXCAT Subcommand

The MAXCAT subcommand sets the upper limit of the number of distinct values that each categorical variable in the analysis can have. The default is 25. This limit affects string variables in the variables list and also the categorical variables that are defined by the CATEGORICAL subcommand. A large number of categories can slow the analysis considerably. If any categorical variable violates this limit, MVA does not run.

Example

```
MVA VARIABLES=populatn density urban religion lifeexpf region
  /CATEGORICAL=region
  /MAXCAT=30
  /MPATTERN.
```

- The CATEGORICAL subcommand specifies that *region*, a numeric variable, is categorical. The variable *religion*, a string variable, is automatically categorical.
- The maximum number of categories in *region* or *religion* is 30. If either variable has more than 30 distinct values, MVA produces only a warning.
- Missing data patterns are shown for those cases that have at least one missing value in the specified variables.
- The summary table lists the number of missing and extreme values for each variable, including those with no missing values.

ID Subcommand

The ID subcommand specifies a variable to label cases. These labels appear in the pattern tables. Without this subcommand, the case numbers are used.

Example

```
MVA VARIABLES=populatn density urban religion lifeexpf region
  /CATEGORICAL=region
  /MAXCAT=20
  /ID=country
  /MPATTERN.
```

- The values of the variable *country* are used as case labels.
- Missing data patterns are shown for those cases that have at least one missing value in the specified variables.

NOUNIVARIATE Subcommand

By default, MVA computes univariate statistics for each variable—the number of cases with nonmissing values, the mean, the standard deviation, the number and percentage of missing values, and the counts of extreme low and high values. (Means, standard deviations, and extreme value counts are not reported for categorical variables.)

- To suppress the univariate statistics, specify NOUNIVARIATE.

Examples

```
MVA VARIABLES=populatn density urban religion lifeexpf region
  /CATEGORICAL=region
  /CROSSTAB PERCENT=0.
```

- Univariate statistics (number of cases, means, and standard deviations) are displayed for *populatn*, *density*, *urban*, and *lifeexpf*. Also, the number of cases, counts and percentages of missing values, and counts of extreme high and low values are displayed.
- The total number of cases and counts and percentages of missing values are displayed for *region* and *religion* (a string variable).
- Separate crosstabulations are displayed for *region* and *religion*.

```
MVA VARIABLES=populatn density urban religion lifeexpf region
  /CATEGORICAL=region.
  /NOUNIVARIATE
  /CROSSTAB PERCENT=0.
```

- Only crosstabulations are displayed (no univariate statistics).

TTEST Subcommand

For each quantitative variable, a series of *t* tests are computed to test the difference of means between two groups defined by a missing indicator variable for each of the other variables. (For more information, see Missing Indicator Variables on p. 1199.) For example, a *t* test is performed on *populatn* between two groups defined by whether their values are present or missing for *calories*. Another *t* test is performed on *populatn* for the two groups defined by whether their values for *density* are present or missing, and the tests continue for the remainder of the variable list.

PERCENT=n *Omit indicator variables with less than the specified percentage of missing values*. You can specify a percentage from 0 to 100. The default is 5, indicating the omission of any variable with less than 5% missing values. If you specify 0, all rows are displayed.

Display of Statistics

The following statistics can be displayed for a *t* test:

- The *t* **statistic**, for comparing the means of two groups defined by whether the indicator variable is coded as missing or nonmissing. (For more information, see Missing Indicator Variables on p. 1199.)

T *Display the* t *statistics.* This setting is the default.

NOT *Suppress the* t *statistics.*

- The **degrees of freedom** associated with the *t* statistic.

DF *Display the degrees of freedom.* This setting is the default.

NODF *Suppress the degrees of freedom.*

- The **probability** (two-tailed) associated with the *t* test, calculated for the variable that is tested without reference to other variables. Care should be taken when interpreting this probability.

PROB	*Display probabilities.*
NOPROB	*Suppress probabilities.* This setting is the default.

- The **number of values in each group**, where groups are defined by values that are coded as missing and present in the indicator variable.

COUNTS	*Display counts.* This setting is the default.
NOCOUNTS	*Suppress counts.*

- The **means** of the groups, where groups are defined by values that are coded as missing and present in the indicator variable.

MEANS	*Display means.* This setting is the default.
NOMEANS	*Suppress means.*

Example

```
MVA VARIABLES=populatn density urban religion lifeexpf region
  /CATEGORICAL=region
  /ID=country
  /TTEST.
```

- The `TTEST` subcommand produces a table of *t* tests. For each quantitative variable named in the variables list, a *t* test is performed, comparing the mean of the values for which the other variable is present against the mean of the values for which the other variable is missing.
- The table displays default statistics, including values of *t*, degrees of freedom, counts, and means.

CROSSTAB Subcommand

`CROSSTAB` produces a table for each categorical variable, showing the frequency and percentage of values that are present (nonmissing) and the percentage of missing values for each category as related to the other variables.

- No tables are produced if there are no categorical variables.
- Each categorical variable yields a table, whether it is a string variable that is assumed to be categorical or a numeric variable that is declared on the `CATEGORICAL` subcommand.
- The categories of the categorical variable define the columns of the table.

- Each of the remaining variables defines several rows—one each for the number of values present, the percentage of values present, and the percentage of system-missing values; and one each for the percentage of values defined as each discrete type of user-missing (if they are defined).

PERCENT=n *Omit rows for variables with less than the specified percentage of missing values*. You can specify a percentage from 0 to 100. The default is 5, indicating the omission of any variable with less than 5% missing values. If you specify 0, all rows are displayed.

Example

```
MVA VARIABLES=age income91 childs jazz folk
  /CATEGORICAL=jazz folk
  /CROSSTAB PERCENT=0.
```

- A table of univariate statistics is displayed by default.
- In the output are two crosstabulations (one crosstabulation for *jazz* and one crosstabulation for *folk*). The table for *jazz* displays, for each category of *jazz*, the number and percentage of present values for *age*, *income91*, *childs*, and *folk*. It also displays, for each category of *jazz*, the percentage of each type of missing value (system-missing and user-missing) in the other variables. The second crosstabulation shows similar counts and percentages for each category of *folk*.
- No rows are omitted, because `PERCENT=0`.

MISMATCH Subcommand

`MISMATCH` produces a matrix showing percentages of cases for a pair of variables in which one variable has a missing value and the other variable has a nonmissing value (a mismatch). The diagonal elements are percentages of missing values for a single variable, while the off-diagonal elements are the percentage of mismatch of the indicator variables. For more information, see Missing Indicator Variables on p. 1199. Rows and columns are sorted on missing patterns.

PERCENT=n *Omit patterns involving less than the specified percentage of cases*. You can specify a percentage from 0 to 100. The default is 5, indicating the omission of any pattern that is found in less than 5% of the cases.

NOSORT *Suppress sorting of the rows and columns*. The order of the variables in the variables list is used. If `ALL` was used in the variables list, the order is that of the data file.

DPATTERN Subcommand

`DPATTERN` lists the missing values and extreme values for each case symbolically. For a list of the symbols that are used, see Symbols.

By default, the cases are listed in the order in which they appear in the file. The following keywords are available:

SORT=varname [(order)] *Sort the cases according to the values of the named variables*. You can specify more than one variable for sorting. Each sort variable can be in ASCENDING or DESCENDING order. The default order is ASCENDING.

DESCRIBE=varlist *List values of each specified variable for each case*.

Example

```
MVA VARIABLES=populatn density urban religion lifeexpf region
  /CATEGORICAL=region
  /ID=country
  /DPATTERN DESCRIBE=region religion SORT=region.
```

- In the data pattern table, the variables form the columns, and each case, identified by its country, defines a row.
- Missing and extreme values are indicated in the table, and, for each row, the number missing and percentage of variables that have missing values are listed.
- The values of *region* and *religion* are listed at the end of the row for each case.
- The cases are sorted by *region* in ascending order.
- Univariate statistics are displayed.

MPATTERN Subcommand

The MPATTERN subcommand symbolically displays patterns of missing values for cases that have missing values. The variables form the columns. Each case that has any missing values in the specified variables forms a row. The rows are sorted by missing-value patterns. For use of symbols, see Symbols.

- The rows are sorted to minimize the differences between missing patterns of consecutive cases.
- The columns are also sorted according to missing patterns of the variables.

The following keywords are available:

NOSORT *Suppress the sorting of variables*. The order of the variables in the variables list is used. If ALL was used in the variables list, the order is that of the data file.

DESCRIBE=varlist *List values of each specified variable for each case*.

Example

```
MVA VARIABLES=populatn density urban religion lifeexpf region
  /CATEGORICAL=region
  /ID=country
  /MPATTERN DESCRIBE=region religion.
```

- A table of missing data patterns is produced.
- The *region* and the *religion* are named for each listed case.

TPATTERN Subcommand

The TPATTERN subcommand displays a tabulated patterns table, which lists the frequency of each missing value pattern. The variables in the variables list form the columns. Each pattern of missing values forms a row, and the frequency of the pattern is displayed.

- An *X* is used to indicate a missing value.
- The rows are sorted to minimize the differences between missing patterns of consecutive cases.
- The columns are sorted according to missing patterns of the variables.

The following keywords are available:

NOSORT	*Suppress the sorting of the columns.* The order of the variables in the variables list is used. If ALL was used in the variables list, the order is that of the data file.
DESCRIBE=varlist	*Display values of variables for each pattern.* Categories for each named categorical variable form columns in which the number of each pattern of missing values is tabulated. For quantitative variables, the mean value is listed for the cases having the pattern.
PERCENT=n	*Omit patterns that describe less than 1% of the cases.* You can specify a percentage from 0 to 100. The default is 1, indicating the omission of any pattern representing less than 1% of the total cases. If you specify 0, all patterns are displayed.

Example

```
MVA VARIABLES=populatn density urban religion lifeexpf region
  /CATEGORICAL=region
  /TPATTERN NOSORT DESCRIBE=populatn region.
```

- Missing value patterns are tabulated. Each row displays a missing value pattern and the number of cases having that pattern.
- DESCRIBE causes the mean value of *populatn* to be listed for each pattern. For the categories in *region*, the frequency distribution is given for the cases having the pattern in each row.

LISTWISE Subcommand

For each quantitative variable in the variables list, the LISTWISE subcommand computes the mean, the covariance between the variables, and the correlation between the variables. The cases that are used in the computations are listwise nonmissing; that is, they have no missing value in any variable that is listed in the VARIABLES subcommand.

Example

```
MVA VARIABLES=populatn density urban religion lifeexpf region
  /CATEGORICAL=region
  /LISTWISE.
```

- Means, covariances, and correlations are displayed for *populatn*, *density*, *urban*, and *lifeexpf*. Only cases that have values for all of these variables are used.

PAIRWISE Subcommand

For each pair of quantitative variables, the PAIRWISE subcommand computes the number of pairwise nonmissing values, the pairwise means, the pairwise standard deviations, the pairwise covariances, and the pairwise correlation matrices. These results are organized as matrices. The cases that are used are all cases having nonmissing values for the pair of variables for which each computation is done.

Example

```
MVA VARIABLES=populatn density urban religion lifeexpf region
  /CATEGORICAL=region
  /PAIRWISE.
```

- Frequencies, means, standard deviations, covariances, and the correlations are displayed for *populatn*, *density*, *urban*, and *lifeexpf*. Each calculation uses all cases that have values for both variables under consideration.

EM Subcommand

The EM subcommand uses an EM (expectation-maximization) algorithm to estimate the means, the covariances, and the Pearson correlations of quantitative variables. This process is an iterative process, which uses two steps for each iteration. The E step computes expected values conditional on the observed data and the current estimates of the parameters. The M step calculates maximum-likelihood estimates of the parameters based on values that are computed in the E step.

- If no variables are listed in the EM subcommand, estimates are performed for all quantitative variables in the variables list.
- If you want to limit the estimation to a subset of the variables in the list, specify a subset of quantitative variables to be estimated after the subcommand name EM. You can also list, after the keyword WITH, the quantitative variables to be used in estimating.
- The output includes tables of means, correlations, and covariances.
- The estimation, by default, assumes that the data are normally distributed. However, you can specify a multivariate *t* distribution with a specified number of degrees of freedom or a mixed normal distribution with any mixture proportion (PROPORTION) and any standard deviation ratio (LAMBDA).
- You can save a data file with the missing values filled in. You must specify a filename and its complete path in single or double quotation marks.
- Criteria keywords and OUTFILE specifications must be enclosed in a single pair of parentheses.

The criteria for the EM subcommand are as follows:

TOLERANCE=value *Numerical accuracy control.* Helps eliminate predictor variables that are highly correlated with other predictor variables and would reduce the accuracy of the matrix inversions that are involved in the calculations. The smaller the tolerance, the more inaccuracy is tolerated. The default value is 0.001.

CONVERGENCE=value *Convergence criterion.* Determines when iteration ceases. If the relative change in the likelihood function is less than this value, convergence is assumed. The value of this ratio must be between 0 and 1. The default value is 0.0001.

ITERATIONS=n *Maximum number of iterations.* Limits the number of iterations in the EM algorithm. Iteration stops after this many iterations even if the convergence criterion is not satisfied. The default value is 25.

Possible distribution assumptions are as follows:

TDF=n *Student's* t *distribution with* n *degrees of freedom.* The degrees of freedom must be specified if you use this keyword. The degrees of freedom must be an integer that is greater than or equal to 2.

LAMBDA=a *Ratio of standard deviations of a mixed normal distribution.* Any positive real number can be specified.

PROPORTION=b *Mixture proportion of two normal distributions.* Any real number between 0 and 1 can specify the mixture proportion of two normal distributions.

The following keyword produces a new data file:

OUTFILE='file' *Specify a filename or previously declared dataset name.* Filenames should be enclosed in quotation marks and are stored in the working directory unless a path is included as part of the file specification. Datasets are available during the current session but are not available in subsequent sessions unless you explicitly save them as data files. Missing values for predicted variables in the file are filled in by using the EM algorithm. (Note that the data that are completed with EM-based imputations will not in general reproduce the EM estimates from MVA.)

Examples

```
MVA VARIABLES=males to tuition
 /EM (OUTFILE='/colleges/emdata.sav').
```

- All variables on the variables list are included in the estimations.
- The output includes the means of the listed variables, a correlation matrix, and a covariance matrix.
- A new data file named *emdata.sav* with imputed values is saved in the */colleges* directory.

```
MVA VARIABLES=all
 /EM males msport WITH males msport gradrate facratio.
```

- For *males* and *msport*, the output includes a vector of means, a correlation matrix, and a covariance matrix.

- The values in the tables are calculated by using imputed values for *males* and *msport*. Existing observations for *males*, *msport*, *gradrate*, and *facratio* are used to impute the values that are used to estimate the means, correlations, and covariances.

```
MVA VARIABLES=males to tuition
 /EM verbal math WITH males msport gradrate facratio
  (TDF=3 OUTFILE '/colleges/emdata.sav').
```

- The analysis uses a *t* distribution with three degrees of freedom.
- A new data file named *emdata.sav* with imputed values is saved in the */colleges* directory.

REGRESSION Subcommand

The REGRESSION subcommand estimates missing values by using multiple linear regression. It can add a random component to the regression estimate. Output includes estimates of means, a covariance matrix, and a correlation matrix of the variables that are specified as predicted.

- By default, all of the variables that are specified as predictors (after WITH) are used in the estimation, but you can limit the number of predictors (independent variables) by using NPREDICTORS.
- Predicted and predictor variables, if specified, must be quantitative.
- By default, REGRESSION adds the observed residuals of a randomly selected complete case to the regression estimates. However, you can specify that the program add random normal, *t*, or no variates instead. The normal and *t* distributions are properly scaled, and the degrees of freedom can be specified for the *t* distribution.
- If the number of complete cases is less than half the total number of cases, the default ADDTYPE is NORMAL instead of RESIDUAL.
- You can save a data file with the missing values filled in. You must specify a filename and its complete path in single or double quotation marks.
- The criteria and OUTFILE specifications for the REGRESSION subcommand must be enclosed in a single pair of parentheses.

The criteria for the REGRESSION subcommand are as follows:

TOLERANCE=value	*Numerical accuracy control.* Helps eliminate predictor variables that are highly correlated with other predictor variables and would reduce the accuracy of the matrix inversions that are involved in the calculations. If a variable passes the tolerance criterion, it is eligible for inclusion. The smaller the tolerance, the more inaccuracy is tolerated. The default value is 0.001.
FLIMIT=n	F-*to-enter limit.* The minimum value of the *F* statistic that a variable must achieve in order to enter the regression estimation. You may want to change this limit, depending on the number of variables and the correlation structure of the data. The default value is 4.
NPREDICTORS=n	*Maximum number of predictor variables.* Limits the total number of predictors in the analysis. The analysis uses the stepwise selected *n* best predictors, entered in accordance with the tolerance. If *n*=0, it is equivalent to replacing each variable with its mean.

ADDTYPE *Type of distribution from which the error term is randomly drawn.* Random errors can be added to the regression estimates before the means, correlations, and covariances are calculated. You can specify one of the following types:

RESIDUAL. Error terms are chosen randomly from the observed residuals of complete cases to be added to the regression estimates.

NORMAL. Error terms are randomly drawn from a distribution with the expected value 0 and the standard deviation equal to the square root of the mean squared error term (sometimes called the **root mean squared error**, or RMSE) of the regression.

T(n). Error terms are randomly drawn from the t(n) distribution and scaled by the RMSE. The degrees of freedom can be specified in parentheses. If T is specified without a value, the default degrees of freedom is 5.

NONE. Estimates are made from the regression model with no error term added.

The following keyword produces a new data file:

OUTFILE *Specify a filename or previously declared dataset name.* Filenames should be enclosed in quotation marks and are stored in the working directory unless a path is included as part of the file specification. Datasets are available during the current session but are not available in subsequent sessions unless you explicitly save them as data files. Missing values for the dependent variables in the file are imputed (filled in) by using the regression algorithm.

Examples

```
MVA VARIABLES=males to tuition
 /REGRESSION (OUTFILE='/colleges/regdata.sav').
```

- All variables in the variables list are included in the estimations.
- The output includes the means of the listed variables, a correlation matrix, and a covariance matrix.
- A new data file named *regdata.sav* with imputed values is saved in the */colleges* directory.

```
MVA VARIABLES=males to tuition
 /REGRESSION males verbal math WITH males verbal math faculty
  (ADDTYPE = T(7)).
```

- The output includes the means of the listed variables, a correlation matrix, and a covariance matrix.
- A *t* distribution with 7 degrees of freedom is used to produce the randomly assigned additions to the estimates.

N OF CASES

```
N OF CASES n
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Example

```
N OF CASES 100.
```

Overview

N OF CASES (alias N) limits the number of cases in the active dataset to the first *n* cases.

Basic Specification

The basic specification is N OF CASES followed by at least one space and a positive integer. Cases in the active dataset are limited to the specified number.

Syntax Rules

- To limit the number of cases for the next procedure only, use the TEMPORARY command before N OF CASES (see TEMPORARY).
- In some versions of the program, N OF CASES can be specified only after a active dataset is defined.

Operations

- N OF CASES takes effect as soon as it is encountered in the command sequence. Thus, special attention should be paid to the position of N OF CASES among commands. For more information, see Command Order on p. 36.
- N OF CASES limits the number of cases that are analyzed by all subsequent procedures in the session. The active dataset will have no more than *n* cases after the first data pass following the N OF CASES command. Any subsequent N OF CASES command that specifies a greater number of cases will be ignored.
- If N OF CASES specifies more cases than can actually be built, the program builds as many cases as possible.
- If N OF CASES is used with SAMPLE or SELECT IF, the program reads as many records as required to build the specified *n* cases. It makes no difference whether N OF CASES precedes or follows SAMPLE or SELECT IF.

Example

```
GET FILE='/data/city.sav'.
N 100.
```

- `N OF CASES` limits the number of cases on the active dataset to the first 100 cases. Cases are limited for all subsequent analyses.

Example

```
DATA LIST FILE='/data/prsnnl.txt'
  / NAME 1-20 (A) AGE 22-23 SALARY 25-30.
N 25.
SELECT IF (SALARY GT 20000).
LIST.
```

- `DATA LIST` defines variables from file *prsnnl.txt*.
- `N OF CASES` limits the active dataset to 25 cases after cases have been selected by `SELECT IF`.
- `SELECT IF` selects only cases in which *SALARY* is greater than $20,000.
- `LIST` produces a listing of the cases in the active dataset. If the original active dataset has fewer than 25 cases in which *SALARY* is greater than 20,000, fewer than 25 cases will be listed.

Example

```
DATA LIST FILE='/data/prsnnl.txt'
  / NAME 1-20 (A) AGE 22-23 SALARY 25-30 DEPT 32.
LIST.
TEMPORARY.
N 25.
FREQUENCIES VAR=SALARY.
N 50.
FREQUENCIES VAR=AGE.
REPORT FORMAT=AUTO /VARS=NAME AGE SALARY /BREAK=DEPT
  /SUMMARY=MEAN.
```

- The first `N OF CASES` command is temporary. Only 25 cases are used in the first `FREQUENCIES` procedure.
- The second `N OF CASES` command is permanent. The second frequency table and the report are based on 50 cases from file *prsnnl.txt*. The active dataset now contains 50 cases (assuming that the original active dataset had at least that many cases).

NAIVEBAYES

NAIVEBAYES is available in SPSS Server.

```

[/OUTFILE MODEL=file]
```

** Default if the subcommand or keyword is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Release History

Release 14.0

- Command introduced.

Example

```
NAIVEBAYES default.
```

Overview

The NAIVEBAYES procedure can be used in three ways:

1. **Predictor selection followed by model building.** The procedure submits a set of predictor variables and selects a smaller subset. Based on the Naïve Bayes model for the selected predictors, the procedure then classifies cases.
2. **Predictor selection only.** The procedure selects a subset of predictors for use in subsequent predictive modeling procedures but does not report classification results.
3. **Model building only.** The procedure fits the Naïve Bayes classification model by using all input predictors.

NAIVEBAYES is available for categorical dependent variables only and is not intended for use with a very large number of predictors.

Options

Methods. The NAIVEBAYES procedure performs predictor selection followed by model building, or the procedure performs predictor selection only, or the procedure performs model building only.

Training and test data. NAIVEBAYES optionally divides the dataset into training and test samples. Predictor selection uses the training data to compute the underlying model, and either the training or the test data can be used to determine the "best" subset of predictors. If the dataset is partitioned, classification results are given for both the training and test samples. Otherwise, results are given for the training sample only.

Binning. The procedure automatically distributes scale predictors into 10 bins, but the number of bins can be changed.

Memory allocation. The NAIVEBAYES procedure automatically allocates 128MB of memory for storing training records when computing average log-likelihoods. The amount of memory that is allocated for this task can be modified.

Timer. The procedure automatically limits processing time to 5 minutes, but a different time limit can be specified.

Maximum or exact subset size. Either a maximum or an exact size can be specified for the subset of selected predictors. If a maximum size is used, the procedure creates a sequence of subsets, from an initial (smaller) subset to the maximum-size subset. The procedure then selects the "best" subset from this sequence.

Missing values. Cases with missing values for the dependent variable or for all predictors are excluded. The NAIVEBAYES procedure has an option for treating user-missing values of categorical variables as valid. User-missing values of scale variables are always treated as invalid.

Output. NAIVEBAYES displays pivot table output by default but offers an option for suppressing most such output. The procedure displays the lists of selected categorical and scale predictors in a text block. These lists can be copied for use in subsequent modeling procedures. The NAIVEBAYES procedure also optionally saves predicted values and probabilities based on the Naïve Bayes model.

Basic Specification

The basic specification is the NAIVEBAYES command followed by a dependent variable.

By default, NAIVEBAYES treats all variables — except the dependent variable and the weight variable if it is defined — as predictors, with the dictionary setting of each predictor determining its measurement level. NAIVEBAYES selects the "best" subset of predictors (based on the Naïve Bayes model) and then classifies cases by using the selected predictors. User-missing values are excluded and pivot table output is displayed by default.

Syntax Rules

- All subcommands are optional.
- Subcommands may be specified in any order.
- Only a single instance of each subcommand is allowed.
- An error occurs if a keyword is specified more than once within a subcommand.
- Parentheses, equal signs, and slashes that are shown in the syntax chart are required.
- The command name, subcommand names, and keywords must be spelled in full.
- Empty subcommands are not honored.

Operations

The NAIVEBAYES procedure automatically excludes cases and predictors with any of the following properties:

- Cases with a missing value for the dependent variable.
- Cases with missing values for all predictors.
- Predictors with missing values for all cases.
- Predictors with the same value for all cases.

The NAIVEBAYES procedure requires predictors to be categorical. Any scale predictors that are input to the procedure are temporarily binned into categorical variables for the procedure.

If predictor selection is used, the NAIVEBAYES procedure selects a subset of predictors that "best" predict the dependent variable, based on the training data. The procedure first creates a sequence of subsets, with an increasing number of predictors in each subset. The predictor that is added to each subsequent subset is the predictor that increases the average log-likelihood the most. The procedure uses simulated data to compute the average log-likelihood when the training dataset cannot fit into memory.

The final subset is obtained by using one of two approaches:

- By default, a maximum subset size is used. This approach creates a sequence of subsets from the initial subset to the maximum-size subset. The "best" subset is chosen by using a BIC-like criterion or a test data criterion.
- A particular subset size may be used to select the subset with the specified size.

If model building is requested, the NAIVEBAYES procedure classifies cases based on the Naïve Bayes model for the input or selected predictors, depending on whether predictor selection is requested. For a given case, the classification—or predicted category—is the dependent variable category with the highest posterior probability.

The NAIVEBAYES procedure uses the SPSS random number generator in the following two scenarios: (1) if a percentage of cases in the active dataset is randomly assigned to the test dataset, and (2) if the procedure creates simulated data to compute the average log-likelihood when the training records cannot fit into memory. To ensure that the same results are obtained regardless of which scenario is in effect when NAIVEBAYES is invoked repeatedly, specify a seed on the SET command. If a seed is not specified, a default random seed is used, and results may differ across runs of the NAIVEBAYES procedure.

Frequency Weight

If a WEIGHT variable is in effect, its values are used as frequency weights by the NAIVEBAYES procedure.

- Cases with missing weights or weights that are less than 0.5 are not used in the analyses.
- The weight values are rounded to the nearest whole numbers before use. For example, 0.5 is rounded to 1, and 2.4 is rounded to 2.

Limitations

SPLIT FILE settings are ignored by the NAIVEBAYES procedure.

Examples

Predictor selection followed by model building

```
NAIVEBAYES default
  /EXCEPT VARIABLES=preddef1 preddef2 preddef3 training
  /TRAININGSAMPLE VARIABLE=training
  /SAVE PREDVAL PREDPROB.
```

- This analysis specifies *default* as the response variable.
- All other variables are to be considered as possible predictors, with the exception of *preddef1*, *preddef2*, *preddef3*, and *training*.
- Cases with a value of 1 on the variable *training* are assigned to the training sample and used to create the series of predictor subsets, while all other cases are assigned to the test sample and used to select the “best” subset.
- Model-predicted values of *default* are saved to the variable *PredictedValue*.
- Model-estimated probabilities for the values of *default* are saved to the variables *PredictedProbability_1* and *PredictedProbability_2*.

Predictor selection only

```
NAIVEBAYES default
```

```
  /EXCEPT VARIABLES=preddef1 preddef2 preddef3 validate
  /TRAININGSAMPLE VARIABLE=validate
  /SUBSET EXACTSIZE=5
  /PRINT CLASSIFICATION=NO.
```

- The NAIVEBAYES procedure treats *default* as the dependent variable and selects a subset of five predictors from all other variables, with the exception of *preddef1*, *preddef2*, *preddef3*, and *validate*.

Model building only

```
NAIVEBAYES response_01
  BY addresscat callcard callid callwait card card2 churn
      commutecarpool confer ebill edcat equip forward internet
      multline owngame ownipod ownpc spousedcat tollfree voice
  WITH cardmon ed equipmon equipten lncardmon lntollmon
      pets_saltfish spoused tollmon tollten
  /SUBSET NOSELECTION
  /SAVE PREDPROB.
```

- This analysis specifies *response_01* as the response variable.
- Variables following the BY keyword are treated as categorical predictors, while those following the WITH keyword are treated as scale.
- The SUBSET subcommand specifies that the procedure should not perform predictor selection. All specified predictors are to be used in creating the classification.
- Model-estimated probabilities for the values of *response_01* are saved to the variables *PredictedProbability_1* and *PredictedProbability_2*.

Variable Lists

The variable lists specify the dependent variable, any categorical predictors (also known as factors), and any scale predictors (also known as covariates).

- The dependent variable must be the first specification on the NAIVEBAYES command.
- The dependent variable may not be the weight variable.
- The dependent variable is the only required specification on the NAIVEBAYES command.
- The dependent variable must have a dictionary setting of ordinal or nominal. In either case, NAIVEBAYES treats the dependent variable as categorical.
- The names of the factors, if any, must be preceded by the keyword BY.
- If keyword BY is specified with no factors, a warning is issued and the keyword is ignored.
- The names of covariates must be preceded by the keyword WITH.
- If keyword WITH is specified with no covariates, a warning is issued and the keyword is ignored.
- If the dependent variable or the weight variable is specified within a factor list or a covariate list, the variable is ignored in the list.
- All variables that are specified within a factor or covariate list must be unique. If duplicate variables are specified within a list, the duplicates are ignored.

- If duplicate variables are specified across the factor and covariate lists, an error is issued.
- The universal keywords TO and ALL may be specified in the factor and covariate lists.
- If the BY and WITH keywords are not specified, all variables in the active dataset—except the dependent variable, the weight variable, and any variables that are specified on the EXCEPT subcommand—are treated as predictors. If the dictionary setting of a predictor is nominal or ordinal, the predictor is treated as a factor. If the dictionary setting is scale, the predictor is treated as a covariate. (Note that any variables on the FORCE subcommand are still forced into each subset of selected predictors.)
- The dependent variable and factor variables can be numeric or string.
- The covariates must be numeric.

EXCEPT Subcommand

The EXCEPT subcommand lists any variables that the NAIVEBAYES procedure should exclude from the factor or covariate lists on the command line. This subcommand is useful if the factor or covariate lists contain a large number of variables—specified by using the TO or ALL keyword, for example—but a few variables (e.g., Case ID or a weight variable) should be excluded.

- The EXCEPT subcommand ignores the following types of variables if they are specified: Duplicate variables; the dependent variable; variables that are not specified on the command line's factor or covariate lists; and variables that are specified on the FORCE subcommand.
- There is no default variable list on the EXCEPT subcommand.

FORCE Subcommand

The FORCE subcommand specifies any predictors that will be in the initial predictor subset and all subsequent predictor subsets. The specified predictors are considered important and will be in the final subset irrespective of any other chosen predictors.

- Variables that are specified on the FORCE subcommand do not need to be specified in the variable lists on the command line.
- The FORCE subcommand overrides variable lists on the command line and overrides the EXCEPT subcommand. If a variable specified on the FORCE subcommand is also specified on the command line or the EXCEPT subcommand, the variable is forced into all subsets.
- There is no default list of forced variables; the default initial subset is the empty set.

FACTORS Keyword

The FACTORS keyword specifies any factors that should be forced into each subset.

- If duplicate variables are specified, the duplicates are ignored.
- The specified variables may not include the dependent variable, the weight variable, or any variable that is specified on the COVARIATES keyword.
- Specified variables may be numeric or string.

COVARIATES Keyword

The COVARIATES keyword specifies any covariates that should be forced into each subset.

- If duplicate variables are specified, the duplicates are ignored.
- The specified variables may not include the dependent variable, the weight variable, or any variable that is specified on the FACTORS keyword.
- Specified variables must be numeric.

TRAININGSAMPLE Subcommand

The TRAININGSAMPLE subcommand indicates the method of partitioning the active dataset into training and test samples. You can specify either a percentage of cases to assign to the training sample, or you can specify a variable that indicates whether a case is assigned to the training sample.

- If TRAININGSAMPLE is not specified, all cases in the active dataset are treated as training data records.

PERCENT Keyword

The PERCENT keyword specifies the percentage of cases in the active dataset to randomly assign to the training sample. All other cases are assigned to the test sample. The percentage must be a number that is greater than 0 and less than 100. There is no default percentage.

If a weight variable is defined, the PERCENT keyword may not be used.

VARIABLE Keyword

The VARIABLE keyword specifies a variable that indicates which cases in the active dataset are assigned to the training sample. Cases with a value of 1 on the variable are assigned to the training sample. All other cases are assigned to the test sample.

- The specified variable may not be the dependent variable, the weight variable, any variable that is specified in the factor or covariate lists of the command line, or any variable that is specified in the factor or covariate lists of the FORCE subcommand.
- The variable must be numeric.

SUBSET Subcommand

The SUBSET subcommand gives settings for the subset of selected predictors.

- There are three mutually exclusive settings: (1) specify a maximum subset size and a method of selecting the best subset, (2) specify an exact subset size, or (3) do not specify a selection.
- Only one of the keywords MAXSIZE, EXACTSIZE, or NOSELECTION may be specified. The BESTSUBSET option is available only if MAXSIZE is specified.

MAXSIZE Keyword

The MAXSIZE keyword specifies the maximum subset size to use when creating the sequence of predictor subsets. The MAXSIZE value is the size of the largest subset beyond any predictors that were forced via the FORCE subcommand. If no predictors are forced, the MAXSIZE value is simply the size of the largest subset.

- Value AUTO indicates that the number should be computed automatically. Alternatively, a positive integer may be specified. The integer must be less than or equal to the number of unique predictors on the NAIVEBAYES command.
- By default, MAXSIZE is used and AUTO is the default value.

BESTSUBSET Keyword

The BESTSUBSET keyword indicates the criterion for finding the best subset when a maximum subset size is used.

- This keyword is honored only if the MAXSIZE keyword is in effect and must be given in parentheses immediately following the MAXSIZE specification.

PSEUDOBIC *Use the pseudo-BIC criterion.* The pseudo-BIC criterion is based on the training sample. If the active dataset is not partitioned into training and test samples, PSEUDOBIC is the default. If the active dataset is partitioned, PSEUDOBIC is available but is not the default.

TESTDATA *Use the test data criterion.* The test data criterion is based on the test sample. If the active dataset is partitioned into training and test samples, TESTDATA is the default. If the active dataset is not partitioned, TESTDATA may not be specified.

EXACTSIZE Keyword

The EXACTSIZE keyword specifies a particular subset size to use. The EXACTSIZE value is the size of the subset beyond any predictors forced via the FORCE subcommand. If no predictors are forced, then the EXACTSIZE value is simply the size of the subset.

- A positive integer may be specified. The integer must be less than the number of unique predictors on the NAIVEBAYES command.
- There is no default value.

NOSELECTION Keyword

The NOSELECTION keyword indicates that all predictors that are specified on the NAIVEBAYES command—excluding any predictors that are also specified on the EXCEPT subcommand—are included in the final subset. This specification is useful if the NAIVEBAYES procedure is used for model building but not predictor selection.

CRITERIA Subcommand

The CRITERIA subcommand specifies computational and resource settings for the NAIVEBAYES procedure.

BINS Keyword

The BINS keyword specifies the number of bins to use when dividing the domain of a scale predictor into equal-width bins. A positive integer greater than 1 may be specified. The default is 10.

MEMALLOCATE Keyword

The MEMALLOCATE keyword specifies the maximum amount of memory in megabytes (MB) that the NAIVEBAYES procedure uses to store training data records when computing the average log-likelihood. If the amount of memory that is required to store records is larger, simulated data are used instead.

- Any number that is greater than or equal to 4 may be specified. Consult your system administrator for the largest value that can be specified on your system. The default is 1024.

TIMER Keyword

The TIMER keyword specifies the maximum number of minutes during which the NAIVEBAYES procedure can run. If the time limit is exceeded, the procedure is terminated and no results are given. Any number that is greater than or equal to 0 may be specified. Specifying 0 turns the timer off completely. The default is 5.

MISSING Subcommand

The MISSING subcommand controls whether user-missing values for categorical variables are treated as valid values. By default, user-missing values for categorical variables are treated as invalid.

- User-missing values for scale variables are always treated as invalid.
- System-missing values for any variables are always treated as invalid.

USERMISSING=EXCLUDE	*User-missing values for categorical variables are treated as invalid values.* This setting is the default.
USERMISSING=INCLUDE	*User-missing values for categorical variables are treated as valid values.*

PRINT Subcommand

The PRINT subcommand indicates the statistical output to display.

CPS	*Case processing summary.* The table summarizes the number of cases that are included and excluded in the analysis. This table is shown by default.
EXCLUDED	*Predictors excluded due to missing or constant values for all cases.* The table lists excluded predictors by type (categorical or scale) and the reasons for being excluded.

SUMMARY	*Statistical summary of the sequence of predictor subsets.* This table is shown by default. The SUMMARY keyword is ignored if NOSELECTION is specified on the SUBSET subcommand.
SELECTED	*Selected predictors by type (categorical or scale).* This table is shown by default. The SELECTED keyword is ignored if NOSELECTION is specified on the SUBSET subcommand.
CLASSIFICATION	*Classification table.* The table gives the number of cases that are classified correctly and incorrectly for each dependent variable category. If test data are defined, classification results are given for the training and the test samples. If test data are not defined, classification results are given only for the training sample. This table is shown by default.
NONE	*Suppress all displayed output except the Notes table and any warnings.* This keyword may not be specified with any other keywords.

SAVE Subcommand

The SAVE subcommand writes optional temporary variables to the active dataset.

PREDVAL(varname)	*Predicted value.* The predicted value is the dependent variable category with the highest posterior probability as estimated by the Naïve Bayes model. A valid variable name must be specified. The default variable name is *PredictedValue*.
PREDPROB(rootname:n)	*Predicted probability.* The predicted probabilities of the first *n* categories of the dependent variable are saved. Suffixes are added to the root name to get a group of variable names that correspond to the dependent variable categories. If a root name is specified, it must be a valid variable name. The root name can be followed by a colon and a positive integer that indicates the number of probabilities to save. The default root name is *PredictedProbability*. The default *n* is 25. To specify *n* without a root name, enter a colon before the number.

OUTFILE Subcommand

The OUTFILE subcommand writes the Naïve Bayes model to an XML file. The Naïve Bayes model is based on the training sample even if the active dataset is partitioned into training and test samples.

A valid file name must be specified on the MODEL keyword.

NEW FILE

```
NEW FILE
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Overview

The NEW FILE command clears the active dataset. NEW FILE is used when you want to build a new active dataset by generating data within an input program (see INPUT PROGRAM—END INPUT PROGRAM).

Basic Specification

NEW FILE is always specified by itself. No other keyword is allowed.

Operations

- NEW FILE creates a new, blank active dataset. The command takes effect as soon as it is encountered.
- When you build an active dataset with GET, DATA LIST, or other file-definition commands (such as ADD FILES or MATCH FILES), the active dataset is automatically replaced. It is not necessary to specify NEW FILE.

NLR

NLR and CNLR are available in the Regression Models option.

```
MODEL PROGRAM parameter=value [parameter=value ...]
transformation commands

[DERIVATIVES
transformation commands]

[CLEAR MODEL PROGRAMS]
```

Procedure CNLR (Constrained Nonlinear Regression):

```
[CONSTRAINED FUNCTIONS
transformation commands]

CNLR dependent var

 [/FILE=file]   [/OUTFILE=file]

 [/PRED=varname]

 [/SAVE [PRED] [RESID[(varname)]] [DERIVATIVES] [LOSS]]

 [/CRITERIA=[ITER n] [MITER n] [CKDER {0.5**}]
                                      {n    }
            [ISTEP {1E+20**}] [FPR n] [LFTOL n]
                   {n      }
            [LSTOL n] [STEPLIMIT {2**}] [NFTOL n]
                                 {n  }
            [FTOL n] [OPTOL n] [CRSHTOL {.01**}]]
                                        {n    }

 [/BOUNDS=expression, expression, ...]

 [/LOSS=varname]

 [/BOOTSTRAP [=n]]
```

Procedure NLR (Nonlinear Regression):

```
NLR dependent var

 [/FILE=file]   [/OUTFILE=file]

 [/PRED=varname]

 [/SAVE [PRED] [RESID [(varname)] [DERIVATIVES]]

 [/CRITERIA=[ITER {100**}] [CKDER {0.5**}]
                  {n    }         {n    }
            [SSCON {1E-8**}]  [PCON {1E-8**}]  [RCON {1E-8**}]]
                   {n     }         {n     }         {n     }
```

**Default if the subcommand or keyword is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
MODEL PROGRAM A=.6.
COMPUTE PRED=EXP(A*X).

NLR Y.
```

Overview

Nonlinear regression is used to estimate parameter values and regression statistics for models that are not linear in their parameters. There are two procedures for estimating nonlinear equations. CNLR (constrained nonlinear regression), which uses a sequential quadratic programming algorithm, is applicable for both constrained and unconstrained problems. NLR (nonlinear regression), which uses a Levenberg-Marquardt algorithm, is applicable only for unconstrained problems.

CNLR is more general. It allows linear and nonlinear constraints on any combination of parameters. It will estimate parameters by minimizing any smooth loss function (objective function) and can optionally compute bootstrap estimates of parameter standard errors and correlations. The individual bootstrap parameter estimates can optionally be saved in a separate SPSS data file.

Both programs estimate the values of the parameters for the model and, optionally, compute and save predicted values, residuals, and derivatives. Final parameter estimates can be saved in an SPSS data file and used in subsequent analyses.

CNLR and NLR use much of the same syntax. Some of the following sections discuss features that are common to both procedures. In these sections, the notation [C]NLR means that either the CNLR or NLR procedure can be specified. Sections that apply only to CNLR or only to NLR are clearly identified.

Options

The Model. You can use any number of transformation commands under MODEL PROGRAM to define complex models.

Derivatives. You can use any number of transformation commands under DERIVATIVES to supply derivatives.

Adding Variables to Active Dataset. You can add predicted values, residuals, and derivatives to the active dataset with the SAVE subcommand.

Writing Parameter Estimates to a New Data File. You can save final parameter estimates as an external SPSS data file by using the OUTFILE subcommand; you can retrieve them in subsequent analyses by using the FILE subcommand.

Controlling Model-Building Criteria. You can control the iteration process that is used in the regression with the CRITERIA subcommand.

Additional CNLR Controls. For CNLR, you can impose linear and nonlinear constraints on the parameters with the BOUNDS subcommand. Using the LOSS subcommand, you can specify a loss function for CNLR to minimize and, using the BOOTSTRAP subcommand, you can provide bootstrap estimates of the parameter standard errors, confidence intervals, and correlations.

Basic Specification

The basic specification requires three commands: MODEL PROGRAM, COMPUTE (or any other computational transformation command), and [C]NLR.

- The MODEL PROGRAM command assigns initial values to the parameters and signifies the beginning of the model program.
- The computational transformation command generates a new variable to define the model. The variable can take any legitimate name, but if the name is not *PRED*, the PRED subcommand will be required.
- The [C]NLR command provides the regression specifications. The minimum specification is the dependent variable.
- By default, the residual sum of squares and estimated values of the model parameters are displayed for each iteration. Statistics that are generated include regression and residual sums of squares and mean squares, corrected and uncorrected total sums of squares, R^2, parameter estimates with their asymptotic standard errors and 95% confidence intervals, and an asymptotic correlation matrix of the parameter estimates.

Command Order

- The model program, beginning with the MODEL PROGRAM command, must precede the [C]NLR command.
- The derivatives program (when used), beginning with the DERIVATIVES command, must follow the model program but precede the [C]NLR command.
- The constrained functions program (when used), beginning with the CONSTRAINED FUNCTIONS command, must immediately precede the CNLR command. The constrained functions program cannot be used with the NLR command.
- The CNLR command must follow the block of transformations for the model program and the derivatives program when specified; the CNLR command must also follow the constrained functions program when specified.
- Subcommands on [C]NLR can be named in any order.

Syntax Rules

- The FILE, OUTFILE, PRED, and SAVE subcommands work the same way for both CNLR and NLR.
- The CRITERIA subcommand is used by both CNLR and NLR, but iteration criteria are different. Therefore, the CRITERIA subcommand is documented separately for CNLR and NLR.
- The BOUNDS, LOSS, and BOOTSTRAP subcommands can be used only with CNLR. They cannot be used with NLR.

Operations

- By default, the predicted values, residuals, and derivatives are created as temporary variables. To save these variables, use the SAVE subcommand.

Weighting Cases

- If case weighting is in effect, [C]NLR uses case weights when calculating the residual sum of squares and derivatives. However, the degrees of freedom in the ANOVA table are always based on unweighted cases.
- When the model program is first invoked for each case, the weight variable's value is set equal to its value in the active dataset. The model program may recalculate that value. For example, to effect a robust estimation, the model program may recalculate the weight variable's value as an inverse function of the residual magnitude. [C]NLR uses the weight variable's value after the model program is executed.

Missing Values

Cases with missing values for any of the dependent or independent variables that are named on the [C]NLR command are excluded.

- Predicted values, but not residuals, can be calculated for cases with missing values on the dependent variable.
- [C]NLR ignores cases that have missing, negative, or zero weights. The procedure displays a warning message if it encounters any negative or zero weights at any time during its execution.
- If a variable that is used in the model program or the derivatives program is omitted from the independent variable list on the [C]NLR command, the predicted value and some or all of the derivatives may be missing for every case. If this situation happens, an error message is generated.

Example

```
MODEL PROGRAM A=.5 B=1.6.
COMPUTE PRED=A*SPEED**B.

DERIVATIVES.
COMPUTE D.A=SPEED**B.
COMPUTE D.B=A*LN(SPEED)*SPEED**B.

NLR STOP.
```

- MODEL PROGRAM assigns values to the model parameters *A* and *B*.
- COMPUTE generates the variable *PRED* to define the nonlinear model using parameters *A* and *B* and the variable *SPEED* from the active dataset. Because this variable is named *PRED*, the PRED subcommand is not required on NLR.
- DERIVATIVES indicates that calculations for derivatives are being supplied.
- The two COMPUTE statements on the DERIVATIVES transformations list calculate the derivatives for the parameters *A* and *B*. If either parameter had been omitted, NLR would have calculated it numerically.
- NLR specifies *STOP* as the dependent variable. It is not necessary to specify *SPEED* as the independent variable because it has been used in the model and derivatives programs.

MODEL PROGRAM Command

The MODEL PROGRAM command assigns initial values to the parameters and signifies the beginning of the model program. The model program specifies the nonlinear equation that is chosen to model the data. There is no default model.

- The model program is required and must precede the [C]NLR command.
- The MODEL PROGRAM command must specify all parameters in the model program. Each parameter must be individually named. Keyword TO is not allowed.
- Parameters can be assigned any acceptable variable name. However, if you intend to write the final parameter estimates to a file with the OUTFILE subcommand, do not use the name *SSE* or *NCASES* (see OUTFILE Subcommand on p. 1230).
- Each parameter in the model program must have an assigned value. The value can be specified on MODEL PROGRAM or read from an existing parameter data file named on the FILE subcommand.
- Zero should be avoided as an initial value because it provides no information about the scale of the parameters. This situation is especially true for CNLR.
- The model program must include at least one command that uses the parameters and the independent variables (or preceding transformations of these) to calculate the predicted value of the dependent variable. This predicted value defines the nonlinear model. There is no default model.
- By default, the program assumes that *PRED* is the name assigned to the variable for the predicted values. If you use a different variable name in the model program, you must supply the name on the PRED subcommand (see PRED Subcommand on p. 1231).
- In the model program, you can assign a label to the variable holding predicted values and also change its print and write formats, but you should not specify missing values for this variable.
- You can use any computational commands (such as COMPUTE, IF, DO IF, LOOP, END LOOP, END IF, RECODE, or COUNT) or output commands (WRITE, PRINT, or XSAVE) in the model program, but you cannot use input commands (such as DATA LIST, GET, MATCH FILES, or ADD FILES).
- Transformations in the model program are used only by [C]NLR, and they do not affect the active dataset. The parameters that are created by the model program do not become a part of the active dataset. Permanent transformations should be specified before the model program.

Caution: Initial Values

The selection of good initial values for the parameters in the model program is very important to the operation of [C]NLR. The selection of poor initial values can result in no solution, a local solution rather than a general solution, or a physically impossible solution.

Example

```
MODEL PROGRAM A=10 B=1 C=5 D=1.
COMPUTE PRED= A*exp(B*X) + C*exp(D*X).
```

- The MODEL PROGRAM command assigns starting values to the four parameters *A, B, C,* and *D*.
- COMPUTE defines the model to be fit as the sum of two exponentials.

DERIVATIVES Command

The optional DERIVATIVES command signifies the beginning of the derivatives program. The derivatives program contains transformation statements for computing some or all of the derivatives of the model. The derivatives program must follow the model program but precede the [C]NLR command.

If the derivatives program is not used, [C]NLR numerically estimates derivatives for all the parameters. Providing derivatives reduces computation time and, in some situations, may result in a better solution.

- The DERIVATIVES command has no further specifications but must be followed by the set of transformation statements that calculate the derivatives.
- You can use any computational commands (such as COMPUTE, IF, DO IF, LOOP, END LOOP, END IF, RECODE, or COUNT) or output commands (WRITE, PRINT, or XSAVE) in the derivatives program, but you cannot use input commands (such as DATA LIST, GET, MATCH FILES, or ADD FILES).
- To name the derivatives, specify the prefix *D.* before each parameter name. For example, the derivative name for the parameter *PARM1* must be *D.PARM1*.
- When a derivative has been calculated by a transformation, the variable for that derivative can be used in subsequent transformations.
- You do not need to supply all of the derivatives. Those derivatives that are not supplied will be estimated by the program. During the first iteration of the nonlinear estimation procedure, derivatives that are calculated in the derivatives program are compared with numerically calculated derivatives. This process serves as a check on the supplied values (see CRITERIA Subcommand on p. 1233).
- Transformations in the derivatives program are used by [C]NLR only and do not affect the active dataset.
- For NLR, the derivative of each parameter must be computed with respect to the predicted function (see LOSS Subcommand on p. 1237).

Example

```
MODEL PROGRAM A=1, B=0, C=1, D=0
COMPUTE PRED = AeBx + CeDx
DERIVATIVES.
COMPUTE D.A = exp (B * X).
COMPUTE D.B = A * exp (B * X) * X.
COMPUTE D.C = exp (D * X).
COMPUTE D.D = C * exp (D * X) * X.
```

- The derivatives program specifies derivatives of the PRED function for the sum of the two exponentials in the model described by the following equation:

$$Y=Ae^{Bx}+Ce^{Dx}$$

Example

```
DERIVATIVES.
COMPUTE D.A = exp (B * X).
COMPUTE D.B = A * X * D.A.
COMPUTE D.C = exp (D * X).
COMPUTE D.D = C * X * D.C.
```

- This example is an alternative way to express the same derivatives program that was specified in the previous example.

CONSTRAINED FUNCTIONS Command

The optional CONSTRAINED FUNCTIONS command signifies the beginning of the constrained functions program, which specifies nonlinear constraints. The constrained functions program is specified after the model program and the derivatives program (when used). It can only be used with, and must precede, the CNLR command. For more information, see BOUNDS Subcommand on p. 1236.

Example

```
MODEL PROGRAM A=.5 B=1.6.
COMPUTE PRED=A*SPEED**B.

CONSTRAINED FUNCTIONS.
COMPUTE CF=A-EXP(B).

CNLR STOP
  /BOUNDS CF LE 0.
```

CLEAR MODEL PROGRAMS Command

CLEAR MODEL PROGRAMS deletes all transformations that are associated with the previously submitted model program, derivative program, and/or constrained functions program. It is primarily used in interactive mode to remove temporary variables that were created by these programs without affecting the active dataset or variables that were created by other transformation programs or temporary programs. It allows you to specify new models, derivatives, or constrained functions without having to run [C]NLR.

It is not necessary to use this command if you have already executed the [C]NLR procedure. Temporary variables that are associated with the procedure are automatically deleted.

CNLR and NLR Commands

Either the CNLR or the NLR command is required to specify the dependent and independent variables for the nonlinear regression.

- For either CNLR or NLR, the minimum specification is a dependent variable.
- Only one dependent variable can be specified. It must be a numeric variable in the active dataset and cannot be a variable that is generated by the model or the derivatives program.

OUTFILE Subcommand

OUTFILE stores final parameter estimates for use on a subsequent [C]NLR command. The only specification on OUTFILE is the target file. Some or all of the values from this file can be read into a subsequent [C]NLR procedure with the FILE subcommand. The parameter data file that is created by OUTFILE stores the following variables:

- All of the split-file variables. OUTFILE writes one case of values for each split-file group in the active dataset.
- All of the parameters named on the MODEL PROGRAM command.
- The labels, formats, and missing values of the split-file variables and parameters defined for them previous to their use in the [C]NLR procedure.
- The sum of squared residuals (named *SSE*). *SSE* has no labels or missing values. The print and write format for *SSE* is F10.8.
- The number of cases on which the analysis was based (named *NCASES*). *NCASES* has no labels or missing values. The print and write format for *NCASES* is F8.0.

When OUTFILE is used, the model program cannot create variables named *SSE* or *NCASES*.

Example

```
MODEL PROGRAM A=.5 B=1.6.
COMPUTE PRED=A*SPEED**B.
NLR STOP /OUTFILE=PARAM.
```

- OUTFILE generates a parameter data file containing one case for four variables: *A*, *B*, *SSE*, and *NCASES*.

FILE Subcommand

FILE reads starting values for the parameters from a parameter data file that was created by an OUTFILE subcommand from a previous [C]NLR procedure. When starting values are read from a file, they do not have to be specified on the MODEL PROGRAM command. Rather, the MODEL PROGRAM command simply names the parameters that correspond to the parameters in the data file.

- The only specification on FILE is the file that contains the starting values.
- Some new parameters may be specified for the model on the MODEL PROGRAM command while other parameters are read from the file that is specified on the FILE subcommand.
- You do not have to name the parameters on MODEL PROGRAM in the order in which they occur in the parameter data file. In addition, you can name a partial list of the variables that are contained in the file.
- If the starting value for a parameter is specified on MODEL PROGRAM, the specification overrides the value that is read from the parameter data file.
- If split-file processing is in effect, the starting values for the first subfile are taken from the first case of the parameter data file. Subfiles are matched with cases in order until the starting-value file runs out of cases. All subsequent subfiles use the starting values for the last case.

- To read starting values from a parameter data file and then replace those values with the final results from [C]NLR, specify the same file on the FILE and OUTFILE subcommands. The input file is read completely before anything is written in the output file.

Example

```
MODEL PROGRAM A B C=1 D=3.
COMPUTE PRED=A*SPEED**B + C*SPEED**D.
NLR STOP /FILE=PARAM /OUTFILE=PARAM.
```

- MODEL PROGRAM names four of the parameters that are used to calculate *PRED* but assigns values to only *C* and *D*. The values of *A* and *B* are read from the existing data file *PARAM*.
- After NLR computes the final estimates of the four parameters, OUTFILE writes over the old input file. If, in addition to these new final estimates, the former starting values of *A* and *B* are still desired, specify a different file on the OUTFILE subcommand.

PRED Subcommand

PRED identifies the variable holding the predicted values.

- The only specification is a variable name, which must be identical to the variable name that is used to calculate predicted values in the model program.
- If the model program names the variable *PRED*, the PRED subcommand can be omitted. Otherwise, the PRED subcommand is required.
- The variable for predicted values is not saved in the active dataset unless the SAVE subcommand is used.

Example

```
MODEL PROGRAM A=.5 B=1.6.
COMPUTE PSTOP=A*SPEED**B.
NLR STOP /PRED=PSTOP.
```

- COMPUTE in the model program creates a variable named *PSTOP* to temporarily store the predicted values for the dependent variable *STOP*.
- PRED identifies *PSTOP* as the variable that is used to define the model for the NLR procedure.

SAVE Subcommand

SAVE is used to save the temporary variables for the predicted values, residuals, and derivatives that are created by the model and the derivatives programs.

- The minimum specification is a single keyword.
- The variables to be saved must have unique names on the active dataset. If a naming conflict exists, the variables are not saved.
- Temporary variables—for example, variables that are created after a TEMPORARY command and parameters that are specified by the model program—are not saved in the active dataset. They will not cause naming conflicts.

The following keywords are available and can be used in any combination and in any order. The new variables are always appended to the active dataset in the order in which these keywords are presented here:

PRED *Save the predicted values.* The variable's name, label, and formats are those specified for it (or assigned by default) in the model program.

RESID [(varname)] *Save the residuals variable.* You can specify a variable name in parentheses following the keyword. If no variable name is specified, the name of this variable is the same as the specification that you use for this keyword. For example, if you use the three-character abbreviation `RES`, the default variable name will be *RES*. The variable has the same print and write format as the predicted values variable that is created by the model program. It has no variable label and no user-defined missing values. It is system-missing for any case in which either the dependent variable is missing or the predicted value cannot be computed.

DERIVATIVES *Save the derivative variables.* The derivative variables are named with the prefix *D.* to the first six characters of the parameter names. Derivative variables use the print and write formats of the predicted values variable and have no value labels or user-missing values. Derivative variables are saved in the same order as the parameters named on `MODEL PROGRAM`. Derivatives are saved for all parameters, whether or not the derivative was supplied in the derivatives program.

LOSS *Save the user-specified loss function variable.* This specification is available only with `CNLR` and only if the `LOSS` subcommand has been specified.

Asymptotic standard errors of predicted values and residuals, and special residuals used for outlier detection and influential case analysis are not provided by the `[C]NLR` procedure. However, for a squared loss function, the asymptotically correct values for all these statistics can be calculated by using the `SAVE` subcommand with `[C]NLR` and then using the `REGRESSION` procedure. In `REGRESSION`, the dependent variable is still the same, and derivatives of the model parameters are used as independent variables. Casewise plots, standard errors of prediction, partial regression plots, and other diagnostics of the regression are valid for the nonlinear model.

Example

```
MODEL PROGRAM A=.5 B=1.6.
COMPUTE PSTOP=A*SPEED**B.
NLR STOP /PRED=PSTOP
  /SAVE=RESID(RSTOP) DERIVATIVES PRED.
REGRESSION VARIABLES=STOP D.A D.B /ORIGIN
  /DEPENDENT=STOP /ENTER D.A D.B /RESIDUALS.
```

- The `SAVE` subcommand creates the residuals variable *RSTOP* and the derivative variables *D.A* and *D.B*.
- Because the `PRED` subcommand identifies *PSTOP* as the variable for predicted values in the nonlinear model, keyword `PRED` on `SAVE` adds the variable *PSTOP* to the active dataset.
- The new variables are added to the active dataset in the following order: *PSTOP, RSTOP, D.A,* and *D.B*.
- The subcommand `RESIDUALS` for `REGRESSION` produces the default analysis of residuals.

CRITERIA Subcommand

CRITERIA controls the values of the cutoff points that are used to stop the iterative calculations in [C]NLR.

- The minimum specification is any of the criteria keywords and an appropriate value. The value can be specified in parentheses after an equals sign, a space, or a comma. Multiple keywords can be specified in any order. Defaults are in effect for keywords that are not specified.
- Keywords available for CRITERIA differ between CNLR and NLR and are discussed separately. However, with both CNLR and NLR, you can specify the critical value for derivative checking.

Checking Derivatives for CNLR and NLR

Upon entering the first iteration, [C]NLR always checks any derivatives that are calculated on the derivatives program by comparing them with numerically calculated derivatives. For each comparison, it computes an agreement score. A score of 1 indicates agreement to machine precision; a score of 0 indicates definite disagreement. If a score is less than 1, either an incorrect derivative was supplied or there were numerical problems in estimating the derivative. The lower the score, the more likely it is that the supplied derivatives are incorrect. Highly correlated parameters may cause disagreement even when a correct derivative is supplied. Be sure to check the derivatives if the agreement score is not 1.

During the first iteration, [C]NLR checks each derivative score. If any score is below 1, it begins displaying a table to show the worst (lowest) score for each derivative. If any score is below the critical value, the program stops.

To specify the critical value, use the following keyword on CRITERIA:

CKDER n — *Critical value for derivative checking.* Specify a number between 0 and 1 for *n*. The default is 0.5. Specify 0 to disable this criterion.

Iteration Criteria for CNLR

The CNLR procedure uses NPSOL (Version 4.0) Fortran Package for Nonlinear Programming (Gill, Murray, Saunders, and Wright, 1986). The CRITERIA subcommand of CNLR gives the control features of NPSOL. The following section summarizes the NPSOL documentation.

CNLR uses a sequential quadratic programming algorithm, with a quadratic programming subproblem to determine the search direction. If constraints or bounds are specified, the first step is to find a point that is feasible with respect to those constraints. Each major iteration sets up a quadratic program to find the search direction, *p*. Minor iterations are used to solve this subproblem. Then, the major iteration determines a steplength α by a line search, and the function is evaluated at the new point. An optimal solution is found when the optimality tolerance criterion is met.

The CRITERIA subcommand has the following keywords when used with CNLR:

ITER n *Maximum number of major iterations.* Specify any positive integer for *n*. The default is max(50, $3(p+m_L)+10m_N$), where *p* is the number of parameters, m_L is the number of linear constraints, and m_N is the number of nonlinear constraints. If the search for a solution stops because this limit is exceeded, CNLR issues a warning message.

MINORITERATION n *Maximum number of minor iterations.* Specify any positive integer. This value is the number of minor iterations allowed within each major iteration. The default is max(50, $3(n+m_L+m_N)$).

CRSHTOL n *Crash tolerance.* CRSHTOL is used to determine whether initial values are within their specified bounds. Specify any value between 0 and 1. The default value is 0.01. A constraint of the form $a'X \geq l$ is considered a valid part of the working set if |*a*'*X*-*l*|<CRSHTOL(1+|*l*|).

STEPLIMIT n *Step limit.* The CNLR algorithm does not allow changes in the length of the parameter vector to exceed a factor of *n*. The limit prevents very early steps from going too far from good initial estimates. Specify any positive value. The default value is 2.

FTOLERANCE n *Feasibility tolerance.* This value is the maximum absolute difference allowed for both linear and nonlinear constraints for a solution to be considered feasible. Specify any value greater than 0. The default value is the square root of your machine's epsilon.

LFTOLERANCE n *Linear feasibility tolerance.* If specified, this value overrides FTOLERANCE for linear constraints and bounds. Specify any value greater than 0. The default value is the square root of your machine's epsilon.

NFTOLERANCE n *Nonlinear feasibility tolerance.* If specified, this value overrides FTOLERANCE for nonlinear constraints. Specify any value greater than 0. The default value is the square root of your machine's epsilon.

LSTOLERANCE n *Line search tolerance.* This value must be between 0 and 1 (but not including 1). It controls the accuracy required of the line search that forms the innermost search loop. The default value, 0.9, specifies an inaccurate search. This setting is appropriate for many problems, particularly if nonlinear constraints are involved. A smaller positive value, corresponding to a more accurate line search, may give better performance if there are no nonlinear constraints, all (or most) derivatives are supplied in the derivatives program, and the data fit in memory.

OPTOLERANCE n *Optimality tolerance.* If an iteration point is a feasible point, and the next step will not produce a relative change in either the parameter vector or the objective function of more than the square root of OPTOLERANCE, an optimal solution has been found. OPTOLERANCE can also be thought of as the number of significant digits in the objective function at the solution. For example, if OPTOLERANCE=10^{-6}, the objective function should have approximately six significant digits of accuracy. Specify any number between the FPRECISION value and 1. The default value for OPTOLERANCE is epsilon**0.8.

FPRECISION n *Function precision.* This measure is a measure of the accuracy with which the objective function can be checked. It acts as a relative precision when the function is large and an absolute precision when the function is small. For example, if the objective function is larger than 1, and six significant digits are desired, FPRECISION should be 1E-6. If, however, the objective function is of the order 0.001, FPRECISION should be 1E-9 to get six digits of accuracy. Specify any number between 0 and 1. The choice of FPRECISION can be very complicated for a badly scaled problem. Chapter 8 of Gill et al. (1981) gives some scaling suggestions. The default value is epsilon**0.9.

ISTEP n *Infinite step size.* This value is the magnitude of the change in parameters that is defined as infinite. That is, if the change in the parameters at a step is greater than ISTEP, the problem is considered unbounded, and estimation stops. Specify any positive number. The default value is 1E+20.

Iteration Criteria for NLR

The NLR procedure uses an adaptation of subroutine LMSTR from the MINPACK package by Garbow et al. Because the NLR algorithm differs substantially from CNLR, the CRITERIA subcommand for NLR has a different set of keywords.

NLR computes parameter estimates by using the Levenberg-Marquardt method. At each iteration, NLR evaluates the estimates against a set of control criteria. The iterative calculations continue until one of five cutoff points is met, at which point the iterations stop and the reason for stopping is displayed.

The CRITERIA subcommand has the following keywords when used with NLR:

ITER n *Maximum number of major and minor iterations allowed.* Specify any positive integer for *n*. The default is 100 iterations per parameter. If the search for a solution stops because this limit is exceeded, NLR issues a warning message.

SSCON n *Convergence criterion for the sum of squares.* Specify any non-negative number for *n*. The default is 1E-8. If successive iterations fail to reduce the sum of squares by this proportion, the procedure stops. Specify 0 to disable this criterion.

PCON n *Convergence criterion for the parameter values.* Specify any non-negative number for *n*. The default is 1E-8. If successive iterations fail to change any of the parameter values by this proportion, the procedure stops. Specify 0 to disable this criterion.

RCON n *Convergence criterion for the correlation between the residuals and the derivatives.* Specify any non-negative number for *n*. The default is 1E-8. If the largest value for the correlation between the residuals and the derivatives equals this value, the procedure stops because it lacks the information that it needs to estimate a direction for its next move. This criterion is often referred to as a gradient convergence criterion. Specify 0 to disable this criterion.

Example

```
MODEL PROGRAM A=.5 B=1.6.
COMPUTE PRED=A*SPEED**B.
NLR STOP /CRITERIA=ITER(80) SSCON=.000001.
```

- CRITERIA changes two of the five cutoff values affecting iteration, ITER and SSCON, and leaves the remaining three, PCON, RCON, and CKDER, at their default values.

BOUNDS Subcommand

The BOUNDS subcommand can be used to specify both linear and nonlinear constraints. It can be used only with CNLR; it cannot be used with NLR.

Simple Bounds and Linear Constraints

BOUNDS can be used to impose bounds on parameter values. These bounds can involve either single parameters or a linear combination of parameters and can be either equalities or inequalities.

- All bounds are specified on the same BOUNDS subcommand and are separated by semicolons.
- The only variables that are allowed on BOUNDS are parameter variables (those variables that are named on MODEL PROGRAM).
- Only * (multiplication), + (addition), - (subtraction), = or EQ, >= or GE, and <= or LE can be used. When two relational operators are used (as in the third bound in the example below), they must both be in the same direction.

Example

```
/BOUNDS 5 >= A;
        B >= 9;
        .01 <= 2*A + C <= 1;
        D + 2*E = 10
```

- BOUNDS imposes bounds on the parameters *A, B, C,* and *D*. Specifications for each parameter are separated by a semicolon.

Nonlinear Constraints

Nonlinear constraints on the parameters can also be specified with the BOUNDS subcommand. The constrained function must be calculated and stored in a variable by a constrained functions program directly preceding the CNLR command. The constraint is then specified on the BOUNDS subcommand.

In general, nonlinear bounds will not be obeyed until an optimal solution has been found. This process is different from simple and linear bounds, which are satisfied at each iteration. The constrained functions must be smooth near the solution.

Example

```
MODEL PROGRAM A=.5 B=1.6.
COMPUTE PRED=A*SPEED**B.

CONSTRAINED FUNCTIONS.
COMPUTE DIFF=A-10**B.

CNLR STOP /BOUNDS DIFF LE 0.
```

- The constrained function is calculated by a constrained functions program and stored in variable *DIFF*. The constrained functions program immediately precedes CNLR.

- BOUNDS imposes bounds on the function (less than or equal to 0).
- CONSTRAINED FUNCTIONS variables and parameters that are named on MODEL PROGRAM cannot be combined in the same BOUNDS expression. For example, you *cannot* specify (DIFF + A) >= 0 on the BOUNDS subcommand.

LOSS Subcommand

LOSS specifies a loss function for CNLR to minimize. By default, CNLR minimizes the sum of squared residuals. LOSS can be used only with CNLR; it cannot be used with NLR.

- The loss function must first be computed in the model program. LOSS is then used to specify the name of the computed variable.
- The minimizing algorithm may fail if it is given a loss function that is not smooth, such as the absolute value of residuals.
- If derivatives are supplied, the derivative of each parameter must be computed with respect to the loss function, rather than the predicted value. The easiest way to do this is in two steps: First compute derivatives of the model, and then compute derivatives of the loss function with respect to the model and multiply by the model derivatives.
- When LOSS is used, the usual summary statistics are not computed. Standard errors, confidence intervals, and correlations of the parameters are available only if the BOOTSTRAP subcommand is specified.

Example

```
MODEL PROGRAM  A=1 B=1.
COMPUTE PRED=EXP(A+B*T)/(1+EXP(A+B*T)).
COMPUTE LOSS=-W*(Y*LN(PRED)+(1-Y)*LN(1-PRED)).

DERIVATIVES.
COMPUTE D.A=PRED/(1+EXP(A+B*T)).
COMPUTE D.B=T*PRED/(1+EXP(A+B*T)).
COMPUTE D.A=(-W*(Y/PRED - (1-Y)/(1-PRED)) * D.A).
COMPUTE D.B=(-W*(Y/PRED - (1-Y)/(1-PRED)) * D.B).

CNLR Y /LOSS=LOSS.
```

- The second COMPUTE command in the model program computes the loss function and stores its values in the variable *LOSS*, which is then specified on the LOSS subcommand.
- Because derivatives are supplied in the derivatives program, the derivatives of all parameters are computed with respect to the loss function, rather than the predicted value.

BOOTSTRAP Subcommand

BOOTSTRAP provides bootstrap estimates of the parameter standard errors, confidence intervals, and correlations. BOOTSTRAP can be used only with CNLR; it cannot be used with NLR.

Bootstrapping is a way of estimating the standard error of a statistic, using repeated samples from the original data set. This process is done by sampling with replacement to get samples of the same size as the original data set.

- The minimum specification is the subcommand keyword. Optionally, specify the number of samples to use for generating bootstrap results.
- By default, BOOTSTRAP generates bootstrap results based on 10*p*(p+1)/2 samples, where p is the number of parameters. That is, 10 samples are drawn for each statistic (standard error or correlation) to be calculated.
- When BOOTSTRAP is used, the nonlinear equation is estimated for each sample. The standard error of each parameter estimate is then calculated as the standard deviation of the bootstrapped estimates. Parameter values from the original data are used as starting values for each bootstrap sample. Even so, bootstrapping is computationally expensive.
- If the OUTFILE subcommand is specified, a case is written to the output file for each bootstrap sample. The first case in the file will be the actual parameter estimates, followed by the bootstrap samples. After the first case is eliminated (using SELECT IF), other procedures (such as FREQUENCIES) can be used to examine the bootstrap distribution.

Example

```
MODEL PROGRAM A=.5 B=1.6.
COMPUTE PSTOP=A*SPEED**B.
CNLR STOP /BOOTSTRAP /OUTFILE=PARAM.
GET FILE=PARAM.
LIST.
COMPUTE ID=$CASENUM.
SELECT IF (ID > 1).
FREQUENCIES A B /FORMAT=NOTABLE /HISTOGRAM.
```

- CNLR generates the bootstrap standard errors, confidence intervals, and parameter correlation matrix. OUTFILE saves the bootstrap estimates in the file *PARAM*.
- GET retrieves the system file *PARAM*.
- LIST lists the different sample estimates, along with the original estimate. *NCASES* in the listing (see OUTFILE Subcommand on p. 1230) refers to the number of distinct cases in the sample because cases are duplicated in each bootstrap sample.
- FREQUENCIES generates histograms of the bootstrapped parameter estimates.

```

** Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Release History

Release 13.0

- ENTRYMETHOD keyword introduced on STEPWISE subcommand.
- REMOVALMETHOD keyword introduced on STEPWISE subcommand.
- IC keyword introduced on PRINT subcommand.

Release 15.0

- ASSOCIATION keyword introduced on PRINT subcommand.

Example

```
NOMREG response.
```

Overview

NOMREG is a procedure for fitting a multinomial logit model to a polytomous nominal dependent variable.

Options

Tuning the algorithm. You can control the values of algorithm-tuning parameters with the CRITERIA subcommand.

Optional output. You can request additional output through the PRINT subcommand.

Exporting the model. You can export the model to an external file. The model information will be written using the Extensible Markup Language (XML).

Basic Specification

The basic specification is one dependent variable.

Syntax Rules

- Minimum syntax—at least one dependent variable must be specified.
- The variable specification must come first.
- Subcommands can be specified in any order.
- Empty subcommands except the MODEL subcommand are ignored.
- The MODEL and the FULLFACTORIAL subcommands are mutually exclusive. Only one of them can be specified at any time.
- The MODEL subcommand stepwise options and the TEST subcommand are mutually exclusive. Only one of them can be specified at any time.

- When repeated subcommands except the TEST subcommand are specified, all specifications except the last valid one are discarded.
- The following words are reserved as keywords or internal commands in the NOMREG procedure: BY, WITH, and WITHIN.
- The set of factors and covariates used in the MODEL subcommand (or implied on the FULLFACTORIAL subcommand) must be a subset of the variable list specified or implied on the SUBPOP subcommand.

Variable List

The variable list specifies the dependent variable and the factors in the model.

- The dependent variable must be the first specification on NOMREG. It can be of any type (numeric or string). Values of the dependent variable are sorted according to the ORDER specification.

ORDER = ASCENDING	*Response categories are sorted in ascending order.* The lowest value defines the first category, and the highest value defines the last category.
ORDER = DATA	*Response categories are not sorted.* The first value encountered in the data defines the first category. The last distinct value defines the last category.
ORDER = DESCENDING	*Response categories are sorted in descending order.* The highest value defines the first category, and the lowest value defines the last category.

- By default, the last response category is used as the base (or reference) category. No model parameters are assigned to the base category. Use the BASE attribute to specify a custom base category.

BASE = FIRST	*The first category is the base category.*
BASE = LAST	*The last category is the base category.*
BASE = value	*The category with the specified value is the base category.* Put the value inside a pair of quotes if either the value is formatted (such as date or currency) or if the dependent variable is the string type.

- Factor variables can be of any type (numeric or string). The factors follow the dependent variable separated by the keyword BY.
- Covariate variables must be numeric. The covariates follow the factors, separated by the keyword WITH.
- Listwise deletion is used. If any variables in a case contain missing values, that case will be excluded.
- If the WEIGHT command was specified, the actual weight values are used for the respective category combination. No rounding or truncation will be done. However, cases with negative and zero weight values are excluded from the analyses.

Example

```
NOMREG response (ORDER = DESCENDING BASE='No') BY factor1.
```

- Values of the variable *response* are sorted in descending order, and the category whose value is *No* is the base category.

Example

```
NOMREG
  movie  BY gender date
  /CRITERIA = CIN(95) DELTA(0) MXITER(100) MXSTEP(5) LCONVERGE(0)
              PCONVERGE(0)
  /INTERCEPT = EXCLUDE
  /PRINT = CLASSTABLE FIT PARAMETER SUMMARY LRT .
```

- The dependent variable is *movie*, and *gender* and *date* are factors.
- `CRITERIA` specifies that the confidence level to use is 95, no delta value should be added to cells with observed zero frequency, and neither the log-likelihood nor parameter estimates convergence criteria should be used. This means that the procedure will stop when either 100 iterations or five step-halving operations have been performed.
- `INTERCEPT` specifies that the intercept should be excluded from the model.
- `PRINT` specifies that the classification table, goodness-of-fit statistics, parameter statistics, model summary, and likelihood-ratio tests should be displayed.

CRITERIA Subcommand

The `CRITERIA` subcommand offers controls on the iterative algorithm used for estimation and specifies numerical tolerance for checking singularity.

BIAS(n) *Bias value added to observed cell frequency.* Specify a non-negative value less than 1. The default value is 0.

CHKSEP(n) *Starting iteration for checking for complete separation.* Specify a non-negative integer. The default value is 20.

CIN(n) *Confidence interval level.* Specify a value greater than or equal to 0 and less than 100. The default value is 95.

DELTA(n) *Delta value added to zero cell frequency.* Specify a non-negative value less than 1. The default value is 0.

LCONVERGE(n) *Log-likelihood function convergence criterion.* Convergence is assumed if the absolute change in the log-likelihood function is less than this value. The criterion is not used if the value is 0. Specify a non-negative value. The default value is 0.

MXITER(n) *Maximum number of iterations.* Specify a positive integer. The default value is 100.

MXSTEP(n) *Maximum step-halving allowed.* Specify a positive integer. The default value is 5.

PCONVERGE(a) *Parameter estimates convergence criterion.* Convergence is assumed if the absolute change in the parameter estimates is less than this value. The criterion is not used if the value is 0. Specify a non-negative value. The default value is 10^{-6}.

SINGULAR(a) *Value used as tolerance in checking singularity.* Specify a positive value. The default value is 10^{-8}.

FULLFACTORIAL Subcommand

The FULLFACTORIAL subcommand generates a specific model: first, the intercept (if included); second, all of the covariates (if specified), in the order in which they are specified; next, all of the main factorial effects; next, all of the two-way factorial interaction effects, all of the three-way factorial interaction effects, and so on, up to the highest possible interaction effect.

- The FULLFACTORIAL and the MODEL subcommands are mutually exclusive. Only one of them can be specified at any time.
- The FULLFACTORIAL subcommand does not take any keywords.

INTERCEPT Subcommand

The INTERCEPT subcommand controls whether intercept terms are included in the model. The number of intercept terms is the number of response categories less one.

INCLUDE *Includes the intercept terms.* This is the default.

EXCLUDE *Excludes the intercept terms.*

MISSING Subcommand

By default, cases with missing values for any of the variables on the NOMREG variable list are excluded from the analysis. The MISSING subcommand allows you to include cases with user-missing values.

- Note that missing values are deleted at the subpopulation level.

EXCLUDE *Excludes both user-missing and system-missing values.* This is the default.

INCLUDE *User-missing values are treated as valid.* System-missing values cannot be included in the analysis.

MODEL Subcommand

The MODEL subcommand specifies the effects in the model.

- The MODEL and the FULLFACTORIAL subcommands are mutually exclusive. Only one of them can be specified at any time.
- If more than one MODEL subcommand is specified, only the last one is in effect.
- Specify a list of terms to be included in the model, separated by commas or spaces. If the MODEL subcommand is omitted or empty, the default model is generated. The default model contains: first, the intercept (if included); second, all of the covariates (if specified), in the order in which they are specified; and next, all of the main factorial effects, in the order in which they are specified.
- If a SUBPOP subcommand is specified, then effects specified in the MODEL subcommand can only be composed using the variables listed on the SUBPOP subcommand.
- To include a main-effect term, enter the name of the factor on the MODEL subcommand.

- To include an interaction-effect term among factors, use the keyword BY or the asterisk (*) to join factors involved in the interaction. For example, A*B*C means a three-way interaction effect of A, B, and C, where A, B, and C are factors. The expression A BY B BY C is equivalent to A*B*C. Factors inside an interaction effect must be distinct. Expressions such as A*C*A and A*A are invalid.
- To include a nested-effect term, use the keyword WITHIN or a pair of parentheses on the MODEL subcommand. For example, A(B) means that A is nested within B, where A and B are factors. The expression A WITHIN B is equivalent to A(B). Factors inside a nested effect must be distinct. Expressions such as A(A) and A(B*A) are invalid.
- Multiple-level nesting is supported. For example, A(B(C)) means that B is nested within C, and A is nested within B(C). When more than one pair of parentheses is present, each pair of parentheses must be enclosed or nested within another pair of parentheses. Thus, A(B)(C) is not valid.
- Nesting within an interaction effect is valid. For example, A(B*C) means that A is nested within B*C.
- Interactions among nested effects are allowed. The correct syntax is the interaction followed by the common nested effect inside the parentheses. For example, interaction between A and B within levels of C should be specified as A*B(C) instead of A(C)*B(C).
- To include a covariate term in the model, enter the name of the covariate on the MODEL subcommand.
- Covariates can be connected, but not nested, using the keyword BY or the asterisk (*) operator. For example, X*X is the product of X and itself. This is equivalent to a covariate whose values are the square of those of X. However, X(Y) is invalid.
- Factor and covariate effects can be connected in many ways. No effects can be nested within a covariate effect. Suppose A and B are factors, and X and Y are covariates. Examples of valid combination of factor and covariate effects are A*X, A*B*X, X(A), X(A*B), X*A(B), X*Y(A*B), and A*B*X*Y.
- A stepwise method can be specified by following the model effects with a vertical bar (|), a stepwise method keyword, an equals sign (=), and a list of variables (or interactions or nested effects) for which the method is to be used.
- If a stepwise method is specified, then the TEST subcommand is ignored.
- If a stepwise method is specified, then it begins with the results of the model defined on the left side of the MODEL subcommand.
- If a stepwise method is specified but no effects are specified on the left side of the MODEL subcommand, then the initial model contains the intercept only (if INTERCEPT = INCLUDE) or the initial model is the null model (if INTERCEPT = EXCLUDE).
- The intercept cannot be specified as an effect in the stepwise method option.
- For all stepwise methods, if two effects have tied significance levels, then the removal or entry is performed on the effect specified first. For example, if the right side of the MODEL subcommand specifies FORWARD A*B A(B), where A*B and A(B) have the same significance level less than PIN, then A*B is entered because it is specified first.

The available stepwise method keywords are:

BACKWARD *Backward elimination.* As a first step, the variables (or interaction effects or nested effects) specified on BACKWARD are entered into the model together and are tested for removal one by one. The variable with the largest significance level of the likelihood-ratio statistic, provided that the value is larger than POUT, is removed, and the model is reestimated. This process continues until no more variables meet the removal criterion or when the current model is the same as a previous model.

FORWARD *Forward entry.* The variables (or interaction effects or nested effects) specified on FORWARD are tested for entry into the model one by one, based on the significance level of the likelihood-ratio statistic. The variable with the smallest significance level less than PIN is entered into the model, and the model is reestimated. Model building stops when no more variables meet the entry criteria.

BSTEP *Backward stepwise.* As a first step, the variables (or interaction effects or nested effects) specified on BSTEP are entered into the model together and are tested for removal one by one. The variable with the largest significance level of the likelihood-ratio statistic, provided that the value is larger than POUT, is removed, and the model is reestimated. This process continues until no more variables meet the removal criterion. Next, variables not in the model are tested for possible entry, based on the significance level of the likelihood-ratio statistic. The variable with the smallest significance level less than PIN is entered, and the model is reestimated. This process repeats, with variables in the model again evaluated for removal. Model building stops when no more variables meet the removal or entry criteria or when the current model is the same as a previous model.

FSTEP *Forward stepwise.* The variables (or interaction effects or nested effects) specified on FSTEP are tested for entry into the model one by one, based on the significance level of the likelihood-ratio statistic. The variable with the smallest significance level less than PIN is entered into the model, and the model is reestimated. Next, variables that are already in the model are tested for removal, based on the significance level of the likelihood-ratio statistic. The variable with the largest probability greater than the specified POUT value is removed, and the model is reestimated. Variables in the model are then evaluated again for removal. Once no more variables satisfy the removal criterion, variables not in the model are evaluated again for entry. Model building stops when no more variables meet the entry or removal criteria or when the current model is the same as a previous one.

Examples

```
NOMREG y BY a b c
/INTERCEPT = INCLUDE
/MODEL = a b c | BACKWARD = a*b a*c b*c a*b*c.
```

- The initial model contains the intercept and main effects a, b, and c. Backward elimination is used to select among the two- and three-way interaction effects.

```
NOMREG y BY a b c
/MODEL = INTERCEPT | FORWARD = a b c.
```

- The initial model contains the intercept. Forward entry is used to select among the main effects a, b, and c.

```
NOMREG y BY a b c
/INTERCEPT = INCLUDE
/MODEL = | FORWARD = a b c.
```

- The initial model contains the intercept. Forward entry is used to select among the main effects a, b, and c.

```
NOMREG y BY a b c
/INTERCEPT = EXCLUDE
/MODEL = | BSTEP = a b c.
```

- The initial model is the null model. Backward stepwise is used to select among the main effects a, b, and c.

```
NOMREG y BY a b c
/MODEL = | FSTEP =.
```

- This MODEL specification yields a syntax error.

STEPWISE Subcommand

The STEPWISE subcommand gives you control of the statistical criteria when stepwise methods are used to build a model. This subcommand is ignored if a stepwise method is not specified on the MODEL subcommand.

RULE(keyword) *Rule for entering or removing terms in stepwise methods.* The default SINGLE indicates that only one effect can be entered or removed at a time, provided that the hierarchy requirement is satisfied for all effects in the model. SFACTOR indicates that only one effect can be entered or removed at a time, provided that the hierarchy requirement is satisfied for all factor-only effects in the model. CONTAINMENT indicates that only one effect can be entered or removed at a time, provided that the containment requirement is satisfied for all effects in the model. NONE indicates that only one effect can be entered or removed at a time, where neither the hierarchy nor the containment requirement need be satisfied for any effects in the model.

MINEFFECT(n) *Minimum number of effects in final model.* The default is 0. The intercept, if any, is not counted among the effects. This criterion is ignored unless one of the stepwise methods BACKWARD or BSTEP is specified.

MAXEFFECT(n) *Maximum number of effects in final model.* The default value is the total number of effects specified or implied on the NOMREG command. The intercept, if any, is not counted among the effects. This criterion is ignored unless one of the stepwise methods FORWARD or FSTEP is specified.

ENTRYMETHOD(keyword) *Method for entering terms in stepwise methods.* The default LR indicates that the likelihood ratio test is used to determine whether a term is entered into the model. SCORE indicates that the score test is used. This criterion is ignored unless one of the stepwise methods FORWARD, BSTEP, or FSTEP is specified.

REMOVALMETHOD(keyword) *Method for removing terms in stepwise methods.* The default LR indicates that the likelihood ratio test is used to determine whether a term is entered into the model. WALD indicates that the Wald test is used. This criterion is ignored unless one of the stepwise methods BACKWARD, BSTEP, or FSTEP is specified.

PIN(a) *Probability of the likelihood-ratio statistic for variable entry.* The default is 0.05. The larger the specified probability, the easier it is for a variable to enter the model. This criterion is ignored unless one of the stepwise methods FORWARD, BSTEP, or FSTEP is specified.

POUT(a) *Probability of the likelihood-ratio statistic for variable removal.* The default is 0.1. The larger the specified probability, the easier it is for a variable to remain in the model. This criterion is ignored unless one of the stepwise methods BACKWARD, BSTEP, or FSTEP is specified.

The hierarchy requirement stipulates that among the effects specified or implied on the MODEL subcommand, for any effect to be in a model, all lower-order effects that are part of the former effect must also be in the model. For example, if A, X, and A*X are specified, then for A*X to be in a model, the effects A and X must also be in the model.

The containment requirement stipulates that among the effects specified or implied on the MODEL subcommand, for any effect to be in the model, all effects contained in the former effect must also be in the model. For any two effects F and F', F is contained in F' if:

- Both effects F and F' involve the same covariate effect, if any. (Note that effects A*X and A*X*X are not considered to involve the same covariate effect because the first involves covariate effect X and the second involves covariate effect X**2.)
- F' consists of more factors than F.
- All factors in F also appear in F'.

The following table illustrates how the hierarchy and containment requirements relate to the RULE options. Each row of the table gives a different set of effects specified on the MODEL subcommand. The columns correspond to the RULE options SINGLE, SFACTOR, and CONTAINMENT. The cells contain the order in which effects must occur in the model. For example, unless otherwise noted, all effects numbered 1 must be in the model for any effects numbered 2 to be in the model.

Table 141-1
Hierarchy and containment requirements

Effects	SINGLE	SFACTOR	CONTAINMENT
A, B, A*B	1. A, B 2. A*B	1. A, B 2. A*B	1. A, B 2. A*B
X, X**2, X**3	1. X 2. X**2 3. X**3	Effects can occur in the model in any order.	Effects can occur in the model in any order.
A, X, X(A)	1. A, X 2. X(A)	Effects can occur in the model in any order.	1. X 2. X(A) Effect A can occur in the model in any order.
A, X, X**2(A)	1. A, X 2. X**2(A)	Effects can occur in the model in any order.	Effects can occur in the model in any order.

OUTFILE Subcommand

The OUTFILE subcommand allows you to specify files to which output is written.

- Only one OUTFILE subcommand is allowed. If you specify more than one, only the last one is executed.
- You must specify at least one keyword and a valid filename in parentheses. There is no default.
- Neither MODEL nor PARAMETER is honored if split file processing is on (SPLIT FILE command) or if more than one dependent (DEPENDENT subcommand) variable is specified.

MODEL(filename) *Write parameter estimates and their covariances to an XML (PMML) file.* Specify the filename in full. NOMREG does not supply an extension. SmartScore and SPSS Server (a separate product) can use this model file to apply the model information to other data files for scoring purposes.

PARAMETER(filename) *Write parameter estimates only to an XML (PMML) file.* Specify the filename in full. NOMREG does not supply an extension. SmartScore and SPSS Server (a separate product) can use this model file to apply the model information to other data files for scoring purposes.

PRINT Subcommand

The PRINT subcommand displays optional output. If no PRINT subcommand is specified, the default output includes a factor information table.

ASSOCIATION *Measures of Monotone Association.* Displays a table with information on the number of concordant pairs, discordant pairs, and tied pairs. The Somers' D, Goodman and Kruskal's Gamma, Kendall's tau-a, and Concordance Index C are also displayed in this table.

CELLPROB *Observed proportion, expected probability, and the residual for each covariate pattern and each response category.*

CLASSTABLE *Classification table.* The square table of frequencies of observed response categories versus the predicted response categories. Each case is classified into the category with the highest predicted probability.

CORB *Asymptotic correlation matrix of the parameter estimates.*

COVB *Asymptotic covariance matrix of the parameter estimates.*

FIT *Goodness-of-fit statistics.* The change in chi-square statistics with respect to a model with intercept terms only (or to a null model when INTERCEPT=EXCLUDE). The table contains the Pearson chi-square and the likelihood-ratio chi-square statistics. The statistics are computed based on the subpopulation classification specified on the SUBPOP subcommand or the default classification.

HISTORY(n) *Iteration history.* The table contains log-likelihood function value and parameter estimates at every *n*th iteration beginning with the 0th iteration (the initial estimates). The default is to print every iteration ($n = 1$). The last iteration is always printed if HISTORY is specified, regardless of the value of *n*.

IC *Information criteria.* The Akaike Information Criterion (AIC) and the Schwarz Bayesian Information Criterion (BIC) are displayed.

KERNEL *Kernel of the log-likelihood.* Displays the value of the kernel of the –2 log-likelihood. The default is to display the full –2 log-likelihood. Note that this keyword has no effect unless the MFI or LRT keywords are specified.

LRT *Likelihood-ratio tests.* The table contains the likelihood-ratio test statistics for the model and model partial effects. If LRT is not specified, just the model test statistic is printed.

PARAMETER	*Parameter estimates.*
SUMMARY	*Model summary.* Cox and Snell's, Nagelkerke's, and McFadden's R^2 statistics.
CPS	*Case processing summary.* This table contains information about the specified categorical variables. Displayed by default.
STEP	*Step summary.* This table summarizes the effects entered or removed at each step in a stepwise method. Displayed by default if a stepwise method is specified. This keyword is ignored if no stepwise method is specified.
MFI	*Model fitting information.* This table compares the fitted and intercept-only or null models. Displayed by default.
NON	*No statistics are displayed.* This option overrides all other specifications on the `PRINT` subcommand.

SAVE Subcommand

The `SAVE` subcommand puts casewise post-estimation statistics back into the active file.

- The new names must be valid variable names and not currently used in the active dataset.
- The rootname must be a valid variable name.
- The rootname can be followed by the number of predicted probabilities saved. The number is a positive integer. For example, if the integer is 5, then the first five predicted probabilities across all split files (if applicable) are saved. The default is 25.
- The new variables are saved into the active file in the order in which the keywords are specified on the subcommand.

ACPROB(newname)	*Estimated probability of classifying a factor/covariate pattern into the actual category.*
ESTPROB(rootname:n)	*Estimated probabilities of classifying a factor/covariate pattern into the response categories.* There are as many number of probabilities as the number of response categories. The predicted probabilities of the first *n* response categories will be saved. The default value for *n* is 25. To specify n without a rootname, enter a colon before the number.
PCPROB(newname)	*Estimated probability of classifying a factor/covariate pattern into the predicted category.* This probability is also the maximum of the estimated probabilities of the factor/covariate pattern.
PREDCAT(newname)	*The response category that has the maximum expected probability for a factor/covariate pattern.*

SCALE Subcommand

The `SCALE` subcommand specifies the dispersion scaling value. Model estimation is not affected by this scaling value. Only the asymptotic covariance matrix of the parameter estimates is affected.

N	*A positive number corresponding to the amount of overdispersion or underdispersion.* The default scaling value is 1, which corresponds to no overdispersion or underdispersion.
DEVIANCE	*Estimates the scaling value by using the deviance function statistic.*
PEARSON	*Estimates the scaling value by using the Pearson chi-square statistic.*

SUBPOP Subcommand

The SUBPOP subcommand allows you to define the subpopulation classification used in computing the goodness-of-fit statistics.

- A variable list is expected if the SUBPOP subcommand is specified. The variables in the list must be a subset of the combined list of factors and covariates specified on the command line.
- Variables specified or implied on the MODEL subcommand must be a subset of the variables specified or implied on the SUBPOP subcommand.
- If the SUBPOP subcommand is omitted, the default classification is based on all of the factors and the covariates specified.
- Missing values are deleted listwise on the subpopulation level.

Example

```
NOMREG
  movie  BY gender date WITH age
  /CRITERIA = CIN(95) DELTA(0) MXITER(100) MXSTEP(5) LCONVERGE(0)
              PCONVERGE(1.0E-6) SINGULAR(1.0E-8)
  /MODEL = gender
  /SUBPOP = gender date
  /INTERCEPT = EXCLUDE .
```

- Although the model consists only of *gender*, the SUBPOP subcommand specifies that goodness-of-fit statistics should be computed based on both *gender* and *date*.

TEST Subcommand

The TEST subcommand allows you to customize your hypothesis tests by directly specifying null hypotheses as linear combinations of parameters.

- TEST is offered only through syntax.
- Multiple TEST subcommands are allowed. Each is handled independently.
- The basic format for the TEST subcommand is an optional list of values enclosed in parentheses, an optional label in quotes, an effect name or the keyword ALL, and a list of values.
- The value list preceding the first effect or the keyword ALL are the constants to which the linear combinations are equated under the null hypotheses. If this value list is omitted, the constants are assumed to be all zeros.
- The label is a string with a maximum length of 255 characters (or 127 double-byte characters). Only one label per linear combination can be specified.
- When ALL is specified, only a list of values can follow. The number of values must equal the number of parameters (including the redundant ones) in the model.
- When effects are specified, only valid effects appearing or implied on the MODEL subcommand can be named. The number of values following an effect name must equal the number of parameters (including the redundant ones) corresponding to that effect. For example, if the effect A*B takes up six parameters, then exactly six values must follow A*B. To specify the

coefficient for the intercept, use the keyword INTERCEPT. Only one value is expected to follow INTERCEPT.

- When multiple linear combinations are specified within the same TEST subcommand, use semicolons to separate each hypothesis.
- The linear combinations are first tested separately for each logit and then simultaneously tested for all of the logits.
- A number can be specified as a fraction with a positive denominator. For example, 1/3 or –1/3 are valid, but 1/–3 is invalid.
- Effects appearing or implied on the MODEL subcommand but not specified on the TEST are assumed to take the value 0 for all of their parameters.

Example

```
NOMREG
  movie  BY gender date
  /CRITERIA = CIN(95) DELTA(0) MXITER(100) MXSTEP(5) LCONVERGE(0)
              PCONVERGE(1.0E-6) SINGULAR(1.0E-8)
  /INTERCEPT = EXCLUDE
  /PRINT = CELLPROB CLASSTABLE FIT CORB COVB HISTORY(1) PARAMETER
           SUMMARY LRT
  /TEST (0 0) = ALL 1 0 0 0;
                ALL 0 1 0 0 .
```

- TEST specifies two separate tests: one in which the coefficient corresponding to the first category for gender is tested for equality with zero, and one in which the coefficient corresponding to the second category for gender is tested for equality with zero.

NONPAR CORR

```
NONPAR CORR VARIABLES= varlist [WITH varlist] [/varlist...]

 [/PRINT={TWOTAIL**}  {SIG**}  {SPEARMAN**}]
         {ONETAIL  }  {NOSIG}  {KENDALL   }
                               {BOTH      }

 [/SAMPLE]

 [/MISSING=[{PAIRWISE**} [INCLUDE]]
           {LISTWISE  }

 [/MATRIX=OUT({*                  })]
              {'savfile'|'dataset'}
```

**Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
NONPAR CORR
  VARIABLES=PRESTIGE SPPRES PAPRES16 DEGREE PADEG MADEG.
```

Overview

NONPAR CORR computes two rank-order correlation coefficients, Spearman's rho and Kendall's tau-*b*, with their significance levels. You can obtain one or both coefficients. NONPAR CORR automatically computes the ranks and stores the cases in memory. Therefore, memory requirements are directly proportional to the number of cases that are being analyzed.

Options

Coefficients and Significance Levels. By default, NONPAR CORR computes Spearman coefficients and displays the two-tailed significance level. You can request a one-tailed test, and you can display the significance level for each coefficient as an annotation by using the PRINT subcommand.

Random Sampling. You can request a random sample of cases by using the SAMPLE subcommand when there is not enough space to store all cases.

Matrix Output. You can write matrix materials to a matrix data file by using the MATRIX subcommand. The matrix materials include the number of cases that are used to compute each coefficient and the Spearman or Kendall coefficients for each variable. These materials can be read by other procedures.

Basic Specification

The basic specification is VARIABLES and a list of numeric variables. By default, Spearman correlation coefficients are calculated.

Subcommand Order

- VARIABLES must be specified first.
- The remaining subcommands can be used in any order.

Operations

- NONPAR CORR produces one or more matrices of correlation coefficients. For each coefficient, NONPAR CORR displays the number of used cases and the significance level.
- The number of valid cases is always displayed. Depending on the specification on the MISSING subcommand, the number of valid cases can be displayed for each pair or in a single annotation.
- If all cases have a missing value for a given pair of variables, or if all cases have the same value for a variable, the coefficient cannot be computed. If a correlation cannot be computed, NONPAR CORR displays a decimal point.
- If both Spearman and Kendall coefficients are requested, and MATRIX is used to write matrix materials to a matrix data file, only Spearman's coefficient will be written with the matrix materials.

Limitations

- A maximum of 25 variable lists is allowed.
- A maximum of 100 variables total per NONPAR CORR command is allowed.

Examples

```
NONPAR CORR VARIABLES=PRESTIGE SPPRES PAPRES16 DEGREE PADEG MADEG.
```

- By default, Spearman correlation coefficients are calculated. The number of cases upon which the correlations are based and the two-tailed significance level are displayed for each correlation.

VARIABLES Subcommand

VARIABLES specifies the variable list.

- All variables must be numeric.
- If keyword WITH is not used, NONPAR CORR displays the correlations of each variable with every other variable in the list.
- To obtain a rectangular matrix, specify two variable lists that are separated by keyword WITH. NONPAR CORR writes a rectangular matrix of variables in the first list correlated with variables in the second list.
- Keyword WITH cannot be used when the MATRIX subcommand is used.

- You can request more than one analysis. Use a slash to separate the specifications for each analysis.

Example

```
NONPAR CORR
  VARIABLES = PRESTIGE SPPRES PAPRES16 WITH DEGREE PADEG MADEG.
```

- The three variables that are listed before WITH define the rows; the three variables that are listed after WITH define the columns of the correlation matrix.
- Spearman's rho is displayed by default.

Example

```
NONPAR CORR VARIABLES=SPPRES PAPRES16 PRESTIGE
                     /SATCITY WITH SATHOBBY SATFAM.
```

- NONPAR CORR produces two Correlations tables.
- By default, Spearman's rho is displayed.

PRINT Subcommand

By default, NONPAR CORR displays Spearman correlation coefficients. The significance levels are displayed below the coefficients. The significance level is based on a two-tailed test. Use PRINT to change these defaults.

- The Spearman and Kendall coefficients are both based on ranks.

SPEARMAN	*Spearman's rho.* Only Spearman coefficients are displayed. This specification is the default.
KENDALL	*Kendall's tau*-b. Only Kendall coefficients are displayed.
BOTH	*Kendall and Spearman coefficients*. Both coefficients are displayed. If MATRIX is used to write the correlation matrix to a matrix data file, only Spearman coefficients are written with the matrix materials.
SIG	*Display the significance level.* This specification is the default.
NOSIG	*Display the significance level in an annotation.*
TWOTAIL	*Two-tailed test of significance.* This test is appropriate when the direction of the relationship cannot be determined in advance, as is often the case in exploratory data analysis. This specification is the default.
ONETAIL	*One-tailed test of significance.* This test is appropriate when the direction of the relationship between a pair of variables can be specified in advance of the analysis.

SAMPLE Subcommand

NONPAR CORR must store cases in memory to build matrices. SAMPLE selects a random sample of cases when computer resources are insufficient to store all cases. SAMPLE has no additional specifications.

MISSING Subcommand

MISSING controls the treatment of missing values.

- PAIRWISE and LISTWISE are alternatives. You can specify INCLUDE with either PAIRWISE or LISTWISE.

PAIRWISE *Exclude missing values pairwise.* Cases with a missing value for one or both variables for a specific correlation coefficient are excluded from the computation of that coefficient. This process allows the maximum available information to be used in every calculation. This process also results in a set of coefficients based on a varying number of cases. The number is displayed for each pair. This specification is the default.

LISTWISE *Exclude missing values listwise.* Cases with a missing value for any variable that is named in a list are excluded from the computation of all coefficients in the Correlations table. The number of used cases is displayed in a single annotation. Each variable list on a command is evaluated separately. Thus, a case that is missing for one matrix might be used in another matrix. This option decreases the amount of required memory and significantly decreases computational time.

INCLUDE *Include user-missing values*. User-missing values are treated as valid values.

MATRIX Subcommand

MATRIX writes matrix materials to a matrix data file. The matrix materials always include the number of cases that are used to compute each coefficient, and the materials include either the Spearman or the Kendall correlation coefficient for each variable, whichever is requested. For more information, see Format of the Matrix Data File on p. 1256.

- You cannot write both Spearman's and Kendall's coefficients to the same matrix data file. To obtain both Spearman's and Kendall's coefficients in matrix format, specify separate NONPAR CORR commands for each coefficient and define different matrix data files for each command.
- If PRINT=BOTH is in effect, NONPAR CORR displays a matrix in the listing file for both coefficients but writes only the Spearman coefficients to the matrix data file.
- NONPAR CORR cannot write matrix materials for rectangular matrices (variable lists containing keyword WITH). If more than one variable list is specified, only the last variable list that does not use keyword WITH is written to the matrix data file.
- The specification on MATRIX is keyword OUT and a quoted file specification or previously declared dataset name (DATASET DECLARE command), enclosed in parentheses.
- If you want to use a correlation matrix that is written by NONPAR CORR in another procedure, change the *ROWTYPE_* value RHO or TAUB to CORR by using the RECODE command.
- Any documents that are contained in the active dataset are not transferred to the matrix file.

OUT ('savfile'|'dataset') *Write a matrix data file or dataset.* Specify either a filename, a previously declared dataset name, or an asterisk, enclosed in parentheses. Filenames should be enclosed in quotes and are stored in the working directory unless a path is included as part of the file specification. If you specify an asterisk (*), the matrix data file replaces the active dataset.

Multiple nonparametric correlation tables

```
NONPAR CORR
  VARIABLES=PRESTIGE SPPRES PAPRES16 DEGREE PADEG MADEG
  /PRESTIGE TO DEGREE /PRESTIGE WITH DEGREE
  /MATRIX OUT('/data/npmat.sav').
```

- Only the matrix for *PRESTIGE* to *DEGREE* is written to the matrix data file because it is the last variable list that does not use keyword `WITH`.

Format of the Matrix Data File

- The matrix data file has two special variables that are created by the program: *ROWTYPE_* and *VARNAME_*.
- *ROWTYPE_* is a short string variable with values N and RHO for Spearman's correlation coefficient. If you specify Kendall's coefficient, the values are N and TAUB.
- *VARNAME_* is a short string variable whose values are the names of the variables that are used to form the correlation matrix. When *ROWTYPE_* is RHO (or TAUB), *VARNAME_* gives the variable that is associated with that row of the correlation matrix.
- The remaining variables in the file are the variables that are used to form the correlation matrix.

Split Files

- When split-file processing is in effect, the first variables in the matrix data file are the split variables, followed by *ROWTYPE_*, *VARNAME_*, and the variables that are used to form the correlation matrix.
- A full set of matrix materials is written for each split-file group that is defined by the split variables.
- A split variable cannot have the same name as any other variable that is written to the matrix data file.
- If split-file processing is in effect when a matrix is written, the same split file must be in effect when that matrix is read by a procedure.

Missing Values

- With `PAIRWISE` treatment of missing values (the default), the matrix of `N`s that is used to compute each coefficient is included with the matrix materials.
- With `LISTWISE` or `INCLUDE` treatments, a single `N` that is used to calculate all coefficients is included with the matrix materials.

Examples

Writing results to a matrix data file

```
GET FILE='/data/GSS80.sav'
  /KEEP PRESTIGE SPPRES PAPRES16 DEGREE PADEG MADEG.
NONPAR CORR VARIABLES=PRESTIGE TO MADEG
  /MATRIX OUT('/data/npmat.sav').
```

- NONPAR CORR reads data from file *GSS80.sav* and writes one set of correlation matrix materials to the file *npmat.sav*.
- The active dataset is still *GSS80.sav*. Subsequent commands are executed on file *GSS80.sav*.

Replacing the active dataset with matrix results

```
GET FILE='/data/GSS80.sav'
  /KEEP PRESTIGE SPPRES PAPRES16 DEGREE PADEG MADEG.
NONPAR CORR VARIABLES=PRESTIGE TO MADEG
  /MATRIX OUT(*).
LIST.
DISPLAY DICTIONARY.
```

- NONPAR CORR writes the same matrix as in the example above. However, the matrix data file replaces the active dataset. The LIST and DISPLAY commands are executed on the matrix file (not on the original active dataset *GSS80.sav*).

NPAR TESTS

```
NPAR TESTS [CHISQUARE=varlist[(lo,hi)]/] [/EXPECTED={EQUAL      }]
                                                    {f1,f2,...fn}

 [/K-S({UNIFORM [min,max]   })=varlist]
       {NORMAL [mean,stddev]}
       {POISSON [mean]      }
       {EXPONENTIAL [mean]  }

 [/RUNS({MEAN  })=varlist]
        {MEDIAN}
        {MODE  }
        {value }

 [/BINOMIAL[({.5})]=varlist[({value1,value2})]]
             { p}            {value        }

 [/MCNEMAR=varlist [WITH varlist [(PAIRED)]]]

 [/SIGN=varlist [WITH varlist [(PAIRED)]]]

 [/WILCOXON=varlist [WITH varlist [(PAIRED)]]]

    |/MH=varlist [WITH varlist [(PAIRED)]]]††

 [/COCHRAN=varlist]

 [/FRIEDMAN=varlist]

 [/KENDALL=varlist]

 [/M-W=varlist BY var (value1,value2)]

 [/K-S=varlist BY var (value1,value2)]

 [/W-W=varlist BY var (value1,value2)]

 [/MOSES[(n)]=varlist BY var (value1,value2)]

 [/K-W=varlist BY var (value1,value2)]

 [/J-T=varlist BY var (value1, value2)]††

 [/MEDIAN[(value)]=varlist BY var (value1,value2)]

 [/MISSING=[{ANALYSIS**}]  [INCLUDE]]
           {LISTWISE  }

 [/SAMPLE]

 [/STATISTICS=[DESCRIPTIVES]  [QUARTILES] [ALL]]

    [/METHOD={MC [CIN({99.0 })] [SAMPLES({10000})] }]††
                     {value}            {value}
          {EXACT [TIMER({5    })]             }
                        {value}
```

**Default if the subcommand is omitted.

††Available only if the Exact Tests option is installed (available only on Windows operating systems).

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
NPAR TESTS K-S(UNIFORM)=V1 /K-S(NORMAL,0,1)=V2.
```

Overview

NPAR TESTS is a collection of nonparametric tests. These tests make minimal assumptions about the underlying distribution of the data. (Siegel and Castellan, 1988) In addition to the nonparametric tests that are available in NPAR TESTS, the *k*-sample chi-square and Fisher's exact test are available in procedure CROSSTABS.

The tests that are available in NPAR TESTS can be grouped into three broad categories based on how the data are organized: one-sample tests, related-samples tests, and independent-samples tests. A one-sample test analyzes one variable. A test for related samples compares two or more variables for the same set of cases. An independent-samples test analyzes one variable that is grouped by categories of another variable.

The one-sample tests that are available in procedure NPAR TESTS are:

- BINOMIAL
- CHISQUARE
- K-S (Kolmogorov-Smirnov)
- RUNS

Tests for two related samples are:

- MCNEMAR
- SIGN
- WILCOXON

Tests for *k* related samples are:

- COCHRAN
- FRIEDMAN
- KENDALL

Tests for two independent samples are:

- M-W (Mann-Whitney)
- K-S (Kolmogorov-Smirnov)
- W-W (Wald-Wolfowitz)
- MOSES

Tests for *k* independent samples are:

- K-W (Kruskal-Wallis)
- MEDIAN

Tests are described below in alphabetical order.

Options

Statistical Display. In addition to the tests, you can request univariate statistics, quartiles, and counts for all variables that are specified on the command. You can also control the pairing of variables in tests for two related samples.

Random Sampling. NPAR TESTS must store cases in memory when computing tests that use ranks. You can use random sampling when there is not enough space to store all cases.

Basic Specification

The basic specification is a single test subcommand and a list of variables to be tested. Some tests require additional specifications. CHISQUARE has an optional subcommand.

Subcommand Order

Subcommands can be used in any order.

Syntax Rules

- The STATISTICS, SAMPLE, and MISSING subcommands are optional. Each subcommand can be specified only once per NPAR TESTS command.
- You can request any or all tests, and you can specify a test subcommand more than once on a single NPAR TESTS command.
- If you specify a variable more than once on a test subcommand, only the first variable is used.
- Keyword ALL in any variable list refers to all user-defined variables in the active dataset.
- Keyword WITH controls pairing of variables in two-related-samples tests.
- Keyword BY introduces the grouping variable in two- and *k*-independent-samples tests.
- Keyword PAIRED can be used with keyword WITH on the MCNEMAR, SIGN, and WILCOXON subcommands to obtain sequential pairing of variables for two related samples.

Operations

- If a string variable is specified on any subcommand, NPAR TESTS will stop executing.
- When ALL is used, requests for tests of variables with themselves are ignored and a warning is displayed.

Limitations

- A maximum of 100 subcommands is allowed.
- A maximum of 500 variables total per NPAR TESTS command is allowed.
- A maximum of 200 values for subcommand CHISQUARE is allowed.

BINOMIAL Subcommand

```
NPAR TESTS BINOMIAL [({.5})]=varlist[({value,value})]
                    {p  }            {value      }
```

BINOMIAL tests whether the observed distribution of a dichotomous variable is the same as what is expected from a specified binomial distribution. By default, each named variable is assumed to have only two values, and the distribution of each named variable is compared to a binomial distribution with *p* (the proportion of cases expected in the first category) equal to 0.5. The default output includes the number of valid cases in each group, the test proportion, and the two-tailed probability of the observed proportion.

Syntax

- The minimum specification is a list of variables to be tested.
- To change the default 0.5 test proportion, specify a value in parentheses immediately after keyword BINOMIAL.
- A single value in parentheses following the variable list is used as a cutting point. Cases with values that are equal to or less than the cutting point form the first category; the remaining cases form the second category.
- If two values appear in parentheses after the variable list, cases with values that are equal to the first value form the first category, and cases with values that are equal to the second value form the second category.
- If no values are specified, the variables must be dichotomous.

Operations

- The proportion observed in the first category is compared to the test proportion. The probability of the observed proportion occurring given the test proportion and a binomial distribution is then computed. A test statistic is calculated for each variable specified.
- If the test proportion is the default (0.5), a two-tailed probability is displayed. For any other test proportion, a one-tailed probability is displayed. The direction of the one-tailed test depends on the observed proportion in the first category. If the observed proportion is more than the test proportion, the significance of observing that many or more in the first category is reported. If the observed proportion is less than or equal to the test proportion, the significance of observing that many or fewer in the first category is reported. In other words, the test is always done in the observed direction.

Example

```
NPAR TESTS BINOMIAL(.667)=V1(0,1).
```

- NPAR TESTS displays the Binomial Test table, showing the number of cases, observed proportion, test proportion (0.667), and the one-tailed significance for each category.
- If more than 0.667 of the cases have value 0 for *V1*, BINOMIAL gives the probability of observing that many or more values of 0 in a binomial distribution with probability 0.667. If fewer than 0.667 of the cases are 0, the test will be of observing that many or fewer values.

CHISQUARE Subcommand

```
NPAR TESTS CHISQUARE=varlist [(lo,hi)] [/EXPECTED={EQUAL**      }]
                                                  {f1,f2,..., fn}
```

The CHISQUARE (alias CHI-SQUARE) one-sample test computes a chi-square statistic based on the differences between the observed and expected frequencies of categories of a variable. By default, equal frequencies are expected in each category. The output includes the frequency distribution, expected frequencies, residuals, chi-square, degrees of freedom, and probability.

Syntax

- The minimum specification is a list of variables to be tested. Optionally, you can specify a value range in parentheses following the variable list. You can also specify expected proportions with the EXPECTED subcommand.
- If you use the EXPECTED subcommand to specify unequal expected frequencies, you must specify a value greater than 0 for each observed category of the variable. The expected frequencies are specified in ascending order of category value. You can use the notation *n*f* to indicate that frequency *f* is expected for *n* consecutive categories.
- Specifying keyword EQUAL on the EXPECTED subcommand has the same effect as omitting the EXPECTED subcommand.
- EXPECTED applies to all variables that are specified on the CHISQUARE subcommand. Use multiple CHISQUARE and EXPECTED subcommands to specify different expected proportions for variables.

Operations

- If no range is specified for the variables that are to be tested, a separate Chi-Square Frequency table is produced for each variable. Each distinct value defines a category.
- If a range is specified, integer-valued categories are established for each value within the range. Non-integer values are truncated before classification. Cases with values that are outside the specified range are excluded. One combined Chi-Square Frequency table is produced for all specified variables.
- Expected values are interpreted as proportions, not absolute values. Values are summed, and each value is divided by the total to calculate the proportion of cases expected in the corresponding category.
- A test statistic is calculated for each specified variable.

Example

```
NPAR TESTS CHISQUARE=V1 (1,5) /EXPECTED= 12, 3*16, 18.
```

- This example requests the chi-square test for values 1 through 5 of variable *V1*.
- The observed frequencies for variable *V1* are compared with the hypothetical distribution of 12/78 occurrences of value 1; 16/78 occurrences each of values 2, 3, and 4; and 18/78 occurrences of value 5.

COCHRAN Subcommand

```
NPAR TESTS COCHRAN=varlist
```

COCHRAN calculates Cochran's *Q,* which tests whether the distribution of values is the same for *k* related dichotomous variables. The output shows the frequency distribution for each variable in the Cochran Frequencies table and the number of cases, Cochran's *Q*, degrees of freedom, and probability in the Test Statistics table.

Syntax

- The minimum specification is a list of two variables.
- The variables must be dichotomous and must be coded with the same two values.

Operations

- A $k \times 2$ contingency table (variables by categories) is constructed for dichotomous variables, and the proportions for each variable are computed. A single test is calculated, comparing all variables.
- Cochran's *Q* statistic has approximately a chi-square distribution.

Example

```
NPAR TESTS COCHRAN=RV1 TO RV3.
```

- This example tests whether the distribution of values 0 and 1 for *RV1*, *RV2*, and *RV3* is the same.

FRIEDMAN Subcommand

```
NPAR TESTS FRIEDMAN=varlist
```

FRIEDMAN tests whether *k* related samples have been drawn from the same population. The output shows the mean rank for each variable in the Friedman Ranks table and the number of valid cases, chi-square, degrees of freedom, and probability in the Test Statistics table.

Syntax

- The minimum specification is a list of two variables.
- Variables should be at least at the ordinal level of measurement.

Operations

- The values of *k* variables are ranked from 1 to *k* for each case, and the mean rank is calculated for each variable over all cases.
- The test statistic has approximately a chi-square distribution. A single test statistic is calculated, comparing all variables.

Example

```
NPAR TESTS FRIEDMAN=V1 V2 V3
```

```
  /STATISTICS=DESCRIPTIVES.
```

- This example tests variables *V1, V2*, and *V3*, and the example requests univariate statistics for all three variables.

J-T Subcommand

```
NPAR TESTS /J-T=varlist BY variable(value1,value2)
```

J-T (alias JONCKHEERE-TERPSTRA) performs the Jonckheere-Terpstra test, which tests whether *k* independent samples that are defined by a grouping variable are from the same population. This test is particularly powerful when the *k* populations have a natural ordering. The output shows the number of levels in the grouping variable; the total number of cases; observed, standardized, mean, and standard deviation of the test statistic; the two-tailed asymptotic significance; and, if a /METHOD subcommand is specified, one-tailed and two-tailed exact or Monte Carlo probabilities. This subcommand is available only if the Exact Tests option is installed.

Syntax

- The minimum specification is a test variable, the keyword BY, a grouping variable, and a pair of values in parentheses.
- Every value in the range defined by the pair of values for the grouping variable forms a group.
- If the /METHOD subcommand is specified, and the number of populations, *k*, is greater than 5, the *p* value is estimated by using the Monte Carlo sampling method. The exact *p* value is not available when *k* exceeds 5.

Operations

- Cases from the *k* groups are ranked in a single series, and the rank sum for each group is computed. A test statistic is calculated for each variable that is specified before BY.
- The Jonckheere-Terpstra statistic has approximately a normal distribution.
- Cases with values other than values in the range that is specified for the grouping variable are excluded.
- The direction of a one-tailed inference is indicated by the sign of the standardized test statistic.

Example

```
NPAR TESTS /J-T=V1 BY V2(0,4)
  /METHOD=EXACT.
```

- This example performs the Jonckheere-Terpstra test for groups that are defined by values 0 through 4 of *V2*. The exact *p* values are calculated.

K-S Subcommand (One-Sample)

```
NPAR TESTS K-S({NORMAL [mean,stddev]})=varlist
               {POISSON [mean]      }
               {UNIFORM [min,max]   }
               {EXPONENTIAL [mean]  }
```

The K-S (alias KOLMOGOROV-SMIRNOV) one-sample test compares the cumulative distribution function for a variable with a uniform, normal, Poisson, or exponential distribution, and the test tests whether the distributions are homogeneous. The parameters of the test distribution can be specified; the defaults are the observed parameters. The output shows the number of valid cases, parameters of the test distribution, most-extreme absolute, positive, and negative differences, Kolmogorov-Smirnov *Z*, and two-tailed probability for each variable.

Syntax

The minimum specification is a distribution keyword and a list of variables. The distribution keywords are NORMAL, POISSON, EXPONENTIAL, and UNIFORM.

- The distribution keyword and its optional parameters must be enclosed within parentheses.
- The distribution keyword must be separated from its parameters by blanks or commas.

NORMAL [mean, stdev]	*Normal distribution.* The default parameters are the observed mean and standard deviation.
POISSON [mean]	*Poisson distribution.* The default parameter is the observed mean.
UNIFORM [min,max]	*Uniform distribution.* The default parameters are the observed minimum and maximum values.
EXPONENTIAL [mean]	*Exponential distribution.* The default parameter is the observed mean.

Operations

- The Kolmogorov-Smirnov *Z* is computed from the largest difference in absolute value between the observed and test distribution functions.
- The K-S probability levels assume that the test distribution is specified entirely in advance. The distribution of the test statistic and resulting probabilities are different when the parameters of the test distribution are estimated from the sample. No correction is made. The power of the test to detect departures from the hypothesized distribution may be seriously diminished. For testing against a normal distribution with estimated parameters, consider the adjusted K-S Lilliefors test that is available in the EXAMINE procedure.
- For a mean of 100,000 or larger, a normal approximation to the Poisson distribution is used.
- A test statistic is calculated for each specified variable.

Example

```
NPAR TESTS K-S(UNIFORM)=V1 /K-S(NORMAL,0,1)=V2.
```

- The first K-S subcommand compares the distribution of *V1* with a uniform distribution that has the same range as *V1*.
- The second K-S subcommand compares the distribution of *V2* with a normal distribution that has a mean of 0 and a standard deviation of 1.

K-S Subcommand (Two-Sample)

```
NPAR TESTS K-S=varlist BY variable(value1,value2)
```

K-S (alias KOLMOGOROV-SMIRNOV) tests whether the distribution of a variable is the same in two independent samples that are defined by a grouping variable. The test is sensitive to any difference in median, dispersion, skewness, and so forth, between the two distributions. The output shows the valid number of cases in each group in the Frequency table. The output also shows the largest absolute, positive, and negative differences between the two groups, the Kolmogorov-Smirnov *Z*, and the two-tailed probability for each variable in the Test Statistics table.

Syntax

- The minimum specification is a test variable, the keyword BY, a grouping variable, and a pair of values in parentheses.
- The test variable should be at least at the ordinal level of measurement.
- Cases with the first value form one group, and cases with the second value form the other group. The order in which values are specified determines which difference is the largest positive and which difference is the largest negative.

Operations

- The observed cumulative distributions are computed for both groups, as are the maximum positive, negative, and absolute differences. A test statistic is calculated for each variable that is named before BY.
- Cases with values other than values that are specified for the grouping variable are excluded.

Example

```
NPAR TESTS K-S=V1 V2 BY V3(0,1).
```

- This example specifies two tests. The first test compares the distribution of *V1* for cases with value 0 for *V3* with the distribution of *V1* for cases with value 1 for *V3*.
- A parallel test is calculated for *V2*.

K-W Subcommand

```
NPAR TESTS K-W=varlist BY variable(value1,value2)
```

K-W (alias KRUSKAL-WALLIS) tests whether *k* independent samples that are defined by a grouping variable are from the same population. The output shows the number of valid cases and the mean rank of the variable in each group in the Ranks table. the output also shows the chi-square, degrees of freedom, and probability in the Test Statistics table.

Syntax

- The minimum specification is a test variable, the keyword BY, a grouping variable, and a pair of values in parentheses.
- Every value in the range defined by the pair of values for the grouping variable forms a group.

Operations

- Cases from the *k* groups are ranked in a single series, and the rank sum for each group is computed. A test statistic is calculated for each variable that is specified before BY.
- Kruskal-Wallis *H* has approximately a chi-square distribution.
- Cases with values other than values in the range that is specified for the grouping variable are excluded.

Example

```
NPAR TESTS K-W=V1 BY V2(0,4).
```

- This example tests *V1* for groups that are defined by values 0 through 4 of *V2*.

KENDALL Subcommand

```
NPAR TESTS KENDALL=varlist
```

KENDALL tests whether *k* related samples are from the same population. *W* is a measure of agreement among judges or raters, where each case is one judge's rating of several items (variables). The output includes the mean rank for each variable in the Ranks table and the valid number of cases, Kendall's *W*, chi-square, degrees of freedom, and probability in the Test Statistics table.

Syntax

The minimum specification is a list of two variables.

Operations

- The values of the *k* variables are ranked from 1 to *k* for each case, and the mean rank is calculated for each variable over all cases. Kendall's *W* and a corresponding chi-square statistic are calculated, correcting for ties. In addition, a single test statistic is calculated for all variables.
- *W* ranges between 0 (no agreement) and 1 (complete agreement).

Example

```
DATA LIST /V1 TO V5 1-10.
BEGIN DATA
2 5 4 5 1
3 3 4 5 3
3 4 4 6 2
2 4 3 6 2
END DATA.
NPAR TESTS KENDALL=ALL.
```

- This example tests four judges (cases) on five items (variables *V1* through *V5*).

M-W Subcommand

```
NPAR TESTS M-W=varlist BY variable(value1,value2)
```

M-W (alias MANN-WHITNEY) tests whether two independent samples that are defined by a grouping variable are from the same population. The test statistic uses the rank of each case to test whether the groups are drawn from the same population. The output shows the number of valid cases of each group; the mean rank of the variable within each group and the sum of ranks in the Ranks table and the Mann-Whitney *U*; Wilcoxon *W* (the rank sum of the smaller group); *Z* statistic; and probability in the Test Statistics table.

Syntax

- The minimum specification is a test variable, the keyword BY, a grouping variable, and a pair of values in parentheses.
- Cases with the first value form one group and cases with the second value form the other group. The order in which the values are specified is unimportant.

Operations

- Cases are ranked in order of increasing size, and test statistic *U* (the number of times that a score from group 1 precedes a score from group 2) is computed.
- An exact significance level is computed if there are 40 or fewer cases. For more than 40 cases, *U* is transformed into a normally distributed *Z* statistic, and a normal approximation *p* value is computed.
- A test statistic is calculated for each variable that is named before BY.
- Cases with values other than values that are specified for the grouping variable are excluded.

Example

```
NPAR TESTS M-W=V1 BY V2(1,2).
```

- This example tests *V1* based on the two groups that are defined by values 1 and 2 of *V2*.

MCNEMAR Subcommand

```
NPAR TESTS MCNEMAR=varlist [WITH varlist [(PAIRED)]]
```

MCNEMAR tests whether combinations of values between two dichotomous variables are equally likely. The output includes a Crosstabulation table for each pair and a Test Statistics table for all pairs, showing the number of valid cases, chi-square, and probability for each pair.

Syntax

- The minimum specification is a list of two variables. Variables must be dichotomous and must have the same two values.
- If keyword WITH is not specified, each variable is paired with every other variable in the list.

- If WITH is specified, each variable before WITH is paired with each variable after WITH. If PAIRED is also specified, the first variable before WITH is paired with the first variable after WITH, the second variable before WITH is paired with the second variable after WITH, and so on. PAIRED cannot be specified without WITH.
- With PAIRED, the number of variables that are specified before and after WITH must be the same. PAIRED must be specified in parentheses after the second variable list.

Operations

- For the purposes of computing the test statistics, only combinations for which the values for the two variables are different are considered.
- If fewer than 25 cases change values from the first variable to the second variable, the binomial distribution is used to compute the probability.

Example

```
NPAR TESTS MCNEMAR=V1 V2 V3.
```

- This example performs the MCNEMAR test on variable pairs *V1* and *V2*, *V1* and *V3*, and *V2* and *V3*.

MEDIAN Subcommand

```
NPAR TESTS MEDIAN [(value)]=varlist BY variable(value1,value2)
```

MEDIAN determines whether *k* independent samples are drawn from populations with the same median. The independent samples are defined by a grouping variable. For each variable, the output shows a table of the number of cases that are greater than and less than or equal to the median in each category in the Frequency table. The output also shows the number of valid cases, the median, chi-square, degrees of freedom, and probability in the Test Statistics table.

Syntax

- The minimum specification is a single test variable, the keyword BY, a grouping variable, and two values in parentheses.
- If the first grouping value is less than the second value, every value in the range that is defined by the pair of values forms a group, and a *k*-sample test is performed.
- If the first value is greater than the second value, two groups are formed by using the two values, and a two-sample test is performed.
- By default, the median is calculated from all cases that are included in the test. To override the default, specify a median value in parentheses following the MEDIAN subcommand keyword.

Operations

- A $2 \times k$ contingency table is constructed with counts of the number of cases that are greater than the median and less than or equal to the median for the *k* groups.
- Test statistics are calculated for each variable that is specified before BY.

- For more than 30 cases, a chi-square statistic is computed. For 30 or fewer cases, Fisher's exact procedure (two-tailed) is used instead of chi-square.
- For a two-sample test, cases with values other than the two specified values are excluded.

Example

```
NPAR TESTS MEDIAN(8.4)=V1 BY V2(1,2) /MEDIAN=V1 BY V2(1,2)
  /MEDIAN=V1 BY V3(1,4) /MEDIAN=V1 BY V3(4,1).
```

- The first two MEDIAN subcommands test variable *V1* grouped by values 1 and 2 of variable *V2*. The first test specifies a median of 8.4, and the second test uses the observed median.
- The third MEDIAN subcommand requests a four-samples test, dividing the sample into four groups based on values 1, 2, 3, and 4 of variable *V3*.
- The last MEDIAN subcommand requests a two-samples test, grouping cases based on values 1 and 4 of *V3* and ignoring all other cases.

MH Subcommand

```
NPAR TESTS /MH=varlist [WITH varlist [(PAIRED)]]
```

MH performs the marginal homogeneity test, which tests whether combinations of values between two paired ordinal variables are equally likely. The marginal homogeneity test is typically used in repeated measures situations. This test is an extension of the McNemar test from binary response to multinomial response. The output shows the number of distinct values for all test variables; the number of valid off-diagonal cell counts; mean; standard deviation; observed and standardized values of the test statistics; the asymptotic two-tailed probability for each pair of variables; and, if a /METHOD subcommand is specified, one-tailed and two-tailed exact or Monte Carlo probabilities.

This subcommand is available only if the Exact Tests option is installed (available only on Windows operating systems).

Syntax

- The minimum specification is a list of two variables. Variables must be polychotomous and must have more than two values. If the variables contain only two values, the McNemar test is performed.
- If keyword WITH is not specified, each variable is paired with every other variable in the list.
- If WITH is specified, each variable before WITH is paired with each variable after WITH. If PAIRED is also specified, the first variable before WITH is paired with the first variable after WITH, the second variable before WITH is paired with the second variable after WITH, and so on. PAIRED cannot be specified without WITH.
- With PAIRED, the number of variables that are specified before and after WITH must be the same. PAIRED must be specified in parentheses after the second variable list.

Operations

- The data consist of paired, dependent responses from two populations. The marginal homogeneity test tests the equality of two multinomial $c \times 1$ tables, and the data can be arranged in the form of a square $c \times c$ contingency table. A $2 \times c$ table is constructed for each off-diagonal cell count. The marginal homogeneity test statistic is computed for cases with different values for the two variables. Only combinations for which the values for the two variables are different are considered. The first row of each $2 \times c$ table specifies the category that was chosen by population 1, and the second row specifies the category that was chosen by population 2. The test statistic is calculated by summing the first row scores across all 2 x *c* tables.

Example

```
NPAR TESTS /MH=V1 V2 V3
  /METHOD=MC.
```

- This example performs the marginal homogeneity test on variable pairs *V1* and *V2*, *V1* and *V3*, and *V2* and *V3*. The exact *p* values are estimated by using the Monte Carlo sampling method.

MOSES Subcommand

```
NPAR TESTS MOSES[(n)]=varlist BY variable(value1,value2)
```

The MOSES test of extreme reactions tests whether the range of an ordinal variable is the same in a control group and a comparison group. The control and comparison groups are defined by a grouping variable. The output includes a Frequency table, showing, for each variable before *BY*, the total number of cases and the number of cases in each group. The output also includes a Test Statistics table, showing the number of removed outliers, span of the control group before and after outliers are removed, and one-tailed probability of the span with and without outliers.

Syntax

- The minimum specification is a test variable, the keyword BY, a grouping variable, and two values in parentheses.
- The test variable must be at least at the ordinal level of measurement.
- The first value of the grouping variable defines the control group, and the second value defines the comparison group.
- By default, 5% of the cases are trimmed from each end of the range of the control group to remove outliers. You can override the default by specifying a value in parentheses following the MOSES subcommand keyword. This value represents an actual number of cases, not a percentage.

Operations

- Values from the groups are arranged in a single ascending sequence. The span of the control group is computed as the number of cases in the sequence containing the lowest and highest control values.
- No adjustments are made for tied cases.

- Cases with values other than values that are specified for the grouping variable are excluded.
- Test statistics are calculated for each variable that is named before BY.

Example

```
NPAR TESTS MOSES=V1 BY V3(0,1) /MOSES=V1 BY V3(1,0).
```

- The first MOSES subcommand tests *V1* by using value 0 of *V3* to define the control group and value 1 for the comparison group. The second MOSES subcommand reverses the comparison and control groups.

RUNS Subcommand

```
NPAR TESTS RUNS({MEAN  })=varlist
               {MEDIAN}
               {MODE  }
               {value }
```

RUNS tests whether the sequence of values of a dichotomized variable is random. The output includes a Run Test table, showing the test value (cut point that is used to dichotomize the variable tested), number of runs, number of cases that are below the cut point, number of cases that are greater than or equal to the cut point, and test statistic *Z* with its two-tailed probability for each variable.

Syntax

- The minimum specification is a cut point in parentheses followed by a test variable.
- The cut point can be specified by an exact value or one of the keywords MEAN, MEDIAN, or MODE.

Operations

- All tested variables are treated as dichotomous: cases with values that are less than the cut point form one category, and cases with values that are greater than or equal to the cut point form the other category.
- Test statistics are calculated for each specified variable.

Example

```
NPAR TESTS RUNS(MEDIAN)=V2 /RUNS(24.5)=V2 /RUNS(1)=V3.
```

- This example performs three runs tests. The first test tests variable *V2* by using the median as the cut point. The second test also tests *V2* by using 24.5 as the cut point. The third test tests variable *V3*, with value 1 specified as the cut point.

SIGN Subcommand

```
NPAR TESTS SIGN=varlist [WITH varlist [(PAIRED)] ]
```

SIGN tests whether the distribution of two paired variables in a two-related-samples test is the same. The output includes a Frequency table, showing, for each pair, the number of positive differences, number of negative differences, number of ties, and the total number. The output also includes a Test Statistics table, showing the *Z* statistic and two-tailed probability.

Syntax

- The minimum specification is a list of two variables.
- Variables should be at least at the ordinal level of measurement.
- If keyword WITH is not specified, each variable in the list is paired with every other variable in the list.
- If keyword WITH is specified, each variable before WITH is paired with each variable after WITH. If PAIRED is also specified, the first variable before WITH is paired with the first variable after WITH, the second variable before WITH is paired with the second variable after WITH, and so on. PAIRED cannot be specified without WITH.
- With PAIRED, the number of variables that are specified before and after WITH must be the same. PAIRED must be specified in parentheses after the second variable list.

Operations

- The positive and negative differences between the pair of variables are counted. Ties are ignored.
- The probability is taken from the binomial distribution if 25 or fewer differences are observed. Otherwise, the probability comes from the *Z* distribution.
- Under the null hypothesis for large sample sizes, *Z* is approximately normally distributed with a mean of 0 and a variance of 1.

Example

```
NPAR TESTS SIGN=N1,M1 WITH N2,M2 (PAIRED).
```

- *N1* is tested with *N2*, and *M1* is tested with *M2*.

W-W Subcommand

```
NPAR TESTS W-W=varlist BY variable(value1,value2)
```

W-W (alias WALD-WOLFOWITZ) tests whether the distribution of a variable is the same in two independent samples. A runs test is performed with group membership as the criterion. The output includes a Frequency table, showing the total number of valid cases for each variable that is specified before BY and the number of valid cases in each group. The output also includes a Test Statistics table, showing the number of runs, *Z*, and one-tailed probability of *Z*. If ties are present, the minimum and maximum number of possible runs, their *Z* statistics, and one-tailed probabilities are displayed.

Syntax

- The minimum specification is a single test variable, the keyword BY, a grouping variable, and two values in parentheses.
- Cases with the first value form one group, and cases with the second value form the other group. The order in which values are specified is unimportant.

Operations

- Cases are combined from both groups and ranked from lowest to highest, and a runs test is performed, using group membership as the criterion. For ties involving cases from both groups, both the minimum and maximum number of possible runs are calculated. Test statistics are calculated for each variable that is specified before BY.
- For a sample size of 30 or less, the exact one-tailed probability is calculated. For a sample size that is greater than 30, the normal approximation is used.
- Cases with values other than values that are specified for the grouping variable are excluded.

Example

```
NPAR TESTS W-W=V1 BY V3(0,1).
```

- This example ranks cases from lowest to highest based on their values for *V1*, and a runs test is performed. Cases with value 0 for *V3* form one group, and cases with value 1 form the other group.

WILCOXON Subcommand

```
NPAR TESTS WILCOXON=varlist [WITH varlist [(PAIRED)] ]
```

WILCOXON tests whether the distribution of two paired variables in two related samples is the same. This test takes into account the magnitude of the differences between two paired variables. The output includes a Ranks table, showing, for each pair, the number of valid cases, positive and negative differences, their respective mean and sum of ranks, and the number of ties. The output also includes a Test Statistics table, showing *Z* and probability of *Z*.

Syntax

- The minimum specification is a list of two variables.
- If keyword WITH is not specified, each variable is paired with every other variable in the list.
- If keyword WITH is specified, each variable before WITH is paired with each variable after WITH. If PAIRED is also specified, the first variable before WITH is paired with the first variable after WITH, the second variable before WITH is paired with the second variable after WITH, and so on. PAIRED cannot be specified without WITH.
- With PAIRED, the number of variables that are specified before and after WITH must be the same. PAIRED must be specified in parentheses after the second variable list.

Operations

- The differences between the pair of variables are counted, the absolute differences are ranked, the positive and negative ranks are summed, and the test statistic *Z* is computed from the positive and negative rank sums.
- Under the null hypothesis for large sample sizes, *Z* is approximately normally distributed with a mean of 0 and a variance of 1.

Example

```
NPAR TESTS WILCOXON=A B WITH C D (PAIRED).
```

- This example pairs *A* with *C* and *B* with *D*. If PAIRED were not specified, the example would also pair *A* with *D* and *B* with *C*.

STATISTICS Subcommand

STATISTICS requests summary statistics for variables that are named on the NPAR TESTS command. Summary statistics are displayed in the Descriptive Statistics table before all test output.

- If STATISTICS is specified without keywords, univariate statistics (keyword DESCRIPTIVES) are displayed.

DESCRIPTIVES	*Univariate statistics.* The displayed statistics include the mean, maximum, minimum, standard deviation, and number of valid cases for each variable named on the command.
QUARTILES	*Quartiles and number of cases.* The 25th, 50th, and 75th percentiles are displayed for each variable that is named on the command.
ALL	*All statistics available on* NPAR TESTS.

MISSING Subcommand

MISSING controls the treatment of cases with missing values.

- ANALYSIS and LISTWISE are alternatives. However, each of those commands can be specified with INCLUDE.

ANALYSIS	*Exclude cases with missing values on a test-by-test basis.* Cases with missing values for a variable that is used for a specific test are omitted from that test. On subcommands that specify several tests, each test is evaluated separately. This setting is the default.
LISTWISE	*Exclude cases with missing values listwise.* Cases with missing values for any variable that is named on any subcommand are excluded from all analyses.
INCLUDE	*Include user-missing values.* User-missing values are treated as valid values.

SAMPLE Subcommand

NPAR TESTS must store cases in memory. SAMPLE allows you to select a random sample of cases when there is not enough space on your computer to store all cases. SAMPLE has no additional specifications.

- Because sampling would invalidate a runs test, this option is ignored when the RUNS subcommand is used.

METHOD Subcommand

METHOD displays additional results for each requested statistic. If no METHOD subcommand is specified, the standard asymptotic results are displayed. If fractional weights have been specified, results for all methods will be calculated on the weight rounded to the nearest integer. This subcommand is available only if you have the Exact Tests add-on option installed, which is only available on Windows operating systems.

MC Displays an unbiased point estimate and confidence interval, based on the Monte Carlo sampling method, for all statistics. Asymptotic results are also displayed. When exact results can be calculated, they will be provided instead of the Monte Carlo results. See Exact Tests for situations under which exact results are provided instead of Monte Carlo results.

CIN(n) Controls the confidence level for the Monte Carlo estimate. CIN is available only when /METHOD=MC is specified. CIN has a default value of 99.0. You can specify a confidence interval between 0.01 and 99.9, inclusive.

SAMPLES Specifies the number of tables that were sampled from the reference set when calculating the Monte Carlo estimate of the exact *p* value. Larger sample sizes lead to narrower confidence limits but also take longer to calculate. You can specify any integer between 1 and 1,000,000,000 as the sample size. SAMPLES has a default value of 10,000.

EXACT Computes the exact significance level for all statistics, in addition to the asymptotic results. If both the EXACT and MC keywords are specified, only exact results are provided. Calculating the exact *p* value can be memory-intensive. If you have specified /METHOD=EXACT and find that you have insufficient memory to calculate results, close any other applications that are currently running. You can also enlarge the size of your swap file (see your Windows manual for more information). If you still cannot obtain exact results, specify /METHOD=MC to obtain the Monte Carlo estimate of the exact *p* value. An optional TIMER keyword is available if you choose /METHOD=EXACT.

TIMER(n) Specifies the maximum number of minutes during which the exact analysis for each statistic can run. If the time limit is reached, the test is terminated, no exact results are provided, and the program begins to calculate the next test in the analysis. TIMER is available only when /METHOD=EXACT is specified. You can specify any integer value for TIMER. Specifying a value of 0 for TIMER turns the timer off completely. TIMER has a default value of 5 minutes. If a test exceeds a time limit of 30 minutes, it is recommended that you use the Monte Carlo method, rather than the exact method.

NUMERIC

```
NUMERIC varlist[(format)] [/varlist...]
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Example

```
NUMERIC V1.
```

Overview

NUMERIC declares new numeric variables that can be referred to in the transformation language before they are assigned values. Commands such as COMPUTE, IF, RECODE, and COUNT can be used to assign values to the new numeric variables.

Basic Specification

The basic specification is the name of the new variables. By default, variables are assigned a format of F8.2 (or the format that is specified on the SET command).

Syntax Rules

- A FORTRAN-like format can be specified in parentheses following a variable or variable list. Each specified format applies to all variables in the list. To specify different formats for different groups of variables, separate each format group with a slash.
- Keyword TO can be used to declare multiple numeric variables. The specified format applies to each variable that is named and implied by the TO construction.
- NUMERIC can be used within an input program to predetermine the order of numeric variables in the dictionary of the active dataset. When used for this purpose, NUMERIC must precede DATA LIST in the input program.

Operations

- NUMERIC takes effect as soon as it is encountered in the command sequence. Special attention should be paid to the position of NUMERIC among commands. For more information, see Command Order on p. 36.
- The specified formats (or the defaults) are used as both print and write formats.
- Permanent or temporary variables are initialized to the system-missing value. Scratch variables are initialized to 0.
- Variables that are named on NUMERIC are added to the working file in the order in which they are specified. The order in which they are used in transformations does not affect their order in the active dataset.

Examples

Declaring Multiple Numeric Variables

```
NUMERIC V1 V2 (F4.0) / V3 (F1.0).
```

- NUMERIC declares variables *V1* and *V2* with format F4.0 and declares variable *V3* with format F1.0.

```
NUMERIC V1 TO V6 (F3.1) / V7 V10 (F6.2).
```

- NUMERIC declares variables *V1*, *V2*, *V3*, *V4*, *V5*, and *V6* with format F3.1 and declares variables *V7* and *V10* with format F6.2.

Specifying Variable Order in the Active Dataset

```
NUMERIC SCALE85 IMPACT85 SCALE86 IMPACT86 SCALE87 IMPACT87
        SCALE88 IMPACT88.
```

- Variables *SCALE85* to *IMPACT88* are added to the active dataset in the order that is specified on NUMERIC. The order in which they are used in transformations does not affect their order in the active dataset.

```
INPUT PROGRAM.
STRING CITY (A24).
NUMERIC POP81 TO POP83 (F9)/ REV81 TO REV83(F10).
DATA LIST FILE=POPDATA RECORDS=3
  /1 POP81 22-30 REV81 31-40
  /2 POP82 22-30 REV82 31-40
  /3 POP83 22-30 REV83 31-40
  /4 CITY 1-24(A).
END INPUT PROGRAM.
```

- STRING and NUMERIC are specified within an input program to predetermine variable order in the active dataset. Though data in the file are in a different order, the working file dictionary uses the order that is specified on STRING and NUMERIC. Thus, *CITY* is the first variable in the dictionary, followed by *POP81, POP82, POP83, REV81, REV82,* and *REV83*.
- Formats are specified for the variables on NUMERIC. Otherwise, the program uses the default numeric format (F8.2) from the NUMERIC command for the dictionary format, even though it uses the format on DATA LIST to read the data. In other words, the dictionary uses the first formats specified, even though DATA LIST may use different formats to read cases.

OLAP CUBES

```
OLAP CUBES {varlist} BY varlist [BY...]

 [/CELLS= [MEAN**] [COUNT**] [STDDEV**]
          [NPCT**] [SPCT**] [SUM** ]
          [MEDIAN] [GMEDIAN] [SEMEAN] [MIN] [MAX] [RANGE]
          [VARIANCE] [KURT] [SEKURT] [SKEW] [SESKEW] [FIRST]
          [LAST] [NPCT(var)][SPCT(var)] [HARMONIC] [GEOMETRIC]
          [DEFAULT] [ALL] [NONE] ]

 [/CREATE [{'catname'}...] =  {GAC    } (gvarname {(gvarvalue gvarvalue)   }
           {DEFAULT  }        {GPC    }          [{(gvarvalue gvarvalue)...}])]
                              {GAC GPC}

                              --or--

                              {VAC    } {(svarname svarname)}
                              {VPC    } {(svarname svarname)...}
                              {VAC VPC}

 [/TITLE ='string'][FOOTNOTE= 'string']
```

**Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
OLAP CUBES sales BY quarter by region.
```

Overview

`OLAP CUBES` produces summary statistics for continuous, quantitative variables within categories defined by one or more categorical grouping variables.

Basic Specification

The basic specification is the command name, `OLAP CUBES`, with a summary variable, the keyword `BY`, and one or more grouping variables.

- The minimum specification is a summary variable, the keyword `BY`, and a grouping variable.
- By default, `OLAP CUBES` displays a Case Processing Summary table showing the number and percentage of cases included, excluded, and their total, and a Layered Report showing means, standard deviations, sums, number of cases for each category, percentage of total N, and percentage of total sum.

Syntax Rules

- Both numeric and string variables can be specified. String variables can be short or long. Summary variables must be numeric.

- String specifications for TITLE and FOOTNOTE cannot exceed 255 characters. Values must be enclosed in quotes. When the specification breaks on multiple lines, enclose each line in quotes and separate the specifications for each line by at least one blank. To specify line breaks in titles and footnotes, use the \n specification.
- Each subcommand can be specified only once. Multiple use results in a warning, and the last specification is used.
- When a variable is specified more than once, only the first occurrence is honored. The same variables specified after different BY keywords will result in an error.

Limitations

- Up to 10 BY keywords can be specified.

Operations

- The data are processed sequentially. It is not necessary to sort the cases before processing. If a BY keyword is used, the output is always sorted.
- A Case Processing Summary table is always generated, showing the number and percentage of the cases included, excluded, and the total.
- For each combination of grouping variables specified after different BY keywords, OLAP CUBES produces a group in the report.

Examples

```
OLAP CUBES SALES BY REGION BY INDUSTRY
  /CELLS=MEAN MEDIAN SUM.
```

- A Case Processing Summary table lists the number and percentage of cases included, excluded, and the total.
- A Layered Report displays the requested statistics for sales for each group defined by each combination of *REGION* and *INDUSTRY.*

Options

Cell Contents. By default, OLAP CUBES displays means, standard deviations, cell counts, sums, percentage of total N, and percentage of total sum. Optionally, you can request any combination of available statistics.

Group Differences. You can display arithmetic and/or percentage differences between categories of a grouping variable or between different variables with the CREATE subcommand.

Format. You can specify a title and a caption for the report using the TITLE and FOOTNOTE subcommands.

TITLE and FOOTNOTE Subcommands

TITLE and FOOTNOTE provide a title and a caption for the Layered Report.

- TITLE and FOOTNOTE are optional and can be placed anywhere.
- The specification on TITLE or FOOTNOTE is a string within quotes. To specify a multiple-line title or footnote, enclose each line in quotes and separate the specifications for each line by at least one blank.
- To insert line breaks in the displayed title or footnote, use the \n specification.
- The string you specify cannot exceed 255 characters.

CELLS Subcommand

By default, OLAP CUBES displays the means, standard deviations, number of cases, sum, percentage of total cases, and percentage of total sum.

- If CELLS is specified without keywords, OLAP CUBES displays the default statistics.
- If any keywords are specified on CELLS, only the requested information is displayed.

DEFAULT	*Means, standard deviations, cell counts, sum, percentage of total N, and percentage of total sum.* This is the default if CELLS is omitted.
MEAN	*Cell means.*
STDDEV	*Cell standard deviations.*
COUNT	*Cell counts.*
MEDIAN	*Cell median.*
GMEDIAN	*Grouped median.*
SEMEAN	*Standard error of cell mean.*
SUM	*Cell sums.*
MIN	*Cell minimum.*
MAX	*Cell maximum.*
RANGE	*Cell range.*
VARIANCE	*Variances.*
KURT	*Cell kurtosis.*
SEKURT	*Standard error of cell kurtosis.*
SKEW	*Cell skewness.*
SESKEW	*Standard error of cell skewness.*
FIRST	*First value.*
LAST	*Last value.*
SPCT	*Percentage of total sum.*
NPCT	*Percentage of total number of cases.*
SPCT(var)	*Percentage of total sum within specified variable.* The specified variable must be one of the grouping variables.
NPCT(var)	*Percentage of total number of cases within specified variable.* The specified variable must be one of the grouping variables.
HARMONIC	*Harmonic mean.*
GEOMETRIC	*Geometric mean.*
ALL	*All cell information.*

CREATE Subcommand

CREATE allows you to calculate and display arithmetic and percentage differences between groups or between variables. You can also define labels for these difference categories.

GAC (gvar(cat1 cat2)) *Arithmetic difference (change) in the summary variable(s) statistics between each specified pair of grouping variable categories.* The keyword must be followed by a grouping variable name specified in parentheses, and the variable name must be followed by one or more pairs of grouping category values. Each pair of values must be enclosed in parentheses inside the parentheses that contain the grouping variable name. String values must be enclosed in single or double quotation marks. You can specify multiple pairs of category values, but you can only specify one grouping variable, and the grouping variable must be one of the grouping variables specified at the beginning of the OLAP CUBES command, after the BY keyword.

The difference calculated is the summary statistic value for the second category specified minus the summary statistic value for the first category specified: cat2 – cat1.

GPC (gvar(cat1 cat2)) *Percentage difference (change) in the summary variable(s) statistics between each specified pair of grouping variable categories.* The keyword must be followed by a grouping variable name enclosed in parentheses, and the variable name must be followed by one or more pairs of grouping category values. Each pair of values must be enclosed in parentheses inside the parentheses that contain the grouping variable name. String values must be enclosed in single or double quotation marks. You can specify multiple pairs of category values, but you can only specify one grouping variable, and the grouping variable must be one of the grouping variables specified at the beginning of the OLAP CUBES command, after the BY keyword.

The percentage difference calculated is the summary statistic value for the second category specified minus the summary statistic value for the first category specified, divided by the summary statistic value for the first category specified: (cat2 – cat1)/cat1.

VAC(svar1 svar2) *Arithmetic difference (change) in summary statistics between each pair of specified summary variables.* Each pair of variables must be enclosed in parentheses, and all specified variables must be specified as summary variables at the beginning of the OLAP CUBES command.

The difference calculated is the summary statistic value for the second variable specified minus the summary statistic value for the first variable specified: svar2 – svar1.

VPC(svar1 svar2) *Percentage difference (change) in summary statistics between each pair of specified summary variables*. Each pair of variables must be enclosed in parentheses, and all specified variables must be specified as summary variables at the beginning of the OLAP CUBES command.

The percentage difference calculated is the summary statistic value for the second variable specified minus the summary statistic value for the first variable specified: (svar2 – svar1)/svar1.

'category label' *Optional label for each difference category created*. These labels must be the first specification in the CREATE subcommand. Each label must be enclosed in single or double quotation marks. If no labels are specified, defined value or variable labels are used. If no labels are defined, data values or variable names are displayed. If multiple differences are created, the order of the labels corresponds to the order the differences are specified. To mix custom labels with default labels, use the keyword DEFAULT for the difference categories without custom labels.

Both arithmetic and percentage differences can be specified in the same command, but you cannot specify both grouping variable differences (GAC/GPC) and summary variable differences (VAC/VPC) in the same command.

Example

```
OLAP CUBES
 sales96   BY region
 /CELLS=SUM NPCT
 /CREATE GAC GPC (region (1 3) (2 3)).
```

- Both the arithmetic (GAC) and percentage (GPC) differences will be calculated.
- Differences will be calculated for two different pairs of categories of the grouping variable *region*.
- The grouping variable specified in the `CREATE` subcommand, *region*, is also specified as a grouping variable at the beginning of the `OLAP CUBES` command.

Example

```
OLAP CUBES
 sales95 sales96   BY region
 /CELLS=SUM NPCT
 /CREATE VAC VPC (sales95 sales96).
```

- Both the arithmetic (VAC) and percentage (VPC) differences will be calculated.
- The difference calculated will be *sales96* - *sales95*.
- The percentage difference calculated will be (*sales96* - *sales95*)/*sales95*.
- The two variables, *sales95* and *sales96* are also specified as summary variables at the beginning of the `OLAP CUBES` command.

Example

```
OLAP CUBES
 sales96   BY region
 /CELLS=SUM NPCT
 /CREATE DEFAULT 'West-East GPC'  DEFAULT 'West-Central % Difference'
 GAC GPC (region (1 3) (2 3)).
```

- Four labels are specified, corresponding to the four difference categories that will be created: arithmetic and percentage differences between regions 3 and 1 and between regions 3 and 2.
- The two `DEFAULT` labels will display the defined value labels or values if there aren't any value labels for the two arithmetic (GAC) difference categories.

OMS

Note: Square brackets used in the OMS syntax chart are required parts of the syntax and are not used to indicate optional elements. Any equals signs (=) displayed in the syntax chart are required. All subcommands except DESTINATION are optional.

```

         {TABTEXT }
         {SAV     }
         {SPV     }

 {OUTFILE = "outfile expression"           }
 {XMLWORKSPACE="name"                      }
 {OUTPUTSET = {SUBTYPES} FOLDER = "dirspec"}
              {LABELS  }

  VIEWER={YES|NO}

  NUMBERED = 'varname'

  IMAGES={YES|NO}
  IMAGEFORMAT={PNG|JPG|EMF|BMP|VML}

  IMAGEROOT='rootname'
  CHARTSIZE=percent

  IMAGEMAP={NO|YES}

  TREEFORMAT={XML|IMAGE}

  CHARTFORMAT={XML|IMAGE}

  TABLES={PIVOTABLE|STATIC}

 /COLUMNS DIMNAMES = ["dimension1" "dimension2" ...]
or
 /COLUMNS SEQUENCE = [R1 R2 ... RALL C1 C2... CALL L1 L2... LALL]

 /TAG = "string"

 /NOWARN
```

- NUMBERED only applies to FORMAT=SAV.
- IMAGES and IMAGEFORMAT only apply to FORMAT=OXML, HTML, and SPV.
- IMAGEROOT and CHARTSIZE only apply to FORMAT=OXML and HTML.
- IMAGEMAP only applies to FORMAT=HTML.

- TREEFORMAT only applies to FORMAT=OXML and SPV.
- CHARTFORMAT only applies to FORMAT=OXML.
- TABLES only applies to FORMAT=SPV files used in Predictive Enterprise Services 3.5.

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Release History

Release 13.0

- TREES keyword introduced on SELECT subcommand.
- IMAGES, IMAGEROOT, CHARTSIZE, and IMAGEFORMAT keywords introduced on DESTINATION subcommand.

Release 14.0

- XMLWORKSPACE keyword introduced on DESTINATION subcommand.

Release 16.0

- IMAGEFORMAT=VML introduced for FORMAT=HTML on DESTINATION subcommand.
- IMAGEMAP keyword introduced for FORMAT=HTML on DESTINATION subcommand.
- FORMAT=SPV introduced for saving output in Viewer format.
- CHARTFORMAT keyword introduced.
- TREEFORMAT keyword introduced.
- TABLES keyword introduced.
- FORMAT=SVWSOXML is no longer supported.

Example

```
OMS
 /DESTINATION FORMAT = OXML OUTFILE = '/mydir/myfile.xml'
  VIEWER = NO.
OMS
 /SELECT TABLES
 /IF COMMANDS = ['Regression']
     SUBTYPES = ['Coefficients']
 /DESTINATION FORMAT = SAV
  OUTFILE = '/mydir/regression_coefficients.sav'.
```

Overview

The OMS command controls the routing and format of output from SPSS to files and can suppress Viewer output. Output formats include: SPSS data file format (SAV), Viewer file format (SPV), XML, HTML, and text.

Basic Specification

The basic specification is the command name followed by a DESTINATION subcommand that contains a FORMAT and/or a VIEWER specification. For FORMAT, an OUTFILE or OUTPUTSET specification is also required.

Syntax Rules

- All subcommands except DESTINATION are optional. No subcommand may occur more than once in each OMS command.
- Multiple OMS commands are allowed. For more information, see Basic Operation below.
- Subcommands can appear in any order.
- If duplicates are found in a list, they are ignored except in /COLUMNS SEQUENCE where they cause an error.
- When a keyword takes a square-bracketed list, the brackets are required even if the list contains only a single item.

Basic Operation

- Once an OMS command is executed, it remains in effect until the end of the session or until ended by an OMSEND command.
- A destination file specified on an OMS command is unavailable to other commands and other applications until the OMS command is ended by an OMSEND command or the end of the session.
- While an OMS command is in effect, the specified destination files are stored in memory (RAM), so active OMS commands that write a large amount of output to external files may consume a large amount of memory.
- Multiple OMS commands are independent of each other (except as noted below). The same output can be routed to different locations in different formats based on the specifications in different OMS commands.
- Display of output objects in the Viewer is determined by the most recent OMS command that includes the particular output type. For example, if an OMS command includes all tables from the FREQUENCIES command and also contains a VIEWER = YES specification, and a subsequent OMS command includes all tables of the subtype 'Statistics' with VIEWER = NO, Statistics tables for subsequent FREQUENCIES commands will *not* be displayed in the Viewer.
- The COLUMNS subcommand has no effect on pivot tables displayed in the Viewer.
- The order of the output objects in any particular destination is the order in which they were created, which is determined by the order and operation of the commands that generate the output.

SELECT Subcommand

SELECT specifies the types of output objects to be routed to the specified destination(s). You can select multiple types. You can also specify ALL with EXCEPT to exclude specified types. If there is no SELECT subcommand, all supported output types are selected.

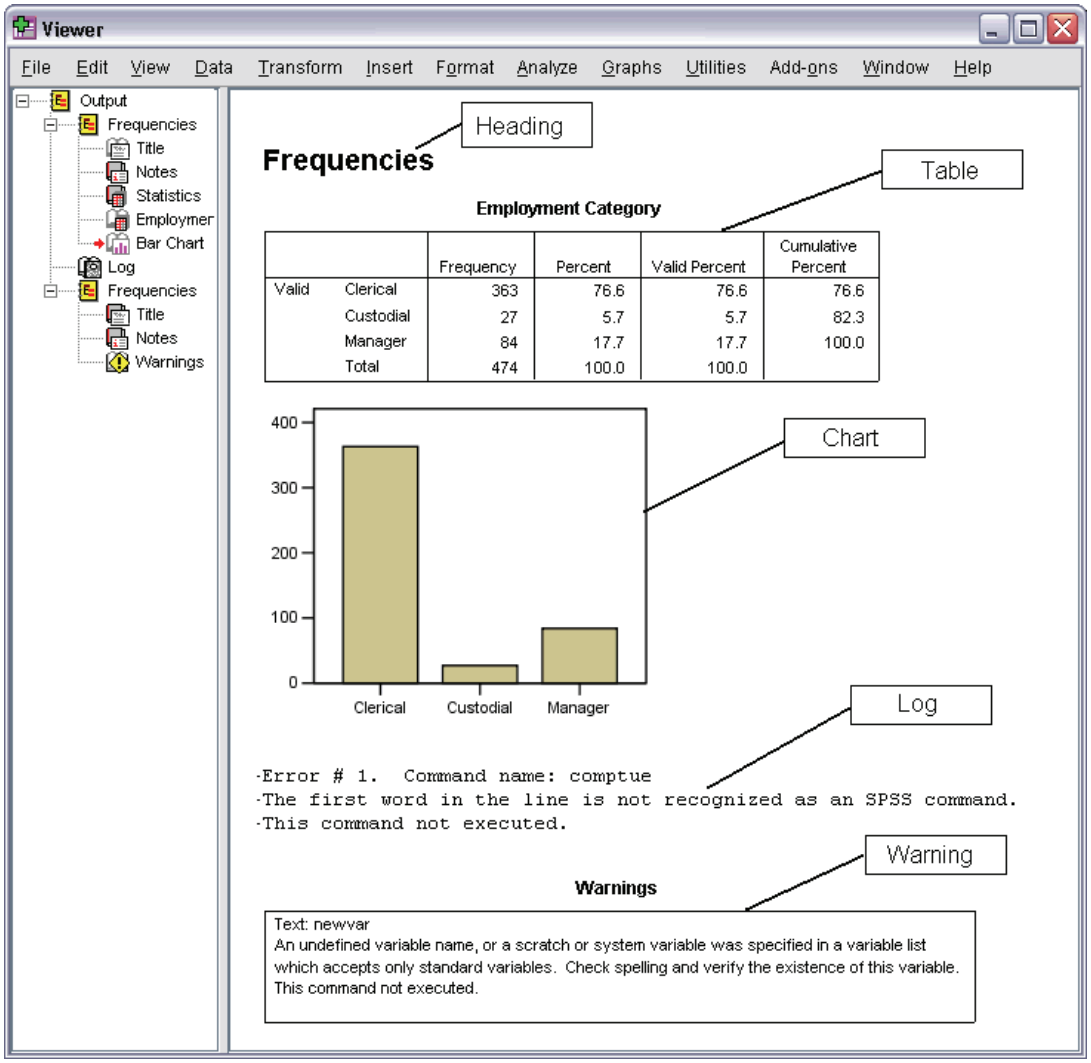
ALL	*All output objects.* This is the default.
CHARTS	*All charts.* This includes charts created by the commands such as GRAPH and GGRAPH and charts created by statistical procedures (for example, the BARCHART subcommand of the FREQUENCIES command). It does not include tree diagrams produced by the TREE procedure.
LOGS	*Log text objects.* Log objects contain certain types of error and warning messages. With SET PRINTBACK=ON, log objects also contain the command syntax executed during the session. Log objects are labeled *Log* in the outline pane of the Viewer.
TABLES	*Output objects that are pivot tables in the Viewer*. This includes Notes tables. Tables are the only output objects that can be routed to the destination format SAV.
TEXTS	*Text objects that aren't logs or headings.* This includes objects labeled *Text Output* in the outline pane of the Viewer.
TREES	*Tree model diagrams produced by the TREE procedure (Classification Tree option).*
HEADINGS	*Text objects labeled Title in the outline pane of the Viewer*. For destination format OXML, heading text objects are not included.
WARNINGS	*Warnings objects.* Warnings objects contain certain types of error and warning messages.
EXCEPT = [list]	*Select all types except those in the bracketed list.*Used with keyword ALL.

Example

```
OMS /SELECT TABLES LOGS TEXTS WARNINGS HEADINGS
    /DESTINATION FORMAT = HTML OUTFILE = '/mypath/myfile1.htm'.
OMS /SELECT ALL EXCEPT = [CHARTS]
    /DESTINATION FORMAT = HTML OUTFILE = '/mypath/myfile2.htm'.
```

The two SELECT subcommands are functionally equivalent. The first one explicitly lists all types but CHARTS, and the second one explicitly excludes only CHARTS.

Figure 146-1
Output object types in the Viewer



Notes Table Limitation

An OMS command that selects only tables will not select a Notes table if the Notes tables is the only table produced by a procedure. This can occur if the command contains syntax errors that result in a Notes table and a warning object, but no other tables. For example:

```
DATA LIST FREE /var1 var2.
BEGIN DATA
1 2
END DATA.
OMS SELECT TABLES
  /DESTINATION FORMAT=HTML
   OUTFILE='/temp/htmltest.htm'.
FREQUENCIES VARIABLES=var1.
DESCRIPTIVES VARIABLES=var02.
OMSEND.
```

The DESCRIPTIVES command refers to a variable that doesn't exist, causing an error that results in the creation of a Notes table and a warning object, but the HTML file will not include this Notes table. To make sure Notes tables are selected when no other tables are created by a procedure, include WARNINGS in the SELECT subcommand, as in:

```
OMS SELECT TABLES WARNINGS
  /DESTINATION FORMAT=HTML
   OUTFILE='/temp/htmltest.htm'.
```

IF Subcommand

The IF subcommand specifies particular output objects of the types determined by SELECT. Without an IF subcommand, all objects of the specified types are selected. If you specify multiple conditions, only those objects that meet *all* conditions will be selected.

Example

```
OMS
 /SELECT TABLES
 /IF COMMANDS = ['Regression']
     SUBTYPES = ['Coefficients']
 /DESTINATION FORMAT = SAV
  OUTFILE = '/mydir/regression_coefficients.sav'.
```

This OMS command specifies that only coefficient tables from the REGRESSION command will be selected.

COMMANDS Keyword

The COMMANDS keyword restricts the selection to the specified command(s). The keyword COMMANDS must be followed by an equals sign (=) and a list of quoted command identifiers enclosed in square bracket, as in:

```
OMS
 /SELECT TABLES
 /IF COMMANDS = ['Frequencies' 'Factor Analysis']
 /DESTINATION...
```

Command identifiers are:

- Unique. No two commands have the same identifier.
- Not case-sensitive.
- Not subject to translation, which means they are the same for all language versions and output languages.
- Often not exactly the same or even similar to the command name. You can obtain the identifier for a particular command from the OMS Control Panel (Utilities menu) or by generating output from the command in the Viewer and then right-clicking the command heading in the outline pane and selecting Copy OMS Command Identifier from the context menu.

Command identifiers are available for all statistical and charting procedures and any other commands that produce blocks of output with their own identifiable heading in the outline pane of the Viewer. For example, CASESTOVARS and VARSTOCASES have corresponding identifiers ('Cases to Variables' and 'Variables to Cases') because they produce their own output blocks (with command headings in the outline pane that happen to match the identifiers), but FLIP does not because any output produced by FLIP is included in a generic Log text object.

SUBTYPES Keyword

The SUBTYPES keyword restricts the selection to the specified table types The keyword SUBTYPES must be followed by an equals sign (=) and a list of quoted subtype identifiers enclosed in square bracket, as in:

```
OMS
 /SELECT TABLES
 /IF SUBTYPES = ['Descriptive Statistics' 'Coefficients']
 /DESTINATION...
```

- Subtypes apply only to tables that would be displayed as pivot tables in the Viewer.
- Like command identifiers, subtype identifiers are not case-sensitive and are not subject to translation.
- Unlike command identifiers, subtype identifiers are not necessarily unique. For example, multiple commands produce a table with the subtype identifier "Descriptive Statistics," but not all of those tables share the same structure. If you want only a particular table type for a particular command, use both the COMMANDS and SUBTYPES keywords.
- The OMS Control Panel (Utilities menu) provides a complete list of subtypes. You can also obtain the identifier for a particular table by generating output from the command in the Viewer and then right-clicking outline item for the Table in the outline pane of the Viewer and selecting Copy OMS Table Subtype from the context menu. The identifiers are generally fairly descriptive of the particular table type.

LABELS Keyword

The LABELS keyword selects particular output objects according to the text displayed in the outline pane of the Viewer. The keyword LABELS must be followed by an equals sign (=) and a list of quoted label text enclosed in square brackets, as in:

```
OMS
 /SELECT TABLES
 /IF LABELS = ['Job category * Gender Crosstabulation']
 /DESTINATION...
```

The LABELS keyword is useful for differentiating between multiple graphs or multiple tables of the same type in which the outline text reflects some attribute of the particular output object such as the variable names or labels. There are, however, a number of factors that can affect the label text:

- If split file processing is on, split file group identification may be appended to the label.

- Labels that include information about variables or values are affected by the OVARS and ONUMBERS settings on the SET command.
- Labels are affected by the current output language setting (SET OLANG).

INSTANCES Keyword

The INSTANCES subcommand selects the *n*th instance of an object matching the other criteria on the IF subcommand within a single command execution. The keyword INSTANCES must be followed by an equals sign (=) and a list of positive integers and/or the keyword LAST enclosed in square brackets.

Example

```
OMS
 /SELECT TABLES
 /IF COMMANDS = ['Frequencies']
     SUBTYPES = ['Frequencies']
     INSTANCES = [1 LAST]
 /DESTINATION...
OMS
 /SELECT TABLES
 /IF COMMANDS = ['Frequencies']
     INSTANCES = [1 LAST]
 /DESTINATION...
```

- The first OMS command will select the first and last frequency tables from each FREQUENCIES command.
- The second OMS command, in the absence of a SUBTYPES or LABELS specification, will select the first and last tables of *any* kind from the selected command. For the FREQUENCIES command (and most other statistical and charting procedures), the first table would be the Notes table.

Wildcards

For COMMANDS, SUBTYPES, and LABELS, you can use an asterisk (*) as a wildcard indicator at the end of a quoted string to include all commands, tables, and/or charts that start with that quoted string, as in:

```
OMS
 /SELECT TABLES
 /IF SUBTYPES = ['Correlation*']
 /DESTINATION...
```

In this example, all table subtypes that begin with “Correlation” will be selected.

The values of LABELS can contain asterisks as part of the value as in “First variable * Second variable Crosstabulation,” but only an asterisk as the last character in the quoted string is interpreted as a wildcard, so:

```
OMS
 /SELECT TABLES
 /IF LABELS = ['First Variable **']
 /DESTINATION...
```

will select all tables with labels that start with “First Variable *”.

EXCEPTIF Subcommand

The EXCEPTIF subcommand excludes specified output object types. It has the same keywords and syntax as IF, with the exception of INSTANCES, which will cause an error if used with EXCEPTIF.

Example

```
OMS
 /SELECT TABLES
 /IF COMMANDS = ['Regression']
 /EXCEPTIF SUBTYPES = ['Notes' 'Case Summar*']
 /DESTINATION...
```

DESTINATION Subcommand

The DESTINATION subcommand is the only required subcommand. It specifies the format and location for the routed output. You can also use this subcommand to control what output is displayed in the Viewer.

- Output continues to flow to a specified destination until its OMS specification is ended, at which point the file is closed. For more information, see Basic Operation on p. 1286.
- Different OMS commands may refer to the same destination file as long as the FORMAT is the same. When a request becomes active, it starts contributing to the appropriate output stream. If the FORMAT differs, an error results. When multiple requests target the same destination, the output is written in the order in which it is created, not the order of OMS commands.

Example

```
OMS
 /DESTINATION FORMAT = OXML OUTFILE = '/mydir/myfile.xml'.
```

FORMAT Keyword

The DESTINATION subcommand must include either a FORMAT or VIEWER specification (or both). The FORMAT keyword specifies the format for the routed output. The keyword must be followed by an equals sign (=) and one of the following alternatives:

HTML	*HTML 4.0.* Output objects that would be pivot tables in the Viewer are converted to simple HTML tables. No TableLook attributes (font characteristics, border styles, colors, etc.) are supported. Text output objects are tagged <PRE> in the HTML. Charts and tree model diagrams can be included as separate image files. The image files are saved in a separate subdirectory (folder).
OXML	*Output XML.* XML that conforms to the spss-output schema (*xml.spss.com/spss/oms*). For more information, see OXML Table Structure on p. 1309.

SAV	*SPSS format data file.* This is a binary file format. All output object types other than tables are excluded. Each column of a table becomes a variable in the data file. To use a data file created with OMS in the same session, you must specify an OMSEND command to end the active OMS request before you can open the data file. For more information, see Routing Output to SAV Files on p. 1301. In Unicode mode, the file encoding is UTF-8; in code page mode, the file encoding is the code page determined by the current locale. See SET command, UNICODE subcommand for more information.
SPV	*SPSS Viewer file format.* This is the same format used when you save the contents of a Viewer window.
TEXT	*Space-separated text.* Output is written as text, with tabular output aligned with spaces for fixed-pitch fonts. Charts are excluded. In Unicode mode, the file encoding is UTF-8; in code page mode, the file encoding is the code page determined by the current locale. See SET command, UNICODE subcommand for more information.
TABTEXT	*Tab-delimited text*. For output that would be pivot tables in the Viewer, tabs delimit table columns elements. Text block lines are written as is; no attempt is made to divide them with tabs at useful places. All charts are excluded. In Unicode mode, the file encoding is UTF-8; in code page mode, the file encoding is the code page determined by the current locale. See SET command, UNICODE subcommand for more information.

NUMBERED Keyword

For FORMAT = SAV, you can also specify the NUMBERED keyword to identify the source tables, which can be useful if the data file is constructed from multiple tables. This creates an additional variable in the data file. The value of the variable is a positive integer that indicates the sequential table number. The default variable name is *TableNumber_*. You can override the default with an equals sign (=) followed by a valid variable name in quotes after the NUMBERED keyword.

Example

```
OMS
 /SELECT TABLES
 /IF COMMANDS = ['Regression'] SUBTYPES = ['Coefficients']
 /DESTINATION = SAV NUMBERED = 'Table_number'
  OUTFILE = 'data.sav'.
```

IMAGES and IMAGEFORMAT Keywords

For HTML and OXML document format, you can include charts and tree diagrams in a number of different graphic formats with the IMAGES and IMAGEFORMAT keywords. For SPV document format, these settings only apply to tree diagrams, not charts.

IMAGES Keyword

- IMAGES=YES produces a separate image file for each chart and/or tree diagram. Image files are saved in a separate subdirectory (folder). The subdirectory name is the name of the destination file without any extension and with "_files" appended to the end. This is the default setting.
- For HTML document format, standard <IMG SRC='filename'> tags are included in the HTML document for each image file.

- For OXML document format, the XML file contains a `chart` element with an `ImageFile` attribute of the general form `<chart imageFile="filepath/filename"/>` for each image file. `IMAGES=YES` has no effect on `FORMAT=OXML` unless you also specify `CHARTFORMAT=IMAGE`. For more information, see CHARTFORMAT Keyword on p. 1296.
- For SPV document format, tree diagrams are included in the Viewer document in the form of static images. `IMAGES=YES` has no effect on `FORMAT=SPV` unless you also specify `TREEFORMAT=IMAGE`. For more information, see TREEFORMAT Keyword on p. 1295.
- For HTML format, `IMAGES=NO` excludes charts and tree diagrams. For OXML and SPV document formats, `IMAGES=NO` causes charts and/or tree diagrams to be included in the document in XML format instead of as separate image files.

IMAGEFORMAT Keyword

- PNG is the default image format.
- For HTML document format, the available image formats are PNG, JPG, EMF, BMP, and VML.
- For OXML document format, the available image formats are PNG, JPG, EMF, and BMP.
- For SPV document format, the available image formats are PNG, JPG, and BMP.
- EMF (enhanced metafile) format is available only on Windows operating systems.
- VML image format does not create separate image files. The VML code that renders the image is embedded in the HTML.
- VML image format does not include tree diagrams.

Note: Not all browsers support VML.

Example

```
OMS SELECT TABLES CHARTS
  /DESTINATION FORMAT=HTML
               IMAGES=YES
               IMAGEFORMAT=JPG
               OUTFILE='/htmloutput/julydata.htm'.
```

CHARTSIZE and IMAGEROOT Keywords

For HTML and OXML document formats, you can control the relative size and root name of chart and tree diagram images, if charts and/or tree diagrams are saved as separate image files.

- **CHARTSIZE=n.** Specifies the scaling, expressed as a percentage value between 10 and 200. The default is `CHARTSIZE=100`.
- **IMAGEROOT='rootname'.** User-specified rootname for image files. Image files are constructed from the rootname, an underscore, and a sequential three-digit number. The rootname should be specified in quotes, as in: `IMAGEROOT='julydata'`.

Example

```
OMS SELECT TABLES CHARTS
  /DESTINATION FORMAT=HTML
```

```
  IMAGES=YES
  CHARTSIZE=50
  IMAGEROOT='rutabaga'
  OUTFILE='/htmloutput/julydata.htm'.
```

IMAGEMAP Keyword

For HTML document format, you can use the IMAGEMAP keyword to create image map tooltips that display information for some chart elements, such as the value of the selected point on a line chart or bar on a bar chart. The default is IMAGEMAP=NO. To include image map tooltips, use IMAGEMAP=YES.

IMAGEMAP has no effect on tree diagram images or document formats other than HTML.

Example

```
OMS SELECT TABLES CHARTS
  /DESTINATION FORMAT=HTML
               IMAGES=YES
               IMAGEFORMAT=PNG
               IMAGEMAP=YES
               OUTFILE='/htmloutput/julydata.htm'.
```

TREEFORMAT Keyword

For OXML and SPV document formats, TREEFORMAT controls the format of tree diagrams (produced by the TREE command). The keyword is followed by and equals sign and one of the following alternatives:

- **XML.** Tree diagrams are included as XML that conforms to the pmml schema (*www.dmg.org*). For SPV format, this is the format required to activate and edit trees in the Viewer window. This is the default.
- **IMAGE.** For SPV format, tree diagrams are included in the Viewer document as static images in the selected format. For OXML format, image files are saved in a separate folder. For more information, see IMAGES and IMAGEFORMAT Keywords on p. 1293.

IMAGES=NO overrides the TREEFORMAT setting and includes tree diagrams in XML format. For more information, see IMAGES and IMAGEFORMAT Keywords on p. 1293.

Example

```
OMS SELECT TABLES TREES
  /DESTINATION FORMAT=SPV
               IMAGES=YES
               IMAGEFORMAT=PNG
               TREEFORMAT=IMAGE
               OUTFILE='/viewerdocs/results.spv'.
```

CHARTFORMAT Keyword

For OXML document format, CHARTFORMAT controls the format of charts. The keyword is followed by and equals sign and one of the following alternatives:

- **XML.** Charts are included as XML that conforms to the vizml schema (*xml.spss.com/spss/visualization*). This is the default.
- **IMAGE.** For SPV format, charts are included in the Viewer document as static images in the selected format. Image files are saved in the selected format in a separate folder. For more information, see IMAGES and IMAGEFORMAT Keywords on p. 1293.

IMAGES=NO overrides the CHARTFORMAT setting and includes charts in XML format. For more information, see IMAGES and IMAGEFORMAT Keywords on p. 1293.

TABLES Keyword

For SPV files used in Predictive Enterprise Services 3.5, the TABLES keyword controls the format of tables. The keyword is followed by an equals sign and one of the following alternatives:

- **PIVOTABLE.** Tables are included as dynamic pivot tables. This is the default.
- **STATIC.** Tables cannot be pivoted.

This keyword only applies to SPV format files used in Predictive Enterprise Services 3.5. It has no effect on pivot tables displayed in the Viewer window.

OUTFILE Keyword

If a FORMAT is specified, the DESTINATION subcommand must also include either an OUTFILE, XMLWORKSPACE, or OUTPUTSET specification. OUTFILE specifies an output file. The keyword must be followed by an equals sign (=) and a file specification in quotes or a previously defined file handle defined with the FILE HANDLE command. With FORMAT=SAV, you can specify a previously defined dataset name instead of a file.

Example

```
OMS
 /DESTINATION FORMAT = OXML OUTFILE = '/mydir/myfile.xml'.
```

XMLWORKSPACE Keyword

For FORMAT=OXML, you can route the output to a "workspace," and the output can then be used in flow control and other programming features available with BEGIN PROGRAM-END PROGRAM.

Example

```
OMS SELECT TABLES
  /IF COMMANDs=['Frequencies'] SUBTYPES=['Frequencies']
 /DESTINATION FORMAT=OXML XMLWORKSPACE='freq_table'.
```

For more information, see BEGIN PROGRAM-END PROGRAM on p. 212.

OUTPUTSET Keyword

OUTPUTSET is an alternative to OUTFILE that allows you to route each output object to a separate file. The keyword must be followed by an equals sign (=) and one of the following alternatives:

LABELS	*Output file names based on output object label text.* Label text is the text that appears in the outline pane of the Viewer. For more information, see LABELS Keyword on p. 1290.
SUBTYPES	*Output file names based on subtype identifiers.* Subtypes apply only to tables. For more information, see SUBTYPES Keyword on p. 1290.

Example

```
OMS
 /SELECT TABLES
 /DESTINATION FORMAT = OXML OUTPUTSET = SUBTYPES.
```

- OUTPUTSET will not overwrite existing files. If a specified file name already exists, an underscore and a sequential integer will be appended to the file name.
- You cannot use OUTPUTSET with FORMAT=SVWSOXML.

FOLDER Keyword

With *OUTPUTSET*, you can also use the FOLDER keyword to specify the location for the routed output. Since you may not know what is considered to be the "current" directory, it's probably a good idea to explicitly specify the location. The keyword must be followed by an equals sign (=) and a valid location specification in quotes.

Example

```
OMS
 /SELECT TABLES
 /IF SUBTYPES = ['Frequencies' 'Descriptive Statistics']
 /DESTINATION FORMAT = OXML OUTPUTSET = SUBTYPES
  FOLDER = '/maindir/nextdir/newdir'.
```

- If the last folder (directory) specified on the path does not exist, it will be created.
- If any folders prior to the last folder on the path do not already exist, the specification is invalid, resulting in an error.

VIEWER Keyword

By default, output is displayed in the Viewer as well as being routed to other formats and destinations specified with the FORMAT keyword. You can use VIEWER = NO to suppress the Viewer display of output for the specified output types. The VIEWER keyword can be used without the FORMAT keyword (and associated OUTFILE or OUPUTSET keywords) to simply control what output is displayed in the Viewer.

Example

```
OMS
 /SELECT TABLES
 /IF SUBTYPES = ['Correlations*']
 /DESTINATION FORMAT SAV OUTFILE = '/mydir/myfile.sav'
  VIEWER = NO.
OMS
 /SELECT TABLES
 /IF SUBTYPES = ['NOTES']
 /DESTINATION VIEWER = NO.
```

- The first OMS command will route tables with subtype names that start with “Correlation” to an SPSS-format data file and will not display those tables in the Viewer. All other output will be displayed in the Viewer
- The second OMS command simply suppresses the Viewer display of all Notes tables, without routing the Notes table output anywhere else.

COLUMNS Subcommand

You can use the COLUMNS subcommand to specify the dimension elements that should appear in the columns. All other dimension elements appear in the rows.

- This subcommand applies only to tables that would be displayed as pivot tables in the Viewer and is ignored without warning if the OMS command does not include any tables.
- With DESTINATION FORMAT = SAV, columns become variables in the data file. If you specify multiple dimension elements on the COLUMNS subcommand, then variable names will be constructed by combining nested element and column labels. For more information, see Routing Output to SAV Files on p. 1301.
- The COLUMNS subcommand has no effect on pivot tables displayed in the Viewer.
- If you specify multiple dimension elements, they are nested in the columns in the order in which they are listed on the COLUMNS subcommand. For example: COLUMNS DIMNAMES=['Variables' 'Statistics'] will nest statistics within variables in the columns.
- If a table doesn’t contain any of the dimension elements listed, then all dimension elements for that table will appear in the rows.

DIMNAMES Keyword

The COLUMNS subcommand must be followed by either the DIMNAMES or SEQUENCE keyword. Each dimension of a table may contain zero or more elements. For example, a simple two-dimensional crosstabulation contains a single row dimension element and a single column dimension element, each with labels based on the variables in those dimensions, plus a single layer dimension element labeled *Statistics* (if English is the output language). These element labels may vary based on the output language (SET OLANG) and/or settings that affect the display of variable names and/or labels in tables (SET TVARS). The keyword DIMNAMES must be followed by an equals sign (=) and a list of quoted dimension element labels enclosed in square brackets.

Example

```
OMS
 /SELECT TABLES
 /IF COMMANDS = ['Correlations' 'Frequencies']
 /DESTINATION FORMAT = SAV OUTPUTSET = SUBTYPES
 /COLUMNS DIMNAMES = ['Statistics'].
```

The labels associated with the dimension elements may not always be obvious. To see all the dimension elements and their labels for a particular pivot table:

- Activate (double-click) the table in the Viewer.
- From the menus choose View > Show All.

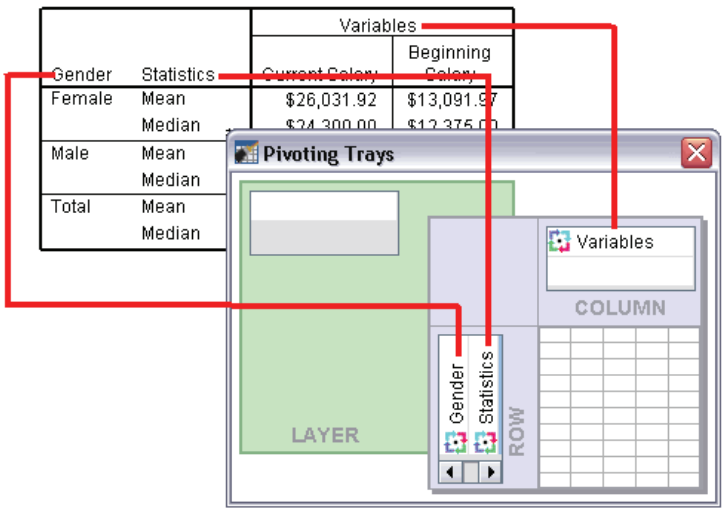
  and/or
- If the pivoting trays aren't displayed, from the menus choose Pivot > Pivoting Trays.
- Hover over each icon in the pivoting trays for a ToolTip pop-up that displays the label.

Figure 146-2
Displaying table dimension element labels

Table without Dimension Element Labels Displayed

		Current Salary	Beginning Salary
Female	Mean	$26,031.92	$13,091.97
	Median	$24,300.00	$12,375.00
Male	Mean	$41,441.78	$20,301.40
	Median	$32,850.00	$15,750.00
Total	Mean	$34,419.57	$17,016.09
	Median	$28,875.00	$15,000.00

Table with Dimension Element Labels Displayed



SEQUENCE Keyword

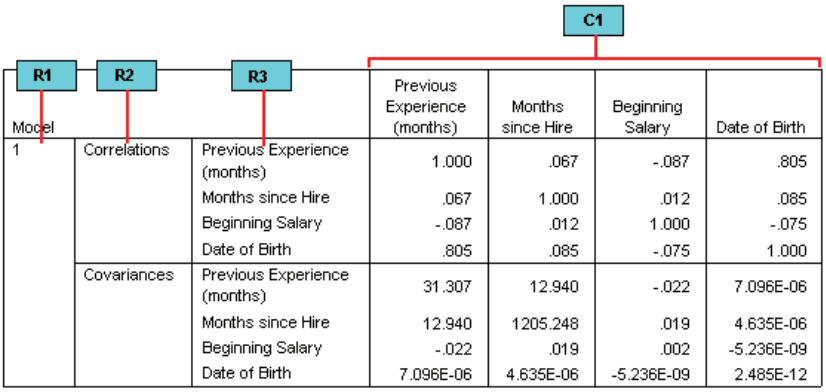
SEQUENCE is an alternative to DIMNAMES that uses positional arguments. These positional arguments do not vary based on output language or output display settings. The SEQUENCE keyword must be followed by an equals sign (=) and a list of positional arguments enclosed in square brackets.

- The general form of a positional argument is a letter indicating the default position of the element—C for column, R for row, or L for layer—followed by a positive integer indicating the default position within that dimension. For example, R1 would indicate the outermost row dimension element.
- A letter indicating the default dimension followed by ALL indicates all elements in that dimension in their default order. For example, RALL would indicate all row dimension elements, and CALL by itself would be unnecessary since it would not alter the default arrangement of the table. ALL cannot be combined with positional sequence numbers in the same dimension.
- SEQUENCE=[CALL RALL LALL] will put all dimension elements in the columns. With FORMAT=SAV, this will result in one case per table in the data file.

Example

```
OMS
 /SELECT TABLES
 /IF COMMANDS = ['Regression'] SUBTYPES = ['Coefficient Correlations']
 /DESTINATION FORMAT = SAV OUTFILE = '/mydir/myfile.sav'
 /COLUMNS SEQUENCE = [R1 R2].
```

Figure 146-3
Positional arguments for dimension elements



Model			Previous Experience (months)	Months since Hire	Beginning Salary	Date of Birth

		Date of Birth	7.096E-06	4.635E-06	-5.236E-09	2.485E-12

TAG Subcommand

OMS commands remain in effect until the end of the session or until you explicitly end them with the OMSEND command, and you can have multiple OMS commands in effect at the same time. You can use the TAG subcommand to assign an ID value to each OMS command, which allows you to selectively end particular OMS commands with a corresponding TAG keyword on the OMSEND command. The ID values assigned on the TAG subcommand are also used to identify OMS commands in the log created by the OMSLOG command.

Example

```
OMS
 /DESTINATION FORMAT = OXML OUTFILE = '/mydir/myfile.xml'
 /TAG = 'oxmlout'.
```

- The TAG subcommand must be followed by an equals sign (=) and a quoted ID value.
- The ID value cannot start with a dollar sign.
- Multiple active OMS commands cannot use the same TAG value.

See OMSEND and OMSLOG for more information.

NOWARN Subcommand

The NOWARN subcommand suppresses all warnings from OMS. The NOWARN subcommand applies only to the current OMS command. It has no additional specifications.

Routing Output to SAV Files

An SPSS data file consists of variables in the columns and cases in the rows, and that's essentially how pivot tables are converted to data files:

- Columns in the table are variables in the data file. Valid variable names are constructed from the column labels.
- Row labels in the table become variables with generic variable names (*Var1*, *Var2*, *Var3*...) in the data file. The values of these variables are the row labels in the table.
- Three table-identifier variables are automatically included in the data file: *Command_*, *Subtype_*, and *Label_*. All three are string variables. The first two are the command and subtype identifiers. *Label_* contains the table title text.
- Rows in the table become cases in the data file.

Data File Created from One Table

Data files can be created from one or more tables. There are two basic variations for data files created from a single table:

- Data file created from a two-dimensional table with no layers.
- Data file created from a three-dimension table with one or more layers.

Example

In the simplest case—a single, two-dimensional table—the table columns become variables and the rows become cases in data file.

Figure 146-4
Single two-dimensional table

Report

Gender		Current Salary	Beginning Salary
Female	Mean	$26,031.92	$13,091.97
	Median	$24,300.00	$12,375.00
	Minimum	$15,750	$9,000
	Maximum	$58,125	$30,000
Male	Mean	$41,441.78	$20,301.40
Total			

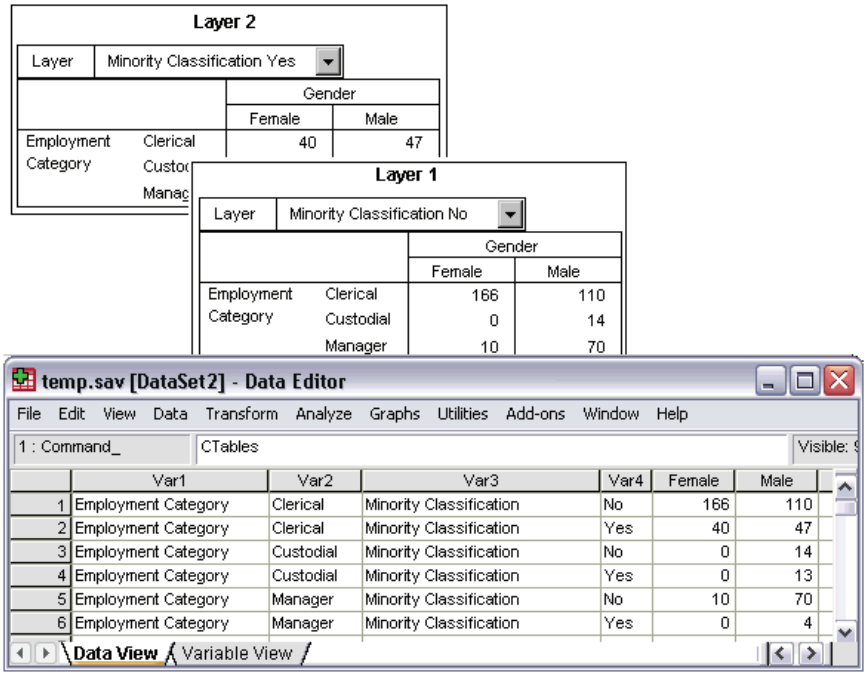
	Command_	Subtype_	Label_	Var1	Var2	CurrentSalary	BeginningSal
1	Means	Report	Report	Female	Mean	$26,031.92	$13,091.97
2	Means	Report	Report	Female	Median	$24,300.00	$12,375.00
3	Means	Report	Report	Female	Minimum	$15,750	$9,000
4	Means	Report	Report	Female	Maximum	$58,125	$30,000
5	Means	Report	Report	Male	Mean	$41,441.78	$20,301.40
6	Means	Report	Report	Male	Median	$32,850.00	$15,750.00
7	Means	Report	Report	Male	Minimum	$19,650	$9,000
8	Means	Report	Report	Male	Maximum	$135,000	$79,980
9	Means	Report	Report	Total	Mean	$34,419.57	$17,016.09

- The first three variables identify the source table by command, subtype, and label.
- The two elements that defined the rows in the table—values of the variable *Gender* and statistical measures—are assigned the generic variable names *Var1* and *Var2*. These are both string variables.
- The column labels from the table are used to create valid variable names. In this case, those variable names are based on the variable labels of the three scale variables summarized in the table. If the variables didn't have defined variable labels or you chose to display variable names instead of variable labels as the column labels in the table, then the variable names in the new data file would be the same as in the source data file.

Example

If the default table display places one or more elements in layers, additional variables are created to identify the layer values.

Figure 146-5
Table with layers



- In the table, the variable labeled *Minority Classification* defines the layers. In the data file, this creates two additional variables: one that identifies the layer element, and one that identifies the categories of the layer element.
- As with the variables created from the row elements, the variables created from the layer elements are string variables with generic variable names (the prefix *Var* followed by a sequential number).

Data Files Created from Multiple Tables

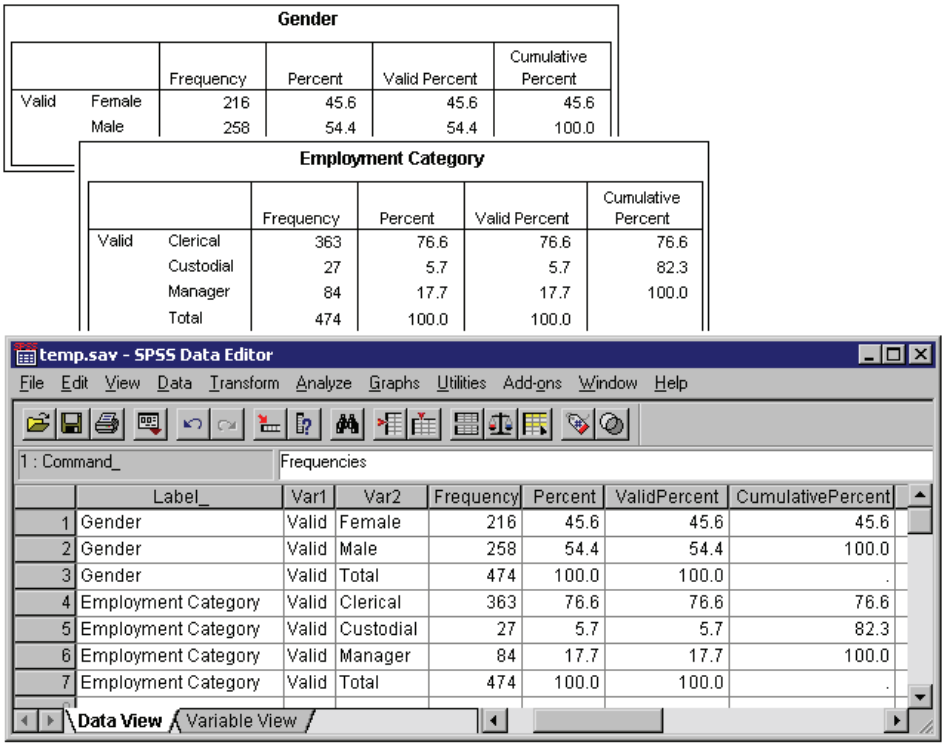
When multiple tables are routed to the same data file, each table is added to the data file in a fashion similar to the `ADD FILES` command.

- Each subsequent table will always add cases to the data file.
- If column labels in the tables differ, each table may also add variables to the data file, with missing values for cases from other tables that don't have an identically labeled column.

Example

Multiple tables that contain the same column labels will typically produce the most immediately useful data files (data files that don't require additional manipulation).

Figure 146-6
Multiple tables with the same column labels



Gender

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	Female	216	45.6	45.6	45.6
	Male	258	54.4	54.4	100.0

Employment Category

		Frequency	Percent	Valid Percent	Cumulative Percent

Data View | Variable View

- The second table contributes additional cases (rows) to the data file but no new variables because the column labels are exactly the same; so there are no large patches of missing data.
- Although the values for *Command_* and *Subtype_* are the same, the *Label_* value identifies the source table for each group of cases because the two frequency tables have different titles.

Example

A new variable is created in the data file for each unique column label in the tables routed to the data file, which will result in blocks of missing values if the tables contain different column labels.

Figure 146-7
Multiple tables with different column labels

Data View | Variable View

- The first table has columns labeled *Beginning Salary* and *Current Salary*, which are not present in the second table, resulting in missing values for those variables for cases from the second table.
- Conversely, the second table has columns labeled *Education level* and *Months since hire*, which are not present in the first table, resulting in missing values for those variables for cases from the first table.
- Mismatched variables, such as those in this example, can occur even with tables of the same subtype. In fact, in this example, both tables are of the same subtype.

Data Files Not Created from Multiple Tables

If any tables do not have the same number of row elements as the other tables, no data file will be created. The number of rows doesn't have to be the same; the number of row *elements* that become variables in the data file must be the same.

For example, a two-variable crosstabulation and a three-variable crosstabulation from `CROSSTABS` contain different numbers of row elements, since the "layer" variable is actually nested within the row variable in the default three-variable crosstabulation display.

Figure 146-8
Tables with different numbers of row elements

Employment Category * Gender Crosstabulation

		Gender		
		Female	Male	Total
Employment Category	Clerical	206	157	363
	Custodial	0	27	27
	Manager	10	74	84
Total		216	258	474

Employment Category * Gender * Minority Classification Crosstabulation

			Gender		
Minority Classification			Female	Male	Total
No	Employment Category	Clerical	166	110	276
		Custodial	0	14	14
		Manager	10	70	80
	Total		176	194	370
Yes	Employment Category	Clerical	40	47	87
		Custodial	0	13	13
		Manager	0	4	4
	Total		40	64	104

In general, the less specific the subtype selection in the OMS command, the less likely you are to get sensible data files, or any data files at all. For example:

```
OMS /SELECT TABLES /DESTINATION FORMAT=SAV OUTFILE='mydata.sav'.
```

will probably fail to create a data file more often than not, since it will select all tables, including Notes tables, which have a table structure that is incompatible with most other table types.

Controlling Column Elements to Control Variables in the Data File

You can use the COLUMNS subcommand to specify which dimension elements should be in the columns and therefore are used to create variables in the generated data file. This is equivalent to pivoting the table in the Viewer.

Example

The DESCRIPTIVES command produces a table of descriptive statistics with variables in the rows and statistics in the columns. A data file created from that table would therefore use the statistics as variables and the original variables as cases. If you want the original variables to be variables in the generated data file and the statistics to be cases:

```
OMS
  /SELECT TABLES
  /IF COMMANDS=['Descriptives'] SUBTYPES=['Descriptive Statistics']
  /DESTINATION FORMAT=SAV OUTFILE='/temp/temp.sav'
  /COLUMNS DIMNAMES=['Variables'].
DESCRIPTIVES VARIABLES=salary salbegin.
OMSEND.
```

- When you use the COLUMNS subcommand, any dimension elements not listed on the subcommand will become rows (cases) in the generated data file.
- Since the descriptive statistics table has only two dimension elements, the syntax COLUMNS DIMNAMES=['Variables'] will put the variables in the columns *and* will put the statistics in the row. So this is equivalent to swapping the positions of the original row and column elements.

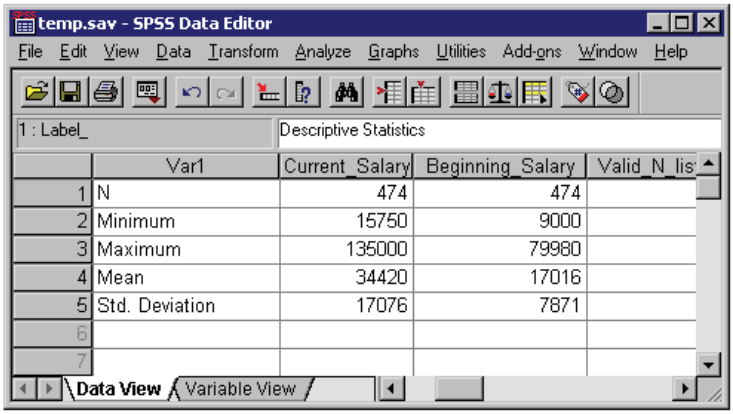
Figure 146-9
Default and pivoted table and generated data file

Default Descriptive Statistics Table

	N	Minimum	Maximum	Mean	Std. Deviation
Current Salary	474	$15,750	$135,000	$34,419.57	$17,075.661
Beginning Salary	474	$9,000	$79,980	$17,016.09	$7,870.638
Valid N (listwise)	474				

Descriptive Statistics Table with Variables in Columns and Statistics in Rows

	Current Salary	Beginning Salary	Valid N (listwise)
N	474	474	474
Minimum	$15,750	$9,000	
Maximum	$135,000	$79,980	
Mean	$34,419.57	$17,016.09	
Std. Deviation	$17,075.661	$7,870.638	



Example

The FREQUENCIES command produces a descriptive statistics table with statistics in the rows, while the DESCRIPTIVES command produces a descriptive statistics table with statistics in the columns. To include both table types in the same data file in a meaningful fashion, you need to change the column dimension for one of them.

```
OMS
  /SELECT TABLES
  /IF COMMANDS=['Frequencies' 'Descriptives']
   SUBTYPES=['Statistics' 'Descriptive Statistics']
  /DESTINATION FORMAT=SAV OUTFILE='/temp/temp.sav'
  /COLUMNS DIMNAMES=['Statistics'].
FREQUENCIES
  VARIABLES=salbegin salary
  /FORMAT=NOTABLE
  /STATISTICS=MINIMUM MAXIMUM MEAN.
DESCRIPTIVES
```

```
  VARIABLES=jobtime prevexp
  /STATISTICS=MEAN MIN MAX.
OMSEND.
```

- The `COLUMNS` subcommand will be applied to all selected table types that have a *Statistics* dimension element.
- Both table types have a *Statistics* dimension element, but since it's already in the column dimension for the table produced by the `DESCRIPTIVES` command, the `COLUMNS` subcommand has no effect on the structure of the data from that table type.
- For the *FREQUENCIES* statistics table, `COLUMNS DIMNAMES=['Statistics']` is equivalent to pivoting the *Statistics* dimension element into the columns and pivoting the *Variables* dimension element into the rows.
- Some of the variables will have missing values, since the table structures still aren't exactly the same with statistics in the columns.

Data View | Variable View

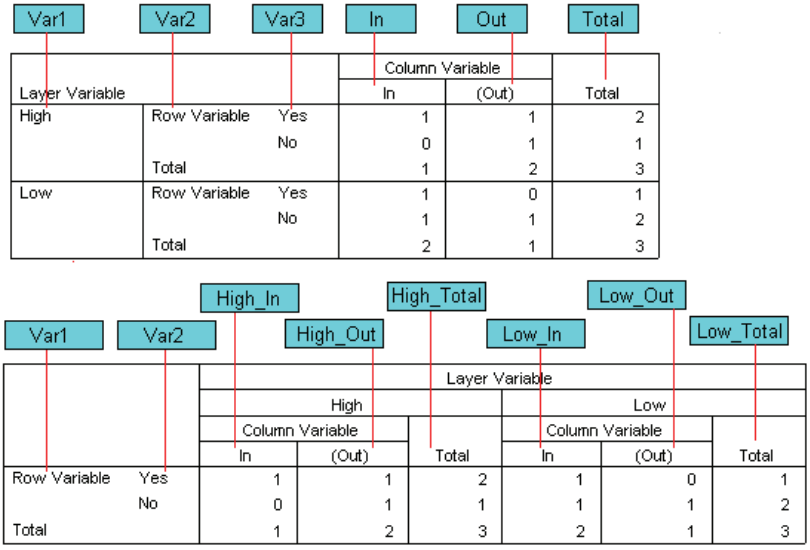
Variable Names

`OMS` constructs valid, unique variable names from column labels.

- Row and layer elements are assigned generic variable names: the prefix `Var` followed by a sequential number.

- Characters that aren't allowed in variable names, such as spaces and parentheses, are removed. For example, "This (Column) Label" would become a variable named *ThisColumnLabel*.
- If the label begins with a character that is allowed in variable names but not allowed as the first character (for example, a number), "@" is inserted as a prefix. For example "2nd" would become a variable named *@2nd*.
- Underscores or periods at the end of labels are removed from the resulting variable names. (The underscores at the end of the automatically generated variables *Command_*, `Subtype_`, and *Label_* are not removed.)
- If more than one element is in the column dimension, variable names are constructed by combining category labels with underscores between category labels. Group labels are not included. For example, if *VarB* is nested under *VarA* in the columns, you would get variables like *CatA1_CatB1*, not *VarA_CatA1_VarB_CatB1*.

Figure 146-11
Variable names in SAV files



OXML Table Structure

OXML is XML that conforms to the spss-output schema.

- `OMS` command and subtype identifiers are used as values of the `command` and `subType` attributes in OXML. For example:

```
<command text="Frequencies" command="Frequencies"...>
 <pivotTable text="Gender" label="Gender" subType="Frequencies"...>
```

  These attribute values are not affected by output language (`SET OLANG`) or display settings for variable names/labels or values/value labels (`SET TVARS` and `SET TNUMBERS`).
- XML is case-sensitive. The element name `pivotTable` is considered a different element from one named "pivottable" or "Pivottable" (the latter two don't exist in OXML).

- Command and subtype identifiers generated by the OMS Control Panel or the OMS Identifiers dialog box (both on the Utilities menu) use the same case as that used for values of the `command` and `subType` OXML attributes.
- All of the information displayed in a table is contained in attribute values in OXML. At the individual cell level, OXML consists of "empty" elements that contain attributes but no "content" other than that contained in attribute values.
- Table structure in OXML is represented row by row; elements that represent columns are nested within the rows, and individual cells are nested within the column elements:

```
<pivotTable...>
 <dimension axis="row"...>
  <dimension axis="column"...>
   <category...>
    <cell text="..." number="..." decimals="..."/>
   </category>
  <category...>
   <cell text="..." number="..." decimals="..."/>
  </category>
 </dimension>
</dimension>
 ...
</pivotTable>
```

The preceding example is a simplified representation of the structure that shows the descendant/ancestor relationships of these elements, but not necessarily the parent/child relationships, because there are typically intervening nested element levels. The following figures show a simple table as displayed in the Viewer and the OXML that represents that table.

Figure 146-12
Simple frequency table

Gender

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	Female	216	45.6	45.6	45.6
	Male	258	54.4	54.4	100.0
	Total	474	100.0	100.0

         </category>
         <category text="Percent">
          <cell text="54.4" number="54.430379746835" decimals="1"/>
         </category>
         <category text="Valid Percent">
          <cell text="54.4" number="54.430379746835" decimals="1"/>
         </category>
         <category text="Cumulative Percent">
          <cell text="100.0" number="100" decimals="1"/>
         </category>
        </dimension>
       </category>
      </group>
      <category text="Total">
       <dimension axis="column" text="Statistics">
        <category text="Frequency">
         <cell text="474" number="474"/>
        </category>
        <category text="Percent">
         <cell text="100.0" number="100" decimals="1"/>
        </category>
        <category text="Valid Percent">
         <cell text="100.0" number="100" decimals="1"/>
        </category>
       </dimension>
      </category>
     </group>
    </dimension>
   </pivotTable>
  </command>
</outputTree>
```

As you may notice, a simple, small table produces a substantial amount of XML. That's partly because the XML contains some information not readily apparent in the original table, some information that might not even be available in the original table, and a certain amount of redundancy.

- The table contents as they are (or would be) displayed in a pivot table in the Viewer are contained in `text` attributes. For example:

```
<command text="Frequencies" command="Frequencies"...>
```

These text attributes can be affected by both output language (`SET OLANG`) and settings that affect the display of variable names/labels and values/value labels (`SET TVARS` and `SET TNUMBERS`). In this example, the `text` attribute value will differ depending on the output language, whereas the `command` attribute value remains the same regardless of output language.

- Wherever variables or values of variables are used in row or column labels, the XML will contain a text attribute and one or more additional attribute values. For example:

```
<dimension axis="row" text="Gender" label="Gender" varName="gender">
...
 <category text="Female"label="Female" string="f" varName="gender">
```

For a numeric variable, there would be a `number` attribute instead of a `string` attribute. The `label` attribute is present only if the variable or values have defined labels.

- The <cell> elements that contain cell values for numbers will contain the `text` attribute and one or more additional attribute values. For example:

```
<cell text="45.6" number="45.569620253165" decimals="1"/>
```

The `number` attribute is the actual, unrounded numeric value, and the `decimals` attribute indicates the number of decimal positions displayed in the table.

- Since columns are nested within rows, the category element that identifies each column is repeated for each row. For example, since the statistics are displayed in the columns, the element `<category text="Frequency">` appears three times in the XML—once for the male row, once for the female row, and once for the total row.

Examples of using XSLT to transform OXML are provided in the Help system.

Command and Subtype Identifiers

The OMS Control Panel (Utilities menu) provides a complete list of command and subtype identifiers. For any command or table displayed in the Viewer, you can find out the command or subtype identifier by right-clicking the item in the Viewer outline pane.

OMSEND

Note: Square brackets used in the OMSEND syntax chart are required parts of the syntax and are not used to indicate optional elements. Any equals signs (=) displayed in the syntax chart are required. All specifications other than the command name OMSEND are optional.

```
OMSEND
 TAG = {['idvalue' 'idvalue'...]}
       {ALL                     }
 FILE = ['filespec' 'filespec'...]
 LOG
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Example

```
OMS
 /DESTINATION FORMAT = OXML OUTFILE = '/mydir/myfile.xml'.
[some commands that produce output]
OMSEND.
[some more commands that produce output]
```

Overview

OMSEND ends active OMS commands. The minimum specification is the command name OMSEND. In the absence of any other specifications, this ends all active OMS commands and logging.

TAG Keyword

The optional TAG keyword identifies specific OMS commands to end, based on the ID value assigned on the OMS TAG subcommand or automatically generated if there is no TAG subcommand. To display the automatically generated ID values for active OMS commands, use the OMSINFO command

The TAG keyword must be followed by an equals sign (=) and a list of quoted ID values or the keyword ALL enclosed in square brackets.

Example

```
OMSEND TAG = ['reg_tables_to_sav' 'freq_tables_to_html'].
```

A warning is issued if any of the specified values don't match any active OMS commands.

FILE Keyword

The optional FILE keyword ends specific OMS commands based on the filename specified with the OUTFILE keyword of the DESTINATION subcommand of the OMS command. The FILE keyword must be followed by an equals sign (=), and a list of quoted file specifications must be enclosed in square brackets.

Example

```
OMSEND
 FILE = ['/mydir/mysavfile.sav' '/otherdir/myhtmlfile.htm'].
```

- If the specified file doesn't exist or isn't associated with a currently running OMS command, a warning is issued.
- The FILE keyword specification has no effect on OMS commands that use OUTPUTSET instead of OUTFILE.

LOG Keyword

IF OMS logging is in effect (OMSLOG command), the LOG keyword ends logging.

Examples

```
OMSEND LOG.
```

In this example, the OMSEND command ends logging without ending any active OMS commands.

OMSINFO

```
OMSINFO.
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Example

```
OMSINFO.
```

Overview

The `OMSINFO` command displays a table of all active `OMS` commands It has no additional specifications.

OMSLOG

```
OMSLOG FILE = 'filespec'
 [/APPEND = [NO ]]
            [YES]
 [/FORMAT = [XML ]]
            [TEXT]
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Example

```
OMSLOG FILE = '/mydir/mylog.xml'.
```

Overview

OMSLOG creates a log file in either XML or text form for subsequent OMS commands during a session.

- The log contains one line or main XML element for each destination file and contains the event name, filename, and location, the ID tag value, and a timestamp. The log also contains an entry when an OMS command is started and stopped.
- The log file remains open, and OMS activity is appended to the log, unless logging is turned off by an OMSEND command or the end of the session.
- A subsequent OMSLOG command that specifies a different log file ends logging to the file specified on the previous OMSLOG command.
- A subsequent OMSLOG file that specifies the same log file will overwrite the current log file for the default FORMAT = XML or in the absence of APPEND = YES for FORMAT = TEXT.
- OMS activity for any OMS commands executed *before* the first OMSLOG command in the session is not recorded in any log file.

Basic Specification

The basic specification is the command name OMSLOG followed by a FILE subcommand that specifies the log filename and location.

Syntax Rules

- The FILE subcommand is required. All other specifications are optional.
- Equals signs (=) shown in the command syntax chart and examples are required, not optional.

FILE Subcommand

The FILE subcommand specifies the log filename and location. The subcommand name must be followed by an equals sign (=) and a file specification in quotes. If the file specification includes location information (drive, directory/folder), the location must be a valid, existing location; otherwise an error will result.

Example

```
OMSLOG FILE = '/mydir/mylog.xml'.
```

APPEND Subcommand

If the FILE subcommand specifies an existing file, by default the file is overwritten. For text format log files, you can use the APPEND subcommand to append new logging information to the file instead of overwriting.

Example

```
OMSLOG FILE = '/mydir/mylog.txt'
  /APPEND = YES
  /FORMAT = TEXT.
```

- APPEND = YES is only valid with FORMAT = TEXT. For XML log files, the APPEND subcommand is ignored.
- APPEND = YES with FORMAT = TEXT will append to an existing file, even if the existing file contains XML-format log information. (An XML file *is* a text file, and OMSLOG does not differentiate based on file extension or content.)
- If the specified file does not exist, APPEND has no effect.

FORMAT Subcommand

The FORMAT subcommand specifies the format of the log file. The default format is XML. You can use FORMAT = TEXT to write the log in simple text format.

ONEWAY

```
ONEWAY  varlist BY varname

               {'savfile'|'dataset'}        {'savfile'|'dataset'}
```

**Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
ONEWAY V1 BY V2.
```

Overview

ONEWAY produces a one-way analysis of variance for an interval-level dependent variable by one numeric independent variable that defines the groups for the analysis. Other procedures that perform an analysis of variance are SUMMARIZE, UNIANOVA, and GLM (GLM is available in the Advanced Models option). Some tests not included in the other procedures are available as options in ONEWAY.

Options

Trend and Contrasts. You can partition the between-groups sums of squares into linear, quadratic, cubic, and higher-order trend components using the POLYNOMIAL subcommand. You can specify up to 10 contrasts to be tested with the *t* statistic on the CONTRAST subcommand.

Post Hoc Tests. You can specify 20 different post hoc tests for comparisons of all possible pairs of group means or multiple comparisons using the POSTHOC subcommand.

Statistical Display. In addition to the default display, you can obtain means, standard deviations, and other descriptive statistics for each group using the STATISTICS subcommand. Fixed- and random-effects statistics as well as Leven's test for homogeneity of variance are also available.

Matrix Input and Output. You can write means, standard deviations, and category frequencies to a matrix data file that can be used in subsequent ONEWAY procedures using the MATRIX subcommand. You can also read matrix materials consisting of means, category frequencies, pooled variance, and degrees of freedom for the pooled variance.

Basic Specification

The basic specification is a dependent variable, keyword BY, and an independent variable. ONEWAY produces an ANOVA table displaying the between- and within-groups sums of squares, mean squares, degrees of freedom, the *F* ratio, and the probability of *F* for each dependent variable by the independent variable.

Subcommand Order

- The variable list must be specified first.
- The remaining subcommands can be specified in any order.

Operations

- All values of the independent variable are used. Each different value creates one category.
- If a string variable is specified as an independent or dependent variable, ONEWAY is not executed.

Limitations

- Maximum 100 dependent variables and 1 independent variable.
- An unlimited number of categories for the independent variable. However, post hoc tests are not performed if the number of nonempty categories exceeds 50. Contrast tests are not performed if the total of empty and nonempty categories exceeds 50.
- Maximum 1 POLYNOMIAL subcommand.
- Maximum 1 POSTHOC subcommand.
- Maximum 10 CONTRAST subcommands.

Example

```
ONEWAY V1 BY V2.
```

- ONEWAY names *V1* as the dependent variable and *V2* as the independent variable.

Analysis List

The analysis list consists of a list of dependent variables, keyword BY, and an independent (grouping) variable.

- Only one analysis list is allowed, and it must be specified before any of the optional subcommands.
- All variables named must be numeric.

POLYNOMIAL Subcommand

POLYNOMIAL partitions the between-groups sums of squares into linear, quadratic, cubic, or higher-order trend components. The display is an expanded analysis-of-variance table that provides the degrees of freedom, sums of squares, mean square, *F*, and probability of *F* for each partition.

- The value specified on POLYNOMIAL indicates the highest-degree polynomial to be used.
- The polynomial value must be a positive integer less than or equal to 5 and less than the number of groups. If the polynomial specified is greater than the number of groups, the highest-degree polynomial possible is assumed.
- Only one POLYNOMIAL subcommand can be specified per ONEWAY command. If more than one is used, only the last one specified is in effect.
- ONEWAY computes the sums of squares for each order polynomial from weighted polynomial contrasts, using the category of the independent variable as the metric. These contrasts are orthogonal.
- With unbalanced designs and equal spacing between groups, ONEWAY also computes sums of squares using the unweighted polynomial contrasts. These contrasts are not orthogonal.
- The deviation sums of squares are always calculated from the weighted sums of squares(Speed, 1976).

Example

```
ONEWAY WELL BY EDUC6
  /POLYNOMIAL=2.
```

- ONEWAY requests an analysis of variance of *WELL* by *EDUC6* with second-order (quadratic) polynomial contrasts.
- The ANOVA table is expanded to include both linear and quadratic terms.

CONTRAST Subcommand

CONTRAST specifies a priori contrasts to be tested by the *t* statistic. The specification on CONTRAST is a vector of coefficients, where each coefficient corresponds to a category of the independent variable. The Contrast Coefficients table displays the specified contrasts for each group and the Contrast Tests table displays the value of the contrast and its standard error, the *t* statistic, and the degrees of freedom and two-tailed probability of *t* for each variable. Both pooled- and separate-variance estimates are displayed.

- A contrast coefficient must be specified or implied for every group defined for the independent variable. If the number of contrast values is not equal to the number of groups, the contrast test is not performed.

- The contrast coefficients for a set should sum to 0. If they do not, a warning is issued. ONEWAY will still give an estimate of this contrast.
- Coefficients are assigned to groups defined by ascending values of the independent variable.
- The notation *n*c* can be used to indicate that coefficient *c* is repeated *n* times.

Example

```
ONEWAY V1 BY V2
  /CONTRAST = -1 -1 1 1
  /CONTRAST = -1 0 0 1
  /CONTRAST = -1 0 .5 .5.
```

- *V2* has four levels.
- The first CONTRAST subcommand contrasts the combination of the first two groups with the combination of the last two groups.
- The second CONTRAST subcommand contrasts the first group with the last group.
- The third CONTRAST subcommand contrasts the first group with the combination of the third and fourth groups.

Example

```
ONEWAY V1 BY V2
  /CONTRAST = -1 1 2*0
  /CONTRAST = -1 1 0 0
  /CONTRAST = -1 1.
```

- The first two CONTRAST subcommands specify the same contrast coefficients for a four-group analysis. The first group is contrasted with the second group in both cases.
- The first CONTRAST uses the *n*c* notation.
- The last CONTRAST does not work because only two coefficients are specified for four groups.

POSTHOC Subcommand

POSTHOC produces post hoc tests for comparisons of all possible pairs of group means or multiple comparisons. In contrast to a priori analyses specified on the CONTRAST subcommand, post hoc analyses are usually not planned at the beginning of the study but are suggested by the data in the course of the study.

- Twenty post hoc tests are available. Some detect homogeneity subsets among the groups of means, some produce pairwise comparisons, and others perform both. POSTHOC produces a Multiple Comparison table showing up to 10 test categories. Nonempty group means are sorted in ascending order, with asterisks indicating significantly different groups. In addition, homogeneous subsets are calculated and displayed in the Homogeneous Subsets table if the test is designed to detect homogeneity subsets.
- When the number of valid cases in the groups varies, the harmonic mean of the group sizes is used as the sample size in the calculation for homogeneity subsets except for QREGW and FREGW. For QREGW and FREGW and tests for pairwise comparison, the sample sizes of individual groups are always used.

- You can specify only one POSTHOC subcommand per ONEWAY command. If more than one is specified, the last specification takes effect.
- You can specify one alpha value used in all POSTHOC tests using keyword ALPHA. The default is 0.05.

SNK *Student-Newman-Keuls procedure based on the Studentized range test.* Used for detecting homogeneity subsets.

TUKEY *Tukey's honestly significant difference.* This test uses the Studentized range statistic to make all pairwise comparisons between groups. Used for pairwise comparison and for detecting homogeneity subsets.

BTUKEY *Tukey's b.* Multiple comparison procedure based on the average of Studentized range tests. Used for detecting homogeneity subsets.

DUNCAN *Duncan's multiple comparison procedure based on the Studentized range test*. Used for detecting homogeneity subsets.

SCHEFFE *Scheffé's multiple comparison* t *test.* Used for pairwise comparison and for detecting homogeneity subsets.

DUNNETT(refcat) *Dunnett's two-tailed t test.* Used for pairwise comparison. Each group is compared to a reference category. You can specify a reference category in parentheses. The default is the last category. This keyword must be spelled out in full.

DUNNETTL(refcat) *Dunnett's one-tailed t test.* Used for pairwise comparison. This test indicates whether the mean of each group (except the reference category) is *smaller* than that of the reference category. You can specify a reference category in parentheses. The default is the last category. This keyword must be spelled out in full.

DUNNETTR(refcat) *Dunnett's one-tailed t test.* Used for pairwise comparison. This test indicates whether the mean of each group (except the reference category) is *larger* than that of the reference category. You can specify a reference category in parentheses. The default is the last category. This keyword must be spelled out in full.

BONFERRONI *Bonferroni t test.* This test is based on Student's *t* statistic and adjusts the observed significance level for the fact that multiple comparisons are made. Used for pairwise comparison.

LSD *Least significant difference t test.* Equivalent to multiple *t* tests between all pairs of groups. Used for pairwise comparison. This test does not control the overall probability of rejecting the hypotheses that some pairs of means are different, while in fact they are equal.

SIDAK *Sidak t test.* Used for pairwise comparison. This test provides tighter bounds than the Bonferroni test.

GT2 *Hochberg's GT2.* Used for pairwise comparison and for detecting homogeneity subsets. This test is based on the Studentized maximum modulus test. Unless the cell sizes are extremely unbalanced, this test is fairly robust even for unequal variances.

GABRIEL *Gabriel's pairwise comparisons test based on the Studentized maximum modulus test.* Used for pairwise comparison and for detecting homogeneity subsets.

FREGW *Ryan-Einot-Gabriel-Welsch's multiple stepdown procedure based on an* F *test.* Used for detecting homogeneity subsets.

QREGW *Ryan-Einot-Gabriel-Welsch's multiple stepdown procedure based on the Studentized range test.* Used for detecting homogeneity subsets.

T2 *Tamhane's T2.* Used for pairwise comparison. This test is based on a *t* test and can be applied in situations where the variances are unequal.

T3	*Tamhane's T3.* Used for pairwise comparison. This test is based on the Studentized maximum modulus test and can be applied in situations where the variances are unequal.
GH	*Games and Howell's pairwise comparisons test based on the Studentized range test.* Used for pairwise comparison. This test can be applied in situations where the variances are unequal.
C	*Dunnett's* C. Used for pairwise comparison. This test is based on the weighted average of Studentized ranges and can be applied in situations where the variances are unequal.
WALLER(kratio)	*Waller-Duncan* t *test.* Used for detecting homogeneity subsets. This test uses a Bayesian approach. The *k*-ratio is the Type 1/Type 2 error seriousness ratio. The default value is 100. You can specify an integer greater than 1 within parentheses.

Example

```
ONEWAY WELL BY EDUC6
  /POSTHOC=SNK SCHEFFE ALPHA=.01.
```

- ONEWAY requests two different post hoc tests. The first uses the Student-Newman-Keuls test and the second uses Scheffé's test. Both tests use an alpha of 0.01.

RANGES Subcommand

RANGES produces results for some post hoc tests. It is available only through syntax. You can always produce the same results using the POSTHOC subcommand.

- Up to 10 RANGE subcommands are allowed. The effect is cumulative. If you specify more than one alpha value for different range tests, the last specified value takes effect for all tests. The default is 0.05.
- Keyword MODLSD on the RANGE subcommand is equivalent to keyword BONFERRONI on the POSTHOC subcommand. Keyword LSDMOD is an alias for MODLSD.

PLOT MEANS Subcommand

PLOT MEANS produces a chart that plots the subgroup means (the means for each group defined by values of the factor variable).

STATISTICS Subcommand

By default, ONEWAY displays the ANOVA table showing between- and within-groups sums of squares, mean squares, degrees of freedom, *F* ratio, and probability of *F*. Use STATISTICS to obtain additional statistics.

BROWNFORSYTHE	*Brown-Forsythe statistic.* The Brown-Forsythe statistic, degrees of freedom, and the significance level are computed for each dependent variable.
WELCH	*Welch statistic.* The Welch statistic, degrees of freedom, and the significance level are computed for each dependent variable.

DESCRIPTIVES *Group descriptive statistics.* The statistics include the number of cases, mean, standard deviation, standard error, minimum, maximum, and 95% confidence interval for each dependent variable for each group.

EFFECTS *Fixed- and random-effects statistics.* The statistics include the standard deviation, standard error, and 95% confidence interval for the fixed-effects model, and the standard error, 95% confidence interval, and estimate of between-components variance for the random-effects model.

HOMOGENEITY *Homogeneity-of-variance tests.* The statistics include Levene statistic, degrees of freedom, and the significance level displayed in the Test of Homogeneity-of-Variances table.

NONE *No optional statistics.* This is the default.

ALL *All statistics available for* ONEWAY.

MISSING Subcommand

MISSING controls the treatment of missing values.

- Keywords ANALYSIS and LISTWISE are alternatives. Each can be used with INCLUDE or EXCLUDE. The default is ANALYSIS and EXCLUDE.
- A case outside of the range specified for the grouping variable is not used.

ANALYSIS *Exclude cases with missing values on a pair-by-pair basis.* A case with a missing value for the dependent or grouping variable for a given analysis is not used for that analysis. This is the default.

LISTWISE *Exclude cases with missing values listwise.* Cases with missing values for any variable named are excluded from all analyses.

EXCLUDE *Exclude cases with user-missing values.* User-missing values are treated as missing. This is the default.

INCLUDE *Include user-missing values.* User-missing values are treated as valid values.

MATRIX Subcommand

MATRIX reads and writes matrix data files.

- Either IN or OUT and a matrix file in parentheses are required.
- You cannot specify both IN and OUT on the same ONEWAY procedure.
- Use MATRIX=NONE to explicitly indicate that a matrix data file is not being written or read.

OUT ('savfile'|'dataset') *Write a matrix data file or dataset.* Specify either a filename, a previously declared dataset name, or an asterisk, enclosed in parentheses. Filenames should be enclosed in quotes and are stored in the working directory unless a path is included as part of the file specification. If you specify an asterisk (*), the matrix data file replaces the active dataset. If you specify an asterisk or a dataset name, the file is not stored on disk unless you use SAVE or XSAVE.

IN ('savfile'|'dataset') *Read a matrix data file or dataset.* Specify either a filename, dataset name created during the current session, or an asterisk enclosed in parentheses. An asterisk reads the matrix data from the active dataset. Filenames should be enclosed in quotes and are read from the working directory unless a path is included as part of the file specification.

Matrix Output

- ONEWAY writes means, standard deviations, and frequencies to a matrix data file that can be used by subsequent ONEWAY procedures. For a description of the file, see Format of the Matrix Data File below.

Matrix Input

- ONEWAY can read the matrices it writes, and it can also read matrix materials that include the means, category frequencies, pooled variance, and degrees of freedom for the pooled variance. The pooled variance has a *ROWTYPE_* value MSE, and the vector of degrees of freedom for the pooled variance has the *ROWTYPE_* value DFE.
- The dependent variables named on ONEWAY can be a subset of the dependent variables in the matrix data file.
- MATRIX=IN cannot be specified unless an active dataset has already been defined. To read an existing matrix data file at the beginning of a session, use GET to retrieve the matrix file and then specify IN(*) on MATRIX.

Format of the Matrix Data File

- The matrix data file includes two special variables created by the program: *ROWTYPE_* and *VARNAME_*.
- *ROWTYPE_* is a short string variable with values MEAN, STDDEV, and N.
- *VARNAME_* is a short string variable that never has values for procedure ONEWAY. *VARNAME_* is included with the matrix materials so that matrices written by ONEWAY can be read by procedures that expect to read a *VARNAME_* variable.
- The independent variable is between variables *ROWTYPE_* and *VARNAME_*.
- The remaining variables in the matrix file are the dependent variables.

Split Files

- When split-file processing is in effect, the first variables in the matrix data file are the split variables, followed by *ROWTYPE_*, the independent variable, *VARNAME_*, and the dependent variables.
- A full set of matrix materials is written for each split-file group defined by the split variable(s).
- A split variable cannot have the same variable name as any other variable written to the matrix data file.
- If split-file processing is in effect when a matrix is written, the same split file must be in effect when that matrix is read by any procedure.
- Generally, matrix rows, independent variables, and dependent variables can be in any order in the matrix data file read by keyword IN. However, all split-file variables must precede variable *ROWTYPE_*, and all split-group rows must be consecutive. ONEWAY ignores unrecognized *ROWTYPE_* values.

Missing Values

Missing-value treatment affects the values written to an matrix data file. When reading a matrix data file, be sure to specify a missing-value treatment on ONEWAY that is compatible with the treatment that was in effect when the matrix materials were generated.

Example

```
GET FILE=GSS80.
ONEWAY  WELL BY EDUC6
  /MATRIX=OUT(ONEMTX).
```

- ONEWAY reads data from file *GSS80* and writes one set of matrix materials to the file *ONEMTX*.
- The active dataset is still *GSS80*. Subsequent commands are executed on *GSS80*.

Example

```
GET FILE=GSS80.
ONEWAY  WELL BY EDUC6
  /MATRIX=OUT(*).
LIST.
```

- ONEWAY writes the same matrix as in the example above. However, the matrix data file replaces the active dataset. The LIST command is executed on the matrix file, not on the *GSS80* file.

Example

```
GET FILE=PRSNNL.
FREQUENCIES VARIABLE=AGE.
ONEWAY  WELL BY EDUC6
 /MATRIX=IN(ONEMTX).
```

- This example performs a frequencies analysis on *PRSNNL* and then uses a different file for ONEWAY. The file is an existing matrix data file.
- MATRIX=IN specifies the matrix data file.
- *ONEMTX* does not replace *PRSNNL* as the active dataset.

Example

```
GET FILE=ONEMTX.
ONEWAY  WELL BY EDUC6
  /MATRIX=IN(*).
```

- The GET command retrieves the matrix data file *ONEMTX*.
- MATRIX=IN specifies an asterisk because the active dataset is the matrix data file *ONEMTX*. If MATRIX=IN(ONEMTX) is specified, the program issues an error message, since *ONEMTX* is already open.
- If the GET command is omitted, the program issues an error message.

Release History

Release 15.0

- Command introduced.

Example

```
OPTIMAL BINNING
  /VARIABLES GUIDE = guide-variable BIN = binning-input-variable
```

Overview

The OPTIMAL BINNING procedure discretizes one or more scale variables (referred to henceforth as **binning input** variables) by distributing the values of each variable into bins. Bins can then be used instead of the original data values of the binning input variables for further analysis. OPTIMAL BINNING is useful for reducing the number of distinct values in the given binning input variables.

Options

Methods. The OPTIMAL BINNING procedure offers the following methods of discretizing binning input variables.

- Unsupervised binning via the equal frequency algorithm discretizes the binning input variables. A guide variable is not required.
- Supervised binning via the MDLP (Minimal Description Length Principle) algorithm discretizes the binning input variables without any preprocessing. It is suitable for datasets with a small number of cases. A guide variable is required.

Output. The OPTIMAL BINNING procedure displays every binning input variable's end point set in pivot table output and offers an option for suppressing this output. In addition, the procedure can save new binned variables corresponding to the binning input variables and can save a command syntax file with commands corresponding to the binning rules.

Basic Specification

The basic specification is the OPTIMAL BINNING command and a VARIABLES subcommand. VARIABLES provides the binning input variables and, if applicable, the guide variable.

- For unsupervised binning via the equal frequency algorithm, a guide variable is not required.
- For supervised binning via the MDLP algorithm and hybrid binning, a guide variable must be specified.

Syntax Rules

- When a supervised binning method is used, a guide variable must be specified on the VARIABLES subcommand.
- Subcommands may be specified only once.
- An error occurs if a variable or keyword is specified more than once within a subcommand.
- Parentheses, slashes, and equals signs shown in the syntax chart are required.
- Empty subcommands are not honored.
- The command name, subcommand names, and keywords must be spelled in full.

Case Frequency

- If a WEIGHT variable is specified, then its values are used as frequency weights by the OPTIMAL BINNING procedure.
- Weight values are rounded to the nearest whole numbers before use. For example, 0.5 is rounded to 1, and 2.4 is rounded to 2.
- The WEIGHT variable may not be specified on any subcommand in the OPTIMAL BINNING procedure.
- Cases with missing weights or weights less than 0.5 are not used in the analyses.

Limitations

The number of distinct values in a guide variable should be less than or equal to 256, irrespective of the platform on which SPSS is running. If the number is greater than 256, this results in an error.

Examples

```
* Optimal Binning.
OPTIMAL BINNING
  /VARIABLES GUIDE=default BIN=age employ address income debtinc creddebt
  othdebt SAVE=YES (INTO=age_bin employ_bin address_bin income_bin debtinc_bin
  creddebt_bin othdebt_bin)
  /CRITERIA METHOD=MDLP
   PREPROCESS=EQUALFREQ (BINS=1000)
   FORCEMERGE=0
   LOWERLIMIT=INCLUSIVE
   LOWEREND=UNBOUNDED
   UPPEREND=UNBOUNDED
  /MISSING SCOPE=PAIRWISE
  /OUTFILE RULES='/bankloan_binning-rules.sps'
  /PRINT ENDPOINTS DESCRIPTIVES ENTROPY.
```

- The procedure will discretize the binning input variables *age*, *employ*, *address*, *income*, *debtinc*, *creddebt*, and *othdebt* using MDLP binning with the guide variable *default*.
- The discretized values for these variables will be stored in the new variables *age_bin*, *employ_bin*, *address_bin*, *income_bin*, *debtinc_bin*, *creddebt_bin*, and *othdebt_bin*.
- If a binning input variable has more than 1000 distinct values, then the equal frequency method will reduce the number to 1000 before performing MDLP binning.
- Command syntax representing the binning rules is saved to the file */bankloan_binning-rules.sps*.
- Bin endpoints, descriptive statistics, and model entropy values are requested for binning input variables.
- Other binning criteria are set to their default values.

VARIABLES Subcommand

The VARIABLES subcommand specifies the guide variable (if applicable) and one or more binning input variables. It can also be used to save new variables containing the binned values.

GUIDE=variable

Guide variable. The bins formed by supervised binning methods are "optimal" with respect to the specified guide variable. You must specify a guide variable to perform MDLP (CRITERIA METHOD = MDLP) or the hybrid method (CRITERIA PREPROCESS = EQUALFREQ METHOD = MDLP). This option is silently ignored if it is specified when the equal frequency method (CRITERIA METHOD = EQUALFREQ) is in effect. The guide variable may be numeric or string.

BIN=varlist

Binning input variable list. These are the variables to be binned. The variable list must include at least one variable. Binning input variables must be numeric.

SAVE = NO | YES (INTO = new varlist)

Create new variables containing binned values. By default, the procedure does not create any new variables (NO). If YES is specified, variables containing the binned values are saved to the active dataset. Optionally, specify the names of the new variables using the INTO keyword.

The number of variables specified on the INTO list must equal the number of variables on the BIN list. All specified names must be valid variable names. Violation of either of these rules results in an error.

If INTO is omitted, new variable names are created by concatenating the guide variable name (if applicable) and an underscore '_', followed by the binning input variable name and an underscore, followed by 'bin'. For example, /VARIABLES GUIDE=E BIN=F G SAVE=YES will generate two new variables: *E_F_bin* and *E_G_bin*.

CRITERIA Subcommand

The CRITERIA subcommand specifies bin creation options.

PREPROCESS=EQUALFREQ(BINS=n) | NONE

Preprocessing method when MDLP binning is used. PREPROCESS = EQUALFREQ creates preliminary bins using the equal frequency method before performing MDLP binning. These preliminary bins—rather than the original data values of the binning input variables—are input to the MDLP binning method.

EQUALFREQ may be followed by parentheses containing the BINS keyword, an equals sign, and an integer greater than 1. The BINS value serves as a preprocessing threshold and specifies the number of bins to create. The default value is EQUALFREQ (BINS = 1000).

If the number of distinct values in a binning input variable is greater than the BINS value, then the number of bins created is no more than the BINS value. Otherwise, no preprocessing is done for the input variable.

NONE requests no preprocessing.

METHOD=MDLP | EQUALFREQ(BINS=n)

Binning method. The MDLP option performs supervised binning via the MDLP algorithm. If METHOD = MDLP is specified, then a guide variable must be specified on the VARIABLES subcommand.

Alternatively, METHOD = EQUALFREQ performs unsupervised binning via the equal frequency algorithm. EQUALFREQ may be followed by parentheses containing the BINS keyword, an equals sign, and an integer greater than 1. The BINS value specifies the number of bins to create. The default value of the BINS argument is 10.

If the number of distinct values in a binning input variable is greater than the BINS value, then the number of bins created is no more than the BINS value. Otherwise, BINS gives an upper bound on the number of bins created. Thus, for example, if BINS = 10 is specified but a binning input variable has at most 10 distinct values, then the number of bins created will equal the number of distinct values in the input variable.

If EQUALFREQ is specified, then the VARIABLES subcommand GUIDE keyword and the CRITERIA subcommand PREPROCESS keyword are silently ignored.

The default METHOD option depends on the presence of a GUIDE specification on the VARIABLES subcommand. If GUIDE is specified, then METHOD = MDLP is the default. If GUIDE is not specified, then METHOD = EQUALFREQ is the default.

LOWEREND = UNBOUNDED | OBSERVED

Specifies how the minimum end point for each binning input variable is defined. Valid option values are `UNBOUNDED` or `OBSERVED`. If `UNBOUNDED`, then the minimum end point extends to negative infinity. If `OBSERVED`, then the minimum observed data value is used.

UPPEREND = UNBOUNDED | OBSERVED

Specifies how the maximum end point for each binning input variable is defined. Valid option values are `UNBOUNDED` or `OBSERVED`. If `UNBOUNDED`, then the maximum end point extends to positive infinity. If `OBSERVED`, then the maximum of the observed data is used.

LOWERLIMIT =INCLUSIVE | EXCLUSIVE

Specifies how the lower limit of an interval is defined. Valid option values are `INCLUSIVE` or `EXCLUSIVE`. Suppose the start and end points of an interval are *p* and *q*, respectively. If `LOWERLIMIT = INCLUSIVE`, then the interval contains values greater than or equal to *p* but less than *q*. If `LOWERLIMIT = EXCLUSIVE`, then the interval contains values greater than *p* and less than or equal to *q*.

FORCEMERGE = value

Small bins threshold. Occasionally, the procedure may produce bins with very few cases. The following strategy deletes these pseudo cut points:

- For a given variable, suppose that the algorithm found n_{final} cut points, and thus $n_{\text{final}}+1$ bins. For bins i = 2, ..., n_{final} (the second lowest-valued bin through the second highest-valued bin), compute

$$\frac{sizeof(b_i)}{\min\left(sizeof\left(b_{i-1}\right),sizeof\left(b_{i+1}\right)\right)}$$

where *sizeof(b)* is the number of cases in the bin.

- When this value is less than the specified merging threshold, b_i is considered sparsely populated and is merged with b_{i-1} or b_{i+1}, whichever has the lower class information entropy.

The procedure makes a single pass through the bins.

The default value of `FORCEMERGE` is 0; by default, forced merging of very small bins is not performed.

MISSING Subcommand

The MISSING subcommand specifies whether missing values are handled using listwise or pairwise deletion.

- User-missing values are always treated as invalid. When recoding the original binning input variable values into a new variable, user-missing values are converted into system-missing values.

SCOPE = PAIRWISE | LISTWISE

Missing value handling method. LISTWISE provides a consistent case base. It operates across all variables specified on the VARIABLES subcommand. If any variable is missing for a case, then the entire case is excluded.

PAIRWISE makes use of as many valid values as possible. When METHOD = MDLP, it operates on each guide and binning input variable pair. The procedure will make use of all cases with nonmissing values on the guide and binning input variable. When METHOD = EQUALFREQ, it uses all cases with nonmissing values for each binning input variable. PAIRWISE is the default.

OUTFILE Subcommand

The OUTFILE subcommand writes syntax to an external command syntax file.

RULES=filespec

Rules file specification. The procedure can generate command syntax that can be used to bin other datasets. The recoding rules are based on the end points determined by the binning algorithm. Specify an external file to contain the saved syntax.

Note that saved variables (see the SAVE keyword in the VARIABLES subcommand) are generated using end points exactly as computed by the algorithm, while the bins created via saved syntax rules use end points converted to and from a decimal representation. Conversion errors in this process can, in certain cases, cause the end points read from syntax to differ from the original ones. The syntax precision of end points is 17 digits.

PRINT Subcommand

The PRINT subcommand controls the display of the output results. If the PRINT subcommand is not specified, then the default output is the end point set for each binning input variable.

ENDPOINTS

Display the binning interval end points for each input variable. This is the default output.

DESCRIPTIVES

Display descriptive information for all binning input variables. For each binning input variable, this option displays the number of cases with valid values, the number of cases with missing values, the number of distinct valid values, and the minimum and maximum values. For the guide variable, this option displays the class distribution for each related binning input variable.

ENTROPY

Display the model entropy for each binning input variable interval when MDLP binning is used. The `ENTROPY` keyword is ignored with a warning if `METHOD = EQUALFREQ` is specified or implied on the `CRITERIA` subcommand.

NONE

Suppress all displayed output except the notes table and any warnings. Specifying `NONE` with any other keywords results in an error.

ORTHOPLAN

ORTHOPLAN is available in the Conjoint option.

```
ORTHOPLAN [FACTORS=varlist ['labels'] (values ['labels'])...]

 [{/REPLACE     }]
  {/OUTFILE='savfile'|'dataset'}

 [/MINIMUM=value]

 [/HOLDOUT=value]  [/MIXHOLD={YES}]
                            {NO }
```

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example:

```
ORTHOPLAN FACTORS=SPEED 'Highest possible speed'
   (70 '70 mph' 100 '100 mph' 130 '130mph')
 WARRANTY 'Length of warranty'
   ('1 year' '3 year' '5 year')
 SEATS (2, 4)
 /MINIMUM=9 /HOLDOUT=6.
```

Overview

ORTHOPLAN generates an orthogonal main-effects plan for a full-concept conjoint analysis. ORTHOPLAN can append or replace an existing active dataset, or it can build an active dataset (if one does not already exist). The generated plan can be listed in full-concept profile, or card, format using PLANCARDS. The file that is created by ORTHOPLAN can be used as the plan file for CONJOINT.

Options

Number of Cases. You can specify the minimum number of cases to be generated in the plan.

Holdout and Simulation Cases. In addition to the experimental main-effects cases, you can generate a specified number of holdout cases and identify input data as simulation cases.

Basic Specification

- The basic specification is ORTHOPLAN followed by FACTORS, a variable list, and a value list in parentheses. ORTHOPLAN will generate cases in the active dataset, with each case representing a profile in the conjoint experimental plan and consisting of a new combination of the factor values. By default, the smallest possible orthogonal plan is generated.
- If you are appending to an existing active dataset that has previously defined values, the FACTORS subcommand is optional.

Subcommand Order

- Subcommands can be named in any order.

Operations

- ORTHOPLAN builds an active dataset (if one does not already exist) by using the variable and value information on the FACTORS subcommand.
- When ORTHOPLAN appends to an active dataset and FACTORS is not used, the factor levels (values) must be defined on a previous ORTHOPLAN or VALUE LABELS command.
- New variables *STATUS_* and *CARD_* are created and added to the active dataset by ORTHOPLAN if they do not already exist. *STATUS_*=0 for experimental cases, 1 for holdout cases, and 2 for simulation cases. Holdout cases are judged by the subjects but are not used when CONJOINT estimates utilities. Instead, the cases are used as a check on the validity of the estimated utilities. Simulation cases are entered by the user. They are factor-level combinations that are not rated by the subjects but are estimated by CONJOINT based on the ratings of the experimental cases. *CARD_* contains the case identification numbers in the generated plan.
- Duplication between experimental cases and simulation cases is reported.
- If a user-entered experimental case (*STATUS_*=0) is duplicated by ORTHOPLAN, only one copy of the case is kept.
- Occasionally, ORTHOPLAN may generate duplicate experimental cases. One way to handle these duplicates is to edit or delete them, in which case the plan is no longer orthogonal. Alternatively, you can try running ORTHOPLAN again. With a different *seed*, ORTHOPLAN might produce a plan without duplicates. See the SEED subcommand on SET for more information about the random seed generator.
- The SPLIT FILE and WEIGHT commands are ignored by ORTHOPLAN.

Limitations

- Missing data are not allowed.
- A maximum of 10 factors and 9 levels can be specified per factor.
- A maximum of 81 cases can be generated by ORTHOPLAN.

Examples

```
ORTHOPLAN FACTORS=SPEED 'Highest possible speed'
   (70 '70 mph' 100 '100 mph' 130 '130mph')
  WARRANTY 'Length of warranty'
   ('1 year' '3 year' '5 year')
  SEATS (2, 4) /MINIMUM=9 /HOLDOUT=6 /OUTFILE='CARPLAN.SAV'.
```

- The FACTORS subcommand defines the factors and levels to be used in building the file. Labels for some of the factors and some of the levels of each factor are also supplied.
- The MINIMUM subcommand specifies that the orthogonal plan should contain at least nine full-concept cases.

- HOLDOUT specifies that six holdout cases should be generated. A new variable, *STATUS_*, is created by ORTHOPLAN to distinguish these holdout cases from the regular experimental cases. Another variable, *CARD_*, is created to assign identification numbers to the plan cases.
- The OUTFILE subcommand saves the plan that is generated by ORTHOPLAN as a data file so that it can be used at a later date with CONJOINT.

Example: Appending Plan to the Working File

```
DATA LIST FREE /SPEED WARRANTY SEATS.
VALUE LABELS speed 70 '70 mph' 100 '100 mph' 130 '130 mph'
 /WARRANTY 1 '1 year' 3 '3 year' 5 '5 year'
 /SEATS 2 '2 seats' 4 '4 seats'.
BEGIN DATA
130 5 2
130 1 4
END DATA.
ORTHOPLAN
 /OUTFILE='CARPLAN.SAV'.
```

- In this example, ORTHOPLAN appends the plan to the active dataset and uses the variables and values that were previously defined in the active dataset as the factors and levels of the plan.
- The data between BEGIN DATA and END DATA are assumed to be simulation cases and are assigned a value of 2 on the newly created *STATUS_* variable.
- The OUTFILE subcommand saves the plan that is generated by ORTHOPLAN as a data file so that it can be used at a later date with CONJOINT.

FACTORS Subcommand

FACTORS specifies the variables to be used as factors and the values to be used as levels in the plan.

- FACTORS is required for building a new active dataset or replacing an existing one. FACTORS is optional for appending to an existing file.
- The keyword FACTORS is followed by a variable list, an optional label for each variable, a list of values for each variable, and optional value labels.
- The list of values and the value labels are enclosed in parentheses. Values can be numeric or they can be strings enclosed in apostrophes.
- The optional variable and value labels are enclosed in apostrophes.
- If the FACTORS subcommand is not used, every variable in the active dataset (other than *STATUS_* and *CARD_*) is used as a factor, and level information is obtained from the value labels that are defined in the active dataset. ORTHOPLAN *must* be able to find value information either from a FACTORS subcommand or from a VALUE LABELS command. (See the VALUE LABELS command for more information.)

Example

```
ORTHOPLAN FACTORS=SPEED 'Highest possible speed'
   (70 '70 mph' 100 '100 mph' 130 '130mph')
  WARRANTY 'Length of warranty'
   (1 '1 year' 3 '3 year' 5 '5 year')
  SEATS 'Number of seats' (2 '2 seats' 4 '4 seats')
  EXCOLOR 'Exterior color'
```

```
  INCOLOR 'Interior color' ('RED' 'BLUE' 'SILVER').
```

- *SPEED*, *WARRANTY*, *SEATS*, *EXCOLOR*, and *INCOLOR* are specified as the factors. They are given the labels *Highest possible speed*, *Length of warranty*, *Number of seats*, *Exterior color*, and *Interior color*.
- Following each factor and its label are the list of values and the value labels in parentheses. Note that the values for two of the factors, *EXCOLOR* and *INCOLOR*, are the same and thus need to be specified only once after both factors are listed.

REPLACE Subcommand

REPLACE can be specified to indicate that the active dataset, if present, should be replaced by the generated plan. There is no further specification after the REPLACE keyword.

- By default, the active dataset is not replaced. Any new variables that are specified on a FACTORS subcommand plus the variables *STATUS_* and *CARD_* are appended to the active dataset.
- REPLACE should be used when the current active dataset has nothing to do with the plan file to be built. The active dataset will be replaced with one that has variables *STATUS_*, *CARD_*, and any other variables that are specified on the FACTORS subcommand.
- If REPLACE is specified, the FACTORS subcommand is required.

OUTFILE Subcommand

OUTFILE saves the orthogonal design to an SPSS data file. The only specification is a name for the output file. This specification can be a filename or a previously declared dataset name. Filenames should be enclosed in quotation marks and are stored in the working directory unless a path is included as part of the file specification. Datasets are available during the current session but are not available in subsequent sessions unless you explicitly save them as data files.

- By default, a new data file is not created. Any new variables that are specified on a FACTORS subcommand plus the variables *STATUS_* and *CARD_* are appended to the active dataset.
- The output data file contains variables *STATUS_*, *CARD_*, and any other variables that are specified on the FACTORS subcommand.
- The file that is created by OUTFILE can be used by other syntax commands, such as PLANCARDS and CONJOINT.
- If both OUTFILE and REPLACE are specified, REPLACE is ignored.

MINIMUM Subcommand

MINIMUM specifies a minimum number of cases for the plan.

- By default, the minimum number of cases necessary for the orthogonal plan is generated.

- MINIMUM is followed by a positive integer that is less than or equal to the total number of cases that can be formed from all possible combinations of the factor levels.
- If ORTHOPLAN cannot generate at least the number of cases requested on MINIMUM, it will generate the largest number it can that fits the specified factors and levels.

HOLDOUT Subcommand

HOLDOUT creates holdout cases in addition to the regular plan cases. Holdout cases are judged by the subjects but are not used when CONJOINT estimates utilities.

- If HOLDOUT is not specified, no holdout cases are produced.
- HOLDOUT is followed by a positive integer that is less than or equal to the total number of cases that can be formed from all possible combinations of factor levels.
- Holdout cases are generated from another random plan, not the main-effects experimental plan. The holdout cases will not duplicate the experimental cases or each other.
- The experimental and holdout cases will be randomly mixed in the generated plan or the holdout cases will be listed after the experimental cases, depending on subcommand MIXHOLD. The value of *STATUS_* for holdout cases is 1. Any simulation cases will follow the experimental and holdout cases.

MIXHOLD Subcommand

MIXHOLD indicates whether holdout cases should be randomly mixed with the experimental cases or should appear separately after the experimental plan in the file.

- If MIXHOLD is not specified, the default is NO, meaning holdout cases will appear after the experimental cases in the file.
- MIXHOLD followed by keyword YES requests that the holdout cases be randomly mixed with the experimental cases.
- MIXHOLD specified without a HOLDOUT subcommand has no effect.

OUTPUT ACTIVATE

```
OUTPUT ACTIVATE [NAME=]name
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Release History

Release 15.0

- Command introduced.

Example

```
GET FILE='/examples/data/SalaryData2005.sav'.
DESCRIPTIVES salbegin salary.
OUTPUT NAME alleduclevels.

TEMPORARY.
SELECT IF (educ>12).
OUTPUT NEW NAME=over12.
DESCRIPTIVES salbegin salary.

GET FILE='/examples/data/SalaryData2000.sav'.
TEMPORARY.
SELECT IF (educ>12).
DESCRIPTIVES salbegin salary.

OUTPUT ACTIVATE alleduclevels.
DESCRIPTIVES salbegin salary.
```

Overview

The `OUTPUT` commands (`OUTPUT NEW`, `OUTPUT NAME`, `OUTPUT ACTIVATE`, `OUTPUT OPEN`, `OUTPUT SAVE`, `OUTPUT CLOSE`) provide the ability to programmatically manage one or many output documents. These functions allow you to:

- Save an output document through syntax.
- Programmatically partition output into separate output documents (for example, results for males in one output document and results for females in a separate one).
- Work with multiple open output documents in a given session, selectively appending new results to the appropriate document.

The `OUTPUT ACTIVATE` command activates an open output document. Subsequent procedure output is directed to this output document until the document is closed or another output document is created, opened, or activated.

Basic Specification

The basic specification for OUTPUT ACTIVATE is the command name followed by the name of an open output document. This is the name assigned by a previous OUTPUT NAME, OUTPUT OPEN, or OUTPUT NEW command; it is not the file name or the name of a Viewer window displaying the output document. The NAME keyword is optional, but if it is used it must be followed by an equals sign.

Operations

- The window containing the activated document becomes the designated output window in the user interface.
- An error occurs, but processing continues, if the named output document does not exist. Output continues to be directed to the last active output document.

Example

```
GET FILE='/examples/data/SurveyData.sav'.

TEMPORARY.
SELECT IF (Sex='Male').
FREQUENCIES VARIABLES=ALL.
OUTPUT NAME males.

TEMPORARY.
SELECT IF (Sex='Female').
OUTPUT NEW NAME=females.
FREQUENCIES VARIABLES=ALL.

GET FILE='/examples/data/Preference.sav'.

TEMPORARY.
SELECT IF (Sex='Female').
DESCRIPTIVES VARIABLES=product1 product2 product3.

TEMPORARY.
SELECT IF (Sex='Male').
OUTPUT ACTIVATE males.
DESCRIPTIVES VARIABLES=product1 product2 product3.

OUTPUT SAVE NAME=males OUTFILE='/examples/output/Males.spv'.
OUTPUT SAVE NAME=females OUTFILE='/examples/output/Females.spv'.
```

- The first GET command loads survey data for males and females.
- FREQUENCIES output for male respondents is written to the active output document. The OUTPUT NAME command is used to assign the name *males* to the active output document.
- FREQUENCIES output for females is written to a new output document named *females*.
- The second GET command loads preferences data for males and females.
- After the second GET command, the output document named *females* is still the active output document. Descriptive statistics for females are appended to this output document.

- `OUTPUT ACTIVATE males` activates the output document named *males*. Descriptive statistics for males are appended to this output document.
- The two open output documents are saved to separate files. Because the operation of saving an output document does not close it, both documents remain open. The output document named *males* remains the active output document.

OUTPUT CLOSE

```
OUTPUT CLOSE [NAME=]{name}
                    {*   }
                    {ALL }
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Release History

Release 15.0

- Command introduced.

Example

```
GET FILE='/examples/data/Males.sav'.
FREQUENCIES VARIABLES=ALL.
OUTPUT SAVE OUTFILE='/examples/output/Males.spv'.
OUTPUT CLOSE *.

GET FILE='/examples/data/Females.sav'.
FREQUENCIES VARIABLES=ALL.
```

Overview

The OUTPUT commands (OUTPUT NEW, OUTPUT NAME, OUTPUT ACTIVATE, OUTPUT OPEN, OUTPUT SAVE, OUTPUT CLOSE) provide the ability to programmatically manage one or many output documents. These functions allow you to:

- Save an output document through syntax.
- Programmatically partition output into separate output documents (for example, results for males in one output document and results for females in a separate one).
- Work with multiple open output documents in a given session, selectively appending new results to the appropriate document.

The OUTPUT CLOSE command closes one or all open output documents.

Basic Specification

The only specification for OUTPUT CLOSE is the command name followed by the name of an open output document, an asterisk (*), or the keyword ALL. The NAME keyword is optional, but if it is used it must be followed by an equals sign.

Operations

- If a name is provided, the specified output document is closed and the association with that name is broken.

- If an asterisk (*) is specified, the active output document is closed. If the active output document has a name, the association with that name is broken.
- If ALL is specified, all open output documents are closed and all associations of names with output documents are broken.
- Output documents are not saved automatically when they are closed. Use OUTPUT SAVE to save the contents of an output document.
- OUTPUT CLOSE is ignored if you specify a nonexistent document.

Example

```
GET FILE='/examples/data/Males.sav'.
FREQUENCIES VARIABLES=ALL.
OUTPUT SAVE OUTFILE='/examples/output/Males.spv'.
OUTPUT CLOSE *.

GET FILE='/examples/data/Females.sav'.
FREQUENCIES VARIABLES=ALL.
```

- FREQUENCIES produces summary statistics for each variable. Procedure output is added to the active output document (one is created automatically if no output document is currently open).
- OUTPUT SAVE writes contents of the active output document to the file */examples/output/Males.spv*.
- OUTPUT CLOSE closes the active output document.
- Output from the second FREQUENCIES command is written to a new output document, which was created automatically when the previously active output document was closed. If OUTPUT CLOSE had not been issued, output for females would have been directed to the output document that contained summaries for males.

OUTPUT DISPLAY

```
OUTPUT DISPLAY
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Release History

Release 15.0

- Command introduced.

Example

```
OUTPUT DISPLAY.
```

Overview

The OUTPUT commands (OUTPUT NEW, OUTPUT NAME, OUTPUT ACTIVATE, OUTPUT OPEN, OUTPUT SAVE, OUTPUT CLOSE) provide the ability to programmatically manage one or many output documents. These functions allow you to:

- Save an output document through syntax.
- Programmatically partition output into separate output documents (for example, results for males in one output document and results for females in a separate one).
- Work with multiple open output documents in a given session, selectively appending new results to the appropriate document.

The OUTPUT DISPLAY command displays a list of open output documents and identifies the one that is currently active. The only specification is the command name OUTPUT DISPLAY.

OUTPUT NAME

```
OUTPUT NAME [NAME]=name
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Release History

Release 15.0

- Command introduced.

Example

```
GET FILE='/examples/data/SalaryData2005.sav'.
DESCRIPTIVES salbegin salary.
OUTPUT NAME alleduclevels.

TEMPORARY.
SELECT IF (educ>12).
OUTPUT NEW NAME=over12.
DESCRIPTIVES salbegin salary.

GET FILE='/examples/data/SalaryData2000.sav'.
TEMPORARY.
SELECT IF (educ>12).
DESCRIPTIVES salbegin salary.

OUTPUT ACTIVATE alleduclevels.
DESCRIPTIVES salbegin salary.
```

Overview

The OUTPUT commands (OUTPUT NEW, OUTPUT NAME, OUTPUT ACTIVATE, OUTPUT OPEN, OUTPUT SAVE, OUTPUT CLOSE) provide the ability to programmatically manage one or many output documents. These functions allow you to:

- Save an output document through syntax.
- Programmatically partition output into separate output documents (for example, results for males in one output document and results for females in a separate one).
- Work with multiple open output documents in a given session, selectively appending new results to the appropriate document.

The OUTPUT NAME command assigns a name to the active output document. The active output document is the one most recently opened (by OUTPUT NEW or OUTPUT OPEN) or activated (by OUTPUT ACTIVATE). The document name is used to reference the document in any subsequent OUTPUT ACTIVATE, OUTPUT SAVE, and OUTPUT CLOSE commands.

Basic Specification

The basic specification for OUTPUT NAME is the command name followed by a name that conforms to variable naming rules. For more information, see Variable Names on p. 43. The NAME keyword is optional, but if it is used it must be followed by an equals sign.

Operations

- The association with the existing name is broken, and the new name is assigned to the document.
- If the specified name is associated with another document, that association is broken and the name is associated with the active output document. The document previously associated with the specified name is assigned a new unique name.

Example

```
GET FILE='/examples/data/SurveyData.sav'.

TEMPORARY.
SELECT IF (Sex='Male').
FREQUENCIES VARIABLES=ALL.
OUTPUT NAME males.

TEMPORARY.
SELECT IF (Sex='Female').
OUTPUT NEW NAME=females.
FREQUENCIES VARIABLES=ALL.

GET FILE='/examples/data/Preference.sav'.

TEMPORARY.
SELECT IF (Sex='Female').
DESCRIPTIVES VARIABLES=product1 product2 product3.

TEMPORARY.
SELECT IF (Sex='Male').
OUTPUT ACTIVATE males.
DESCRIPTIVES VARIABLES=product1 product2 product3.

OUTPUT SAVE NAME=males OUTFILE='/examples/output/Males.spv'.
OUTPUT SAVE NAME=females OUTFILE='/examples/output/Females.spv'.
```

- The first GET command loads survey data for males and females.
- FREQUENCIES output for male respondents is written to the active output document. The OUTPUT NAME command is used to assign the name *males* to the active output document.
- FREQUENCIES output for female respondents is written to a new output document named *females*.
- The second GET command loads preferences data for males and females.
- Descriptive statistics for females are appended to the output document named *females* and those for males are appended to the output document named *males*. Each output document now contains both survey and preferences results.
- The two open output documents are saved to separate files. Because the operation of saving an output document does not close it, both documents remain open. The output document named *males* remains the active output document.

OUTPUT NEW

```
OUTPUT NEW [NAME=name]
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Release History

Release 15.0

- Command introduced.

Release 16.0

- TYPE keyword is obsolete and is ignored.

Example

```
GET FILE='/examples/data/Males.sav'.
FREQUENCIES VARIABLES=ALL.
OUTPUT SAVE OUTFILE='/examples/output/Males.spv'.
OUTPUT NEW.

GET FILE='/examples/data/Females.sav'.
FREQUENCIES VARIABLES=ALL.
OUTPUT SAVE OUTFILE='/examples/output/Females.spv'.
```

Overview

The OUTPUT commands (OUTPUT NEW, OUTPUT NAME, OUTPUT ACTIVATE, OUTPUT OPEN, OUTPUT SAVE, OUTPUT CLOSE) provide the ability to programmatically manage one or many output documents. These functions allow you to:

- Save an output document through syntax.
- Programmatically partition output into separate output documents (for example, results for males in one output document and results for females in a separate one).
- Work with multiple open output documents in a given session, selectively appending new results to the appropriate document.

The OUTPUT NEW command creates a new output document, which becomes the active output document. Subsequent procedure output is directed to the new output document until the document is closed or another output document is created, opened, or activated.

Basic Specification

The basic specification for OUTPUT NEW is simply the command name.

TYPE Keyword

This keyword is obsolete and is ignored. The only valid output type is Viewer. Draft Viewer format is no longer supported. To produce text output equivalent to Draft Viewer output use OMS. For more information, see OMS on p. 1284.

NAME Keyword

By default, the newly created output document is provided with a unique name. You can optionally specify a custom name for the output document, overriding the default name. The document name is used to reference the document in any subsequent OUTPUT ACTIVATE, OUTPUT SAVE, and OUTPUT CLOSE commands.

- The specified name must conform to variable naming rules. For more information, see Variable Names on p. 43.
- If the specified name is associated with another document, that association is broken and the name is associated with the new document. The document previously associated with the specified name is assigned a new unique name.

Syntax Rules

- An error occurs if a keyword is specified more than once.
- Keywords must be spelled in full.
- Equals signs (=) used in the syntax chart are required elements.

Operations

The new output document is opened in a window in the user interface and becomes the designated output window.

Limitations

Because each window requires a minimum amount of memory, there is a limit to the number of windows, SPSS or otherwise, that can be concurrently open on a given system. The particular number depends on the specifications of your system and may be independent of total memory due to OS constraints.

Example

```
GET FILE='/examples/data/Males.sav'.
FREQUENCIES VARIABLES=ALL.
OUTPUT SAVE OUTFILE='/examples/output/Males.spv'.
OUTPUT NEW.

GET FILE='/examples/data/Females.sav'.
FREQUENCIES VARIABLES=ALL.
OUTPUT SAVE OUTFILE='/examples/output/Females.spv'.
```

- FREQUENCIES produces summary statistics for each variable in */examples/data/Males.sav*. The output from FREQUENCIES is added to the active output document (one is created automatically if no output document is currently open).

- `OUTPUT SAVE` writes the contents of the active output document to */examples/output/Males.spv*.
- `OUTPUT NEW` creates a new Viewer document, which becomes the active output document.
- The subsequent `FREQUENCIES` command produces output for females using the data in */examples/data/Females.sav*. `OUTPUT SAVE` writes this output to */examples/output/Females.spv*.

As shown in this example, `OUTPUT NEW` allows you to direct results to an output document other than the one that is currently active. If `OUTPUT NEW` were not specified, */examples/output/Females.spv* would contain frequencies for both males and females.

OUTPUT OPEN

```
OUTPUT OPEN FILE='file specification' [NAME=name]
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Release History

Release 15.0

- Command introduced.

Example

```
OUTPUT OPEN FILE='/examples/output/Q1Output.spv'.
GET FILE='/examples/data/March.sav'.
FREQUENCIES VARIABLES=ALL.
OUTPUT SAVE OUTFILE='/examples/output/Q1Output.spv'.
```

Overview

The OUTPUT commands (OUTPUT NEW, OUTPUT NAME, OUTPUT ACTIVATE, OUTPUT OPEN, OUTPUT SAVE, OUTPUT CLOSE) provide the ability to programmatically manage one or many output documents. These functions allow you to:

- Save an output document through syntax.
- Programmatically partition output into separate output documents (for example, results for males in one output document and results for females in a separate one).
- Work with multiple open output documents in a given session, selectively appending new results to the appropriate document.

The OUTPUT OPEN command opens a Viewer document, which becomes the active output document. You can use OUTPUT OPEN to append output to an existing output document. Once opened, subsequent procedure output is directed to the document until it is closed or until another output document is created, opened, or activated.

Basic Specification

The basic specification for OUTPUT OPEN is the command name followed by a file specification for the file to open.

NAME Keyword

By default, the newly opened output document is provided with a unique name. You can optionally specify a custom name for the output document, overriding the default name. The document name is used to reference the document in any subsequent OUTPUT ACTIVATE, OUTPUT SAVE, and OUTPUT CLOSE commands.

- The specified name must conform to variable naming rules. For more information, see Variable Names on p. 43.
- If the specified name is associated with another document, that association is broken and the name is associated with the newly opened document. The document previously associated with the specified name is assigned a new unique name.

Syntax Rules

- An error occurs if a keyword is specified more than once.
- Keywords must be spelled in full.
- Equals signs (=) used in the syntax chart are required elements.

Operations

- The output document is opened in a window in the user interface and becomes the designated output window.
- An error occurs, but processing continues, if the specified file is not found. Output continues to be directed to the last active output document.
- An error occurs, but processing continues, if the specified file is not a Viewer document. Output continues to be directed to the last active output document.
- Attempting to execute OUTPUT OPEN from SPSSB (a batch-processing facility that is available with SPSS Server) generates a syntax error that halts execution. In this regard, OUTPUT OPEN is incompatible with SPSSB since it opens a Viewer document and there is no mechanism to convert that document type to output types supported by SPSSB, such as HTML.
- OUTPUT OPEN honors file handles and changes to the working directory made with the CD command.

Limitations

Because each window requires a minimum amount of memory, there is a limit to the number of windows, SPSS or otherwise, that can be concurrently open on a given system. The particular number depends on the specifications of your system and may be independent of total memory due to OS constraints.

Example

```
OUTPUT OPEN FILE='/examples/output/Q1Output.spv'.
GET FILE='/examples/data/March.sav'.
FREQUENCIES VARIABLES=ALL.
OUTPUT SAVE OUTFILE='/examples/output/Q1Output.spv'.
```

- `OUTPUT OPEN` opens the Viewer document */examples/output/Q1Output.spv*. The document contains summaries for the months of January and February.
- The `GET` command opens a file containing data for the month of March.
- The `FREQUENCIES` command produces summaries for March data, which are appended to the active output document.
- `OUTPUT SAVE` saves the active output document to */examples/output/Q1Output.spv*. The saved document contains results for each of the three months in the first quarter.

OUTPUT SAVE

```
OUTPUT SAVE [NAME={*   }]  OUTFILE='file specification' [TYPE={SPV**}]
                  {name}                                    (SPW  }
```

** Default if the keyword is omitted.

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Release History

Release 15.0

- Command introduced.

Release 16.0

- TYPE keyword introduced.

Example

```
OUTPUT OPEN FILE='/examples/output/Q1Output.spv'.
GET FILE='/examples/data/March.sav'.
FREQUENCIES VARIABLES=ALL.
OUTPUT SAVE OUTFILE='/examples/output/Q1Output.spv'.
```

Overview

The OUTPUT commands (OUTPUT NEW, OUTPUT NAME, OUTPUT ACTIVATE, OUTPUT OPEN, OUTPUT SAVE, OUTPUT CLOSE) provide the ability to programmatically manage one or many output documents. These functions allow you to:

- Save an output document through syntax.
- Programmatically partition output into separate output documents (for example, results for males in one output document and results for females in a separate one).
- Work with multiple open output documents in a given session, selectively appending new results to the appropriate document.

The OUTPUT SAVE command saves the contents of an open output document to a file.

Basic Specification

The basic specification for OUTPUT SAVE is the command name followed by a file specification for the destination file.

Name Keyword

Use the NAME keyword to save an output document other than the active one. Provide the name associated with the document.

Type Keyword

Use the TYPE keyword to specify the format of the output file—SPV for standard output files and SPW for the SPSS Web Reports format. Files in the SPW format that are stored in a Predictive Enterprise Repository will be able to be viewed and manipulated over the Web, in real time, using a standard browser in a future release (post 3.0) of SPSS Predictive Enterprise Services.

- *spw* files created from OUTPUT SAVE contain all visible objects from the associated Viewer window, and pivot tables are saved as interactive, meaning they can be manipulated when viewed over the Web. If you need greater control over items saved to an *spw* file, use the OMS command.

Syntax Rules

- An error occurs if a keyword is specified more than once.
- Keywords must be spelled in full.
- Equals signs (=) used in the syntax chart are required elements.

Operations

- By default, the active output document is saved. The active output document is the one most recently opened (by OUTPUT NEW or OUTPUT OPEN) or activated (by OUTPUT ACTIVATE).
- If the specified file already exists, OUTPUT SAVE overwrites it without warning.
- An error occurs if you specify a nonexistent output document.
- An error occurs if the file specification is invalid.
- OUTPUT SAVE saves the document but does not close it. Use OUTPUT CLOSE to close the document.
- OUTPUT SAVE honors file handles and changes to the working directory made with the CD command.

Operations for SPSSB

For SPSSB (a batch-processing facility that is available with SPSS Server), output requested by OUTPUT SAVE is produced in addition to, and independent of, the usual SPSSB output stream, whose destination (console or file) is specified on the SPSSB command line. The output type is determined by the -type switch on the SPSSB command line (text, by default). This is the case regardless of the extension provided with the file specification on the OUTFILE subcommand.

- OUTPUT SAVE writes text (-type text), HTML (-type html), or Output XML (-type oxml). For HTML output, images (charts, trees, maps) are saved in a separate subdirectory (folder). The subdirectory name is the name of the HTML destination file without any extension and with *_files* appended to the end. For example, if the HTML destination file is *julydata.htm*, the images subdirectory will be named *julydata_files*.

- OUTPUT SAVE ignores -type sav and -type sxml and creates HTML output in those cases.
- OUTPUT SAVE honors the following SPSSB command line switches pertaining to the display of output: -t, -pb, -n, -rs, -cs, -notes, -show, -hide, -keep, -drop, -nl, and -nfc.
- OUTPUT SAVE ignores the SPSSB command line switch -st.

Example

```
OUTPUT OPEN FILE='/examples/output/Q1Output.spv'.
GET FILE='/examples/data/March.sav'.
FREQUENCIES VARIABLES=ALL.
OUTPUT SAVE OUTFILE='/examples/output/Q1Output.spv'.
```

- OUTPUT OPEN opens the Viewer document */examples/output/Q1Output.spv*. The document contains summaries for the months of January and February.
- GET opens a file containing new data for March.
- FREQUENCIES produces frequencies for March data, which are appended to the active output document.
- OUTPUT SAVE saves the contents of the active output document to */examples/output/Q1Output.spv*, which now contains results for the entire first quarter.

OVERALS

OVERALS is available in the Categories option.

```
OVERALS VARIABLES=varlist (max)

/ANALYSIS=varlist[({ORDI**})]
                  {SNOM  }
                  {MNOM  }
                  {NUME  }

/SETS= n (# of vars in set 1, ..., # of vars in set n)

[/NOBSERVATIONS=value]

[/DIMENSION={2**  }]
            {value}

[/INITIAL={NUMERICAL**}]
          {RANDOM     }

[/MAXITER={100**}]
          {value}

[/CONVERGENCE={.00001**}]
              {value   }

[/PRINT=[DEFAULT] [FREQ**] [QUANT] [CENTROID**]
        [HISTORY] [WEIGHTS**]
        [OBJECT] [FIT] [NONE]]

[/PLOT=[NDIM=({1    ,2    }**)]
              {value,value}
              {ALL  ,MAX  }
       [DEFAULT[(n)]] [OBJECT**[(varlist)][(n)]]
       [QUANT[(varlist)][(n)]] [LOADINGS**[(n)]]
       [TRANS[(varlist)]] [CENTROID[(varlist)][(n)]]
       [NONE]]

[/SAVE=[rootname][(value)]]

[/MATRIX=OUT({*                 })]
             {'savfile'|'dataset'}
```

**Default if the subcommand or keyword is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
OVERALS VARIABLES=PRETEST1 PRETEST2 POSTEST1 POSTEST2(20)
SES(5) SCHOOL(3)
/ANALYSIS=PRETEST1 TO POSTEST2 (NUME) SES (ORDI) SCHOOL (SNOM)
/SETS=3(2,2,2).
```

Overview

OVERALS performs nonlinear canonical correlation analysis on two or more sets of variables. Variables can have different optimal scaling levels, and no assumptions are made about the distribution of the variables or the linearity of the relationships.

Options

Optimal Scaling Levels. You can specify the level of optimal scaling at which you want to analyze each variable.

Number of Dimensions. You can specify how many dimensions OVERALS should compute.

Iterations and Convergence. You can specify the maximum number of iterations and the value of a convergence criterion.

Display Output. The output can include all available statistics, only the default statistics, or only the specific statistics that you request. You can also control whether some of these statistics are plotted.

Saving Scores. You can save object scores in the active dataset.

Writing Matrices. You can write a matrix data file containing quantification scores, centroids, weights, and loadings for use in further analyses.

Basic Specification

- The basic specification is command OVERALS, the VARIABLES subcommand, the ANALYSIS subcommand, and the SETS subcommand. By default, OVERALS estimates a two-dimensional solution and displays a table listing optimal scaling levels of each variable by set, eigenvalues and loss values by set, marginal frequencies, centroids and weights for all variables, and plots of the object scores and component loadings.

Subcommand Order

- The VARIABLES subcommand, ANALYSIS subcommand, and SETS subcommand must appear in that order before all other subcommands.
- Other subcommands can appear in any order.

Operations

- If the ANALYSIS subcommand is specified more than once, OVERALS is not executed. For all other subcommands, if a subcommand is specified more than once, only the last occurrence is executed.
- OVERALS treats every value in the range 1 to the maximum value that is specified on VARIABLES as a valid category. To avoid unnecessary output, use the AUTORECODE or RECODE command to recode a categorical variable that has nonsequential values or that has a large number of categories. For variables that are treated as numeric, recoding is not recommended because the characteristic of equal intervals in the data will not be maintained (see AUTORECODE and RECODE for more information).

Limitations

- String variables are not allowed; use AUTORECODE to recode nominal string variables.
- The data must be positive integers. Zeros and negative values are treated as system-missing, which means that they are excluded from the analysis. Fractional values are truncated after the decimal and are included in the analysis. If one of the levels of a categorical variable has been coded 0 or some negative value, and you want to treat it as a valid category, use the AUTORECODE or RECODE command to recode the values of that variable.

- OVERALS ignores user-missing value specifications. Positive user-missing values that are less than the maximum value that is specified on the VARIABLES subcommand are treated as valid category values and are included in the analysis. If you do not want the category to be included, use COMPUTE or RECODE to change the value to a value outside of the valid range. Values outside of the range (less than 1 or greater than the maximum value) are treated as system-missing and are excluded from the analysis.
- If one variable in a set has missing data, all variables in that set are missing for that object (case).
- Each set must have at least three valid (non-missing, non-empty) cases.

Examples

```
OVERALS VARIABLES=PRETEST1 PRETEST2 POSTEST1 POSTEST2(20)
SES(5) SCHOOL(3)
/ANALYSIS=PRETEST1 TO POSTEST2 (NUME) SES (ORDI) SCHOOL (SNOM)
/SETS=3(2,2,2)
/PRINT=OBJECT FIT
/PLOT=QUANT(PRETEST1 TO SCHOOL).
```

- VARIABLES defines the variables and their maximum values.
- ANALYSIS specifies that all variables from *PRETEST1* to *POSTEST2* are to be analyzed at the numeric level of optimal scaling, *SES* is to be analyzed at the ordinal level, and *SCHOOL* is to be analyzed as a single nominal. These variables are all of the variables that will be used in the analysis.
- SETS specifies that there are three sets of variables to be analyzed and two variables in each set.
- PRINT lists the object and fit scores.
- PLOT plots the single-category and multiple-category coordinates of all variables in the analysis.

VARIABLES Subcommand

VARIABLES specifies all variables in the current OVERALS procedure.

- The VARIABLES subcommand is required and precedes all other subcommands. The actual word VARIABLES can be omitted.
- Each variable or variable list is followed by the maximum value in parentheses.

ANALYSIS Subcommand

ANALYSIS specifies the variables to be used in the analysis and the optimal scaling level at which each variable is to be analyzed.

- The ANALYSIS subcommand is required and follows the VARIABLES subcommand.
- The specification on ANALYSIS is a variable list and an optional keyword in parentheses, indicating the level of optimal scaling.

- The variables on ANALYSIS must also be specified on the VARIABLES subcommand.
- Only active variables are listed on the ANALYSIS subcommand. **Active variables** are those variables that are used in the computation of the solution. **Passive variables**, those variables that are listed on the VARIABLES subcommand but not on the ANALYSIS subcommand, are ignored in the OVERALS solution. Object score plots can still be labeled by passive variables.

The following keywords can be specified to indicate the optimal scaling level:

MNOM *Multiple nominal*. The quantifications can be different for each dimension. When all variables are multiple nominal, and there is only one variable in each set, OVERALS gives the same results as HOMALS.

SNOM *Single nominal*. OVERALS gives only one quantification for each category. Objects in the same category (cases with the same value on a variable) obtain the same quantification. When all variables are SNOM, ORDI, or NUME, and there is only one variable per set, OVERALS gives the same results as PRINCALS.

ORDI *Ordinal*. This setting is the default for variables that are listed without optimal scaling levels. The order of the categories of the observed variable is preserved in the quantified variable.

NUME *Numerical*. Interval or ratio scaling level. OVERALS assumes that the observed variable already has numerical values for its categories. When all variables are quantified at the numerical level, and there is only one variable per set, the OVERALS analysis is analogous to classical principal components analysis.

These keywords can apply to a variable list as well as to a single variable. Thus, the default ORDI is not applied to a variable without a keyword if a subsequent variable on the list has a keyword.

SETS Subcommand

SETS specifies how many sets of variables exist and how many variables are in each set.

- SETS is required and must follow the ANALYSIS subcommand.
- SETS is followed by an integer to indicate the number of variable sets. Following this integer is a list of values in parentheses, indicating the number of variables in each set.
- There must be at least two sets.
- The sum of the values in parentheses must equal the number of variables specified on the ANALYSIS subcommand. The variables in each set are read consecutively from the ANALYSIS subcommand.

An example is as follows:

```
/SETS=2(2,3)
```

This specification indicates that there are two sets. The first two variables that are named on ANALYSIS are the first set, and the last three variables that are named on ANALYSIS are the second set.

NOBSERVATIONS Subcommand

NOBSERVATIONS specifies how many cases are used in the analysis.

- If NOBSERVATIONS is not specified, all available observations in the active dataset are used.
- NOBSERVATIONS is followed by an integer, indicating that the first *n* cases are to be used.

DIMENSION Subcommand

DIMENSION specifies the number of dimensions that you want OVERALS to compute.

- If you do not specify the DIMENSION subcommand, OVERALS computes two dimensions.
- DIMENSION is followed by an integer indicating the number of dimensions.
- If all variables are SNOM (single nominal), ORDI (ordinal), or NUME (numerical), the maximum number of dimensions that you can specify is the total number of variables on the ANALYSIS subcommand.
- If some or all variables are MNOM (multiple nominal), the maximum number of dimensions that you can specify is the number of MNOM variable levels (categories) plus the number of non-MNOM variables, minus the number of MNOM variables.
- The maximum number of dimensions must be less than the number of observations minus 1.
- If the number of sets is 2, and all variables are SNOM, ORDI, or NUME, the number of dimensions should not be more than the number of variables in the smaller set.
- If the specified value is too large, OVERALS tries to adjust the number of dimensions to the allowable maximum. OVERALS might not be able to adjust if there are MNOM variables with missing data.

INITIAL Subcommand

The INITIAL subcommand specifies the method that is used to compute the initial configuration.

- The specification on INITIAL is keyword NUMERICAL or RANDOM. If the INITIAL subcommand is not specified, NUMERICAL is the default.

NUMERICAL *Treat all variables except multiple nominal as numerical.* This specification is best to use when there are no SNOM variables.

RANDOM *Compute a random initial configuration.* This specification should be used only when some or all variables are SNOM.

MAXITER Subcommand

MAXITER specifies the maximum number of iterations that OVERALS can go through in its computations.

- If MAXITER is not specified, OVERALS will iterate up to 100 times.
- The specification on MAXITER is an integer indicating the maximum number of iterations.

CONVERGENCE Subcommand

CONVERGENCE specifies a convergence criterion value. OVERALS stops iterating if the difference in fit between the last two iterations is less than the CONVERGENCE value.

- The default CONVERGENCE value is 0.00001.
- The specification on CONVERGENCE is any value that is greater than 0.000001. (Values that are less than this value might seriously affect performance.)

PRINT Subcommand

PRINT controls which statistics are included in your display output. The default output includes a table that lists optimal scaling levels of each variable by set; eigenvalues and loss values by set by dimension; and the output that is produced by keywords FREQ, CENTROID, and WEIGHTS.

The following keywords are available:

FREQ	*Marginal frequencies for the variables in the analysis.*
HISTORY	*History of the iterations.*
FIT	*Multiple fit, single fit, and single loss per variable.*
CENTROID	*Category quantification scores, the projected centroids, and the centroids.*
OBJECT	*Object scores.*
QUANT	*Category quantifications and the single and multiple coordinates.*
WEIGHTS	*Weights and component loadings.*
DEFAULT	*FREQ, CENTROID, and WEIGHTS.*
NONE	*Summary loss statistics.*

PLOT Subcommand

PLOT can be used to produce plots of transformations, object scores, coordinates, centroids, and component loadings.

- If PLOT is not specified, plots of the object scores and component loadings are produced.

The following keywords can be specified on PLOT:

LOADINGS	*Plot of the component loadings.*
OBJECT	*Plot of the object scores.*
TRANS	*Plot of category quantifications.*
QUANT	*Plot of all category coordinates.*
CENTROID	*Plot of all category centroids.*
DEFAULT	*OBJECT and LOADINGS.*
NONE	*No plots.*

- Keywords OBJECT, QUANT, and CENTROID can each be followed by a variable list in parentheses to indicate that plots should be labeled with these variables. For QUANT and CENTROID, the variables must be specified on both the VARIABLES and ANALYSIS subcommands. For OBJECT, the variables must be specified on VARIABLES but need not appear on ANALYSIS, meaning that variables that are not used in the computations can still be used to label OBJECT plots. If the variable list is omitted, the default plots are produced.

- Object score plots use category labels corresponding to all categories within the defined range. Objects in a category that is outside the defined range are labeled with the label corresponding to the category immediately following the defined maximum category.
- If TRANS is followed by a variable list, only plots for those variables are produced. If a variable list is not specified, plots are produced for each variable.
- All keywords except NONE can be followed by an integer in parentheses to indicate how many characters of the variable or value label are to be used on the plot. (If you specified a variable list after OBJECT, CENTROID, TRANS, or QUANT, you can specify the value in parentheses after the list.) The value can range from 1 to 20. If the value is omitted, 12 characters are used. Spaces between words count as characters.
- If a variable label is missing, the variable name is used for that variable. If a value label is missing, the actual value is used.
- Make sure that your variable and value labels are unique by at least one letter in order to distinguish them on the plots.
- When points overlap, the points are described in a summary following the plot.

In addition to the plot keywords, the following keyword can be specified:

NDIM *Dimension pairs to be plotted.* NDIM is followed by a pair of values in parentheses. If NDIM is not specified, plots are produced for dimension 1 versus dimension 2.

- The first value indicates the dimension that is plotted against all higher dimensions. This value can be any integer from 1 to the number of dimensions minus 1.
- The second value indicates the highest dimension to be used in plotting the dimension pairs. This value can be any integer from 2 to the number of dimensions.
- Keyword ALL can be used instead of the first value to indicate that all dimensions are paired with higher dimensions.
- Keyword MAX can be used instead of the second value to indicate that plots should be produced up to and including the highest dimension fit by the procedure.

Example

```
OVERALS COLA1 COLA2 JUICE1 JUICE2 (4)
/ANALYSIS=COLA1 COLA2 JUICE1 JUICE2 (SNOM)
/SETS=2(2,2)
/PLOT NDIM(1,3) QUANT(5).
```

- The NDIM(1,3) specification indicates that plots should be produced for two dimension pairs—dimension 1 versus dimension 2 and dimension 1 versus dimension 3.
- QUANT requests plots of the category quantifications. The (5) specification indicates that the first five characters of the value labels are to be used on the plots.

Example

```
OVERALS COLA1 COLA2 JUICE1 JUICE2 (4)
/ANALYSIS=COLA1 COLA2 JUICE1 JUICE2 (SNOM)
/SETS=2(2,2)
```

```
/PLOT NDIM(ALL,3) QUANT(5).
```

- This plot is the same as above except for the ALL specification following NDIM, which indicates that all possible pairs up to the second value should be plotted. QUANT plots will be produced for dimension 1 versus dimension 2, dimension 2 versus dimension 3, and dimension 1 versus dimension 3.

SAVE Subcommand

SAVE lets you add variables containing the object scores that are computed by OVERALS to the active dataset.

- If SAVE is not specified, object scores are not added to the active dataset.
- A variable rootname can be specified on the SAVE subcommand, to which OVERALS adds the number of the dimension. Only one rootname can be specified, and it can contain up to six characters.
- If a rootname is not specified, unique variable names are automatically generated. The variable names are *OVEn_m*, where *n* is a dimension number and *m* is a set number. If three dimensions are saved, the first set of names are *OVE1_1*, *OVE2_1*, and *OVE3_1*. If another OVERALS is then run, the variable names for the second set are *OVE1_2*, *OVE2_2*, *OVE3_2*, and so on.
- Following the name, the number of dimensions for which you want object scores saved can be listed in parentheses. The number cannot exceed the value of the DIMENSION subcommand.
- The prefix should be unique for each OVERALS command in the same session. Otherwise,, OVERALS replaces the prefix with *DIM*, *OBJ*, or *OBSAVE*. If all of these prefixes already exist, SAVE is not executed.
- If the number of dimensions is not specified, the SAVE subcommand saves object scores for all dimensions.
- If you replace the active dataset by specifying an asterisk (*) on a MATRIX subcommand, the SAVE subcommand is not executed.

Example

```
OVERALS CAR1 CAR2 CAR3(5) PRICE(10)
/SET=2(3,1)
/ANALYSIS=CAR1 TO CAR3(SNOM) PRICE(NUME)
/DIMENSIONS=3
/SAVE=DIM(2).
```

- Analyzed items include three single nominal variables, *CAR1*, *CAR2*, and *CAR3* (each with 5 categories) and one numeric level variable (with 10 categories).
- The DIMENSIONS subcommand requests results for three dimensions.
- SAVE adds the object scores from the first two dimensions to the active dataset. The names of these new variables will be *DIM00001* and *DIM00002*, respectively.

MATRIX Subcommand

The MATRIX subcommand is used to write category quantifications, coordinates, centroids, weights, and component loadings to a matrix data file.

- The specification on MATRIX is keyword OUT and a quoted file specification or previously declared dataset name (DATASET DECLARE command), enclosed in parentheses.
- You can specify an asterisk (*) instead of a file to replace the active dataset.
- All values are written to the same file.
- The matrix data file has one case for each value of each original variable.

The variables of the matrix data file and their values are as follows:

ROWTYPE_	*String variable containing value QUANT for the category quantifications, SCOOR_ for the single-category coordinates, MCOOR_ for multiple-category coordinates, CENTRO_ for centroids, PCENTRO_ for projected centroids, WEIGHT_ for weights, and LOADING_ for the component scores*.
LEVEL	*String variable containing the values (or value labels, if present) of each original variable for category quantifications*. For cases with *ROWTYPE_=LOADING_* or *WEIGHT_*, the value of *LEVEL* is blank.
VARNAME_	*String variable containing the original variable names*.
VARTYPE_	*String variable containing values MULTIPLE, SINGLE N, ORDINAL, or NUMERICAL, depending on the level of optimal scaling that is specified for the variable*.
SET_	*The set number of the original variable*.
DIM1...DIMn	*Numeric variables containing the category quantifications, the single-category coordinates, multiple-category coordinates, weights, centroids, projected centroids, and component loadings for each dimension*. Each variable is labeled *DIMn*, where *n* represents the dimension number. Any values that cannot be computed are assigned 0 in the file.

PACF

```
PACF VARIABLES= series names

 [/DIFF={1}]
        {n}

 [/SDIFF={1}]
         {n}

 [/PERIOD=n]

 [/{NOLOG**}]
   {LN     }

 [/SEASONAL]

 [/MXAUTO={16**}]
          {n   }

 [/APPLY [='model name']]
```

**Default if the subcommand is omitted and there is no corresponding specification on the TSET command.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
PACF VARIABLES = TICKETS.
```

Overview

PACF displays and plots the sample partial autocorrelation function of one or more time series. You can also display and plot the partial autocorrelations of transformed series by requesting natural log and differencing transformations from within the procedure.

Options

Modification of the Series. You can use the LN subcommand to request a natural log transformation of the series, and you can use the SDIFF and DIFF subcommand to request seasonal and nonseasonal differencing to any degree. With seasonal differencing, you can specify the periodicity on the PERIOD subcommand.

Statistical Output. With the MXAUTO subcommand, you can specify the number of lags for which you want values to be displayed and plotted, overriding the maximum value that is specified on TSET. You can also use the SEASONAL subcommand to display and plot values only at periodic lags.

Basic Specification

The basic specification is one or more series names. For each specified series, PACF automatically displays the partial autocorrelation value and standard error value for each lag. PACF also plots the partial autocorrelations and marks the bounds of two standard errors on the plot. By default, PACF displays and plots partial autocorrelations for up to 16 lags (or the number of lags that are specified on TSET).

Subcommand Order

- Subcommands can be specified in any order.

Syntax Rules

- VARIABLES can be specified only once.
- Other subcommands can be specified more than once, but only the last specification of each subcommand is executed.

Operations

- Subcommand specifications apply to all series that are named on the PACF command.
- If the LN subcommand is specified, any differencing that is requested on that PACF command is done on log-transformed series.
- Confidence limits are displayed in the plot, marking the bounds of two standard errors at each lag.

Limitations

- A maximum of one VARIABLES subcommand is allowed. There is no limit on the number of series that are named on the list.

Example

```
PACF VARIABLES = TICKETS
  /LN
  /DIFF=1
  /SDIFF=1
  /PERIOD=12
  /MXAUTO=25.
```

- This example produces a plot of the partial autocorrelation function for the series *TICKETS* after a natural log transformation, differencing, and seasonal differencing have been applied to the series. Along with the plot, the partial autocorrelation value and standard error are displayed for each lag.
- LN transforms the data by using the natural logarithm (base *e*) of the series.
- DIFF differences the series once.
- SDIFF and PERIOD apply one degree of seasonal differencing with a period of 12.
- MXAUTO specifies 25 for the maximum number of lags for which output is to be produced.

VARIABLES Subcommand

VARIABLES specifies the series names and is the only required subcommand.

DIFF Subcommand

DIFF specifies the degree of differencing that is used to convert a nonstationary series to a stationary series with a constant mean and variance before the partial autocorrelations are computed.

- You can specify 0 or any positive integer on DIFF.
- If DIFF is specified without a value, the default is 1.
- The number of values that are used in the calculations decreases by 1 for each degree of differencing.

Example

```
PACF VARIABLES = SALES
  /DIFF=1.
```

- In this example, the series *SALES* will be differenced once before the partial autocorrelations are computed and plotted.

SDIFF Subcommand

If the series exhibits a seasonal or periodic pattern, you can use the SDIFF subcommand to seasonally difference the series before obtaining partial autocorrelations. SDIFF indicates the degree of seasonal differencing.

- The specification on SDIFF can be 0 or any positive integer.
- If SDIFF is specified without a value, the default is 1.
- The number of seasons that are used in the calculations decreases by 1 for each degree of seasonal differencing.
- The length of the period that is used by SDIFF is specified on the PERIOD subcommand. If the PERIOD subcommand is not specified, the periodicity that was established on the TSET or DATE command is used (see the PERIOD subcommand).

PERIOD Subcommand

PERIOD indicates the length of the period to be used by the SDIFF or SEASONAL subcommand. PERIOD indicates how many observations are in one period or season.

- The specification on PERIOD can be any positive integer that is greater than 1.
- PERIOD is ignored if it is used without the SDIFF or SEASONAL subcommand.

- If PERIOD is not specified, the periodicity that was established on TSET PERIOD is in effect. If TSET PERIOD is not specified, the periodicity that was established on the DATE command is used. If periodicity was not established anywhere, the SDIFF and SEASONAL subcommands are not executed.

Example

```
PACF VARIABLES = SALES
  /SDIFF=1
  /PERIOD=12.
```

- This PACF command applies one degree of seasonal differencing with a periodicity of 12 to the series *SALES* before partial autocorrelations are computed and plotted.

LN and NOLOG Subcommands

LN transforms the data by using the natural logarithm (base *e*) of the series and is used to remove varying amplitude over time. NOLOG indicates that the data should not be log transformed. NOLOG is the default.

- If you specify LN on a PACF command, any differencing that is requested on that command is performed on the log-transformed series.
- There are no additional specifications on LN or NOLOG.
- Only the last LN or NOLOG subcommand on a PACF command is executed.
- If a natural log transformation is requested when there are values in the series that are less than or equal to 0, PACF will not be produced for that series because nonpositive values cannot be log-transformed.
- NOLOG is generally used with an APPLY subcommand to turn off a previous LN specification.

Example

```
PACF VARIABLES = SALES
  /LN.
```

- This command transforms the series *SALES* by using the natural log transformation and then computes and plots partial autocorrelations.

SEASONAL Subcommand

Use SEASONAL to focus attention on the seasonal component by displaying and plotting autocorrelations only at periodic lags.

- There are no additional specifications on SEASONAL.
- If SEASONAL is specified, values are displayed and plotted at the periodic lags that are indicated on the PERIOD subcommand. If PERIOD is not specified, the periodicity that was established on the TSET or DATE command is used (see the PERIOD subcommand).
- If SEASONAL is not specified, partial autocorrelations for all lags (up to the maximum) are displayed and plotted.

Example

```
PACF VARIABLES = SALES
  /SEASONAL
  /PERIOD=12.
```

- In this example, partial autocorrelations are displayed and plotted at every 12th lag.

MXAUTO Subcommand

MXAUTO specifies the maximum number of lags for a series.

- The specification on MXAUTO must be a positive integer.
- If MXAUTO is not specified, the default number of lags is the value that was set on TSET MXAUTO. If TSET MXAUTO is not specified, the default is 16.
- The value on MXAUTO overrides the value that was set on TSET MXAUTO.

Example

```
PACF VARIABLES = SALES
  /MXAUTO=14.
```

- This command specifies 14 for the maximum number of partial autocorrelations that can be displayed and plotted for series *SALES*.

APPLY Subcommand

APPLY allows you to use a previously defined PACF model without having to repeat the specifications.

- The only specification on APPLY is the name of a previous model enclosed in quotes. If a model name is not specified, the model that was specified on the previous PACF command is used.
- To change one or more model specifications, specify the subcommands of only those portions that you want to change, placing the specifications after the APPLY subcommand.
- If no series are specified on the PACF command, the series that were originally specified with the model that is being reapplied are used.
- To change the series that are used with the model, enter new series names before or after the APPLY subcommand.

Example

```
PACF VARIABLES = TICKETS
  /LN
  /DIFF=1
  /SDIFF=1
  /PER=12
  /MXAUTO=25.
PACF VARIABLES = ROUNDTRP
  /APPLY.
```

- The first command specifies a maximum of 25 partial autocorrelations for the series *TICKETS* after it has been log-transformed, differenced once, and had one degree of seasonal differencing with a periodicity of 12 applied to it. This model is assigned the default name *MOD_1*.
- The second command displays and plots partial autocorrelations for series *ROUNDTRP* by using the same model that was specified for series *TICKETS*.

PARTIAL CORR

```
PARTIAL CORR VARIABLES= varlist [WITH varlist]
    BY varlist [(levels)] [/varlist...]

 [/SIGNIFICANCE={TWOTAIL**}]
                {ONETAIL  }

 [/STATISTICS=[NONE**] [CORR] [DESCRIPTIVES] [BADCORR] [ALL]]

 [/FORMAT={MATRIX** }]
          {SERIAL   }
          {CONDENSED}

 [/MISSING=[{LISTWISE**}]  [{EXCLUDE**}]]
            {ANALYSIS  }    {INCLUDE  }

 [/MATRIX= [IN({*                  })] [OUT({*                  })]]
               {'savfile'|'dataset'}        {'savfile'|'dataset'}
```

**Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
PARTIAL CORR VARIABLES=PUBTRANS MECHANIC BY NETPURSE(1).
```

Overview

PARTIAL CORR produces partial correlation coefficients that describe the relationship between two variables while adjusting for the effects of one or more additional variables. PARTIAL CORR calculates a matrix of Pearson product-moment correlations. PARTIAL CORR can also read the zero-order correlation matrix as input. Other procedures that produce zero-order correlation matrices that can be read by PARTIAL CORR include CORRELATIONS, REGRESSION, DISCRIMINANT, and FACTOR.

Options

Significance Levels. By default, the significance level for each partial correlation coefficient is based on a two-tailed test. Optionally, you can request a one-tailed test using the SIGNIFICANCE subcommand.

Statistics. In addition to the partial correlation coefficient, degrees of freedom, and significance level, you can use the STATISTICS subcommand to obtain the mean, standard deviation, and number of nonmissing cases for each variable, as well as zero-order correlation coefficients for each pair of variables.

Format. You can specify condensed format, which suppresses the degrees of freedom and significance level for each coefficient, and you can print only nonredundant coefficients in serial string format by using the FORMAT subcommand.

Matrix Input and Output. You can read and write zero-order correlation matrices by using the MATRIX subcommand.

Basic Specification

The basic specification is the VARIABLES subcommand, which specifies a list of variables to be correlated, and one or more control variables following keyword BY. PARTIAL CORR calculates the partial correlation of each variable with every other variable that was specified on the correlation variable list.

Subcommand Order

Subcommands can be specified in any order.

Operations

- PARTIAL CORR produces one matrix of partial correlation coefficients for each of up to five order values. For each coefficient, PARTIAL CORR prints the degrees of freedom and the significance level.
- This procedure uses the multithreaded options specified by SET THREADS and SET MCACHE.

Limitations

- A maximum of 25 variable lists on a single PARTIAL CORR command is allowed. Each variable list contains a correlation list, a control list, and order values.
- A maximum of 400 variables total can be named or implied per PARTIAL CORR command.
- A maximum of 100 control variables is allowed.
- A maximum of 5 different order values per single list is allowed. The largest order value that can be specified is 100.

Example

```
PARTIAL CORR VARIABLES=PUBTRANS MECHANIC BUSDRVER BY NETPURSE(1).
```

- PARTIAL CORR produces a square matrix containing three unique first-order partial correlations: *PUBTRANS* with *MECHANIC* controlling for *NETPURSE*; *PUBTRANS* with *BUSDRVER* controlling for *NETPURSE*; and *MECHANIC* with *BUSDRVER* controlling for *NETPURSE*.

VARIABLES Subcommand

VARIABLES requires a *correlation list* of one or more pairs of variables for which partial correlations are desired and requires a *control list* of one or more variables that will be used as controls for the variables in the correlation list, followed by optional order values in parentheses.

- The correlation list specifies pairs of variables to be correlated while controlling for the variables in the control list.

- To request a square or lower-triangular matrix, do not use keyword WITH in the correlation list. This specification obtains the partial correlation of every variable with every other variable in the list.
- To request a rectangular matrix, specify a list of correlation variables followed by keyword WITH and a second list of variables. This specification obtains the partial correlation of specific variable pairs. The first variable list defines the rows of the matrix, and the second list defines the columns.
- The control list is specified after keyword BY.
- The correlation between a pair of variables is referred to as a *zero-order correlation*. Controlling for one variable produces a first-order partial correlation, controlling for two variables produces a second-order partial correlation, and so on.
- To indicate the exact partials that are to be computed, you can specify order values in parentheses following the control list. These values also determine the partial correlation matrix or matrices to be printed. Up to five order values can be specified. Separate each value with at least one space or comma. The default order value is the number of control variables.
- One partial is produced for every unique combination of control variables for each order value.
- To specify multiple analyses, use multiple VARIABLES subcommands or a slash to separate each set of specifications on one VARIABLES subcommand. PARTIAL CORR computes the zero-order correlation matrix for each analysis list separately.

Obtaining the Partial Correlation for Specific Variable Pairs

```
PARTIAL CORR
  VARIABLES = RENT FOOD PUBTRANS WITH TEACHER MANAGER BY NETSALRY(1).
```

- PARTIAL CORR produces a rectangular matrix. Variables *RENT*, *FOOD*, and *PUBTRANS* form the matrix rows, and variables *TEACHER* and *MANAGER* form the columns.

Specifying Order Values

```
PARTIAL CORR
  VARIABLES = RENT WITH TEACHER BY NETSALRY, NETPRICE (1).
PARTIAL CORR
  VARIABLES = RENT WITH TEACHER BY NETSALRY, NETPRICE (2).
PARTIAL CORR
  VARIABLES = RENT WITH TEACHER BY NETSALRY, NETPRICE (1,2).
PARTIAL CORR
  VARIABLES = RENT FOOD PUBTRANS BY NETSALRY NETPURSE NETPRICE (1,3).
```

- The first PARTIAL CORR produces two first-order partials: *RENT* with *TEACHER* controlling for *NETSALRY*, and *RENT* with *TEACHER* controlling for *NETPRICE*.
- The second PARTIAL CORR produces one second-order partial of *RENT* with *TEACHER* controlling simultaneously for *NETSALRY* and *NETPRICE*.
- The third PARTIAL CORR specifies both sets of partials that were specified by the previous two commands.
- The fourth PARTIAL CORR produces three first-order partials (controlling for *NETSALRY*, *NETPURSE*, and *NETPRICE* individually) and one third-order partial (controlling for all three control variables simultaneously).

Specifying Multiple Sets of Correlation Lists, Control Lists, and Order Values

```
PARTIAL
  VARIABLES = CORR RENT FOOD WITH TEACHER BY NETSALRY NETPRICE (1,2)
    /WCLOTHES MCLOTHES BY NETPRICE (1).
```

- PARTIAL CORR produces three matrices for the first correlation list, control list, and order values.
- The second correlation list, control list, and order value produce one matrix.

SIGNIFICANCE Subcommand

SIGNIFICANCE determines whether the significance level is based on a one-tailed or two-tailed test.

- By default, the significance level is based on a two-tailed test. This setting is appropriate when the direction of the relationship between a pair of variables cannot be specified in advance of the analysis.
- When the direction of the relationship can be determined in advance, a one-tailed test is appropriate.

TWOTAIL *Two-tailed test of significance.* This setting is the default.

ONETAIL *One-tailed test of significance.*

STATISTICS Subcommand

By default, the partial correlation coefficient, degrees of freedom, and significance level are displayed. Use STATISTICS to obtain additional statistics.

- If both CORR and BADCORR are requested, CORR takes precedence over BADCORR, and the zero-order correlations are displayed.

CORR *Zero-order correlations with degrees of freedom and significance level.*

DESCRIPTIVES *Mean, standard deviation, and number of nonmissing cases.* Descriptive statistics are not available with matrix input.

BADCORR *Zero-order correlation coefficients only if any zero-order correlations cannot be computed.* Noncomputable coefficients are displayed as a period.

NONE *No additional statistics.* This setting is the default.

ALL *All additional statistics that are available with* PARTIAL CORR.

FORMAT Subcommand

FORMAT determines page format.

- If both CONDENSED and SERIAL are specified, only SERIAL is in effect.

MATRIX *Display degrees of freedom and significance level in matrix format.* This format requires four lines per matrix row and displays the degrees of freedom and the significance level. The output includes redundant coefficients. This setting is the default.

CONDENSED *Suppress the degrees of freedom and significance level*. This format requires only one line per matrix row and suppresses the degrees of freedom and significance. A single asterisk (*) following a coefficient indicates a significance level of 0.05 or less. Two asterisks (**) following a coefficient indicate a significance level of 0.01 or less.

SERIAL *Display only the nonredundant coefficients in serial string format*. The coefficients, degrees of freedom, and significance levels from the first row of the matrix are displayed first, followed by all unique coefficients from the second row and so on for all rows of the matrix.

MISSING Subcommand

MISSING controls the treatment of cases with missing values.

- When multiple analysis lists are specified, missing values are handled separately for each analysis list. Thus, different sets of cases can be used for different lists.
- When pairwise deletion is in effect (keyword ANALYSIS), the degrees of freedom for a particular partial coefficient are based on the smallest number of cases that are used in the calculation of any of the simple correlations.
- LISTWISE and ANALYSIS are alternatives. However, each command can be used with either INCLUDE or EXCLUDE. The default is LISTWISE and EXCLUDE.

LISTWISE *Exclude cases with missing values listwise.* Cases with missing values for any of the variables that are listed for an analysis—including control variables—are not used in the calculation of the zero-order correlation coefficient. This setting is the default.

ANALYSIS *Exclude cases with missing values on a pair-by-pair basis.* Cases with missing values for one or both of a pair of variables are not used in the calculation of zero-order correlation coefficients.

EXCLUDE *Exclude user-missing values*. User-missing values are treated as missing. This setting is the default.

INCLUDE *Include user-missing values*. User-missing values are treated as valid values.

MATRIX Subcommand

MATRIX reads and writes matrix data files.

- Either IN or OUT and a matrix file in parentheses is required. When both IN and OUT are used on the same PARTIAL CORR procedure, they can be specified on separate MATRIX subcommands or they can both be specified on the same subcommand.

OUT ('savfile'|'dataset') *Write a matrix data file or dataset.* Specify either a filename, a previously declared dataset name, or an asterisk, enclosed in parentheses. Filenames should be enclosed in quotes and are stored in the working directory unless a path is included as part of the file specification. If you specify an asterisk (*), the matrix data file replaces the active dataset. If you specify an asterisk or a dataset name, the file is not stored on disk unless you use SAVE or XSAVE.

IN ('savfile'|'dataset') *Read a matrix data file or dataset.* Specify either a filename, dataset name created during the current session, or an asterisk enclosed in parentheses. An asterisk reads the matrix data from the active dataset. Filenames should be enclosed in quotes and are read from the working directory unless a path is included as part of the file specification.

Matrix Output

- The matrix materials that PARTIAL CORR writes can be used by subsequent PARTIAL CORR procedures or by other procedures that read correlation-type matrices.
- In addition to the partial correlation coefficients, the matrix materials that PARTIAL CORR writes include the mean, standard deviation, and number of cases that are used to compute each coefficient (see Format of the Matrix Data File on p. 1377 for a description of the file). If PARTIAL CORR reads matrix data and then writes matrix materials based on those data, the matrix data file that it writes will not include means and standard deviations.
- PARTIAL CORR writes a full square matrix for the analysis that is specified on the first VARIABLES subcommand (or the first analysis list if keyword VARIABLES is omitted). No matrix is written for subsequent variable lists.
- Any documents that are contained in the active dataset are not transferred to the matrix file.

Matrix Input

- When matrix materials are read from a file other than the active dataset, both the active dataset and the matrix data file that is specified on IN must contain all variables that are specified on the VARIABLES subcommands.
- MATRIX=IN cannot be specified unless a active dataset has already been defined. To read an existing matrix data file at the beginning of a session, use GET to retrieve the matrix file and then specify IN(*) on MATRIX.
- PARTIAL CORR can read correlation-type matrices written by other procedures.
- The program reads variable names, variable and value labels, and print and write formats from the dictionary of the matrix data file.

Format of the Matrix Data File

- The matrix data file includes two special variables that are created by the program: *ROWTYPE_* and *VARNAME_*.

- *ROWTYPE_* is a short string variable with values N, MEAN, STDDEV, and PCORR (for the partial correlation coefficient).
- *VARNAME_* is a short string variable whose values are the names of the variables that are used to form the correlation matrix. When *ROWTYPE_* is PCORR, *VARNAME_* gives the variable that is associated with that row of the correlation matrix.
- The remaining variables in the file are the variables that are used to form the correlation matrix.

Split Files

- When split-file processing is in effect, the first variables in the matrix data file are the split variables, followed by *ROWTYPE_*, *VARNAME_*, and the variables that are used to form the correlation matrix.
- A full set of matrix materials is written for each split-file group that is defined by the split variables.
- A split variable cannot have the same variable name as any other variable that is written to the matrix data file.
- If split-file processing is in effect when a matrix is written, the same split file must be in effect when that matrix is read by any procedure.

Missing Values

- With pairwise treatment of missing values (`MISSING=ANALYSIS` is specified), the matrix of Ns that is used to compute each coefficient is included with the matrix materials.
- With `LISTWISE` treatment, a single N that is used to calculate all coefficients is included with the matrix materials.
- When reading a matrix data file, be sure to specify a missing-value treatment on `PARTIAL CORR` that is compatible with the missing-value treatment that was in effect when the matrix materials were produced.

Examples

Writing Results to a Matrix Data File

```
GET FILE='/data/city.sav'.
PARTIAL CORR VARIABLES=BUSDRVER MECHANIC ENGINEER TEACHER COOK
                       BY  NETSALRY(1)
  /MATRIX=OUT('/data/partial_matrix.sav').
```

- `PARTIAL CORR` reads data from file *city.sav* and writes one set of matrix materials to file *partial_matrix.sav*.
- The active dataset is still *city.sav*. Subsequent commands are executed on *city.sav*.

Writing Matrix Results That Replace the Active Dataset

```
GET FILE='/data/city.sav'.
PARTIAL CORR VARIABLES=BUSDRVER MECHANIC ENGINEER TEACHER COOK
  BY  NETSALRY(1)   /MATRIX=OUT(*).
LIST.
```

- PARTIAL CORR writes the same matrix as in the example above. However, the matrix data file replaces the active dataset. The LIST command is executed on the matrix file, not on the *CITY* file.

Using a Matrix Data File as Input

```
GET FILE='/data/personnel.sav'.
FREQUENCIES VARIABLES=AGE.
PARTIAL CORR VARIABLES=BUSDRVER MECHANIC ENGINEER TEACHER COOK
   BY  NETSALRY(1)   /MATRIX=IN('/data/corr_matrix.sav').
```

- This example performs a frequencies analysis on file *personnel.sav* and then uses a different file for PARTIAL CORR. The file is an existing matrix data file.
- MATRIX=IN specifies the matrix data file. Both the active dataset and the *corr_matrix.sav* file must contain all variables that are specified on the VARIABLES subcommand on PARTIAL CORR.
- The *corr_matrix.sav* file does not replace *personnel.sav* as the active dataset.

Using an Active Dataset That Contains Matrix Data

```
GET FILE='/data/corr_matrix.sav'.
PARTIAL CORR VARIABLES=BUSDRVER MECHANIC ENGINEER TEACHER COOK
                       BY NETSALRY(1)
  /MATRIX=IN(*).
```

- The GET command retrieves the matrix data file *corr_matrix.sav*.
- MATRIX=IN specifies an asterisk because the active dataset is the matrix file *CORMTX*. If MATRIX=IN('/data/corr_matrix.sav') is specified, the program issues an error message.
- If the GET command is omitted, the program issues an error message.

```
GET FILE='/data/city.sav'.
REGRESSION MATRIX=OUT(*)
  /VARIABLES=NETPURSE PUBTRANS MECHANIC BUSDRVER
  /DEPENDENT=NETPURSE /ENTER.
PARTIAL CORR
  VARIABLES = PUBTRANS MECHANIC BUSDRVER BY NETPURSE(1) /MATRIX=IN(*).
```

- GET retrieves the SPSS-format data file *city.sav*.
- REGRESSION computes correlations among the specified variables. MATRIX=OUT(*) writes a matrix data file that replaces the active dataset.
- The MATRIX=IN(*) specification on PARTIAL CORR reads the matrix materials in the active dataset.

PER ATTRIBUTES

PER ATTRIBUTES is available in the SPSS Adaptor for Enterprise Services option.

```
PER ATTRIBUTES FILE='file specification'
    [DESCRIPTION='description']
    [KEYWORDS='keywords']
    [AUTHOR='author']
    [VERSIONLABEL='label']
    [EXPIRATION=days]
    [TOPICS='topics']
    [/SECURITY ID='id' [PERMISSION= [READ**] [WRITE] [DELETE] [MODIFY] [OWNER] ] ]
```

** Default if the keyword is omitted.

Release History

Release 16.0

- Command introduced.

Example

```
PER COPY
  FILE='/myscripts/cust_value.py'
  OUTFILE='SPSSCR://scripts/cust_value.py'.
PER ATTRIBUTES FILE='SPSSCR://scripts/cust_value.py'
  DESCRIPTION='Customer Value Calculation'
  KEYWORDS='customer;value'.
```

Overview

The PER ATTRIBUTES command allows you to set attributes—such as a version label and security settings—for an object in a Predictive Enterprise Repository.

- When copying to a repository with the PER COPY command, use the PER ATTRIBUTES command (following PER COPY) to specify attributes of the object.

Basic Specification

The basic specification is the FILE keyword, which specifies the repository object whose attributes are to be set. All other keywords and subcommands are optional.

Syntax Rules

- The SECURITY subcommand can be specified multiple times.
- Each keyword can only be specified once.
- Keywords and subcommands can be used in any order.
- Keywords and subcommand names must be spelled in full.
- Equals signs (=) shown in the syntax chart are required.

Operations

- Use of the PER ATTRIBUTES command requires a connection to a Predictive Enterprise Repository. Connections are established with the PER CONNECT command.
- PER ATTRIBUTES overwrites any existing values of specified attributes.

FILE Keyword

The FILE keyword is required and specifies the repository object whose attributes are to be set.

- The form of the file specification for an object in a Predictive Enterprise Repository is the scheme name SPSSCR (short for *SPSS Content Repository*), followed by a colon, either one or two slashes (forward or backward), and a file path, all enclosed in quotes. For example:

  ```
  'SPSSCR://scripts/myscript.py'
  ```

- Paths can be specified with forward slashes (/) or backslashes (\).
- You can define a file handle to a file or a directory in a repository and use that handle in file specifications for repository objects.
- You can use the CD command to set the working directory to a directory in the currently connected repository, allowing you to use relative paths in file specifications for repository objects.
- File specifications for repository objects must specify the filename exactly as provided when the file was stored. If the file was stored with an extension, then you must supply the extension. If the file was stored without an extension then do not include one.

For examples of file specifications, see the examples for the PER COPY command on p. 1388.

DESCRIPTION Keyword

The DESCRIPTION keyword specifies a description for an object in a Predictive Enterprise Repository and replaces any existing description for the object. Specify the value as a quoted string.

Example

```
PER ATTRIBUTES FILE='SPSSCR://scripts/cust_value.py'
  DESCRIPTION='Customer Value Calculation'.
```

KEYWORDS Keyword

KEYWORDS specifies one or more keywords to associate with an object in a Predictive Enterprise Repository to aid in searching. Specify the value as a quoted string.

- Multiple keywords should be separated by semicolons.
- Blank spaces at the beginning and end of each keyword are ignored, but blank spaces within keywords are honored.
- The specified keywords replace any existing ones for the object.

Example

```
PER ATTRIBUTES FILE='SPSSCR://scripts/cust_value.py'
  KEYWORDS='customer;value'.
```

AUTHOR Keyword

The AUTHOR keyword specifies the author of an object in a Predictive Enterprise Repository. By default, the author is set to the login name of the user who created the object. Specify the value as a quoted string.

Example

```
PER ATTRIBUTES FILE='SPSSCR://scripts/cust_value.py'
  AUTHOR='GSWEET'.
```

VERSIONLABEL Keyword

The VERSIONLABEL keyword specifies a version label for an object in a Predictive Enterprise Repository—for example, “production” or “development.” Two versions of an object cannot have the same label. If you specify a label that is currently in use by a previous version, the label will be removed from the previous version and associated with the version you’re modifying. Specify the value as a quoted string.

- By default, the specified version label will be applied to the latest version of the object. You can apply a label to a version other than the latest one by specifying the version in the file specification on the FILE keyword. For more information, see File Specifications for Predictive Enterprise Repository Objects on p. 2060.

Example

```
PER ATTRIBUTES FILE='SPSSCR://scripts/cust_value.py'
  VERSIONLABEL='development'.
```

EXPIRATION Keyword

The EXPIRATION keyword specifies an expiration date for an object in a Predictive Enterprise Repository. This provides a mechanism to make sure dated information is not displayed after a certain date. Expired documents are not deleted but are automatically removed to a special category where they can be accessed only by the site administrator, who can delete, archive, or republish them.

- Specify the value as an integer representing the number of days from the current day (inclusive) to the last day (inclusive) that the document will be active.

Example

```
PER ATTRIBUTES FILE='SPSSCR://scripts/cust_value.py'
  EXPIRATION = 366.
```

TOPICS Keyword

The TOPICS keyword allows you to associate an object in a Predictive Enterprise Repository with one or more topics. Topics allow you to organize documents by subject matter and have a hierarchical structure.

- Topics are specified as a quoted path that includes each level of the hierarchy for that topic, with successive levels separated by a forward slash. A forward slash at the beginning of the path is optional.
- Use a semicolon as the delimiter when specifying multiple topics.
- Objects can only be associated with existing topics. PER ATTRIBUTES cannot be used to create new topics.
- The specified topics replace any existing ones for the object.

Example

```
PER ATTRIBUTES FILE='SPSSCR://scripts/cust_value.py'
  TOPICS = '/engineering/scripts;/marketing/analyses'.
```

SECURITY Subcommand

The SECURITY subcommand allows you to specify security settings for an object in a Predictive Enterprise Repository. Specify the identifier of the user or group with the ID keyword, and specify the access level with the PERMISSION keyword. You can specify settings for multiple users or groups by including multiple instances of the SECURITY subcommand.

ID Keyword

The ID keyword specifies the ID of the user or group for which access is being granted. Specify the value in quotes.

PERMISSION Keyword

The PERMISSION keyword is optional and specifies the access level granted to the specified user or group. One or more of the following access levels can be specified: READ, WRITE, MODIFY (grants ability to modify permissions), DELETE, and OWNER.

- If PERMISSION is omitted, the access level is READ.
- READ access is always granted, whether or not it is specified on the PERMISSION keyword.
- If OWNER is specified, all other values are ignored (an owner has all permissions).

Example

```
PER ATTRIBUTES FILE='SPSSCR://scripts/cust_value.py'
  /SECURITY ID='admin' PERMISSION=OWNER
  /SECURITY ID='--everyone--' PERMISSION=READ WRITE.
```

PER CONNECT

PER CONNECT is available in the SPSS Adaptor for Predictive Enterprise Services option.

```
PER CONNECT
    /SERVER HOST='host[:{8080**}]' [SSL={NO**}]
                        {port  }        {YES }
    /LOGIN  USER='userid'
            PASSWORD='password'
            [DOMAIN='network domain']
            [ENCRYPTEDPWD={YES**}]
                          {NO   }
```

** Default if the keyword or value is omitted.

Release History

Release 15.0

- Command introduced.

Example

```
PER CONNECT
    /SERVER HOST='PER1'
    /LOGIN  USER='MyUserID'
            PASSWORD='abc12345'
            ENCRYPTEDPWD=NO.
```

Overview

The PER CONNECT command establishes a connection to a Predictive Enterprise Repository and logs in the user. A connection enables you to store objects to, and retrieve objects from, a repository.

Options

Server. You can specify a connection port and whether to connect to the specified server using Secure Socket Layer (SSL) technology, if it is enabled on the server.

Login. You can specify whether the password is provided as encrypted or unencrypted (plain text).

Basic Specification

The basic specification for PER CONNECT is the host server, user name, and password. By default, server port 8080 is used, the connection is established without SSL, and the specified password is assumed to be encrypted. To create an encrypted password, generate (paste) the PER CONNECT command syntax from the Predictive Enterprise Repository Connect dialog box.

Syntax Rules

- Each subcommand can be specified only once.
- Subcommands can be used in any order.
- An error occurs if a keyword or attribute is specified more than once within a subcommand.
- Equals signs (=) and forward slashes (/) shown in the syntax chart are required.
- Subcommand names and keywords must be spelled in full.

Operations

- `PER CONNECT` establishes a connection to a Predictive Enterprise Repository and logs in the specified user. Any existing repository connection terminates when the new one is established.
- The connection terminates if the SPSS session ends.
- An error occurs if a connection cannot be established to the specified host server.
- An error occurs if the connection cannot be authenticated—for example, if the password is invalid for the specified user.

Example

```
PER CONNECT
    /SERVER HOST='PER1:80'
    /LOGIN  USER='MyUserID'
            PASSWORD='abc12345'
            ENCRYPTEDPWD=NO.
```

- The `SERVER` subcommand specifies a connection to host `'PER1'` on port 80.
- `ENCRYPTEDPWD=NO` indicates that the password is not encrypted.

SERVER Subcommand

The `SERVER` subcommand specifies the host server and whether to establish a secure connection.

HOST *Server that hosts the repository.* Specify the name of the server in quotes. The default port is 8080. To connect to another port, specify the port number after the host name; for example, `'PER1:80'`. A colon must separate the host name and port.

SSL *Use Secure Socket Layer technology.* Specifies whether to establish a secure connection to the host server. The default is `NO`. SSL is available only if supported on the host server.

LOGIN Subcommand

The `LOGIN` subcommand specifies login information, including user name and password.

USER *User name.* Specify the user name in quotes.

PASSWORD *Password.* Specify the password in quotes.

DOMAIN	*Network domain.* You can optionally specify the network domain where the user name is defined. In general, the network domain need not be specified unless you are using a Windows Active Directory or LDAP domain. Contact your local Predictive Enterprise Repository administrator for details.
ENCRYPTED-PWD	*Password encryption.* By default, the specified password is treated as encrypted. To indicate that the password is entered as plain text, specify `ENCRYPTEDPWD=NO`.

PER COPY

PER COPY is available in the SPSS Adaptor for Enterprise Services option.

```
PER COPY
    FILE='file specification'
    OUTFILE='file specification'.
```

Release History

Release 16.0

- Command introduced.

Example

```
PER COPY
  FILE='/myscripts/demo.py'
  OUTFILE='SPSSCR://scripts/demo.py'.
```

Overview

The PER COPY command allows you to copy an arbitrary file from the local file system to a Predictive Enterprise Repository or to copy a file from a Predictive Enterprise Repository to the local file system.

- When copying to a repository, use the PER ATTRIBUTES command—following PER COPY—to specify properties such as a description, keywords, and security settings for the object.

Basic Specification

The only specification is the FILE keyword, which specifies the source file, and the OUTFILE keyword, which specifies the target location. Each keyword can specify a location in the local file system or a location in the current Predictive Enterprise Repository.

File Specifications for Repository Objects

- The form of the file specification for an object in a Predictive Enterprise Repository is the scheme name SPSSCR (short for *SPSS Content Repository*), followed by a colon, either one or two slashes (forward or backward), and a file path, all enclosed in quotes. For example:

  ```
  'SPSSCR://scripts/myscript.py'
  ```

- Paths can be specified with forward slashes (/) or backslashes (\).
- You can define a file handle to a file or a directory in a repository and use that handle in file specifications for repository objects.

- You can use the CD command to set the working directory to a directory in the currently connected repository, allowing you to use relative paths in file specifications for repository objects.
- File extensions are not added to files stored to a repository. Files are stored to a repository with an automatically determined MIME type that describes the type of file. Including a file extension is not necessary but is recommended.
- When copying a file from a repository you must specify the filename exactly as provided when the file was stored. If the file was stored with an extension, then you must supply the extension. If the file was stored without an extension then do not include one.
- When copying from a repository, the latest version of the specified object is retrieved. To specify a version by label, use SPSSCR://<path>#L.<label>. To specify a version by the version marker (consists of an integer version number followed by a time stamp that uniquely specifies a version), use SPSSCR://<path>#M.<version marker>. For more information, see File Specifications for Predictive Enterprise Repository Objects on p. 2060.

Operations

- PER COPY will fail if a Predictive Enterprise Repository location is specified (for either FILE or OUTFILE) and there is no connection to a repository. Connections are established with the PER CONNECT command.
- Specifying an existing repository file on the OUTFILE keyword results in a new version of the file, as opposed to overwriting the latest version.
- The PERMISSIONS, SAVE, and XSAVE commands will generate errors if you attempt to set permissions for repository objects. Permissions for repository objects are set with the PER ATTRIBUTES command or using administration tools included with Predictive Enterprise Services.
- The ERASE FILE command will generate an error if you attempt to delete a repository object.

Examples

Copying from the Local File System to a Repository

```
PER COPY
  FILE='/myscripts/cust_value.py'
  OUTFILE='SPSSCR://scripts/cust_value.py'.
PER ATTRIBUTES FILE='SPSSCR://scripts/cust_value.py'
  KEYWORDS='customer;value'
  /SECURITY ID='rprime' PERMISSION=OWNER.
```

- The local file */myscripts/cust_value.py* is copied to the location */scripts/cust_value.py* in the current Predictive Enterprise Repository.
- The PER ATTRIBUTES command specifies keywords and security settings for this repository object.

Copying from a Repository to the Local File System

```
PER COPY
  FILE='SPSSCR://scripts/demo.py'
  OUTFILE='/myscripts/demo.py'.
```

- The repository object */scripts/demo.py* is copied to the local file */myscripts/demo.py*.

Copying from a Labelled Version in a Repository to the Local File System

```
PER COPY
  FILE='SPSSCR://scripts/demo.py#L.production'
  OUTFILE='/myscripts/demo.py'.
```

- The version of the repository object */scripts/demo.py* with the label *production* is copied to the local file */myscripts/demo.py*.

Using a File Handle to a Repository Location

```
FILE HANDLE custval /NAME='SPSSCR://CustomerValue'.
PER COPY
  FILE='custval/cust_value.py'
  OUTFILE='/myscripts/cust_value.py'.
```

- The handle *custval* is associated with the repository directory */CustomerValue*, and the `PER COPY` command retrieves the latest version of the file *cust_value.py* from this directory in the current repository.

Setting the Working Directory to a Repository Location

```
CD 'SPSSCR://CustomerValue'.
PER COPY
  FILE='cust_value.py'
  OUTFILE='/myscripts/cust_value.py'.
```

- The working directory is set to the repository directory */CustomerValue*, and the `PER COPY` command retrieves the latest version of the file *cust_value.py* from this directory in the current repository.

PERMISSIONS

```
PERMISSIONS FILE='filespec'

  /PERMISSIONS {READONLY }
               {WRITEABLE}
```

Example

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

```
PERMISSIONS FILE='/mydir/mydata.sav'
  /PERMISSIONS READONLY.
```

Overview

PERMISSIONS changes the read/write permissions for the specified file, using the operating system facilities for changing permissions.

Syntax Rules

- A FILE specification and a PERMISSIONS subcommand are both required.
- The file specification should be enclosed in single quotation marks or double quotation marks.

PERMISSIONS Subcommand

READONLY *File permissions are set to read-only for all users.* The file cannot be saved by using the same file name with subsequent changes unless the read/write permissions are changed in the operating system or a subsequent PERMISSIONS command specifies PERMISSIONS=WRITEABLE.

WRITEABLE *File permissions are set to allow writing for the file owner.* If file permissions were set to read-only for other users, the file remains read-only for them.

Your ability to change the read/write permissions may be restricted by the operating system.

PLANCARDS

PLANCARDS is available in the Conjoint option.

```
PLANCARDS [FACTORS=varlist]

 [/FORMAT={LIST}]
          {CARD}
          {BOTH}

 [/TITLE='string']

 [/FOOTER='string']

 [/OUTFILE=file]
```

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Release History

Release 14.0

- PAGINATE subcommand is obsolete and no longer supported.

Example

```
PLANCARDS /TITLE='Car for Sale'.
```

Overview

PLANCARDS produces profiles, or cards, from a plan file for a conjoint analysis study. The plan file can be generated by ORTHOPLAN or entered by the user. The printed profiles can be used as the experimental stimuli that subjects judge in terms of preference.

Options

Format. You can produce profiles in the format of a single list or formatted so that each profile is displayed separately.

Titles and Footers. You can specify title and footer labels that appear at the top and bottom of the output (for single list format) or at the top and bottom of each profile (when the profiles are displayed separately).

Basic Specification

- The basic specification is PLANCARDS, which produces a listing of profiles, using all variables in the active dataset except *STATUS_* and *CARD_* as factors.

Subcommand Order

- Subcommands can be named in any order.

Operations

- PLANCARDS assumes that the active dataset represents a plan for a full-profile (full-concept) conjoint study. Each "case" in such a file is one profile in the conjoint experimental plan.
- Factor and factor-level labels in the active dataset—generated by ORTHOPLAN or by the VARIABLE and VALUE LABELS commands—are used in the output.
- The command SPLIT FILE is ignored for single-profile format. In listing format, each subfile represents a different plan, and a new listing begins for each subfile.
- The WEIGHT command is ignored by PLANCARDS.

Limitations

- Missing values are not recognized as missing and are treated like other values.

Examples

```
ORTHOPLAN FACTORS=SPEED 'Highest possible speed'
   (70 '70 mph' 100 '100 mph' 130 '130 mph')
  WARRANTY 'Length of warranty' ('1 year' '3 year' '5 year')
  SEATS 'Number of seats' (2, 4) /MINIMUM=9 /HOLDOUT=6.
PLANCARDS FORMAT=BOTH
 /TITLE='Car for Sale'.
```

- ORTHOPLAN generates a set of profiles (cases) for a full-profile conjoint analysis in the active dataset.
- PLANCARDS displays the profiles, along with the title *Car for Sale*.

Example: User-entered Plan

```
DATA LIST FREE/ COST NEWNESS EXPER NAME REP
                GUARAN TRIAL TRUST.
VARIABLE LABELS
  COST 'Product cost'
  NEWNESS 'Product newness'
  EXPER 'Brand experience'
  NAME "Manufacturer's Name"
  REP "Distributor's reputation"
  GUARAN 'Money-back Guarantee'
  TRIAL 'Free sample/trial'
  TRUST 'Endorsed by a trusted person'.
VALUE LABELS
  COST 1 'LOW' 2 'HIGH'/
  NEWNESS 1 'NEW' 2 'OLD'/
  EXPER 1 'SOME' 2 'NONE'/
  NAME 1 'ESTABLISHED' 2 'UNKNOWN'/
  REP 1 'GOOD' 2 'UNKNOWN'/
  GUARAN 1 'YES' 2 'NO'/
  TRIAL 1 'YES' 2 'NO'/
  TRUST 1 'YES' 2 'NO'.
BEGIN DATA
 1 2 2 1 2 2 2 1
 2 2 2 1 1 1 2 1
 2 2 1 2 2 1 1 1
 2 1 2 1 2 2 1 2
 2 1 1 2 2 2 2 1
 2 1 2 2 1 1 2 2
 1 1 2 2 1 2 1 1
 1 1 1 1 2 1 2 2
```

```
 1 2 1 2 1 2 2 2
 1 1 1 1 1 1 1 1
 2 2 1 1 1 2 1 2
 1 2 2 2 2 1 1 2
END DATA.
PLANCARDS.
```

- In this example, the plan is entered and defined by the user rather than by ORTHOPLAN.
- PLANCARDS uses the information in the active dataset to produce a set of profiles. Because no format is specified, the default format (single list) is used. The variables and values in this example were taken from Akaah & Korgaonkar (Akaah and Korgaonkar, 1988).

FACTORS Subcommand

FACTORS identifies the variables to be used as factors and the order in which their labels are to appear in the output. String variables are permitted.

- Keyword FACTORS is followed by a variable list.
- By default, if FACTORS is not specified, all variables in the active dataset (except those variables that are named *STATUS_* or *CARD_*) are used as factors in the order in which they appear in the file. (See the ORTHOPLAN command for information about variables *STATUS_* and *CARD_*.)

FORMAT Subcommand

FORMAT specifies how the profiles should be displayed. The choices are **listing** format (LIST keyword) and **single-profile** format (CARD keyword). Listing format displays the profiles in the form of a single list. For single-profile format, output is displayed so that each profile is presented separately.

- The keyword FORMAT is followed by LIST, CARD, or BOTH. (ALL is an alias for BOTH.)
- The default format is LIST.
- With LIST format, holdout profiles are differentiated from experimental profiles, and simulation profiles are listed separately following the experimental and holdout profiles. With CARD format, holdout profiles are not differentiated, and simulation profiles are not produced.
- If FORMAT=LIST is specified along with the OUTFILE subcommand, the OUTFILE subcommand is ignored (OUTFILE only applies to CARD format). Specifying OUTFILE with FORMAT=BOTH is equivalent to OUTFILE with FORMAT=CARD.

Example

```
PLANCARDS FORMAT=CARD /OUTFILE='DESIGN.FRM'
  /TITLE=' ' 'Profile #)CARD' /FOOTER='RANK:'.
```

- FORMAT=CARD specifies that the output will be in single-profile format.
- The profiles are written to the file *DESIGN.FRM*.
- Each profile in *DESIGN.FRM* will have the title Profile #n at the top and the label RANK: at the bottom, where *n* is a profile identification number.

The output for the first two profiles is shown below.

Figure 167-1
Single-profile format

```
Profile #1

Product cost  LOW
Product newness  OLD
Brand experience  NONE
Manufacturer's Name  ESTABLISHED
Distributor's reputation  UNKNOWN
Money-back Guarantee  NO
Free sample/trial  NO
Endorsed by a trusted person  YES

RANK:

Profile #2

Product cost  HIGH
Product newness  OLD
Brand experience  NONE
Manufacturer's Name  ESTABLISHED
Distributor's reputation  GOOD
Money-back Guarantee  YES
Free sample/trial  NO
Endorsed by a trusted person  YES

RANK:

  . . .
```

OUTFILE Subcommand

`OUTFILE` names an external file where profiles in single-profile format are to be written. Profiles in listing format are not written to an external file.

- By default, no external file is written.
- The `OUTFILE` keyword is followed by the name of an external file. The file is specified in the usual manner for your system.
- If the `OUTFILE` subcommand is specified along with `FORMAT=LIST`, the `OUTFILE` subcommand is ignored (`OUTFILE` only applies to `FORMAT=CARD`).

TITLE Subcommand

`TITLE` specifies a string to be used at the top of the output (in listing format) or at the top of each new profile (in single-profile format).

- Default titles are provided, except for output that is directed to an external file with the `OUTFILE` subcommand.
- The keyword `TITLE` is followed by a string enclosed in apostrophes.
- Quotation marks can be used to enclose the string instead of apostrophes when you want to use an apostrophe in the title.
- Multiple strings per `TITLE` subcommand can be specified; each string will appear on a separate line.

- Use an empty string (‘ ‘) to cause a blank line.
- Multiple TITLE subcommands can be specified; each subcommand will appear on a separate line.
- If the special character sequence)CARD is specified anywhere in the title, PLANCARDS will replace it with the sequential profile number in single-profile-formatted output. This character sequence is not translated in listing format.

FOOTER Subcommand

FOOTER specifies a string to be used at the bottom of the output (in listing format) or at the bottom of each profile (in single-profile format).

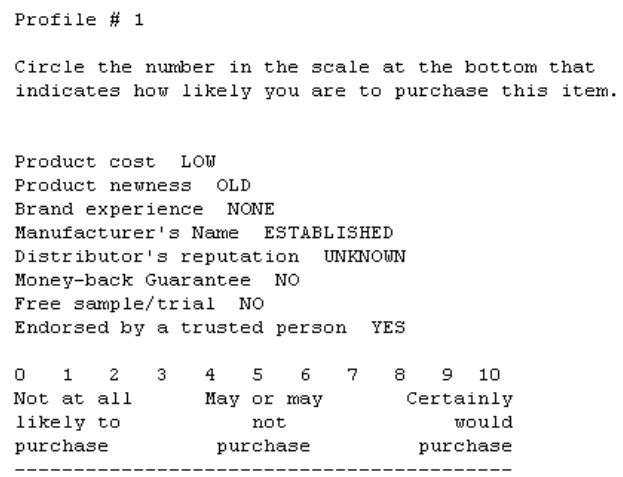
- If FOOTER is not used, nothing appears after the last attribute.
- FOOTER is followed by a string enclosed in apostrophes.
- Quotation marks can be used to enclose the string instead of apostrophes when you want to use an apostrophe in the footer.
- Multiple strings per FOOTER subcommand can be specified; each string will appear on a separate line.
- Use an empty string (‘ ‘) to cause a blank line.
- Multiple FOOTER subcommands can be specified; each subcommand will appear on a separate line.
- If the special character sequence)CARD is specified anywhere in the footer, PLANCARDS will replace it with the sequential profile number in single-profile-formatted output. This character sequence is not translated in listing format.

Example

```
PLANCARDS
 TITLE='Profile # )CARD' ' '
   'Circle the number in the scale at the bottom that'
   'indicates how likely you are to purchase this item.' ' '
 /FOOTER= '0   1   2   3   4   5   6   7   8   9  10'
          'Not at all      May or may       Certainly'
          'likely to           not             would'
          'purchase         purchase         purchase'
          '----------------------------------------'
 /FORMAT=CARD
 /OUTFILE='DESIGN.FRM'.
```

The above example would produce the following output, in *DESIGN.FRM*, for the first profile:

Figure 167-2
Footer with multiple strings



PLS

PLS is an extension command that requires the Python Extension Module to be installed on the system where you plan to run PLS. The PLS Extension Module must be installed separately and the installer can be downloaded from *http://www.spss.com/devcentral*.

Note: The PLS Extension Module is dependent upon Python software. SPSS is not the owner or licensor of the Python software. Any user of Python must agree to the terms of the Python license agreement located on the Python Web site. SPSS is not making any statement about the quality of the Python program. SPSS fully disclaims all liability associated with your use of the Python program.

```
PLS dependent variable [MLEVEL={N}] [REFERENCE={FIRST }]
                                {O}             {LAST**}
                                {S}             {value }
    [dependent variable...]
    [BY factor list] [WITH covariate list]

[/ID VARIABLE = variable]

[/MODEL effect [...effect]]

[/OUTDATASET [CASES=SPSS dataset]
             [LATENTFACTORS=SPSS dataset]
             [PREDICTORS=SPSS dataset]]

[/CRITERIA  LATENTFACTORS={5**    }]
                          {integer}
```

** Default if the subcommand or keyword is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Release History

Release 16.0

- Command introduced.

Example

```
PLS Response WITH Price.
```

Overview

The PLS procedure estimates partial least squares regression models. Partial least squares is a predictive technique that is an alternative to ordinary least squares (OLS) regression, canonical correlation, or structural equation modeling for analysis of systems of independent and response variables. It is particularly useful when predictor variables are highly correlated or when the number of predictors exceeds the number of cases.

PLS combines features of principal components analysis and multiple regression. It first extracts a set of latent factors that explains as much of the covariance as possible between the independent and dependent variables. Then a regression step predicts values of the dependent variables using the decomposition of the independent variables.

Partial least squares regression is also known as "Projection to Latent Structure".

Options

Response Variables. PLS estimates univariate and multivariate models. If you specify one or more categorical dependent variables, a classification model is estimated. If you specify one or more scale dependent variables, a regression model is estimated. Mixed regression and classification models are supported.

Predictors. Predictors can be categorical or continuous variables. Both main effects and interaction terms can be estimated.

Method. You can specify the maximum number of latent factors to extract. By default, five latent factors are extracted.

Export. You can save casewise, factorwise, and predictorwise model results to SPSS datasets.

Basic Specification

- PLS is an extension command and will not be recognized by the system until you use the EXTENSION command to add PLS to the command table. The syntax diagram for PLS is defined in *plscommand.xml*, which is installed in the *\extensions* subdirectory of the main installation directory. For more information, see EXTENSION on p. 647.
- The minimum specification is one or more dependent variables and one or more predictors.
- The procedure displays the following tables: proportion of variance explained (by latent factor), latent factor weights, latent factor loadings, independent variable importance in projection (VIP), and regression parameter estimates (by dependent variable).

Operations

- All model variables are centered and standardized, including indicator variables representing categorical variables.
- If a WEIGHT variable is specified, its values are used as frequency weights. Weight values are rounded to the nearest whole number before use. Cases with missing weights or weights less than 0.5 are not used in the analyses.
- User- and system-missing values are treated as invalid.
- Memory allocated via SET WORKSPACE is unavailable to extension commands; when running PLS on large datasets, you may actually *lower* the size of your workspace.

Syntax Rules

- The PLS command is required. All subcommands are optional.
- Only a single instance of each subcommand is allowed.
- An error occurs if an attribute or keyword is specified more than once within a subcommand.

- Equals signs and parentheses shown in the syntax chart are required.
- Subcommand names and keywords must be spelled in full.
- Empty subcommands are not allowed.

Examples

```
PLS Response WITH Price.
```

- PLS estimates a univariate prediction model that regresses *Response* on *Price*.
- Measurement level is not explicitly specified for dependent variable *Response*. Thus, if *Response* is categorical (nominal or ordinal), a classification model is estimated; otherwise, if *Response* is scale, a regression model is estimated.
- Variable *Price* is treated as a continuous predictor (covariate).

Classification Model (Explicitly Specified)

```
PLS Response MLEVEL=N REFERENCE=5 BY Region WITH Price.
```

- PLS estimates a univariate prediction model.
- Since dependent variable *Response* is specified as nominal (N), a classification model is estimated. Value 5 is used as the reference category.
- Variable *Region* is treated as a categorical predictor and *Price* is treated as a continuous predictor (covariate). By default, a main effects model is estimated.

Multivariate Model

```
PLS Q1 MLEVEL=S Q2 MLEVEL=S BY Region Edlevel
  /MODEL Region Edlevel Region*Edlevel.
```

- PLS estimates a multivariate regression model.
- Both dependent variables, *Q1* and *Q2*, are treated as scale (continuous) variables.
- Variables *Region* and *Edlevel* are treated as categorical predictors.
- MODEL specifies a fully factorial ANOVA model that includes main effects for *Region* and *Edlevel* as well as the interaction between the two predictors.

Variable Lists

The command line variable lists specify the dependent variables, any categorical predictors (factors), and any scale predictors (covariates). ALL and TO keywords are supported in all variable lists.

Dependent Variables

A list of one or more dependent variables must be the first specification on the PLS command.

- Dependent variables can be numeric or string.
- If a dependent variable is specified more than once, only the last specification is honored for the variable.

MLEVEL Keyword

By default, the measurement level recorded in the data dictionary is honored for dependent variables.

- The MLEVEL keyword can be specified after the name of any dependent variable to override its dictionary level of measurement. Specify N (nominal), O (ordinal), or S (scale). Note that the PLS procedure does not distinguish between ordinal and nominal dependent variables; it treats both as categorical.
- If MLEVEL is not specified and no setting is recorded in the data dictionary, then a numeric variable is treated as scale and a string variable is treated as categorical.
- A string dependent variable may be defined as ordinal or nominal only.
- MLEVEL applies only to the variable that immediately precedes it in the dependent variable list. For example, `Age Income [S]` and `Age TO Income [S]` assign the scale level of measurement to *Income* only. The keyword ALL followed by a measurement level specification applies that measurement level to all dependent variables.

REFERENCE Keyword

The REFERENCE keyword specifies the value of the dependent variable to use as the reference category for parameter estimation. REFERENCE can be specified after the name of any dependent variables but is honored only for categorical dependent variables. It is silently ignored for scale variables.

- Specify FIRST, LAST, or a value. If you specify FIRST, the lowest value is treated as the reference category. LAST (the default) treats highest value of the dependent variable as the reference category.
- If you specify a value it must exist in the data and be consistent with the type and format of the dependent variable. String and formatted (for example, date or time) values must be quoted.
- REFERENCE applies only to the variable that immediately precedes it in the dependent variable list. The keyword ALL followed by a REFERENCE specification applies that reference category to all categorical dependent variables.

Predictor Variables

- At least one predictor must be specified.
- The names of the categorical predictors, if any, must be preceded by the keyword BY. If keyword BY is specified with no factors, then a warning is issued and BY is ignored.
- The names of the covariates, if any, must be preceded by the keyword WITH. If keyword WITH is specified with no covariates, then a warning is issued and WITH is ignored.
- Categorical predictor variables can be numeric or string.
- Covariates must be numeric.

- If the dependent variable is specified within a categorical predictor list or a covariate list, then it is ignored in the list.
- All variables specified within a categorical predictor or covariate list must be unique. If duplicate variables are specified within a list, then the duplicates are ignored.
- If duplicate variables are specified across the predictor lists, then an error is issued.

ID Subcommand

The ID subcommand specifies a variable that is used as a unique identifier in casewise output and saved datasets (see the OUTDATASET Subcommand). If this option is not specified, case number is used as the identifier.

Specify a string or numeric variable. An error is issued if the identifier variable is specified as a dependent or predictor variable.

MODEL Subcommand

The MODEL subcommand is used to specify model effects.

- Specify a list of terms to be included in the model.
- If the MODEL subcommand is not specified, the default model includes main effects for any categorical predictors and covariates.
- To include a term for the main effect of a categorical predictor or covariate, enter the name of the variable.
- To include a term for an interaction among predictors, use the keyword BY or the asterisk (*) to join the variables involved in the interaction. For example, A*B means a two-way interaction effect of A and B. A*A is not allowed because variables inside an interaction effect must be distinct.
- Interactions among covariates are valid, as are interactions between categorical predictors and covariates.
- Nested terms are not supported in the PLS procedure.

OUTDATASET Subcommand

The OUTDATASET subcommand requests output datasets and plots for model estimates. You can obtain casewise, factorwise, and predictorwise results. None are produced by default.

CASES Keyword

CASES saves the following caseswise model estimates: predicted values, residuals, distance to latent factor model, and latent factor scores. It also plots latent factor scores.

Specify the name of an SPSS dataset. The dataset name must be unique within an invocation of the PLS procedure. If you specify the name of an existing dataset, its contents are replaced; otherwise, a new dataset is created. An error is generated if an external file is specified.

LATENTFACTORS Keyword

LATENTFACTORS saves latent factor loadings and latent factor weights. It also plots latent factor weights.

Specify the name of an SPSS dataset. The dataset name must be unique within an invocation of the PLS procedure. If you specify the name of an existing dataset, its contents are replaced; otherwise, a new dataset is created. An error is generated if an external file is specified.

PREDICTORS Keyword

PREDICTORS saves regression parameter estimates and variable importance to projection (VIP). It also plots VIP by latent factor.

Specify the name of an SPSS dataset. The dataset name must be unique within an invocation of the PLS procedure. If you specify the name of an existing dataset, its contents are replaced; otherwise, a new dataset is created. An error is generated if an external file is specified.

CRITERIA Subcommand

The CRITERIA subcommand specifies model estimation criteria.

LATENTFACTORS Keyword

The LATENTFACTORS keyword specifies an upper limit on the number of latent factors that are extracted. By default, a maximum of five factors are extracted. The value must be a positive integer.

The number of latent factors that is actually extracted may be fewer than the number requested. For example, it is limited by the number of cases and predictors (whichever is smaller).

PLUM

```
PLUM dependent variable [BY factor varlist] [WITH covariate varlist]

[/CRITERIA = [CIN({95** })] [DELTA({0**   })] [MXITER({100**})] [MXSTEP({5**})]
                  {value}          {value }           {n    }           {n  }
             [LCONVERGE({0**  })] [PCONVERGE({1.0E-6**})] [SINGULAR({1.0E-8**})]
                        {value}              {value   }             {value   }
             [BIAS] ]

[/LINK = {CAUCHIT}]
         {CLOGLOG}

[/SCALE = [effect effect ...] ]

[/TEST [(valuelist)] = [`label'] effect valuelist [effect valuelist] ...;
       [effect valuelist [effect valuelist] ...;] ... ]

[/TEST [(valuelist)] = [`label'] ALL list; [ALL list;] ... ].
```

** Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
PLUM chist.
```

Overview

This procedure makes use of a general class of models to allow you to analyze the relationship between a polytomous ordinal dependent variable and a set of predictors. These models utilize the ordinal nature of the dependent variable and eliminate the need for rescaling.

Options

Link Functions. Five link functions are available for specifying the model with the `LINK` subcommand.

Tuning the Algorithm. You can control the values of algorithm-tuning parameters with the `CRITERIA` subcommand.

Optional Output. You can request additional output through the PRINT subcommand.

Basic Specification

The basic specification is one dependent variable.

Syntax Rules

- A minimum of one dependent variable must be specified.
- The variable specification must come first and can be specified only once.
- Subcommands can be specified in any order.
- When subcommands (except the TEST subcommand) are repeated, previous specifications are discarded and the last subcommand is in effect.
- Empty subcommands (except the LOCATION and the SCALE subcommands) are ignored. An empty LOCATION or SCALE subcommand indicates a simple additive model.
- The words BY, WITH, and WITHIN are reserved keywords in this procedure.

Example

```
PLUM
  chist  BY numcred othnstal housng  WITH age duration
  /LOCATION = numcred age duration
  /CRITERIA = CIN(95) DELTA(0) LCONVERGE(0) MXITER(100) MXSTEP(5)
              PCONVERGE(0)
  /LINK = CLOGLOG
  /PRINT = FIT PARAMETER SUMMARY TPARALLEL.
```

- *chist* is the dependent variable, *numcred*, *othnstal*, and *housing* are factors, and *age* and *duration* are covariates.
- The location model is based on *numcred*, *age*, and *duration*. Note, however, that goodness-of-fit statistics will be based on *all* of the factors and covariates on the variable list.
- CRITERIA specifies that the confidence level to use is 95, no delta value should be added to cells with observed zero frequency, and neither the log-likelihood nor parameter estimates convergence criteria should be used. This means that the procedure will stop when either 100 iterations or 5 step-halving operations have been performed.
- LINK specifies that the complementary log-log function should be used.
- PRINT specifies that the goodness-of-fit statistics, parameter statistics, model summary, and test of parallel lines should be displayed.

Variable List

The variable list specifies the dependent variable, factors, and covariates in the model.

- The dependent variable must be the first specification on the command line.
- The dependent variable is assumed to be an ordinal variable and can be of any type (numeric versus string). The order is determined by sorting the level of the dependent variable in ascending order. The lowest value defines the first category.

- Factor variables can be of any type (numeric versus string). Factor levels are sorted in ascending order. The lowest value defines the first category.
- Covariate variables must be numeric.
- Names of the factors follow the dependent variable separated by the keyword BY.
- Enter the covariates, if any, following the factors. Use the keyword WITH to separate covariates from factors (if any) and the dependent variable.

Weight Variable

- If a WEIGHT variable is specified, this procedure will take the non-missing weight values, rounded to the nearest integer, as frequencies.
- Cases with negative frequencies are always excluded.

CRITERIA Subcommand

The CRITERIA subcommand offers controls on the iterative algorithm used for estimation, specifies numerical tolerance for checking singularity, and offers options to customize your output.

BIAS *Bias value added to all observed cell frequencies*. Specify a non-negative value less than 1. The default value is 0.0.

CIN *Confidence interval level.* Specify a value greater than or equal to 0 and less than 100. The default value is 95.

DELTA *Delta value added to observed zero frequency.* Specify a non-negative value less than 1. The default value is 0.0.

LCONVERGE *Log-likelihood function convergence criterion.* Convergence is assumed if the absolute change or relative change in the log-likelihood function is less than this value. The criterion is not used if the value is 0. Specify a non-negative value. The default value is 0.

MXITER *Maximum number of iterations.* Specify a non-negative integer. The default value is 100. Specifying 0 gives the initial estimates.

MXSTEP *Maximum step-halving allowed.* Specify a positive integer. The default value is 5.

PCONVERGE *Parameter estimates convergence criterion.* Convergence is assumed if the maximum absolute change in each of the parameter estimates is less than this value. The criterion is not used if the value is 0. Specify a non-negative value. The default value is 10^{-6}.

SINGULAR *Value used as tolerance in checking singularity.* Specify a positive value. The default value is 10^{-8}.

LINK Subcommand

The LINK subcommand offers five link functions to specify the model.

- If LINK is not specified, LOGIT is the default.
- The five keywords are mutually exclusive. Only one of them can be specified and only once.

CAUCHIT *Cauchit function.* $f(x) = \tan(\pi(x - 0.5))$.

CLOGLOG *Complementary log-log function.* $f(x) = \log(-\log(1 - x))$.

LOGIT	*Logit function.* f(x) = log(x / (1 – x)). This is the default link function.
NLOGLOG	*Negative log-log function.* f(x) = –log(– log(x)).
PROBIT	*Probit function.* $f(x) = \Phi^{-1}(x)$, where Φ^{-1} is the inverse standard normal cumulative distribution function.

LOCATION Subcommand

The LOCATION subcommand specifies the location model.

- Specify a list of terms to be included in the location model, separated by commas or spaces.
- The default location model is generated if the subcommand is not specified or empty. The default model contains the intercept, all of the covariates (if specified) in the order in which they are specified, and all of the main factorial effects in the order in which they are specified on the variable list.
- To include the intercept term explicitly, enter the keyword INTERCEPT on the subcommand.
- To include a main effect term, enter the name of the factor on the subcommand.
- To include an interaction effect term among factors, use the keyword BY or the asterisk (*) to join factors involved in the interaction. For example, A*B*C means a three-way interaction effect of A, B, and C, where A, B, and C are factors. The expression A BY B BY C is equivalent to A*B*C. Factors inside an interaction effect must be distinct. Expressions such as A*C*A and A*A are invalid. The keyword INTERCEPT cannot be used to construct an interaction term.
- To include a nested effect term, use the keyword WITHIN or a pair of parentheses on the subcommand. For example, A(B) means that A is nested within B, where A and B are factors. The expression A WITHIN B is equivalent to A(B). Factors inside a nested effect must be distinct. Expressions such as A(A) and A(B*A) are invalid.
- Multiple level nesting is supported. For example, A(B(C)) means that B is nested within C, and A is nested within B(C). When more than one pair of parentheses is present, each pair of parentheses must be enclosed or nested within another pair of parentheses. Thus, A(B)(C) is not valid.
- Nesting within an interaction effect is valid. For example, A(B*C) means that A is nested within B*C.
- Interactions among nested effects are allowed. The correct syntax is the interaction followed by the common nested effect inside the parentheses. For example, interaction between A and B within levels of C should be specified as A*B(C) instead of A(C)*B(C).
- To include a covariate term in the model, enter the name of the covariate on the subcommand.
- Covariates can be connected, but not nested, using the keyword BY or the asterisk (*) operator. For example, X*X is the product of X and itself. This is equivalent to a covariate whose values are the square of those of X. On the contrary, X(Y) is invalid.
- Factor and covariate effects can be connected in many ways. No effects can be nested within a covariate effect. Suppose A and B are factors and X and Y are covariates. Examples of valid combination of factor and covariate effects are A*X, A*B*X, X(A), X(A*B), X*A(B), X*Y(A*B), and A*B*X*Y.

Example

```
PLUM
  chist  BY numcred othnstal
  /CRITERIA = CIN(95) DELTA(0) LCONVERGE(0) MXITER(100) MXSTEP(5)
              PCONVERGE(0)
  /LOCATION = numcred othnstal numcred*othnstal.
```

- LOCATION specifies that the location model consists of *numcred*, *othnstal*, and their interaction effect.

MISSING Subcommand

By default, cases with missing values for any of the variables on the variable list are excluded from the analysis. The MISSING subcommand allows you to include cases with user-missing values.

- If MISSING is not specified, the default is EXCLUDE.
- Listwise deletion is always used in this procedure.
- Keywords EXCLUDE and INCLUDE are mutually exclusive. Only one of them can be specified and only once.

EXCLUDE *Exclude both user-missing and system-missing values.* This is the default.

INCLUDE *User-missing values are treated as valid.* System-missing values cannot be included in the analysis.

PRINT Subcommand

The PRINT subcommand controls the display of optional output. If no PRINT subcommand is specified, default output includes a case-processing summary table.

CELLINFO *Cell information.* Observed and expected frequencies by category and cumulative, Pearson residual for cumulative and category frequencies, and observed and expected probabilities of each response category separately and cumulatively by covariate pattern combination.

CORB *Asymptotic correlation matrix of the parameter estimates.*

COVB *Asymptotic covariance matrix of the parameter estimates.*

FIT *Goodness-of-fit statistics.* The Pearson chi-square and the likelihood-ratio chi-square statistics. The statistics are computed based on the classification specified on the variable list.

HISTORY *Iteration history.* The table contains log-likelihood function value and parameter estimates every *n* iterations. The default value is $n = 1$. The first and the last iterations are always printed if HISTORY is specified and regardless of the value of *n*.

KERNEL *Use the kernel of the log-likelihood function for display instead of the complete log-likelihood function.*

TPARALLEL *Test of parallel lines assumption.* Produce a chi-squared score test of the parallel lines assumption.

PARAMETER *Parameter statistics.* The parameter estimates, the standard errors, the significances, and the confidence interval.

SUMMARY *Model summary.* The Cox & Snell's R^2, the Nagelkerke's R^2, and the McFadden's R^2 statistics.

SAVE Subcommand

The SAVE subcommand puts casewise post-estimation statistics back into the active file.

- The new variables must have valid variable names that are not in use in the working file.
- The rootname must be a valid variable name.
- The new variables are saved to the working file in the order the keywords are specified on the subcommand.

ESTPROB	*Estimated probabilities of classifying a factor/covariate pattern into the response categories.* The predicted probabilities of the first *n* categories are saved. The default number of categories is 25. To specify a number of categories without a rootname, put a colon before the number.
PREDCAT	*The response category that has the maximum expected probability for a factor/covariate pattern.*
PCPROB	*Estimated probability of classifying a factor/covariate pattern into the predicted category.* This probability is the maximum of the estimated probabilities of the factor/covariate pattern.
ACPROB	*Estimated probability of classifying a factor/covariate pattern into the actual category.*

Example

```
PLUM
  chist  BY numcred othnstal
  /CRITERIA = CIN(95) DELTA(0) LCONVERGE(0) MXITER(100) MXSTEP(5)
              PCONVERGE(0)
  /SAVE = ACPROB(correct) PRPROB.
```

- SAVE specifies that the estimated probabilities of correctly classifying each case should be saved to the variable *correct*. The estimated probabilities of classifying each case into the predicted category are saved to the default variable *pcp_k*, where *k* is the smallest integer for which *pcp_k* does not already exist.

SCALE Subcommand

The SCALE subcommand specifies the scale component in the model.

- Specify a list of terms to be included in the model, separated by commas or spaces.
- The model will have no scale component if the subcommand is omitted.
- No scale component is generated if the subcommand is not specified or empty.
- To include a main effect term, enter the name of the factor on the subcommand.
- The keyword INTERCEPT is not allowed on the subcommand.
- To include an interaction effect term among factors, use the keyword BY or the asterisk (*) to join factors involved in the interaction. For example, A*B*C means a three-way interaction effect of A, B, and C, where A, B, and C are factors. The expression A BY B BY C is equivalent to A*B*C. Factors inside an interaction effect must be distinct. Expressions such as A*C*A and A*A are invalid.

- To include a nested effect term, use the keyword WITHIN or a pair of parentheses on the subcommand. For example, A(B) means that A is nested within B, where A and B are factors. The expression A WITHIN B is equivalent to A(B). Factors inside a nested effect must be distinct. Expressions such as A(A) and A(B*A) are invalid.
- Multiple level nesting is supported. For example, A(B(C)) means that B is nested within C, and A is nested within B(C). When more than one pair of parentheses is present, each pair of parentheses must be enclosed or nested within another pair of parentheses. Thus, A(B)(C) is not valid.
- Nesting within an interaction effect is valid. For example, A(B*C) means that A is nested within B*C.
- Interactions among nested effects are allowed. The correct syntax is the interaction followed by the common nested effect inside the parentheses. For example, interaction between A and B within levels of C should be specified as A*B(C) instead of A(C)*B(C).
- To include a covariate term in the model, enter the name of the covariate on the subcommand.
- Covariates can be connected, but not nested, using the keyword BY or the asterisk (*) operator. For example, X*X is the product of X and itself. This is equivalent to a covariate whose values are the square of those of X. On the contrary, X(Y) is invalid.
- Factor and covariate effects can be connected in many ways. No effects can be nested within a covariate effect. Suppose A and B are factors, and X and Y are covariates. Examples of valid combination of factor and covariate effects are A*X, A*B*X, X(A), X(A*B), X*A(B), X*Y(A*B), and A*B*X*Y.

TEST Subcommand

The TEST subcommand allows you to customize your hypothesis tests by directly specifying null hypotheses as linear combinations of parameters.

- TEST is offered only through syntax.
- Multiple TEST subcommands are allowed. Each is handled independently.
- The basic format of the TEST subcommand is an optional list of values enclosed in a pair of parentheses, an optional label in quotes, an effect name or the keyword ALL, and a list of values.
- To specify the coefficient for the intercept, use the keyword INTERCEPT. The number of values after INTERCEPT must be equal to the number of response categories minus 1.
- When multiple linear combinations are specified within the same TEST subcommand, a semicolon terminates each linear combination, except the last one.
- The linear combinations are separately tested for each category of the dependent variable and then simultaneously tested for all the categories.
- If specified, the value list that immediately follows the subcommand name is the constant that the linear combinations are equated to under the null hypotheses. If this value list is omitted, the constants are assumed to be all zeros.
- The optional label is a string with a maximum length of 255 bytes. Only one label per TEST subcommand can be specified.

- Only valid effects appearing or implied on the LOCATION or the SCALE subcommands can be specified in a linear combination. If an effect appears in both subcommands, then enter the effect only once on the TEST subcommand.
- To specify coefficient for the intercept, use the keyword INTERCEPT. Only one value is expected to follow INTERCEPT.
- The number of values following an effect name must equal the number of parameters (including the redundant ones) corresponding to that effect. For example, if the effect A*B takes up six parameters, then exactly six values must follow A*B.
- A number can be specified as a fraction with a positive denominator. For example, 1/3 or –1/3 are valid, but 1/–3 is invalid.
- When ALL is specified, only a list of values can follow. The number of values must equal the combined number of LOCATION and SCALE parameters (including the redundant ones).
- Effects appearing or implied on the LOCATION or the SCALE subcommands but not specified on the TEST are assumed to take the value 0 for all their parameters.
- Effect names and the ALL keywords are mutually exclusive within a single TEST subcommand.
- If ALL is specified for the first row in a TEST matrix, then all subsequent rows should begin with the ALL keyword.
- If effects are specified for the first row in a TEST matrix, then all subsequent rows should use effect name (thus ALL is not allowed).

Example

```
PLUM
  chist  BY housng
  /CRITERIA = CIN(95) DELTA(0) LCONVERGE(0) MXITER(100) MXSTEP(5)
              PCONVERGE(1.0E-6) SINGULAR(1.0E-8)
  /LINK = CLOGLOG
  /PRINT = CELLINFO CORB COVB FIT HISTORY(1) PARAMETER
           SUMMARY TPARALLEL
  /TEST(0 0) =  ALL 1 -1 0 0 0 0 0;
                ALL 0 0 1 -1 0 0 0.
```

- There are a total of seven parameter coefficients in the model; four for the thresholds, and three for the factor *housng*. TEST specifies two separate tests: one in which the first and second thresholds are tested for equality, and one in which the third and fourth thresholds are tested for equality.

POINT

```
POINT KEY=varname
  [FILE='file'] [ENCODING='encoding specification']
```

Release History

Release 16.0

- ENCODING subcommand added for Unicode support.

Example

```
POINT FILE=DRIVERS /KEY=#FRSTAGE.
```

Overview

POINT establishes the location at which sequential access begins (or resumes) in a keyed file. A keyed file is a file that provides access to information by a record key. An example of a keyed file is a file containing a social security number and other information about a firm's employees. The social security number can be used to identify the records in the file. For additional information about keyed files, see KEYED DATA LIST.

POINT prepares for reading the key-sequenced dataset sequentially from a point that the key value controls. Data selection commands can then be used to limit the file to the portion that you want to analyze. A DATA LIST command is used to read the data. To read keyed files (and also direct-access files), see KEYED DATA LIST.

Basic Specification

The basic specification is the KEY subcommand and a string variable. The value of the string variable is used as the file key for determining where sequential retrieval (via DATA LIST) begins or resumes.

Subcommand Order

- Subcommands can be named in any order.
- Each POINT command must precede its corresponding DATA LIST command.

Syntax Rules

- POINT can be used more than once to change the order of retrieval during processing.
- POINT must be specified in an input program and therefore cannot be used to add cases to an existing file.

Operations

- The next DATA LIST command that is executed after the POINT command (for the same file) will read a record whose key value is at least as large as the value of the specified key. To prevent an infinite loop in which the same record is read again and again, the value of the variable that is specified on KEY must change from case to case, or the POINT command must be set up to execute only once.
- If the file contains a record whose key exactly matches the value of the KEY variable, the next execution of DATA LIST will read that record, the second execution of DATA LIST will read the next record, and so on.
- If an exact match between key and variable is not found, the results depend on the operating system. On IBM implementations, reading begins or resumes at the record that has the next higher key. If the value of the key is shorter than the file key, the value of the key variable is logically extended with the lowest character in the collating sequence. For example, if the value of the key variable is the single letter M, retrieval begins or resumes at the first record that has a key (regardless of length) beginning with the letter M or a character that is higher in the collating sequence.
- POINT does not report on whether the file contains a record that exactly matches the specified key. To check for missing records, use LIST to display the data that were read by the subsequent DATA LIST command.

Examples

Basic Example

```
FILE HANDLE DRIVERS/ file specifications.
POINT FILE=DRIVERS /KEY=#FRSTAGE.
```

- FILE HANDLE defines the handle for the data file to be read by POINT. The handle is specified on the FILE subcommand on POINT.
- KEY on POINT specifies the key variable. The key variable must be a string, and it must already exist as the result of a prior DATA LIST, KEYED DATA LIST, or transformation command.

Selecting a Subset of Records from a Keyed File

```
FILE HANDLE    DRIVERS/ file specifications.
INPUT PROGRAM.
STRING         #FRSTAGE(A2).
DO IF          #FRSTAGE = ' '.     /* First case check
+  COMPUTE     #FRSTAGE = '26'.    /* Initial key
+  POINT       FILE=DRIVERS /KEY=#FRSTAGE.
END IF.
DATA LIST      FILE=DRIVERS NOTABLE/
               AGE 19-20(A) SEX 21(A) TICKETS 12-13.
DO IF          AGE > '30'.
+  END FILE.
END IF.
END INPUT PROGRAM.
LIST.
```

- This example illustrates how to execute POINT for only the first case. The file contains information about traffic violations, and it uses the individual's age as the key. Ages between 26 and 30 are selected.
- FILE HANDLE specifies the file handle DRIVERS.
- The INPUT PROGRAM and END INPUT PROGRAM commands begin and end the block of commands that build cases. POINT must appear in an input program.
- STRING declares the string variable *#FRSTAGE*, whose value will be used as the key on the POINT command. Because *#FRSTAGE* is a string variable, it is initialized as blanks.
- The first DO IF-END IF structure is executed only if no records have been read (that is, when *#FRSTAGE* is blank). When *#FRSTAGE* is blank, COMPUTE resets *#FRSTAGE* to 26, which is the initial value. POINT is executed, and it causes the first execution of DATA LIST to read a record whose key is at least 26. Because the value of *#FRSTAGE* is now 26, the DO IF-END IF structure is not executed again.
- DATA LIST reads the variables *AGE*, *SEX*, and *TICKETS* from the file *DRIVERS*.
- The second DO IF–END IF structure executes an END FILE command as soon as a record is read that contains a driver's age that is greater than 30. The program does not add this last case to the working file when it ends the file (see END FILE).

FILE Subcommand

FILE specifies a file handle for the keyed data file. The file handle must have been previously defined on a FILE HANDLE command.

- FILE is optional.
- If FILE is omitted, POINT reads from the last file that is specified on an input command, such as DATA LIST.

Example

```
FILE HANDLE DRIVERS/ file specifications.
POINT FILE=DRIVERS /KEY=#NXTCASE.
```

- FILE HANDLE specifies *DRIVERS* as the file handle for the data. The FILE subcommand on POINT specifies file handle *DRIVERS*.

ENCODING Subcommand

ENCODING specifies the encoding format of the file. The keyword is followed by an equals sign and a quoted encoding specification.

- In Unicode mode, the default is UTF8. For more information, see SET command, UNICODE subcommand.
- In code page mode, the default is the current locale setting. For more information, see SET command, LOCALE subcommand.

- The quoted encoding value can be: `Locale` (the current locale setting), `UTF8`, `UTF16`, `UTF16BE` (big endian), `UTF16LE` (little endian), a numeric Windows code page value (for example, '1252'), or an IANA code page value (for example, 'iso8859-1' or cp1252).
- In Unicode mode, the defined width of string variables is tripled for code page and UTF-16 text data files. Use ALTER TYPE to automatically adjust the defined width of string variables.

KEY Subcommand

`KEY` specifies the variable whose value will be used as the file key for determining where sequential retrieval by `DATA LIST` will begin or resume. This variable must be a string variable, and it must already exist as the result of a prior `DATA LIST`, `KEYED DATA LIST`, or transformation command.

- `KEY` is required. Its only specification is a single variable. The variable can be a permanent variable or a scratch variable.
- Although the keys on a file are inherently numbers, such as social security numbers, the `STRING` function can be used to convert the numeric variable to a string. For more information, see String/Numeric Conversion Functions on p. 106.

Example

```
FILE HANDLE DRIVERS/ file specifications.
POINT FILE=DRIVERS /KEY=#NXTCASE.
```

- `KEY` indicates that the value of the existing scratch variable *#FRSTAGE* will be used as the key to reading each record.
- Variable *#FRSTAGE* must be an existing string variable.

PPLOT

```
PPLOT VARIABLES= varlist

 [/DISTRIBUTION={NORMAL(a,b)** }  ]
                {EXPONENTIAL(a)}
                {WEIBUL(a,b)   }
                {PARETO(a,b)   }
                {LNORMAL(a,b)  }
                {BETA(a,b)     }
                {GAMMA(a,b)    }
                {LOGISTIC(a,b) }
                {LAPLACE(a,b)  }
                {UNIFORM(a,b)  }
                {HNORMAL(a)    }
                {CHI(df)       }
                {STUDENT(df)   }

 [/FRACTION={BLOM**}]
            {RANKIT}
            {TUKEY }
            {VW    }

 [/TIES={MEAN**  }]
        {LOW     }
        {HIGH    }
        {BREAK}

 [/{NOSTANDARDIZE**}]
   {STANDARDIZE    }

 [/TYPE={Q-Q**}]
        {P-P  }

         {n}

 [/PERIOD=n]

 [/{NOLOG**}]
   {LN     }

 [/APPLY [='model name']]
```

**Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
PPLOT VARIABLES = VARX
  /FRACTION=TUKEY
  /DIFF=2.
```

Overview

PPLOT (alias NPPLOT) produces probability plots of one or more sequence or time series variables. The variables can be standardized, differenced, and/or transformed before plotting. Expected normal values or deviations from expected normal values can be plotted.

Options

Variable Modification. You can use the LN subcommand to request a natural log transformation of the sequence or time series variables, and you can use the SDIFF and DIFF subcommands to request seasonal and nonseasonal differencing to any degree. With seasonal differencing, you can specify the periodicity on the PERIOD subcommand. You can also plot standardized series by using the STANDARDIZE subcommand.

Plot Type. You can request p-p (proportion-proportion) or q-q (quantile-quantile) plots on the TYPE subcommand. With the PLOT subcommand, you can display normal plots, detrended plots, or both.

Distribution Type. You can specify the distribution type on the DISTRIBUTION subcommand. The cumulative distribution function (CDF) and the inverse distribution function (IDF) for the specified distribution type are used to compute the expected values in the p-p and q-q plots, respectively.

Score Calculations. On the FRACTION subcommand, you can specify one of several fractional rank formulas to use for estimating the empirical distribution in p-p plots and computing expected quantiles in q-q plots. You can specify the treatment of tied values on the TIE subcommand.

Basic Specification

The basic specification is one or more variable names.

- For each specified variable, PPLOT produces two q-q plots of the observed values (one plot versus expected normal values and the other plot versus deviations from normal values. By default, expected normal values are calculated by using Blom's transformation.
- Observed values define the horizontal axis, and expected normal values or deviations define the vertical axis.

Subcommand Order

- Subcommands can be specified in any order.

Syntax Rules

- VARIABLES can be specified only once.
- Other subcommands can be specified more than once, but only the last specification of each subcommand is executed.

Operations

- Subcommand specifications apply to all plots that are produced by PPLOT.
- If the LN subcommand is specified, any differencing or standardization that is requested on that PPLOT is done on the log-transformed series.

- If differencing (DIFF or SDIFF) is specified, any standardization is done on the differenced series.

Limitations

- A maximum of 1 VARIABLES subcommand is allowed. There is no limit on the number of variables that are named on the list.

Example

```
PPLOT VARIABLES = VARX
  /FRACTION=TUKEY
  /DIFF=2.
```

- This command produces two normal q-q plots of *VARX*(one plot not detrended and the other plot detrended).
- The expected quantile values are calculated by using Tukey's transformation.
- The variable is differenced twice before plotting.

VARIABLES Subcommand

VARIABLES specifies the sequence or time series variables to be plotted and is the only required subcommand.

DISTRIBUTION Subcommand

DISTRIBUTION specifies the distribution type of your data. The default is NORMAL if the subcommand is not specified or is specified without a keyword. If the parameters of the distribution type are not specified, DISTRIBUTION estimates them from the sample data and displays them with the plots.

NORMAL(a,b)	*Normal distribution.* The location parameter *a* can be any numeric value, while the scale parameter *b* must be positive. If they are not specified, DISTRIBUTION estimates them from the sample mean and sample standard deviation.
EXPONENTIAL(a)	*Exponential distribution.* The scale parameter *a* must be positive. If the parameter is not specified, DISTRIBUTION estimates it from the sample mean. Negative observations are not allowed.
WEIBULL(a,b)	*Weibull distribution.* The scale and shape parameters *a* and *b* must be positive. If they are not specified, DISTRIBUTION estimates them using the least square method. Negative observations are not allowed.
PARETO(a,b)	*Pareto distribution.* The threshold and shape parameters *a* and *b* must be positive. If they are not specified, DISTRIBUTION assumes *a* equals the minimum observation and estimates *b* by the maximum likelihood method. Negative observations are not allowed.
LNORMAL(a,b)	*Lognormal distribution.* The scale and shape parameters *a* and *b* must be positive. If they are not specified, DISTRIBUTION estimates them from the mean and standard deviation of the natural logarithm of the sample data. Negative observations are not allowed.

BETA(a,b)	*Beta distribution.* The shape1 and shape2 parameters *a* and *b* must be positive. If they are not specified, DISTRIBUTION estimates them from the sample mean and sample standard deviation. All observations must be between 0 and 1, inclusive.
GAMMA(a,b)	*Gamma distribution.* The shape and scale parameters *a* and *b* must be positive. If they are not specified, DISTRIBUTION estimates them from the sample mean and sample standard deviation. Negative observations are not allowed.
LOGISTIC(a,b)	*Logistic distribution.* LOGISTIC takes a location and a scale parameter (*a* and *b)*. The scale parameter *(b*) must be positive. If the parameters are not specified, DISTRIBUTION estimates them from the sample mean and sample standard deviation.
LAPLACE(a,b)	*Laplace or double exponential distribution.* LAPLACE takes a location and a scale parameter (*a* and *b)*. The scale parameter *(b*) must be positive. If the parameters are not specified, DISTRIBUTION estimates them from the sample mean and sample standard deviation.
UNIFORM(a,b)	*Uniform distribution.* UNIFORM takes a minimum and a maximum parameter *(a* and *b)*. Parameter *a* must be equal to or greater than *b.* If the parameters are not specified, DISTRIBUTION assumes them from the sample data.
HNORMAL(a)	*Half-normal distribution.* Data are assumed to be location-free or centralized. (Location parameter=0.) You can specify the scale parameter *a* or let DISTRIBUTION estimate it by using the maximum likelihood method.
CHI(df)	*Chi-square distribution.* You must specify the degrees of freedom (*df)*. Negative observations are not allowed.
STUDENT(df)	*Student's* t *distribution.* You must specify the degrees of freedom (*df).*

FRACTION Subcommand

FRACTION specifies the formula to be used in estimating the empirical distribution in p-p plots and calculating the expected quantile values in q-q plots.

- Only one formula can be specified. If more than one formula is specified, only the first formula is used.
- If the FRACTION subcommand is not specified, BLOM is used by default.
- These formulas produce noticeable differences for short series only.

Four formulas are available:

BLOM	Blom's transformation, defined by the formula $(r - (3/8)) / (n + (1/4))$, where *n* is the number of observations and *r* is the rank, ranging from 1 to *n*(Blom, 1958).
RANKIT	Formula $(r - (1/2)) / n$, where *n* is the number of observations and *r* is the rank, ranging from 1 to *n*(Chambers, Cleveland, Kleiner, and Tukey, 1983).
TUKEY	Tukey's transformation, defined by the formula $(r - (1/3)) / (n + (1/3))$, where *n* is the number of observations and *r* is the rank, ranging from 1 to *n*(Tukey, 1962).
VW	Van der Waerden's transformation, defined by the formula $r / (n + 1)$, where *n* is the number of observations and *r* is the rank, ranging from 1 to *n*(Lehmann, 1975).

Example

```
PPLOT VARIABLES = VARX
```

```
/FRACTION=VW.
```

- This PPLOT command uses van der Waerden's transformation to approximate the proportion estimate *p*, which is used in the inverse distribution function.
- By default, two q-q plots are produced.

TIES Subcommand

TIES determines the way that tied values are handled. The default method is MEAN.

MEAN	*Mean rank of tied values is used for ties.* This setting is the default.
LOW	*Lowest rank of tied values is used for ties.*
HIGH	*Highest rank of tied values is used for ties.*
BREAK	*Consecutive ranks with ties sharing the same value.* Each distinct value of the ranked variable is assigned a consecutive rank. Ties share the same rank.

TYPE Subcommand

TYPE specifies the type of plot to produce. The default is Q-Q. The plots show a quantile-quantile plot and a proportion-proportion plot using the same data (with a normal distribution).

Q-Q	*Quantile-quantile plots.* The quantiles of the observed values are plotted against the quantiles of the specified distribution.
P-P	*Proportion-proportion plots*. The observed cumulative proportion is plotted against the expected cumulative proportion if the data were a sample from a specified distribution.

Figure 171-1
Normal q-q plot of household income

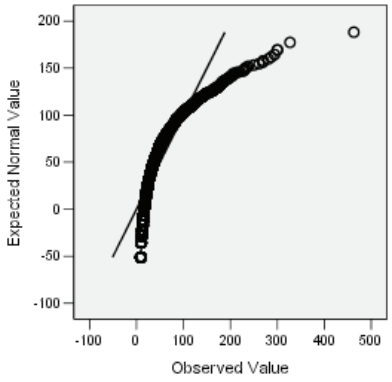

Figure 171-2
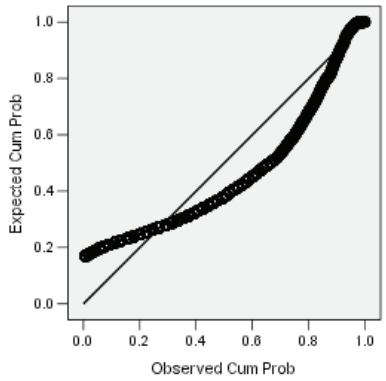
Normal p-p plot of household income



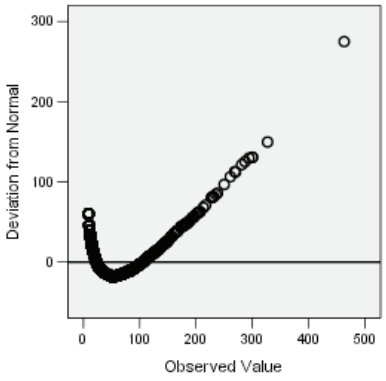
PLOT Subcommand

PLOT specifies whether to produce a plot of observed values versus expected values, a plot of observed values versus deviations from expected values, or both. The plots shown in TYPE Subcommand are nondetrended plots. The figure below shows a detrended q-q plot.

BOTH	*Display both detrended and nondetrended normal plots.* This is the default.
NORMAL	*Display nondetrended normal plots.* The observed values are plotted against the expected values.
DETRENDED	*Display detrended plots.* The observed values are plotted against the deviations from the expected values.

- If you specify PLOT more than once, only the last specification is executed.
- Deviations are calculated by subtracting the expected value from the observed value.
- In low resolution, a dash is used in a detrended plot to indicate where the deviation from the expected is 0.

Figure 171-3
Detrended normal q-q plot of household income



STANDARDIZE and NOSTANDARDIZE Subcommands

STANDARDIZE transforms the sequence or time series variables into a sample with a mean of 0 and a standard deviation of 1. NOSTANDARDIZE is the default and indicates that the series should not be standardized.

- There are no additional specifications on the STANDARDIZE or NOSTANDARDIZE subcommands.
- Only the last STANDARDIZE or NOSTANDARDIZE subcommand on the PPLOT command is executed.
- The STANDARDIZE and NOSTANDARDIZE subcommands have no effect on expected values, which are always standardized.
- NOSTANDARDIZE is generally used with an APPLY subcommand to turn off a previous STANDARDIZE specification.

Example

```
PPLOT VARIABLES = VARX
  /STANDARDIZE.
```

- This example produces two q-q normal-probability plots of *VARX* with standardized observed values.

DIFF Subcommand

DIFF specifies the degree of differencing that is used before plotting to convert a nonstationary variable into a stationary variable with a constant mean and variance.

- You can specify any positive integer on DIFF.
- If DIFF is specified without a value, the default is 1.
- The number of plotted values decreases by 1 for each degree of differencing.

Example

```
PPLOT VARIABLES = TICKETS
  /DIFF=2.
```

- In this example, *TICKETS* is differenced twice before the expected and observed values are plotted.

SDIFF Subcommand

If the variable exhibits a seasonal or periodic pattern, you can use the SDIFF subcommand to seasonally difference the variable before plotting.

- The specification on SDIFF indicates the degree of seasonal differencing and can be any positive integer.
- If SDIFF is specified without a value, the degree of seasonal differencing defaults to 1.

- The number of plotted seasons decreases by 1 for each degree of seasonal differencing.
- The length of the period that is used by SDIFF is specified on the PERIOD subcommand. If the PERIOD subcommand is not specified, the periodicity that is established on the TSET or DATE command is used (see PERIOD Subcommand).

PERIOD Subcommand

PERIOD indicates the length of the period to be used by the SDIFF subcommand.

- The specification on PERIOD indicates how many observations are in one period or season. You can specify any positive integer on PERIOD.
- The PERIOD subcommand is ignored if it is used without the SDIFF subcommand.
- If PERIOD is not specified, the periodicity that is established on TSET PERIOD is in effect. If TSET PERIOD is not specified either, the periodicity that is established on the DATE command is used. If periodicity was not established anywhere, the SDIFF subcommand will not be executed.

Example

```
PPLOT VARIABLES = TICKETS
  /SDIFF=1
  /PERIOD=12.
```

- This command applies 1 degree of seasonal differencing with 12 observations per season to the variable *TICKETS*.

LN and NOLOG Subcommands

LN transforms the data by using the natural logarithm (base *e*) to remove varying amplitude. NOLOG indicates that the data should not be log transformed. NOLOG is the default.

- There are no additional specifications on LN or NOLOG.
- Only the last LN or NOLOG subcommand on a PPLOT command is executed.
- If a natural log transformation is requested, cases with values that are less than or equal to 0 will be set to system-missing, because nonpositive values cannot be log-transformed.
- NOLOG is generally used with an APPLY subcommand to turn off a previous LN specification.

Example

```
PPLOT VARIABLES = TICKETS
  /FRACTION=TUKEY
  /DIFF=1
  /LN.
PPLOT VARIABLES = EARNINGS
  /APPLY
  /NOLOG.
```

- The first command requests a natural log transformation of variable *TICKETS* before plotting.
- The second command applies the previous PPLOT specifications to variable *EARNINGS*. However, *EARNINGS* is not log-transformed before plotting.

APPLY Subcommand

APPLY allows you to produce a plot by using previously defined specifications without having to repeat the PPLOT subcommands.

- The only specification on APPLY is the name of a previous model in quotation marks. If a model name is not specified, the model that is specified on the previous PPLOT command is used.
- To change any plot specifications, specify the subcommands of only those portions that you want to change. Make these entries after the APPLY subcommand.
- If no variables are specified, the variables that were specified for the original plot are used.
- To change the variables that are used with the model, enter new variable names before or after the APPLY subcommand.
- The distribution type is applied, but the parameters are not applied.

Example

```
PPLOT VARIABLES = X1
  /FRACTION=TUKEY.
PPLOT VARIABLES = Z1
  /APPLY.
```

- The first command produces two q-q normal-probability plots of *X1*, using Tukey's transformation to compute the expected values.
- The second command requests the same plots for variable *Z1*.

Example

```
PPLOT VARIABLES = X1 Y1 Z1
  /FRACTION=VW.
PPLOT APPLY
  /FRACTION=BLOM.
```

- The first command uses van der Waerden's transformation to calculate expected normal values of *X1*, *Y1*, and *Z1*.
- The second command uses Blom's transformation for the same three series.

Example

```
PPLOT VARIABLES = VARX
  /FRACTION=RANKIT
  /DIFF
  /STANDARDIZE.
PPLOT VARIABLES = VARY
  /APPLY
  /NOSTANDARDIZE.
```

- The first command differences and standardizes series *VARX* and then produces a normal probability plot by using the RANKIT transformation.
- The second command applies the previous plot specifications to *VARY* but does not standardize the series.

PREDICT

```
PREDICT  [{start date       }] [THRU [{end date       }]]
          {start case number}         {end case number}
                                      {END            }
```

Example

```
PREDICT Y 61 THRU Y 65.
```

Overview

PREDICT specifies the observations that mark the beginning and end of the forecast period. If the forecast period extends beyond the length of the series, PREDICT extends the series in the active dataset to allow room for the forecast observations.

Basic Specification

The minimum specification on PREDICT is either the start or the end of the range, or it is keyword THRU. PREDICT sets up a forecast period beginning and ending with the specified dates or case numbers. The default starting point is the observation immediately after the end of the series or, if USE is specified, the observation immediately after the end of the use range (the historical period). The default end is the last observation in the series.

Operations

- PREDICT is executed when the data are read for the next forecasting procedure (ARIMA in the Trends add-on module, CURVEFIT in the Base system, and 2SLS in the Regression Models add-on module).
- PREDICT is ignored by non-forecasting procedures.
- Case number specifications refer to the sequential numbers that are assigned to cases as they are read.
- If the forecast period extends beyond the length of the series, PREDICT extends the series in the active dataset to allow room for the forecast observations.
- New observations that are added to the end of existing series will contain non-missing date variables, forecast values (variable *FIT#n*), confidence interval limits (variables *LCL#n* and *UCL#n*), and, for ARIMA models, standard error of the predicted value (*SEP#n*). For all other variables, including the original series, the new cases will be system-missing.
- PREDICT cannot forecast beyond the end of the series for ARIMA with regressors and 2SLS. However, PREDICT*can* forecast values for the dependent variable if the independent variables have valid values in the predict period.
- If the use and predict periods overlap, the model is still estimated by using all observations in the use period.

- USE and PREDICT can be used together to perform forecasting validation. To do this, specify a use period that ends before the existing end of the series, and specify a predict period starting with the next observation.
- If there is a gap between the end of the use period and the start of the specified predict period, the program uses the first observation after the end of the use period as the start of the predict period. (This setting is the default.)
- The DATE command turns off all existing USE and PREDICT specifications.
- PREDICT remains in effect in a session until it is changed by another PREDICT command or until a new DATE command is issued.
- If more than one forecasting procedure is specified after PREDICT, the USE command should be specified between procedures so that the original series—without any new, system-missing cases—will be used each time. Alternatively, you can specify

  ```
  TSET NEWVAR = NONE
  ```

  before the first forecasting procedure so that you can evaluate model statistics without creating new variables or adding new cases with missing values to the original series.

Limitations

A maximum of one range (one start and/or one end) can be specified per PREDICT command.

Syntax Rules

- You can specify a start, an end, or both.
- The start and end are specified as either date specifications or case (observation) numbers.
- Date specifications and case numbers cannot be mixed on one PREDICT command.
- Keyword THRU is required if the end of the range is specified.
- Keyword THRU by itself defines a PREDICT range starting with the first observation after the use range and ending with the end of the series. If USE has not been specified, PREDICT THRU is meaningless.

Date Specifications

- A date specification consists of DATE keywords and values (see the DATE command on p. 536). These specifications must correspond to existing date variables.
- If more than one date variable exists, the highest-order variable must be included in the date specification.
- Values on keyword YEAR must have the same format (two or four digits) as the YEAR specifications on the DATE command.

Case Specifications

The case number specification is the sequence number of the case (observation) as it is read by the program.

Valid Range

- The start date must precede the end date.
- The start case number must be less than the end case number.
- The start can be any observation ranging from the second observation in the historical period that is specified on USE to the observation immediately following the end of the historical period. If USE is not specified, the start can be any observation ranging from the second observation in the series to the observation immediately following the end of the series.
- For most models, the start of the predict period should not be too close to the start of the use period.
- The predict and use periods should not be exactly the same.
- The start of the predict period should not precede the start of the use period.

Examples

Specifying the Forecast Period as a Date Range

```
PREDICT Y 61 THRU Y 65.
```

- This command specifies a forecast period from 1961 to 1965.
- The active dataset must include variable *YEAR_*, which, in this example, contains only the last two digits of each year.
- If variable *MONTH_* also exists, the above command is equivalent to

  ```
  PREDICT Y 61 M 1 THRU Y 65 M 12.
  ```

```
PREDICT W 28 THRU W 56.
```

- This command specifies a forecast period from the 28th week to the 56th week.
- The active dataset must include variable *WEEK_*.
- If variable *DAY_* also exists, the above command is equivalent to

  ```
  PREDICT W 28 D 1 THRU W 56 D 7.
  ```

Specifying the Forecast Period as a Case Range

```
PREDICT 61 THRU 65.
```

- This command specifies a forecast period from the 61st case (observation) to the 65th case.

Using the Default Start Date

```
PREDICT THRU Y 65.
```

- This command uses the default start date, which is the observation immediately following the end of the use period. If USE is not specified, the default start is the observation immediately following the end of the series.
- The forecast period extends from the start date through year 1965.

- The active dataset must include variable *YEAR_*.
- Keyword `THRU` is required.

Specifying the Forecast Period by Using Date Variables

```
PREDICT THRU CYCLE 4 OBS 17.
```

- This example uses the date variables *OBS_* and *CYCLE_*, which must exist in the active dataset.
- *CYCLE*, the highest order, must be included on `PREDICT`.
- Keyword `THRU` is required.
- The forecast period extends from the default start to the 17th observation of cycle 4.

PREFSCAL

PREFSCAL is available in the Categories option.

```
PREFSCAL VARIABLES = varlist

   [/INPUT = [ROWS({n    })]
                  {rowid}
             [SOURCES({1**     })]]
                      {n       }
                      {sourceid}

   [/PROXIMITIES = {DISSIMILARITIES**}]
                   {SIMILARITIES     }

   [/WEIGHTS = varlist]

   [/INITIAL = {CLASSICAL[({TRIANGLE**})]}]
                          {SPEARMAN  }
               {CORRESPONDENCE           }
               {ROSSCLIFF                }
               {CENTROIDS[({1})]         }
                         {n}
               {RANDOM[({1})]            }
                       {n}
               {(filespec) [varlist]     }

   [/CONDITION = {ROW** }]
                 {MATRIX}
                 {UNCONDITIONAL    }

              [TRANSFORMATIONS('savfile'|'dataset')]]
```

* Default if the keyword is omitted.

** Default if the subcommand or keyword is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Release History

Release 14.0

- Command introduced.

Example

```
PREFSCAL var01 TO var02.
```

Overview

PREFSCAL performs multidimensional unfolding of proximity data to find a least-squares representation of the row and column objects in a low-dimensional space. Individual differences models are allowed for multiple sources. A majorization algorithm minimizes penalized Stress and guarantees monotone convergence for optionally transformed, metric and nonmetric data under a variety of models and constraints.

Options

Data Input. You can read one or more rectangular matrices of proximities. Additionally, you can read weights, an initial configuration, and fixed coordinates.

Methodological Assumptions. On the CONDITION subcommand, you can specify transformations for all sources (unconditional), separate transformations for each source (matrix-conditional), or separate transformations for each row (row-conditional). Using the TRANSFORMATION subcommand, you can treat proximities as nonmetric (ordinal or smooth ordinal), as quasi-metric (splines), or as metric (linear with or without intercept). Ordinal and smooth ordinal transformations can keep tied observations tied (discrete) or untie them (continuous). You can use the PROXIMITIES subcommand to specify whether your proximities are similarities or dissimilarities.

Model Selection. You can specify multidimensional unfolding models by selecting a combination of PREFSCAL subcommands, keywords, and criteria. The subcommand MODEL offers the Identity model and two individual differences models. You can specify other selections on the CRITERIA subcommand.

Penalties. You can specify two penalty parameters in order to avoid degenerate solutions. On the PENALTY subcommand, LAMBDA is specified for the strength, and OMEGA is specified for the range. Penalized Stress penalizes solutions with insufficient variation in the transformed proximities.

Constraints. You can specify fixed coordinates on the RESTRICTIONS subcommand to restrict some or all common space coordinates of either row objects or column objects.

Output. You can produce output that includes the original and transformed proximities, history of iterations, common and individual configurations, individual space weights, distances, and decomposition of the Stress. Plots can be produced of common and individual configurations (biplots), individual space weights, transformations, fit, and residuals.

Basic Specification

The basic specification is PREFSCAL followed by a variable list. By default, PREFSCAL produces a two-dimensional metric Euclidean multidimensional unfolding solution (Identity model). Input is expected to contain one or more rectangular matrices with proximities that are dissimilarities. The transformation of the proximities is row-conditional. The analysis uses a classical scaling start as initial configuration. By default, output includes fit and Stress values, the coordinates of the common space, and a joint plot of the common space configuration.

Syntax Rules

- If there is only one source, the model is always assumed to be Identity.
- In the case of duplicate or contradicting subcommand specification, only the later subcommand applies.
- There is no constraint with respect to the syntax order.

Limitations

- PREFSCAL needs at least two objects in each set. At least two variables need to be specified in the variable list (two column objects), and the active data file needs to contain at least two cases (two row objects).
- PREFSCAL does not honor SPLIT FILE.

Examples

```
PREFSCAL
  VARIABLES=TP BT EMM JD CT BMM HRB TMd BTJ TMn CB DP GD CC CMB
  /INPUT=SOURCES(srcid )
  /INITIAL=CLASSICAL (SPEARMAN)
  /CONDITION=ROW
  /TRANSFORMATION=NONE
  /PROXIMITIES=DISSIMILARITIES
  /MODEL=WEIGHTED
  /CRITERIA=DIMENSIONS(2,2) DIFFSTRESS(.000001) MINSTRESS(.0001)
  MAXITER(5000)
```

```
  /PENALTY=LAMBDA(0.5) OMEGA(1.0)
  /PRINT=MEASURES COMMON
  /PLOT=COMMON WEIGHTS INDIVIDUAL ( ALL ) .
```

- This syntax specifies an analysis on variables *tp (Toast pop-up)* through *cmb (Corn muffin and butter)*. The variable *srcid* is used to identify the sources.
- The INITIAL subcommand specifies that the starting values be imputed using Spearman distances.
- The MODEL subcommand specifies a weighted Euclidean model, which allows each individual space to weight the dimensions of the common space differently.
- The PLOT subcommand requests plots of the common space, individual spaces, and individual space weights.
- All other parameters fall back to their default values.

VARIABLES Subcommand

The variable list identifies the columns in the proximity matrix or matrices that PREFSCAL reads. Each variable identifies one column of the proximity matrix, with each case in the active dataset representing one row.

- Only numeric variables may be specified.
- PREFSCAL reads data row by row, and the columns are represented by the variables on the variable list.

Example

```
DATA LIST
  /var01 var02.
BEGIN DATA
  1 6
  5 4
  4 2
END DATA.
PREFSCAL var01 TO var02.
```

- This example specifies an analysis on a 3 × 2 proximity matrix (3 rows and 2 columns).

INPUT Subcommand

The INPUT subcommand specifies the number of rows in one source, the number of sources, or both. Specifying a row identifier, *rowid*, or a source identifier, *sourceid*, specifically identifies either the row objects or sources and provides a variable that may contain row object or source labels. Specifying only one keyword computes the number of row objects or sources according to the following formula: C=R × S, where C is the number of cases, R is the number of row objects,

and S is the number of sources. By specifying both keywords, PREFSCAL takes the first R × S cases from the active file.

ROWS *Number of rows.* This specifies the number of row objects in one source. A variable in parentheses specifies a row identifier. The values must be positive nonzero integers. The values of this variable specify the identifier of the rows that contain the proximities. Within one source, the values of this identifier only need to be discriminating. Over sources, the values of the row identifier must be in the same order.

SOURCES *Number of sources.* This keyword specifies the number of sources. By default, the number of sources is 1. Otherwise, the number of cases in the active file must be dividable by the number of sources. A variable in parentheses specifically specifies a source identifier. The values of this identifier specify the sources and must be positive nonzero integers. The rows within one source must be consecutive cases in the active data file.

- *rowid* and *sourceid* may not be specified on the PREFSCAL variable list.
- Duplicate cell specification is not taken care of. In this case, the final specification applies.

Example

```
DATA LIST
  /var01 TO var15 rowid sourceid.
BEGIN DATA
  13 12 07 03 05 04 08 11 10 15 02 01 06 09 14   1  1
  15 11 06 03 10 05 14 08 09 12 07 01 04 02 13   2  1
  15 10 12 14 03 02 09 08 07 11 01 06 04 05 13   3  1
  (...)
  10 03 02 14 09 01 08 12 13 04 11 05 15 06 07  41  1
  13 03 01 14 04 10 05 15 06 02 11 07 12 08 09  42  1
  15 03 05 12 02 08 07 13 01 04 06 10 11 09 14   1  2
  15 04 03 11 07 05 14 01 02 06 08 13 09 12 10   2  2
  15 02 07 12 05 06 04 08 01 03 09 10 11 14 13   3  2
  (...)

  (...)
  09 04 07 10 11 02 08 12 13 05 14 06 15 01 03  41  6
  15 10 01 12 02 06 08 14 13 11 09 03 04 05 07  42  6
END DATA.
```

- The active data file has 252 cases, containing 6 sources with 42 row objects per source and containing 15 column objects. Additionally, 2 identifying variables, *rowid* and *sourceid*, are specified to identify the row objects and sources, respectively.

```
PREFSCAL var01 TO var15
  /INPUT = ROWS(42).
```

- PREFSCAL reads 15 columns and 42 rows per source—thus, 6 sources in total (252/42).

```
PREFSCAL var01 TO var15
  /INPUT = SOURCES(6).
```

- PREFSCAL reads 15 columns and 6 sources, with 42 rows each (252/6).

```
PREFSCAL var01 TO var15
  /INPUT = ROWS(rowid).
```

- PREFSCAL reads 15 columns and 42 rows per source. The row objects are specified by *rowid*, which ranges from 1 to 42, the number of row objects in this case (per source, thus 6 sources). When a lower value is found in the row object identifier variable, a new source is started.

```
PREFSCAL var01 TO var15
  /INPUT = SOURCES(sourceid).
```

- PREFSCAL reads 15 columns and 6 sources. The sources are specified by *sourceid*, which ranges from 1 to the number of sources (in this case, from 1 to 6). When a higher value is found in the source identifier variable, a new source is started.

```
COMPUTE rowid = 1+MOD($casenum-1,42).
COMPUTE sourceid = 1+TRUNC(($casenum-1)/42).
SORT CASES BY sourceid (A) rowid (A).
VALUE LABELS sourceid 1 'overall'  2 'bacon'  3 'cereal'
                      4 'pancakes' 5 'normal' 6 'snack'.
PREFSCAL var01 TO var15
  /INPUT = ROWS(rowid) SOURCES(sourceid).
```

- First, a row object identifier and a source identifier are computed. The active data file is sorted by *rowid* and *sourceid*. The variable *sourceid* is given value labels. PREFSCAL reads 15 columns and 6 sources per row object, with 42 row objects in total. The first nine case of the active data file look like this:

```
13 12  7  3  5  4  8 11 10 15  2  1  6  9 14 1 1
15  3  5 12  2  8  7 13  1  4  6 10 11  9 14 1 2
14 10  9  3  7  6 12 15  8 11  5  1  4  2 13 1 3
14  9  7  1 11  6 12 15 13 10  3  4  2  5  8 1 4
10 12  8  4  9  6  7 15 14 13  3  1  5  2 11 1 5
14 11  8  4  9  6  7 15 10 12  3  2  5  1 13 1 6
15 11  6  3 10  5 14  8  9 12  7  1  4  2 13 2 1
15  4  3 11  7  5 14  1  2  6  8 13  9 12 10 2 2
15  8  2  3 10  1 14  5  6  9 11 12  4 13  7 2 3
(...)
```

PROXIMITIES Subcommand

The PROXIMITIES subcommand specifies the type of proximities that are used in the analysis. The term **proximity** is used for either similarity or dissimilarity data. Internally, PREFSCAL works with dissimilarities. Therefore, PREFSCAL converts similarities into dissimilarities by reflecting the data about its midpoint (depending on the conditionality chosen on the CONDITION subcommand), thus preserving the endpoints and the range.

DISSIMILARITIES	*Dissimilarity data.* This specification is the default when PROXIMITIES is not specified. Small dissimilarities correspond to small distances, and large dissimilarities correspond to large distances.
SIMILARITIES	*Similarity data.* Small similarities correspond to large distances, and large similarities correspond to small distances.

Example

```
PREFSCAL var01 TO var09
  /PROXIMITIES = SIMILARITIES.
```

- In this example, PREFSCAL expects the proximities to be similarities.

WEIGHTS Subcommand

The WEIGHTS subcommand specifies the variables that contain the nonnegative weights for the proximities that are included in the active dataset.

- The number and order of the variables in the variable list is important. The first variable in the WEIGHTS variable list corresponds to the first variable on the PREFSCAL variable list. This correspondence is repeated for all variables on the variable lists. Every proximity has its own weight. Therefore, the number of variables on the WEIGHTS subcommand must be equal to the number of variables on the PREFSCAL variable list.
- Negative weights are not allowed. If negative weights are specified, an error message is issued, and the procedure aborts.
- The weight variable (set with WEIGHT BY) allows for the weighting of entire rows. The weight variable must contain positive, nonzero values.

Example

```
DATA LIST FILE = 'breakfast.dat' FREE
  /var01 TO var15 wgt01 TO wgt15.
PREFSCAL var01 TO var15
  /WEIGHTS = wgt01 TO wgt15.
```

- In this example, the PREFSCAL variable list indicate that there are 15 column objects, of which the weights can be found in *wgt01* to *wgt15*.
- *wgt01* contains the weights for *var01*, *wgt02* contains the weights for *var02*, and so on.

INITIAL Subcommand

INITIAL defines the initial or starting configuration of the common space for the analysis. When a reduction in dimensionality is specified on the CRITERIA subcommand, a derivation of coordinates in the higher dimensionality is used as starting configuration in the lower dimensionality.

- You can specify one of the five keywords that are listed below.
- You can specify a variable list containing the initial configuration.

CLASSICAL *Classical scaling start.* This specification is the default. The rectangular proximity matrix is used to supplement the intra-blocks (values between rows and between columns) of the complete symmetrical MDS matrix by means of the triangular inequality or Spearman distances. When the complete matrix is formed, a classical scaling solution is used as initial configuration.

ROSSCLIFF *Ross-Cliff start.* The Ross-Cliff start uses the results of a singular value decomposition on the double centered and squared proximity matrix as the initial values for the row and column objects.

CORRESPONDENCE *Correspondence start.* The correspondence start uses the results of a correspondence analysis on the reversed data (similarities instead of dissimilarities) with symmetric normalization of row and column scores. For more information, see CORRESPONDENCE on p. 314.

CENTROIDS(n) *Centroids start.* PREFSCAL starts by positioning the row objects in the configuration by using an eigenvalue decomposition. Then, the column objects are positioned at the centroid of first choices (or second if *n*=2 or third if *n*=3, etc.). The number of choices (*n*) must be a positive integer between 1 and the number of columns. The default is 1.

RANDOM(n) *(Multiple) random start.* You can specify the number of random starts (*n*), where *n* is any positive integer. The random sequence can be controlled by the SET SEED procedure (thus, not by a subcommand within the PREFSCAL procedure). All *n* analyses start with a different random configuration. In the output, all *n* final Stress values are reported, as well as the initial seeds of each analysis (for reproduction purposes), followed by the full output of the analysis with the lowest penalized Stress value. The default number of random starts is 1.

CLASSICAL Keyword

TRIANGLE *Imputation using the triangle inequality.* If TRIANGLE is specified, the intra-blocks are filled by using the triangular inequality.

SPEARMAN *Imputation with Spearman distances.* If SPEARMAN is specified, the Spearman distances between all objects are used to create a symmetrical MDS matrix.

Instead of these keywords, a filespec in parentheses can be given to specify the SPSS data file containing the coordinates of the initial configuration. The row and column coordinates are stacked, with the column coordinates following the row coordinates. The closing parenthesis of the filespec can be followed by a variable list. If the variable list is omitted, the procedure automatically selects the first *MAXDIM* variables in the external file, where *MAXDIM* is the maximum number of dimensions that are requested for the analysis on /CRITERIA = DIMENSIONS(min, max). Missing values are not allowed as initial coordinates. An error is issued whenever this situation occurs.

Example

```
PREFSCAL var01 TO var15
  /INITIAL = RANDOM(100).
```

- This example performs 100 analyses (each analysis starting with a different random configuration). The results of the analysis with the lowest final Stress are displayed in the output.

CONDITION Subcommand

CONDITION specifies the range of proximities that are compared within one transformation list. The TRANSFORMATION subcommand specifies the type of transformation.

ROW	*Row conditional.* Only the proximities within each row are compared with each other. The comparison is carried out for each row separately. This setting is the default.
MATRIX	*Matrix conditional.* Only the proximities within each source are compared with each other. The comparison is carried out for each source separately.
UNCONDITIONAL	*Unconditional.* This specification is appropriate when the proximities in all sources can be compared with each other, and it results in a single transformation of all sources simultaneously.

- Note that if there is only one source, MATRIX and UNCONDITIONAL yield the same result.

Example

```
PREFSCAL var01 TO var09
  /CONDITION = UNCONDITIONAL
  /TRANSFORMATION = LINEAR(INTERCEPT).
```

- In this example, the proximities are linearly transformed, including an intercept. The transformation is carried out over all proximities simultaneously.

TRANSFORMATION Subcommand

The TRANSFORMATION subcommand offers four different options for optimal transformation of the original proximities. The resulting values are called transformed proximities. The distances between the objects in the configuration should match these transformed proximities as closely as possible. The CONDITION subcommand specifies over which proximities the transformation is computed. The default transformation is ORDINAL with ties kept tied.

NONE	*No scale transformation.* The INTERCEPT keyword can be specified in parentheses following the NONE keyword. If INTERCEPT is specified, an intercept is estimated in the transformation.
LINEAR	*Linear transformation.* With this transformation, the transformed proximities are proportional to the original proximities (that is, the transformation function estimates a slope, and the intercept is fixed at 0). The INTERCEPT keyword can be specified in parentheses following the LINEAR keyword. If INTERCEPT is specified, an intercept is estimated in the transformation, resulting in an interval transformation. Without the keyword INTERCEPT, LINEAR only estimates a slope, which coincides with a ratio transformation.
ORDINAL	*Ordinal transformation.* The transformed proximities have the same order as the original proximities. ORDINAL can be followed by a keyword in parentheses to indicate how to handle tied proximities.

SMOOTH *Smooth ordinal transformation.* The transformed proximities have the same order as the original proximities, including a smoothness restriction. This restriction takes the differences between subsequent values into account. Restricting subsequent differences allows for a smooth ordinal transformation. SMOOTH can be followed by a keyword in parentheses to indicate how to handle tied proximities.

SPLINE *Monotone spline transformation.* The transformed proximities are a smooth nondecreasing piecewise polynomial transformation of the original proximities of the chosen degree. The pieces are specified by the number and placement of the interior knots, of which the number can be specified with INKNOT.

ORDINAL and SMOOTH Keywords

UNTIE *Untie ties.* Allowing tied proximities to be untied during transformations (also known as the primary approach to ties).

KEEPTIES *Keep ties tied.* Keeping tied proximities tied during transformations (also known as secondary approach to ties). This setting is the default.

SPLINE Keyword

INTERCEPT *Include intercept.* If INTERCEPT is specified, an intercept is estimated in the transformation. Omitting this keyword sets the lower exterior knot equal to 0.

DEGREE *The degree of the polynomial.* If DEGREE is not specified, the degree is assumed to be 2. The integer range of DEGREE is 1, 2, or 3.

INKNOT *The number of interior knots.* If INKNOT is not specified, the number of interior knots is assumed to be 1. The integer range of INKNOT is between 0 and the number of different proximities minus 2.

Example

```
PREFSCAL var01 TO var15
  /TRANSFORMATION = ORDINAL(UNTIE).
```

- In this example, the proximities are ordinally transformed, where tied proximities are allowed to be untied.
- The CONDITION subcommand is omitted, and thus, the default conditionality ROW is in effect, which implies that the transformation is performed for each row separately.

MODEL Subcommand

MODEL defines the scaling model for the analysis if more than one source is present. IDENTITY is the default model. The other models are individual differences models.

IDENTITY *Identity model.* All sources have the same individual configuration. This model is the default model, and it is not an individual differences model.

WEIGHTED *Weighted Euclidean model.* This model is an individual differences model (and equivalent to the INDSCAL model). Each source has an individual space, in which every dimension of the common space is weighted differentially.

GENERALIZED *Generalized Euclidean model.* This model is an individual differences model (and equivalent to the IDIOSCAL model). Each source has an individual space that is equal to a differential rotation of the common space, followed by a differential weighting of the dimensions.

- If IDENTITY is specified for only one source, this subcommand is silently ignored.
- If an individual differences model is specified for only one source, a warning is issued, and the model is set to IDENTITY.

Example

```
PREFSCAL var01 TO var15
  /INPUT = SOURCES(6)
  /MODEL = WEIGHTED.
```

- A weighted Euclidean model is fitted for the six specified sources. As indicated on the INPUT subcommand, the number of cases must be dividable by 6 in this case.

RESTRICTIONS Subcommand

PREFSCAL allows (some) coordinates to be fixed in the common space configuration. Fixing an entire set (all row objects or all column objects) corresponds to performing external unfolding.

ROW *Row restriction.* PREFSCAL allows one row object, multiple row objects, or all row objects to be free (NONE) or fixed to given coordinates (COORDINATES).

COLUMN *Column restriction.* PREFSCAL allows one column object, multiple column objects, or all column objects to be free (NONE) or fixed to given coordinates (COORDINATES).

ROW or COLUMN Keywords

NONE *No restriction.* The specified set of objects (ROW or COLUMN) has no restriction.

COORDINATES Coordinates must be followed by a filespec in parentheses to specify the external SPSS data file that contains the fixed coordinates for the specified set of objects. Following the parenthesized filespec, a variable list can be given. If the variable list is omitted, the procedure automatically selects the first *MAXDIM* variables in the external SPSS data file, where *MAXDIM* is the maximum number of dimensions that are requested for the analysis on /CRITERIA = DIMENSIONS(min, max).

The number of cases for each variable in the external SPSS data file must be equal to the number of objects of the specified set (ROW or COLUMN).

A missing value can be used to indicate that the coordinate on that dimension is free. The coordinates of objects with nonmissing values are kept fixed during the analysis.

Example

```
PREFSCAL var01 TO var15
  /RESTRICTIONS = ROW(NONE)
  /RESTRICTIONS = COLUMN(COORDINATES ("indcol.sav")).
```

- In this example, there are 15 column objects.

- The coordinates of the row objects are not restricted. Although this specification is the default, it is explicitly stated here in the syntax.
- The column objects have restrictions on the coordinates. The fixed coordinates are specified in the SPSS data file *indcol.sav*. If *indcol.sav* contains more than two variables, only the first two variables are taken as fixed coordinates, because the maximum dimensionality is 2, and specific variables on the RESTRICTIONS subcommand are not given.

PENALTY Subcommand

The PENALTY subcommand specifies the values for the penalty parameters. The two keywords can be used to set the strength and the range of the penalty. The penalty itself is based on the coefficient of variation of the transformed proximities.

LAMBDA *Strength parameter.* This parameter sets the strength of the penalty. The default value is 0.75. The range of this parameter is between 0 (exclusive) and 1 (inclusive). The smaller the values of lambda, the stronger the penalty (and vice versa).

OMEGA *Range parameter.* This parameter sets the range of the penalty (that is, the moment the penalty becomes active). The parameter must have a non-negative value. If OMEGA is 0, the penalty is inactive. Increasing OMEGA provides a more active penalty. By default (OMEGA = 1.0), the range is equal to the variation coefficient of the original proximities. If OMEGA is increased, the function will search for a solution with a higher variation of the transformed proximities

Example

```
PREFSCAL var01 TO var09
  /PENALTY = LAMBDA(0.5)
             OMEGA(2.0).
```

- In this example, the variation range is increased by setting OMEGA equal to 2.0.

CRITERIA Subcommand

You can use CRITERIA to set the dimensionality and criteria for terminating the algorithm. You can specify one or more of the following keywords:

DIMENSIONS(min,max) *Minimum and maximum number of dimensions.* By default, PREFSCAL computes a solution in two dimensions. The minimum and maximum number of dimensions can be any integer between 1 and the number of objects minus 1 inclusive, as long as the minimum is less than or equal to the maximum. PREFSCAL starts computing a solution in the largest dimensionality and reduces the dimensionality in steps of one, until the lowest dimensionality is reached. Specifying a single value represents both minimum and maximum number of dimensions; thus, DIMENSIONS(4) is equivalent to DIMENSIONS(4,4).

MAXITER(n) *Maximum number of iterations.* By default, *n*=5000, specifying the maximum number of iterations that are performed while one of the convergence criteria below (DIFFSTRESS and MINSTRESS) is not reached. Decreasing this number might give less accurate results, but will take less time. The value *n* must have a non-negative integer value.

DIFFSTRESS *Convergence criterion.* PREFSCAL minimizes the goodness-of-fit index "penalized Stress." By default, PREFSCAL stops iterating when the relative difference in consecutive penalized Stress values is less than or equal to 0.000001. To obtain a more accurate solution, you can specify a smaller value. The specified value must be nonnegative.

MINSTRESS *Minimum Stress value.* By default, PREFSCAL stops iterating when the penalized Stress value itself is small (that is, less than or equal to 0.001). To obtain a more accurate solution, you can specify a smaller value. The specified value must be nonnegative.

Example

```
PREFSCAL var01 TO var15
  /CRITERIA = DIMENSIONS(2,4) MAXITER(10000) DIFFSTRESS(1.0E-8).
```

- The maximum number of dimensions equals 4, and the minimum number of dimensions equals 2. PREFSCAL computes a four-dimensional, three-dimensional, and two-dimensional solution, respectively.
- The maximum number of iterations is set to 10000.
- The relative difference in penalized Stress convergence criterion is sharpened to 1.0E-8.

PRINT Subcommand

The PRINT subcommand controls the display of tables. By default, PREFSCAL displays the Stress and fit values for each analysis, the coordinates of the common space, and, if applicable, the individual space weights.

- Omitting the PRINT subcommand or specifying PRINT without keywords is equivalent to specifying COMMON and WEIGHTS.
- If a keyword(s) is specified, only the output for that particular keyword(s) is displayed.
- Inapplicable keywords are silently ignored. That is, a specified keyword for which no output is available—for example, the keyword INDIVIDUAL with only one source specified—will be silently ignored.

NONE *No optional output.* Displays only the penalized Stress and corresponding fit values.

INPUT *Input data.* Displays tables of the original proximities and, if present, the data weights, the initial configuration, and the fixed coordinates.

MULTIPLE *Multiple random starts.* Displays the random number seed and penalized Stress value of each random start.

INITIAL *Initial common space.* Displays the coordinates of the initial common space.

HISTORY *History of iterations.* Displays the history of iterations of the main algorithm.

MEASURES *Fit measures.* Displays different measures. The table contains several goodness-of-fit, badness-of-fit, Stress, and fit values. This setting is specified by default.

DECOMPOSITION *Decomposition of Stress.* Displays a objects, rows, and sources decomposition of penalized Stress, including row, column, and source totals.

COMMON *Common space.* Displays the coordinates of the common space. This is specified by default.

DISTANCES	*Distances.* Displays the distances between the objects in the configuration. This keyword must be used in combination with COMMON or INDIVIDUAL to actually produce a table with distances.
WEIGHTS	*Individual space weights.* Displays the individual space weights, if applicable (that is, if one of the individual differences models is specified on the MODEL subcommand). Depending on the model, the space weights are decomposed in rotation weights and dimension weights, which are also displayed. This setting is specified by default.
INDIVIDUAL	*Individual spaces.* The coordinates of the individual spaces are displayed only if one of the individual differences models is specified on the MODEL subcommand.
TRANSFORMATION	*Transformed proximities.* Displays the transformed proximities.

Example

```
PREFSCAL var01 TO var15
  /INPUT = ROWS(42)
  /MODEL = WEIGHTED
  /PRINT = HISTORY COMMON MEASURES.
```

- Here, a weighted Euclidean model is specified with multiple sources.
- The optional output consists of a table with the history of iterations, the coordinates of the common space, and Stress and fit measures.

PLOT Subcommand

The PLOT subcommand controls the display of plots. By default, PREFSCAL displays the object points of the common space and, if applicable, the individual space weights.

- Omitting the PLOT subcommand or specifying PLOT without keywords produces the default plots.
- If a keyword(s) is specified, only the plot for that particular keyword(s) is displayed.
- Inapplicable keywords (for example, STRESS with equal minimum and maximum number of dimensions on the CRITERIA subcommand) are silently ignored.
- Multiple value lists are allowed for INDIVIDUAL, TRANSFORMATIONS, SHEPARD, FIT, and RESIDUALS. For each value list, a separate plot will be displayed.

NONE	*No plots.* PREFSCAL does not produce any plot.
MULTIPLE	*Multiple random starts.* Displays a stacked histogram of penalized Stress, displaying both Stress and penalty.
INITIAL	*Initial common space.* Displays a scatterplot matrix of the coordinates of the initial common space.
STRESS	*Scree plot.* Produces a lineplot of penalized Stress versus dimensions. This plot is only produced if the maximum number of dimensions is larger than the minimum number of dimensions.
COMMON	*Common space.* A scatterplot matrix of coordinates of the common space is displayed. This setting is the default.

WEIGHTS *Individual space weights.* A scatterplot is produced for the individual space weights. This setting is only applicable if one of the individual differences models is specified on the MODEL subcommand. For the weighted Euclidean model, the weights for all sources are displayed in a plot, with one dimension on each axis. For the generalized Euclidean model, one plot is produced per dimension, indicating both rotation and weighting of that dimension for each source.

INDIVIDUAL(valuelist) *Individual spaces.* The coordinates of the individual spaces are displayed in scatterplot matrices. This setting is only applicable if one of the individual differences models is specified on the MODEL subcommand. For each source that is specified on the value list, a scatterplot matrix of coordinates of the individual space is displayed. The sources are specified by a number between 1 and the total number of sources or is specified by a value from the sourceid, which is specified on the INPUT subcommand.

TRANSFORMATIONS(valuelist) *Transformation plots.* A line plot is produced of the original proximities versus the transformed proximities. On the value list, the names (identifiers) for which the plot is to be produced must be specified. Because the CONDITION subcommand allows for the specification of multiple transformation lists, the value lists depend on the conditionality. In case of row-conditional transformations, the names are row identifiers (either a number between 1 and the total number of rows, or a value from the rowid, which is specified on the INPUT subcommand). In the case of matrix-conditional transformations, the values indicate sources identifiers (either a number between 1 and the total number of sources, or a value from the sourceid, which is specified on the INPUT subcommand). An unconditional transformation only consists of one list and does not allow further specification.

SHEPARD(valuelist) *Shepard plots.* The original proximities versus both transformed proximities and distances. The distances are indicated by points, and the transformed proximities are indicated by a line. On the value list, the names (identifiers) for which the plot is to be produced must be specified. Because the CONDITION subcommand allows for the specification of multiple transformation lists, the value lists depend on the conditionality. In case of row-conditional transformations, the names are row identifiers (either a number between 1 and the total number of rows, or a value from the rowid, which is specified on the INPUT subcommand). In the case of matrix-conditional transformations, the values indicate sources identifiers (either a number between 1 and the total number of sources, or a value from the sourceid, which is specified on the INPUT subcommand). An unconditional transformation only consists of one list and does not allow further specification.

FIT(valuelist) *Scatterplots of Fit.* The transformed proximities versus the distances are plotted in a scatterplot. On the value list, the names (identifiers) of the sources for which the plot is to be produced must be specified. The sources are specified by a number between 1 and the total number of sources or are specified by a value from the sourceid, which is specified on the INPUT subcommand.

RESIDUALS(valuelist) *Residuals plots.* The transformed proximities versus the residuals (transformed proximities minus distances) are plotted in a scatterplot. On the value list, the names (identifiers) of the sources for which the plot is to be produced must be specified. The sources are specified by a number between 1 and the total number of sources or are specified by a value from the sourceid, which is specified on the INPUT subcommand.

Example

```
PREFSCAL var01 TO var15
  /INPUT = SOURCE(6)
  /MODEL = WEIGHTED
  /CRITERIA = DIMENSIONS(3)
  /PLOT = COMMON
          INDIVIDUAL(2)
          TRANSFORMATIONS(1 TO 42)(1 2)
          FIT(2).
```

- Here, the syntax specifies a weighted Euclidean model with six sources in three dimensions.
- COMMON produces a scatterplot matrix defined by dimensions 1, 2, and 3.
- A scatterplot matrix with threedimensions is produced only for the source 2.
- Two transformation plots are produced, one plot with all 42 rows and one plot with only row 1 and 2. Rows are specified with the TRANSFORMATIONS keyword because the default value on CONDITION is ROW.
- A scatterplot of fit is produced for the source 2.

OPTIONS Subcommand

The OPTIONS subcommand specifies additional markings for the row objects in plots. For this purpose, the values of variables are used to specify markers and colors for the row objects.

MARKERS(variable) *Row object markers.* The values of the variable are used to cycle through all possible markers.

COLORS(variable) *Row object colors.* The values of the variable are used to cycle through all colors.

Example

```
DATA LIST
  /var01 TO var15 rowid gender age.
PREFSCAL var01 TO var15
  /INPUT   = ROW(rowid)
```

```
/OPTIONS = MARKERS(gender) COLORS(age).
```

- In the joint plot of the common space configuration, the row objects are labeled with the values or value labels of the variable *rowid*. Additionally, the points are marked according to the values on the variable *gender* and are colored depending on the values of the variable *age*.

OUTFILE Subcommand

OUTFILE saves coordinates of the common space, individual space weights, distances, and transformed proximities to an SPSS data file or previously declared dataset (DATASET DECLARE command). The data file/dataset name must be different for each keyword.

COMMON ('savfile'|'dataset')
Common space coordinates. The coordinates of the common space. The columns (variables) represent the dimensions *DIM_1*, *DIM_2*, ..., *DIM_n* of the common space. The number of cases in the external file equals the total number of objects (row plus column objects).

WEIGHTS ('savfile'|'dataset')
Individual space weights. The individual space weights. The columns represent the dimensions *DIM_1*, *DIM_2*, …, *DIM_n* of the space weights. The number of cases depends on the individual differences model specified on the MODEL subcommand. The weighted Euclidean model uses diagonal weight matrices. Only the diagonals are written to file, and the number of cases is equal to the number of sources. The generalized Euclidean model has full-rank nonsingular weight matrices, one matrix for each source. The matrices are stacked beneath each other in the external SPSS data file. The number of cases equals the number of sources times the number of dimensions.

DISTANCES ('savfile'|'dataset')
Distances. The matrices containing the distances between the objects for each source are stacked beneath each other in the external SPSS data file. The number of variables in the data file is equal to the total number of objects (*ROW_1*, *ROW_2*, ..., *ROW_n*, *COL_1*, *COL_2*, …, *COL_m*). The number of cases in the data file is equal to the total number of objects times the number of sources.

TRANSFORMATION ('file'|'dataset')
Transformed proximities. The matrices containing the transformed proximities for each source are stacked beneath each other in the external SPSS data file. The number of variables in the external file is equal to the total number of objects (*ROW_1*, *ROW_2*, ..., *ROW_n*, *COL_1*, *COL_2*, …, *COL_m*). The number of cases in the external file is equal to the total number of objects times the number of sources.

Example

```
PREFSCAL var01 TO var15
  /OUTFILE = COMMON('/data/start.sav').
```

- Here, the coordinates of the common space are written to the external SPSS data file *start.sav*.
- Filenames should be enclosed in quotes and are stored in the working directory unless a path is included as part of the file specification. datasets are available during the current session but are not available in subsequent sessions unless you explicitly save them as data files.

PRESERVE

```
PRESERVE
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Overview

PRESERVE stores current SET specifications that can later be restored by the RESTORE command. PRESERVE and RESTORE are especially useful with the macro facility. PRESERVE-RESTORE sequences can be nested up to five levels.

Basic Specification

The only specification is the command keyword. PRESERVE has no additional specifications.

Limitations

PRESERVE does not store SET THREADS and SET MCACHE settings.

Example

```
GET FILE=PRSNNL.
FREQUENCIES VAR=DIVISION /STATISTICS=ALL.
PRESERVE.
SET WIDTH=90 UNDEFINED=NOWARN BLANKS=000 CASE=UPLOW.
SORT CASES BY DIVISION.
REPORT FORMAT=AUTO LIST /VARS=LNAME FNAME DEPT SOCSEC SALARY
  /BREAK=DIVISION /SUMMARY=MEAN.
RESTORE.
```

- GET reads the SPSS-format data file *PRSNNL*.
- FREQUENCIES requests a frequency table and all statistics for the variable *DIVISION*.
- PRESERVE stores all current SET specifications.
- SET changes several subcommand settings.
- REPORT requests a report that is organized by the variable *DIVISION*.
- RESTORE reestablishes the SET specifications that were in effect when PRESERVE was specified.

PRINCALS

PRINCALS is available in the Categories option.

```
PRINCALS VARIABLES=varlist(max)

[/ANALYSIS=varlist[({ORDI**})]]
                    {SNOM  }
                    {MNOM  }
                    {NUME  }

[/NOBSERVATIONS=value]

[/DIMENSION={2**  }]
            {value}

[/MAXITER={100**}]
          {value}

[/CONVERGENCE={.00001**}]
              {value   }

[/PRINT=[DEFAULT] [FREQ**] [EIGEN**] [LOADINGS**] [QUANT]
        [HISTORY] [CORRELATION] [OBJECT] [ALL] [NONE]]

[/PLOT=[NDIM=({1    ,2    }**)]
              {value,value}
              {ALL  ,MAX  }
       [DEFAULT[(n)]] [OBJECT**[(varlist)][(n)]]
       [QUANT**[(varlist)][(n)]] [LOADINGS[(n)]]
       [ALL[(n)]] [NONE]]

[/SAVE=[rootname] [(value}]

[/MATRIX=OUT({*   })]
             {'file'|'dataset'}
```

**Default if the subcommand or keyword is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Overview

PRINCALS (*princ*ipal *c*omponents analysis by means of *a*lternating *l*east *s*quares) analyzes a set of variables for major dimensions of variation. The variables can be of mixed optimal scaling levels, and the relationships among observed variables are not assumed to be linear.

Options

Optimal Scaling Level. You can specify the optimal scaling level for each variable to be used in the analysis.

Number of Cases. You can restrict the analysis to the first *n* observations.

Number of Dimensions. You can specify how many dimensions PRINCALS should compute.

Iterations and Convergence. You can specify the maximum number of iterations and the value of a convergence criterion.

Display Output. The output can include all available statistics, only the default statistics, or only the specific statistics you request. You can also control whether some of these statistics are plotted.

Saving Scores. You can save object scores in the active dataset.

Writing Matrices. You can write a matrix data file containing category quantifications and loadings for use in further analyses.

Basic Specification

- The basic specification is the PRINCALS command and the VARIABLES subcommand. PRINCALS performs the analysis assuming an ordinal level of optimal scaling for all variables and uses all cases to compute a two-dimensional solution. By default, marginal frequencies, eigenvalues, and summary measures of fit and loss are displayed, and quantifications and object scores are plotted.

Subcommand Order

- The VARIABLES subcommand must precede all others.
- Other subcommands can appear in any order.

Operations

- If the ANALYSIS subcommand is specified more than once, PRINCALS is not executed. For all other subcommands, only the last occurrence of each subcommand is executed.
- PRINCALS treats every value in the range of 1 to the maximum value specified on VARIABLES as a valid category. Use the AUTORECODE or RECODE command if you want to recode a categorical variable with nonsequential values or with a large number of categories to avoid unnecessary output. For variables treated as numeric, recoding is *not* recommended because the intervals between consecutive categories will not be maintained.

Limitations

- String variables are not allowed; use AUTORECODE to recode nominal string variables into numeric ones before using PRINCALS.
- The data must be positive integers. Zeros and negative values are treated as system-missing and are excluded from the analysis. Fractional values are truncated after the decimal and are included in the analysis. If one of the levels of a categorical variable has been coded 0 or a negative value and you want to treat it as a valid category, use the AUTORECODE or RECODE command to recode the values of that variable (see AUTORECODE and RECODE for more information).
- PRINCALS ignores user-missing value specifications. Positive user-missing values less than the maximum value on the VARIABLES subcommand are treated as valid category values and are included in the analysis. If you do not want the category included, you can use COMPUTE or RECODE to change the value to something outside of the valid range. Values outside of the range (less than 1 or greater than the maximum value) are treated as system-missing.

Example

```
PRINCALS VARIABLES=ACOLA BCOLA(2) PRICEA PRICEB(5)
/ANALYSIS=ACOLA BCOLA(SNOM) PRICEA PRICEB(NUME)
/PRINT=QUANT OBJECT.
```

- VARIABLES defines the variables and their maximum number of levels.
- The ANALYSIS subcommand specifies that variables *ACOLA* and *BCOLA* are single nominal (SNOM) and that variables *PRICEA* and *PRICEB* are numeric (NUME).
- The PRINT subcommand lists the category quantifications and object scores.
- By default, plots of the category quantifications and the object scores are produced.

VARIABLES Subcommand

VARIABLES specifies all of the variables that will be used in the current PRINCALS procedure.

- The VARIABLES subcommand is required and precedes all other subcommands. The actual word VARIABLES can be omitted.
- Each variable or variable list is followed by the maximum number of categories (levels) in parentheses.
- The number specified in parentheses indicates the number of categories *and* the maximum category value. For example, *VAR1(3)* indicates that *VAR1* has three categories coded 1, 2, and 3. However, if a variable is not coded with consecutive integers, the number of categories used in the analysis will differ from the number of observed categories. For example, if a three category variable is coded {2, 4, 6}, the maximum category value is 6. The analysis treats the variable as having six categories, three of which are not observed and receive quantifications of 0.
- To avoid unnecessary output, use the AUTORECODE or RECODE command before PRINCALS to recode a categorical variable that was coded with nonsequential values. As noted in "Limitations," recoding is *not* recommended with variables treated as numeric (see AUTORECODE and RECODE for more information).

Example

```
DATA LIST FREE/V1 V2 V3.
BEGIN DATA
3 1 1
6 1 1
3 1 3
3 2 2
3 2 2
6 2 2
6 1 3
6 2 2
3 2 2
6 2 1
END DATA.
AUTORECODE V1 /INTO NEWVAR1.
PRINCALS VARIABLES=NEWVAR1 V2(2) V3(3).
```

- DATA LIST defines three variables, *V1*, *V2*, and *V3*.

- *V1* has two levels, coded 3 and 6, *V2* has two levels, coded 1 and 2, and *V3* has three levels, coded 1, 2, and 3.
- The AUTORECODE command creates *NEWVAR1* containing recoded values of *V1*. Values of 3 are recoded to 1, and values of 6 are recoded to 2.
- A maximum value of 2 can then be specified on the VARIABLES subcommand as the maximum category value for both *NEWVAR1* and *V2*. A maximum value of 3 is specified for *V3*.

ANALYSIS Subcommand

ANALYSIS specifies the variables to be used in the computations and the optimal scaling level used by PRINCALS to quantify each variable or variable list.

- If ANALYSIS is not specified, an ordinal level of optimal scaling is assumed for all variables.
- The specification on ANALYSIS is a variable list and an optional keyword in parentheses to indicate the optimal scaling level.
- The variables on the variable list must also be specified on the VARIABLES subcommand.
- Variables listed on the VARIABLES subcommand but not on the ANALYSIS subcommand can still be used to label object scores on the PLOT subcommand.

The following keywords can be specified to indicate the optimal scaling level:

MNOM	*Multiple nominal*. The quantifications can be different for each dimension. When all variables are multiple nominal, PRINCALS gives the same results as HOMALS.
SNOM	*Single nominal*. PRINCALS gives only one quantification for each category. Objects in the same category (cases with the same value on a variable) obtain the same quantification. When DIMENSION=1 and all variables are SNOM, this solution is the same as that of the first HOMALS dimension.
ORDI	*Ordinal*. This is the default for variables listed without optimal scaling levels and for all variables if the ANALYSIS subcommand is not used. The order of the categories of the observed variable is preserved in the quantified variable.
NUME	*Numerical*. This is the interval or ratio level of optimal scaling. PRINCALS assumes that the observed variable already has numerical values for its categories. When all variables are at the numerical level, the PRINCALS analysis is analogous to classical principal components analysis.

These keywords can apply to a variable list as well as to a single variable. Thus, the default ORDI is not applied to a variable without a keyword if a subsequent variable on the list has a keyword.

NOBSERVATIONS Subcommand

NOBSERVATIONS specifies how many cases are used in the analysis.

- If NOBSERVATIONS is not specified, all available observations in the active dataset are used.
- NOBSERVATIONS is followed by an integer indicating that the first *n* cases are to be used.

DIMENSION Subcommand

DIMENSION specifies the number of dimensions that you want PRINCALS to compute.

- If you do not specify the DIMENSION subcommand, PRINCALS computes two dimensions.
- DIMENSION is followed by an integer indicating the number of dimensions.
- If all of the variables are SNOM (single nominal), ORDI (ordinal), or NUME (numerical), the maximum number of dimensions you can specify is the smaller of the number of observations minus 1 *or* the total number of variables.
- If some or all of the variables are MNOM (multiple nominal), the maximum number of dimensions is the smaller of the number of observations minus 1 *or* the total number of valid MNOM variable levels (categories) plus the number of SNOM, ORDI, and NUME variables, minus the number of MNOM variables without missing values.
- PRINCALS adjusts the number of dimensions to the maximum if the specified value is too large.
- The minimum number of dimensions is 1.

MAXITER Subcommand

MAXITER specifies the maximum number of iterations PRINCALS can go through in its computations.

- If MAXITER is not specified, PRINCALS will iterate up to 100 times.
- MAXITER is followed by an integer indicating the maximum number of iterations allowed.

CONVERGENCE Subcommand

CONVERGENCE specifies a convergence criterion value. PRINCALS stops iterating if the difference in total fit between the last two iterations is less than the CONVERGENCE value.

- If CONVERGENCE is not specified, the default value is 0.00001.
- The specification on CONVERGENCE is a convergence criterion value.

PRINT Subcommand

PRINT controls which statistics are included in your output. The default output includes frequencies, eigenvalues, loadings, and summary measures of fit and loss.

PRINT is followed by one or more of the following keywords:

FREQ	*Marginal frequencies for the variables in the analysis*.
HISTORY	*History of the iterations*.
EIGEN	*Eigenvalues*.
CORRELATION	*Correlation matrix for the transformed variables in the analysis*. No correlation matrix is produced if there are any missing data.
OBJECT	*Object scores*.
QUANT	*Category quantifications and category coordinates for SNOM, ORDI, and NUME variables and category quantifications in each dimension for MNOM variables*.
LOADINGS	*Component loadings for SNOM, ORDI, and NUME variables*.

DEFAULT	*FREQ, EIGEN, LOADINGS, and QUANT*.
ALL	*All of the available statistics*.
NONE	*Summary measures of fit*.

PLOT Subcommand

PLOT can be used to produce plots of category quantifications, object scores, and component loadings.

- If PLOT is not specified, plots of the object scores and the quantifications are produced.
- No plots are produced for a one-dimensional solution.

PLOT is followed by one or more of the following keywords:

LOADINGS	*Plots of the component loadings of SNOM, ORDI, and NUME variables*.
OBJECT	*Plots of the object scores*.
QUANT	*Plots of the category quantifications for MNOM variables and plots of the single-category coordinates for SNOM, ORDI, and NUME variables*.
DEFAULT	*QUANT and OBJECT*.
ALL	*All available plots*.
NONE	*No plots*.

- The keywords OBJECT and QUANT can each be followed by a variable list in parentheses to indicate that plots should be labeled with these variables. For QUANT, the variables must be specified on both the VARIABLES and ANALYSIS subcommands. For OBJECT, the variables must be specified on VARIABLES but need not appear on the ANALYSIS subcommand. This means that variables not included in the computations can still be used to label OBJECT plots. If the variable list is omitted, only the default plots are produced.
- Object scores plots labeled with variables that appear on the ANALYSIS subcommand use category labels corresponding to all categories within the defined range. Objects in a category that is outside the defined range are labeled with the label corresponding to the next category greater than the defined maximum category.
- Object scores plots labeled with variables not included on the ANALYSIS subcommand use all category labels, regardless of whether or not the category value is inside the defined range.
- All of the keywords except NONE can be followed by an integer in parentheses to indicate how many characters of the variable or value label are to be used on the plot. (If you specify a variable list after OBJECT or QUANT, you can specify the value in parentheses after the list.) The value can range from 1 to 20. If the value is omitted, 12 characters are used. Spaces between words count as characters.
- The LOADINGS plots and one of the QUANT plots use variable labels; all other plots that use labels use value labels.
- If a variable label is missing, the variable name is used for that variable. If a value label is missing, the actual value is used.
- You should make sure that your variable and value labels are unique by at least one letter in order to distinguish them on the plots.

- When points overlap, the points involved are described in a summary following the plot.

Example

```
PRINCALS VARIABLES COLA1 (4) COLA2 (4) COLA3 (4) COLA4 (2)
/ANALYSIS COLA1 COLA2 (SNOM) COLA3 (ORDI) COLA4 (ORDI)
/PLOT OBJECT(COLA4).
```

- Four variables are included in the analysis.
- OBJECT requests a plot of the object scores labeled with the values of *COLA4*. Any object whose *COLA4* value is not 1 or 2 is labeled 3 (or the value label for category 3, if defined).

Example

```
PRINCALS VARIABLES COLA1 (4) COLA2 (4) COLA3 (4) COLA4 (2)
/ANALYSIS COLA1 COLA2 (SNOM) COLA3 (ORDI)
/PLOT OBJECT(COLA4).
```

- Three variables are included in the analysis.
- OBJECT requests a plot of the object scores labeled with the values of *COLA4,* a variable not included in the analysis. Objects are labeled using all values of *COLA4.*

In addition to the plot keywords, the following can be specified:

NDIM *Dimension pairs to be plotted.* NDIM is followed by a pair of values in parentheses. If NDIM is not specified, plots are produced for dimension 1 versus dimension 2.

- The first value indicates the dimension that is plotted against all higher dimensions. This value can be any integer from 1 to the number of dimensions minus 1.
- The second value indicates the highest dimension to be used in plotting the dimension pairs. This value can be any integer from 2 to the number of dimensions.
- The keyword ALL can be used instead of the first value to indicate that all dimensions are paired with higher dimensions.
- The keyword MAX can be used instead of the second value to indicate that plots should be produced up to, and including, the highest dimension fit by the procedure.

Example

```
PRINCALS COLA1 COLA2 COLA3 COLA4 (4)
/PLOT NDIM(1,3) QUANT(5).
```

- The NDIM(1,3) specification indicates that plots should be produced for two dimension pairs—dimension 1 versus dimension 2 and dimension 1 versus dimension 3.
- QUANT requests plots of the category quantifications. The (5) specification indicates that the first five characters of the value labels are to be used on the plots.

Example

```
PRINCALS COLA1 COLA2 COLA3 COLA4 (4)
```

```
/PLOT NDIM(ALL,3) QUANT(5).
```

- This plot is the same as above except for the ALL specification following NDIM. This indicates that all possible pairs up to the second value should be plotted, so QUANT plots will be produced for dimension 1 versus dimension 2, dimension 2 versus dimension 3, and dimension 1 versus dimension 3.

SAVE Subcommand

SAVE lets you add variables containing the object scores computed by PRINCALS to the active dataset.

- If SAVE is not specified, object scores are not added to the active dataset.
- A variable rootname can be specified on the SAVE subcommand to which PRINCALS adds the number of the dimension. Only one rootname can be specified, and it can contain up to six characters.
- If a rootname is not specified, unique variable names are automatically generated. The variable names are *PRIn_m*, where *n* is a dimension number and *m* is a set number. If three dimensions are saved, the first set of names is *PRI1_1*, *PRI2_1*, and *PRI3_1*. If another PRINCALS is then run, the variable names for the second set are *PRI1_2*, *PRI2_2*, *PRI3_2*, and so on.
- Following the name, the number of dimensions for which you want to save object scores can be listed in parentheses. The number cannot exceed the value of the DIMENSION subcommand.
- If the number of dimensions is not specified, the SAVE subcommand saves object scores for all dimensions.
- If you replace the active dataset by specifying an asterisk (*) on a MATRIX subcommand, the SAVE subcommand is not executed.
- The prefix should be unique for each PRINCALS command in the same session. If it is not, PRINCALS replaces the prefix with *DIM*, *OBJ*, or *OBSAVE*. If all of these already exist, SAVE is not executed.

Example

```
PRINCALS CAR1 CAR2 CAR3(5) PRICE (10)
/ANALYSIS=CAR1 TO CAR3(SNOM) PRICE(NUM)
/DIMENSIONS=3
/SAVE=DIM(2).
```

- Three nominal variables, *CAR1*, *CAR2*, and *CAR3*, each with five categories, and one numerical (interval level) variable, with ten categories, are analyzed in this PRINCALS example.
- The DIMENSIONS subcommand requests results for three dimensions.
- SAVE adds the object scores from the first two dimensions to the active dataset. The names of these new variables will be *DIM00001* and *DIM00002*, respectively.

MATRIX Subcommand

The MATRIX subcommand is used to write category quantifications, single-category coordinates, and component loadings to a matrix data file.

- The specification on MATRIX is the keyword OUT and a quoted file specification of previously declared dataset name (DATASET DECLARE command), enclosed in parentheses.
- You can specify an asterisk (*) instead of a file to replace the active dataset .
- The category quantifications, coordinates, and component loadings are written to the same file.
- The matrix data file has one case for each value of each original variable.

The variables of the matrix data file and their values are:

ROWTYPE_ *String variable rowtype_ containing value QUANT for the category quantifications, SCOOR_ for single-category coordinates, MCOOR_ for multiple-category coordinates, and LOADING_ for the component scores*.

LEVEL *String variable containing the values (or value labels if present) of each original variable for category quantifications.* For cases with *ROWTYPE_=LOADING_*, the value of *LEVEL* is blank.

VARNAME_ *String variable containing the original variable names*.

VARTYPE_ *String variable containing values MULTIPLE, SINGLE N, ORDINAL, or NUMERICAL, depending on the optimal scaling level specified for the variable*.

DIM1...DIMn *Numeric variables containing category quantifications, the single-category coordinates, and component loadings for each dimension*. Each variable is labeled *DIMn*, where *n* represents the dimension number. The single-category coordinates and component loadings are written only for SNOM, ORDI, and NUME variables.

PRINT

```
PRINT [OUTFILE=file] [ENCODING='encoding specification']
  [RECORDS={1}] [{NOTABLE}]
            {n}   {TABLE  }

 /{1    } varlist [{col location [(format)]}] [varlist...]
  {rec #}          {(format list)          }
                   {*                      }

 [/{2    }...]
   {rec #}
```

This command does not read the active dataset. It is stored, pending execution with the next command that reads the dataset. For more information, see Command Order on p. 36.

Release History

Release 16.0

- ENCODING subcommand added for Unicode support.

Example

```
PRINT / MOHIRED YRHIRED DEPT SALARY NAME.
```

Overview

PRINT displays the values of variables for each case in the data. PRINT is simple enough for a quick check on data definitions and transformations and flexible enough for formatting simple reports.

Options

Formats. You can specify formats for the variables (see Formats on p. 1458).

Strings. You can specify string values within the variable specifications. The strings can be used to label values or to create extra space between values. Strings can also be used as column headings. (See Strings on p. 1459.)

Output File. You can use the OUTFILE subcommand to direct the output to a specified file.

Summary Table. You can use the TABLE subcommand to display a table that summarizes variable formats.

Basic Specification

The basic specification is a slash followed by a variable list. The output displays values for all variables that are named on the list.

Subcommand Order

Subcommands can be specified in any order. However, all subcommands must be specified before the slash that precedes the start of the variable specifications.

Syntax Rules

- A slash must precede the variable specifications. The first slash begins the definition of the first (and possibly only) line per case of the PRINT display.
- Specified variables must already exist, but they can be numeric, string, scratch, temporary, or system variables. Subscripted variable names, such as *X(1)* for the first element in vector *X,* cannot be used.
- Keyword ALL can be used to display the values of all user-defined variables in the active dataset.

Operations

- PRINT is executed once for each case that is constructed from the data file.
- PRINT is a transformation and is not executed unless it is followed by a procedure or the EXECUTE command.
- Because PRINT is a transformation command, the output might be mixed with casewise procedure output. Procedures that produce individual case listings (such as LIST) should not be used immediately after PRINT. An intervening EXECUTE or procedure command should be specified.
- Values are displayed with a blank space between them. However, if a format is specified for a variable, the blank space for that variable's values is suppressed.
- Values are displayed in the output as the data are read. The PRINT output appears before the output from the first procedure.
- If more variables are specified than can be displayed in 132 columns or within the width that is specified on SET WIDTH, the program displays an error message. You must reduce the number of variables or split the output into several records.
- User-missing values are displayed exactly like valid values. System-missing values are represented by a period.

Examples

Displaying Values for a Selected List of Variables

```
PRINT  / MOHIRED YRHIRED DEPT SALARY NAME.
FREQUENCIES VARIABLES=DEPT.
```

- PRINT displays values for each variable on the variable list. The FREQUENCIES procedure reads the data and causes PRINT to be executed.
- All variables are displayed by using their dictionary formats. One blank space separates the values of each variable.

Displaying Values for All User-Defined Variables

```
PRINT /ALL.
EXECUTE.
```

- PRINT displays values for all user-defined variables in the active dataset. The EXECUTE command executes PRINT.

Formats

By default, PRINT uses the dictionary print formats. You can specify formats for some or all variables that are specified on PRINT. For a string variable, the specified format must have a width at least as large as the width of the dictionary format. String values are truncated if the specified width is smaller than the width of the dictionary format.

- Format specifications can be either column-style or FORTRAN-like (see DATA LIST). The column location that is specified with column-style formats or that is implied with FORTRAN-like formats refers to the column in which the variable will be displayed.
- A format specification following a list of variables applies to all variables in the list. Use an asterisk to prevent the specified format from applying to variables that precede the asterisk. The specification of column locations implies a default print format, and that format applies to all previous variables if no asterisk is used.
- Printable numeric formats are F, COMMA, DOLLAR, CC, DOT, N, E, PCT, PIBHEX, RBHEX, Z, and the date and time formats. Printable string formats are A and AHEX. Note that hex and binary formats use different widths. For example, the AHEX format must have a width that is twice the width of the corresponding A format. For more information about specifying formats and more information about the available formats, see DATA LIST and Variable Types and Formats on p. 49.
- Format specifications are in effect only for the PRINT command. The specifications do not change the dictionary print formats.
- When a format is specified for a variable, the automatic blank following the variable in the output is suppressed. To preserve the blank between variables, use a string (see Strings on p. 1459), specify blank columns in the format, or use an X or T format element (see DATA LIST for information about X and T).

Example

```
PRINT / TENURE (F2.0) ' ' MOHIRED YRHIRED DEPT *
        SALARY85 TO SALARY88 (4(DOLLAR8,1X)) NAME.
EXECUTE.
```

- Format F2.0 is specified for *TENURE*. A blank string is specified after *TENURE* because the automatic blank following the variable is suppressed by the format specification.
- *MOHIRED, YRHIRED,* and *DEPT* are displayed with default formats because the asterisk prevents them from receiving the DOLLAR8 format that is specified for *SALARY85* to *SALARY88*. The automatic blank is preserved for *MOHIRED, YRHIRED,* and *DEPT*, but the blank is suppressed for *SALARY85* to *SALARY88* by the format specification. The 1X format

element is therefore specified with DOLLAR8 to add one blank after each value of *SALARY85* to *SALARY88*.

- NAME uses the default dictionary format.

Strings

You can specify string values within the variable list. Strings must be enclosed in quotes.

- If a format is specified for a variable list, the application of the format is interrupted by a specified string. Thus, the string has the same effect within a variable list as an asterisk.
- Strings can be used to create column headings for the displayed variables. The PRINT command that specifies the column headings must be used within a DO IF-END IF structure. If you want the column headings to begin a new page in the output, use a PRINT EJECT command (rather than PRINT) to specify the headings (see PRINT EJECT).

Including Strings in the Output

```
PRINT / NAME 'HIRED=' MOHIRED(F2) '/' YRHIRED
             '  SALARY=' SALARY (DOLLAR8).
EXECUTE.
```

- Three strings are specified. The strings HIRED= and SALARY= label the values being displayed. The slash that is specified between *MOHIRED* and *YRHIRED* creates a composite hiring date. The F2 format is supplied for variable *MOHIRED* in order to suppress the blank that would follow it if the dictionary format were used.
- *NAME* and *YRHIRED* are displayed with default formats. The 'HIRED=' specification prevents the F2 format from applying to *NAME*, and the 'SALARY=' specification prevents the DOLLAR8 format from applying to *YRHIRED*.

Setting Up Column Headers

```
DO IF $CASENUM EQ 1.
PRINT /'   NAME ' 1 'DEPT' 25 'HIRED' 30 '  SALARY' 35.
END IF.
PRINT / NAME DEPT *
        MOHIRED 30-31 '/' YRHIRED *
        SALARY 35-42(DOLLAR).
EXECUTE.
```

- The first PRINT command specifies strings only. The integer after each string specifies the beginning column number of the string. The strings will be used as column headings for the variables. DO IF $CASENUM EQ 1 causes the first PRINT command to be executed only once, as the first case is processed. END IF closes the structure.
- The second PRINT command specifies the variables to be displayed. This command is executed once for each case in the data. Column locations are specified to align the values with the column headings. In this example, the T format element could also have been used

to align the variables and the column headings. For example, `MOHIRED (T30,F2)` begins the display of values for variable *MOHIRED* in column 30.

- The asterisk after *DEPT* prevents the format that is specified for *MOHIRED* from applying to *NAME* and *DEPT*. The asterisk after *YRHIRED* prevents the format that is specified for *SALARY* from applying to *YRHIRED*.

RECORDS Subcommand

`RECORDS` indicates the total number of lines that are displayed per case. The number that is specified on `RECORDS` is informational only. The actual specification that causes variables to be displayed on a new line is a slash within the variable specifications. Each new line is requested by another slash.

- `RECORDS` must be specified before the slash that precedes the start of the variable specifications.
- The only specification on `RECORDS` is an integer to indicate the number of records for the output. If the number does not agree with the actual number of records that are indicated by slashes, the program issues a warning and ignores the specification on `RECORDS`.
- Specifications for each line of output must begin with a slash. An integer can follow the slash, indicating the line on which values are to be displayed. The integer is informational only and cannot be used to rearrange the order of records in the output. If the integer does not agree with the actual record number that is indicated by the number of slashes in the variable specifications, the integer is ignored.
- A slash that is not followed by a variable list generates a blank line in the output.

Examples

```
PRINT RECORDS=3 /EMPLOYID NAME DEPT
                /EMPLOYID TENURE SALARY
                /.
EXECUTE.
```

- `PRINT` displays the values of an individual's name and department on one line, displays tenure and salary on the next line, and displays the employee identification number on both lines, followed by a blank third line. Two lines are displayed for each case, and cases in the output are separated by a blank line.

```
PRINT RECORDS=3 /1 EMPLOYID NAME DEPT
                /2 EMPLOYID TENURE SALARY
                /3.
```

- This `PRINT` command is equivalent to the command in the preceding example.

```
PRINT / EMPLOYID NAME DEPT / EMPLOYID TENURE SALARY /.
```

- This `PRINT` command is equivalent to the commands in the two preceding examples.

OUTFILE Subcommand

OUTFILE specifies a file for the output from the PRINT command. By default, PRINT output is included with the rest of the output from the session.

- OUTFILE must be specified before the slash that precedes the start of the variable specifications.
- The output from PRINT cannot exceed 132 characters, even if the external file is defined with a longer record length.

Example

```
PRINT OUTFILE=PRINTOUT
   /1 EMPLOYID DEPT SALARY /2 NAME.
EXECUTE.
```

- OUTFILE specifies *PRINTOUT* as the file that receives the PRINT output.

ENCODING Subcommand

ENCODING specifies the encoding format of the file. The keyword is followed by an equals sign and a quoted encoding specification.

- In Unicode mode, the default is UTF8. For more information, see SET command, UNICODE subcommand.
- In code page mode, the default is the current locale setting. For more information, see SET command, LOCALE subcommand.
- The quoted encoding value can be: Locale (the current locale setting), UTF8, UTF16, UTF16BE (big endian), UTF16LE (little endian), a numeric Windows code page value (for example, '1252'), or an IANA code page value (for example, 'iso8859-1' or cp1252).
- If there is no OUTFILE subcommand, the ENCODING subcommand is ignored.

TABLE Subcommand

TABLE requests a table that shows how the variable information is formatted. NOTABLE, which suppresses the format table, is the default.

- TABLE must be specified before the slash that precedes the start of the variable specifications.

Example

```
PRINT TABLE /1 EMPLOYID DEPT SALARY /2  NAME.
EXECUTE.
```

- TABLE requests a summary table that describes the PRINT specifications. The table is included with the PRINT output.

PRINT EJECT

```
PRINT EJECT [OUTFILE='file'] [ENCODING='encoding specification']
  [RECORDS={1}] [{NOTABLE}]
            {n}   {TABLE  }

  /{1    } varlist [{col location [(format)]}] [varlist...]
   {rec #}          {(format list)          }
                    {*                      }

 [/{2    }...]
   {rec #}
```

This command does not read the active dataset. It is stored, pending execution with the next command that reads the dataset. For more information, see Command Order on p. 36.

Release History

Release 16.0

- ENCODING subcommand added for Unicode support.

Example

```
DO IF $CASENUM EQ 1.
PRINT EJECT /'   NAME ' 1 'DEPT' 25 'HIRED' 30 '  SALARY' 35.
END IF.
PRINT / NAME DEPT *
        MOHIRED(T30,F2) '/' YRHIRED *
        SALARY (T35,DOLLAR8).
EXECUTE.
```

Overview

PRINT EJECT displays specified information at the top of a new page of the output. Each time that it is executed, PRINT EJECT causes a page ejection. If not used in a DO IF-END IF structure, PRINT EJECT is executed for each case in the data, and each case is displayed on a separate page.

PRINT EJECT is designed to be used with the PRINT command to insert titles and column headings above the values that are displayed by PRINT. PRINT can also generate titles and headings, but PRINT cannot be used to control page ejections.

PRINT EJECT and PRINT can be used for writing simple reports.

Options

The options that are available for PRINT EJECT are identical to the options that are available for PRINT:

- You can specify formats for the variables.
- You can specify string values within the variable specifications. With PRINT EJECT, the strings are usually used as titles or column headings and often include a specification for column location.

- You can use the RECORDS subcommand to display each case on more than one line.
- You can use the OUTFILE subcommand to direct the output to a specified file.
- You can use the TABLE subcommand to display a table that summarizes variable formats.
- You can use ENCODING to specify the file encoding. If there is no OUTFILE subcommand, the ENCODING subcommand is ignored.

For additional information, refer to PRINT.

Basic Specification

The basic specification is a slash followed by a variable list and/or a list of string values that will be used as column headings or titles. The values for each variable or string are displayed on the top line of a new page in the output. PRINT EJECT is usually used within a DO IF-END IF structure to control the page ejections.

Operations

- PRINT EJECT is a transformation and is not executed unless it is followed by a procedure or the EXECUTE command.
- If not used within a DO IF-END IF structure, PRINT EJECT is executed for each case in the data and displays the values for each case on a separate page.
- Values are displayed with a blank space between them. However, if a format is specified for a variable, the blank space for that variable's values is suppressed.
- Values are displayed in the output as the data are read. The PRINT output appears before the output from the first procedure.
- If more variables are specified than can be displayed in 132 columns or within the width that is specified on SET WIDTH, the program displays an error message. You must reduce the number of variables or split the output into several records.
- User-missing values are displayed exactly like valid values. System-missing values are represented by a period.

Examples

Displaying Column Headings on the First Output Page Only

```
DO IF $CASENUM EQ 1.
PRINT EJECT /'   NAME ' 1 'DEPT' 25 'HIRED' 30 '  SALARY' 35.
END IF.
PRINT / NAME DEPT *
        MOHIRED(T30,F2) '/' YRHIRED *
        SALARY (T35,DOLLAR8).
EXECUTE.
```

- PRINT EJECT specifies strings to be used as column headings and causes a page ejection. DO IF-END IF causes the PRINT EJECT command to be executed only once, when the system variable *$CASENUM* equals 1 (the value that is assigned to the first case in the file). Thus, column headings are displayed on the first page of the output only. The next example shows how to display column headings at the top of every page of the output.

- If a PRINT command were used in place of PRINT EJECT, the column headings would begin immediately after the command printback.

Displaying Column Headings on Each Output Page

```
DO IF MOD($CASENUM,50) = 1.
PRINT  EJECT  FILE=OUT /'   NAME ' 1 'DEPT' 25 'HIRED' 30 '  SALARY' 35.
END IF.
PRINT FILE=OUT / NAME DEPT *
        MOHIRED 30-31 '/' YRHIRED *
        SALARY 35-42(DOLLAR).
EXECUTE.
```

- In this example, DO IF specifies that PRINT EJECT is executed if MOD (the remainder) of *$CASENUM* divided by 50 equals 1 (see Arithmetic Functions on p. 67 for information on the MOD function). Thus, column headings are displayed on a new page after every 50th case.
- If PRINT were used instead of PRINT EJECT, column headings would be displayed after every 50th case but would not appear at the top of a new page.
- Both PRINT EJECT and PRINT specify the same file for the output. If the FILE subcommands on PRINT EJECT and PRINT do not specify the same file, the column headings and the displayed values end up in different files.

PRINT FORMATS

```
PRINT FORMATS varlist(format) [varlist...]
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Example

```
PRINT FORMATS SALARY (DOLLAR8) / HOURLY (DOLLAR7.2)
            / RAISE BONUS (PCT2).
```

Overview

PRINT FORMATS changes variable print formats. Print formats are output formats and control the form in which values are displayed by a procedure or by the PRINT command.

PRINT FORMATS changes only print formats. To change write formats, use the WRITE FORMATS command. To change both the print and write formats with a single specification, use the FORMATS command. For information about assigning input formats during data definition, see DATA LIST. For more information, see Variable Types and Formats on p. 49.

Basic Specification

The basic specification is a variable list followed by the new format specification in parentheses. All specified variables receive the new format.

Syntax Rules

- You can specify more than one variable or variable list, followed by a format in parentheses. Only one format can be specified after each variable list. For clarity, each set of specifications can be separated by a slash.
- You can use keyword TO to refer to consecutive variables in the active dataset.
- The specified width of a format must include enough positions to accommodate any punctuation characters, such as decimal points, commas, dollar signs, or date and time delimiters. (This situation differs from assigning an *input* format on DATA LIST, where the program automatically expands the input format to accommodate punctuation characters in output.)
- Custom currency formats (CCw, CCw.d) must first be defined on the SET command before they can be used on PRINT FORMATS.
- For string variables, you can only use PRINT FORMATS to switch between A and AHEX formats. PRINT FORMATS cannot be used to change the length of string variables. To change the defined length of a string variable, use the ALTER TYPE command.

Operations

- Unlike most transformations, PRINT FORMATS takes effect as soon as it is encountered in the command sequence. Special attention should be paid to the position of PRINT FORMATS among commands.
- Variables that are not specified on PRINT FORMATS retain their current print formats in the active dataset. To see the current formats, use the DISPLAY command.
- The new print formats are changed only in the active dataset and are in effect for the duration of the session or until changed again with a PRINT FORMATS or FORMATS command. Print formats in the original data file (if this file exists) are not changed, unless the file is resaved with the SAVE or XSAVE command.
- New numeric variables that are created with transformation commands are assigned default print formats of F8.2 (or the format that is specified on the FORMAT subcommand of SET). The FORMATS command can be used to change the new variable's print formats.
- New string variables that are created with transformation commands are assigned the format that is specified on the STRING command that declares the variable. PRINT FORMATS cannot be used to change the format of a new string variable.
- If a numeric data value exceeds its width specification, the program still attempts to display some value. First, the program rounds decimal values, then removes punctuation characters, and then tries scientific notation. Finally, if there is still not enough space, the program produces asterisks indicating that a value is present but cannot be displayed in the assigned width.

Examples

Basic Example

```
PRINT FORMATS SALARY (DOLLAR8) / HOURLY (DOLLAR7.2)
           / RAISE BONUS (PCT2).
```

- The print format for *SALARY* is changed to DOLLAR with eight positions, including the dollar sign and comma when appropriate. The value 11550 is displayed as $11,550. An eight-digit number requires a DOLLAR11 format specification: eight characters for digits, two characters for commas, and one character for the dollar sign.
- The print format for *HOURLY* is changed to DOLLAR with seven positions, including the dollar sign, decimal point, and two decimal places. The number 115 is displayed as $115.00. If DOLLAR6.2 had been specified, the value 115 would be displayed as $115.0. The program would truncate the last 0 because a width of 6 is not enough to display the full value.
- The print format for both *RAISE* and *BONUS* is changed to PCT with two positions: one position for the percentage and one position for the percent sign. The value 9 is displayed as 9%. Because the width allows for only two positions, the value 10 is displayed as 10.

Changing Default Formats

```
COMPUTE V3=V1 + V2.
PRINT FORMATS V3 (F3.1).
```

- COMPUTE creates the new numeric variable *V3*. By default, *V3* is assigned an F8.2 format (or the default format that is specified on SET).
- PRINT FORMATS changes the print format for *V3* to F3.1.

Working With Custom Currency Formats

```
SET CCA='-/-.Dfl ..-'.
PRINT FORMATS COST (CCA14.2).
```

- SET defines a European currency format for the custom currency format type CCA.
- PRINT FORMATS assigns the print format CCA to variable *COST*. With the format defined for CCA on SET, the value 37419 is displayed as Dfl’37.419,00. See the SET command for more information about custom currency formats.

PRINT SPACE

```
PRINT SPACE [OUTFILE='file'] [ENCODING='encoding specification']
  [numeric expression]
```

This command does not read the active dataset. It is stored, pending execution with the next command that reads the dataset. For more information, see Command Order on p. 36.

Release History

Release 16.0

- ENCODING subcommand added for Unicode support.

Example

```
PRINT SPACE.
```

Overview

PRINT SPACE displays blank lines in the output and is generally used with a PRINT or WRITE command. Because PRINT SPACE displays a blank line each time that the command is executed, it is often used in a DO IF-END IF structure.

Basic Specification

The basic specification is the command PRINT SPACE.

Syntax Rules

- To display more than one blank line, specify a numeric expression after PRINT SPACE. The expression can be an integer or a complex expression.
- OUTFILE directs the output to a specified file. OUTFILE should be specified if an OUTFILE subcommand is specified on the PRINT or WRITE command that is used with PRINT SPACE. The OUTFILE subcommand on PRINT SPACE and PRINT or WRITE should specify the same file.
- ENCODING specifies the encoding for the output file. If there is no OUTFILE subcommand, the ENCODING subcommand is ignored.

Operations

- If not used in a DO IF-END IF structure, PRINT SPACE is executed for each case in the data and displays a blank line for every case.

Examples

Inserting a Blank Line after the Output for Each Case

```
PRINT / NAME DEPT82 *
        MOHIRED(T30,F2) '/' YRHIRED *
        SALARY82 (T35,DOLLAR8).
PRINT SPACE.
EXECUTE.
```

- Each time that it is executed, PRINT SPACE displays one blank line. Because PRINT SPACE is not used in a DO IF–END IF structure, PRINT SPACE is executed once for each case. In effect, the output is double-spaced.

Using PRINT SPACE Inside a DO IF-END IF Structure

```
NUMERIC #LINE.
DO IF MOD(#LINE,5) = 0.
PRINT SPACE 2.
END IF.
COMPUTE #LINE=#LINE + 1.
PRINT / NAME DEPT *
        MOHIRED 30-31 '/' YRHIRED *
        SALARY 35-42(DOLLAR).
EXECUTE.
```

- DO IF specifies that PRINT SPACE will be executed if MOD (the remainder) of *#LINE* divided by 5 equals 1. Because *#LINE* is incremented by 1 for each case, PRINT SPACE is executed once for every five cases. (See Arithmetic Functions on p. 67 for information about the MOD function.)
- PRINT SPACE specifies two blank lines. Cases are displayed in groups of five with two blank lines between each group.

Using an Expression to Specify the Number of Blank Lines

```
* Printing addresses on labels.

COMPUTE #LINES=0.               /*Initiate #LINES to 0
DATA LIST FILE=ADDRESS/RECORD 1-40 (A).  /*Read a record
COMPUTE #LINES=#LINES+1.        /*Bump counter and print
WRITE OUTFILE=LABELS /RECORD.

DO IF RECORD EQ ' '.            /*Blank between addresses
+  PRINT SPACE OUTFILE=LABELS 8 - #LINES.  /*Add extra blank #LINES
+  COMPUTE #LINES=0.
END IF.
EXECUTE.
```

- PRINT SPACE uses a complex expression for specifying the number of blank lines to display. The data contain a variable number of input records for each name and address, which must be printed in a fixed number of lines for mailing labels. The goal is to know when the last line for each address has been printed, how many lines have printed, and therefore how many blank records must be printed in order for the next address to fit on the next label. The example assumes that there is already one blank line between each address on input and that you want to print eight lines per label.

- The `DATA LIST` command defines the data. Each line of the address is contained in columns 1–40 of the data file and is assigned the variable name *RECORD*. For the blank line between each address, *RECORD* is blank.
- Variable *#LINES* is initialized to 0 as a scratch variable and is incremented for each record that is written. When the program encounters a blank line (`RECORD EQ ' '`), `PRINT SPACE` prints a number of blank lines that is equal to 8 minus the number already printed, and *#LINES* is then reset to 0.
- `OUTFILE` on `PRINT SPACE` specifies the same file that is specified by `OUTFILE` on `WRITE`.

PROBIT

PROBIT is available in the Regression Models option.

```
PROBIT response-count varname OF observation-count varname
       WITH varlist [BY varname(min,max)]

 [/MODEL={PROBIT**}]
         {LOGIT   }
         {BOTH    }

 [/LOG=[{10** }]
        {2.718}
        {value}
        {NONE }

 [/CRITERIA=[{OPTOL   }({epsilon**0.8})][P({0.15**})][STEPLIMIT({0.1**})]
             {CONVERGE} {n           }     {p     }              {n    }

            [ITERATE({max(50,3(p+1))**})]]
                     {n               }

 [/NATRES[=value]]

 [/PRINT={[CI**] [FREQ**] [RMP**]} [PARALL] [NONE] [ALL]]
         {DEFAULT**               }

 [/MISSING=[{EXCLUDE**}]  ]
            {INCLUDE  }
```

**Default if the subcommand or keyword is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
PROBIT  R OF N BY ROOT(1,2) WITH X
  /MODEL = BOTH.
```

Overview

PROBIT can be used to estimate the effects of one or more independent variables on a dichotomous dependent variable (such as dead or alive, employed or unemployed, product purchased or not). The program is designed for dose-response analyses and related models, but PROBIT can also estimate logistic regression models.

Options

The Model. You can request a probit or logit response model, or both, for the observed response proportions with the MODEL subcommand.

Transform Predictors. You can control the base of the log transformation applied to the predictors or request no log transformation with the LOG subcommand.

Natural Response Rates. You can instruct PROBIT to estimate the natural response rate (threshold) of the model or supply a known natural response rate to be used in the solution with the NATRES subcommand.

Algorithm Control Parameters. You can specify values of algorithm control parameters, such as the limit on iterations, using the CRITERIA subcommand.

Statistics. By default, PROBIT calculates frequencies, fiducial confidence intervals, and the relative median potency. It also produces a plot of the observed probits or logits against the values of a single independent variable. Optionally, you can use the PRINT subcommand to request a test of the parallelism of regression lines for different levels of the grouping variable or to suppress any or all of these statistics.

Basic Specification

- The basic specification is the response-count variable, keyword OF, the observation-count variable, keyword WITH, and at least one independent variable.
- PROBIT calculates maximum-likelihood estimates for the parameters of the default probit response model and automatically displays estimates of the regression coefficient and intercept terms, their standard errors, a covariance matrix of parameter estimates, and a Pearson chi-square goodness-of-fit test of the model.

Subcommand Order

- The variable specification must be first.
- Subcommands can be named in any order.

Syntax Rules

- The variables must include a response count, an observation count, and at least one predictor. A categorical grouping variable is optional.
- All subcommands are optional and each can appear only once.
- Generally, data should not be entered for individual observations. PROBIT expects predictor values, response counts, and the total number of observations as the input case.
- If the data are available only in a case-by-case form, use AGGREGATE first to compute the required response and observation counts.

Operations

- The transformed response variable is predicted as a linear function of other variables using the nonlinear-optimization method. Note that the previous releases used the iteratively weighted least-squares method, which has a different way of transforming the response variables. For more information, see MODEL Subcommand on p. 1475.
- If individual cases are entered in the data, PROBIT skips the plot of transformed response proportions and predictor values.
- If individual cases are entered, the chi-square goodness-of-fit statistic and associated degrees of freedom are based on the individual cases. The case-based chi-square goodness-of-fit statistic generally differs from that calculated for the same data in aggregated form.

Limitations

- Only one prediction model can be tested on a single PROBIT command, although both probit and logit response models can be requested for that prediction.
- Confidence limits, the plot of transformed response proportions and predictor values, and computation of relative median potency are necessarily limited to single-predictor models.

Examples

```
PROBIT  R OF N BY ROOT(1,2) WITH X
  /MODEL = BOTH.
```

- This example specifies that both the probit and logit response models be applied to the response frequency *R*, given *N* total observations and the predictor *X*.
- By default, the predictor is log transformed.

Example: Using data in a case-by-case form

```
DATA LIST FREE / PREPARTN DOSE RESPONSE.
BEGIN DATA
1 1.5 0
 ...
4 20.0 1
END DATA.
COMPUTE SUBJECT = 1.
PROBIT RESPONSE OF SUBJECT BY PREPARTN(1,4) WITH DOSE.
```

- This dose-response model (Finney, 1971) illustrates a case-by-case analysis. A researcher tests four different preparations at varying doses and observes whether each subject responds. The data are individually recorded for each subject, with 1 indicating a response and 0 indicating no response. The number of observations is always 1 and is stored in variable *SUBJECT*.
- PROBIT warns that the data are in a case-by-case form and that the plot is therefore skipped.
- The goodness-of-fit test and associated degrees of freedom are based on individual cases, not dosage groups.
- PROBIT displays predicted and observed frequencies for all individual input cases.

Example: Aggregating case-by-case data

```
DATA LIST FREE/PREPARTN DOSE RESPONSE.
BEGIN DATA
     1.00     1.50      .00
     ...
     4.00    20.00     1.00
END DATA.
AGGREGATE OUTFILE=*
  /BREAK=PREPARTN DOSE
  /SUBJECTS=N(RESPONSE)
  /NRESP=SUM(RESPONSE).
PROBIT NRESP OF SUBJECTS BY PREPARTN(1,4) WITH DOSE.
```

- This example analyzes the same dose-response model as the previous example, but the data are first aggregated.

- AGGREGATE summarizes the data by cases representing all subjects who received the same preparation (*PREPARTN*) at the same dose (*DOSE*).
- The number of cases having a nonmissing response is recorded in the aggregated variable *SUBJECTS*.
- Because *RESPONSE* is coded 0 for no response and 1 for a response, the sum of the values gives the number of observations with a response.
- PROBIT requests a default analysis.
- The parameter estimates for this analysis are the same as those calculated for individual cases in the example above. The chi-square test, however, is based on the number of dosages.

Variable Specification

The variable specification on PROBIT identifies the variables for response count, observation count, groups, and predictors. The variable specification is required.

- The variables must be specified first. The specification must include the response-count variable, followed by the keyword OF and then the observation-count variable.
- If the value of the response-count variable exceeds that of the observation-count variable, a procedure error occurs and PROBIT is not executed.
- At least one predictor (covariate) must be specified following the keyword WITH. The number of predictors is limited only by available workspace. All predictors must be continuous variables.
- You can specify a grouping variable (factor) after the keyword BY. Only one variable can be specified. It must be numeric and can contain only integer values. You must specify, in parentheses, a range indicating the minimum and maximum values for the grouping variable. Each integer value in the specified range defines a group.
- Cases with values for the grouping variable that are outside the specified range are excluded from the analysis.
- Keywords BY and WITH can appear in either order. However, both must follow the response-and-observation-count variables.

Example

```
PROBIT R OF N WITH X.
```

- The number of observations having the measured response appears in variable *R*, and the total number of observations is in *N*. The predictor is *X*.

Example

```
PROBIT  R OF N BY ROOT(1,2) WITH X.

PROBIT  R OF N WITH X BY ROOT(1,2).
```

- Because keywords BY and WITH can be used in either order, these two commands are equivalent. Each command specifies *X* as a continuous predictor and *ROOT* as a categorical grouping variable.

- Groups are identified by the levels of variable *ROOT*, which may be 1 or 2.
- For each combination of predictor and grouping variables, the variable *R* contains the number of observations with the response of interest, and *N* contains the total number of observations.

MODEL Subcommand

MODEL specifies the form of the dichotomous-response model. Response models can be thought of as transformations (*T*) of response rates, which are proportions or probabilities (*p*). Note the difference in the transformations between the current version and the previous versions.

- A **probit** is the inverse of the cumulative standard normal distribution function. Thus, for any proportion, the probit transformation returns the value below which that proportion of standard normal deviates is found. For the probit response model, the program uses $T(p) = \text{PROBIT}(p)$. Hence:

  T (0.025) = PROBIT (0.025) = –1.96

  T (0.400) = PROBIT (0.400) = –0.25

  T (0.500) = PROBIT (0.500) = 0.00

  T (0.950) = PROBIT (0.950) = 1.64

- A **logit** is simply the natural log of the odds ratio, $p/(1-p)$. In the Probit procedure, the response function is given as $T(p) = \log_e(p/(1-p))$. Hence:

  T (0.025) = LOGIT (0.025) = –3.66

  T (0.400) = LOGIT (0.400) = –0.40

  T (0.500) = LOGIT (0.500) = 0.00

  T (0.950) = LOGIT (0.950) = 2.94

You can request one or both of the models on the MODEL subcommand. The default is PROBIT if the subcommand is not specified or is specified with no keyword.

PROBIT	*Probit response model.* This is the default.
LOGIT	*Logit response model.*
BOTH	*Both probit and logit response models.* PROBIT displays all the output for the logit model followed by the output for the probit model.

- If subgroups and multiple-predictor variables are defined, PROBIT estimates a separate intercept, a_j, for each subgroup and a regression coefficient, b_i, for each predictor.

LOG Subcommand

LOG specifies the base of the logarithmic transformation of the predictor variables or suppresses the default log transformation.

- LOG applies to all predictors.
- To transform only selected predictors, use COMPUTE commands before the Probit procedure. Then specify NONE on the LOG subcommand.

- If LOG is omitted, a logarithm base of 10 is used.
- If LOG is used without a specification, the natural logarithm base *e* (2.718) is used.
- If you have a control group in your data and specify NONE on the LOG subcommand, the control group is included in the analysis. For more information, see NATRES Subcommand on p. 1476.

You can specify one of the following on LOG:

value	*Logarithm base to be applied to all predictors.*
NONE	*No transformation of the predictors.*

Example

```
PROBIT R OF N BY ROOT (1,2) WITH X
  /LOG = 2.
```

- LOG specifies a base-2 logarithmic transformation.

CRITERIA Subcommand

Use CRITERIA to specify the values of control parameters for the PROBIT algorithm. You can specify any or all of the keywords below. Defaults remain in effect for parameters that are not changed.

OPTOL(n)	*Optimality tolerance.* Alias CONVERGE. If an iteration point is a feasible point and the next step will not produce a relative change in either the parameter vector or the log-likelihood function of more than the square root of *n*, an optimal solution has been found. OPTOL can also be thought of as the number of significant digits in the log-likelihood function at the solution. For example, if OPTOL=10^{-6}, the log-likelihood function should have approximately six significant digits of accuracy. The default value is machine epsilon**0.8.
ITERATE(n)	*Iteration limit.* Specify the maximum number of iterations. The default is max (50, 3(p + 1)), where p is the number of parameters in the model.
P(p)	*Heterogeneity criterion probability.* Specify a cutoff value between 0 and 1 for the significance of the goodness-of-fit test. The cutoff value determines whether a heterogeneity factor is included in calculations of confidence levels for effective levels of a predictor. If the significance of chi-square is greater than the cutoff, the heterogeneity factor is not included. If you specify 0, this criterion is disabled; if you specify 1, a heterogeneity factor is automatically included. The default is 0.15.
STEPLIMIT(n)	*Step limit.* The PROBIT algorithm does not allow changes in the length of the parameter vector to exceed a factor of *n*. This limit prevents very early steps from going too far from good initial estimates. Specify any positive value. The default value is 0.1.
CONVERGE(n)	*Alias of OPTOL.*

NATRES Subcommand

You can use NATRES either to supply a known natural response rate to be used in the solution or to instruct PROBIT to estimate the natural (or threshold) response rate of the model.

- To supply a known natural response rate as a constraint on the model solution, specify a value less than 1 on NATRES.
- To instruct PROBIT to estimate the natural response rate of the model, you can indicate a control group by giving a 0 value to any of the predictor variables. PROBIT displays the estimate of the natural response rate and the standard error and includes the estimate in the covariance/correlation matrix as NAT RESP.
- If no control group is indicated and NATRES is specified without a given value, PROBIT estimates the natural response rate from the entire data and informs you that no control group has been provided. The estimate of the natural response rate and the standard error are displayed and NAT RESP is included in the covariance/correlation matrix.
- If you have a control group in your data and specify NONE on the LOG subcommand, the control group is included in the analysis.

Example

```
DATA LIST FREE / SOLUTION DOSE NOBSN NRESP.
BEGIN DATA
1  5 100 20
1 10  80 30
1  0 100 10
...
END DATA.

PROBIT NRESP OF NOBSN BY SOLUTION(1,4) WITH DOSE
  /NATRES.
```

- This example reads four variables and requests a default analysis with an estimate of the natural response rate.
- The predictor variable, *DOSE*, has a value of 0 for the third case.
- The response count (10) and the observation count (100) for this case establish the initial estimate of the natural response rate.
- Because the default log transformation is performed, the control group is not included in the analysis.

Example

```
DATA LIST FREE / SOLUTION DOSE NOBSN NRESP.
BEGIN DATA
1  5 100 20
1 10  80 30
1  0 100 10
  ...
END DATA.

PROBIT NRESP OF NOBSN BY SOLUTION(1,4) WITH DOSE
  /NATRES = 0.10.
```

- This example reads four variables and requests an analysis in which the natural response rate is set to 0.10. The values of the control group are ignored.
- The control group is excluded from the analysis because the default log transformation is performed.

PRINT Subcommand

Use PRINT to control the statistics calculated by PROBIT.

- PROBIT always displays the plot (for a single-predictor model) and the parameter estimates and covariances for the probit model.
- If PRINT is used, the requested statistics are calculated and displayed in addition to the parameter estimates and plot.
- If PRINT is not specified or is specified without any keyword, FREQ, CI, and RMP are calculated and displayed in addition to the parameter estimates and plot.

DEFAULT *FREQ, CI, and RMP.* This is the default if PRINT is not specified or is specified by itself.

FREQ *Frequencies.* Display a table of observed and predicted frequencies with their residual values. If observations are entered on a case-by-case basis, this listing can be quite lengthy.

CI *Fiducial confidence intervals.* Print fiducial confidence intervals (Finney et al., 1971) for the levels of the predictor needed to produce each proportion of responses. PROBIT displays this default output for single-predictor models only. If a categorical grouping variable is specified, PROBIT produces a table of confidence intervals for each group. If the Pearson chi-square goodness-of-fit test is significant ($p < 0.15$ by default), PROBIT uses a heterogeneity factor to calculate the limits.

RMP *Relative median potency.* Display the relative median potency (RMP) of each pair of groups defined by the grouping variable. PROBIT displays this default output for single-predictor models only. For any pair of groups, the RMP is the ratio of the stimulus tolerances in those groups. **Stimulus tolerance** is the value of the predictor necessary to produce a 50% response rate. If the derived model for one predictor and two groups estimates that a predictor value of 21 produces a 50% response rate in the first group, and that a predictor value of 15 produces a 50% response rate in the second group, the relative median potency would be 21/15 = 1.40. In biological assay analyses, RMP measures the comparative strength of preparations.

PARALL *Parallelism test.* Produce a test of the parallelism of regression lines for different levels of the grouping variable. This test displays a chi-square value and its associated probability. It requires an additional pass through the data and, thus, additional processing time.

NONE *Display only the unconditional output.* This option can be used to override any other specification on the PRINT subcommand for PROBIT.

ALL *All available output.* This is the same as requesting FREQ, CI, RMP, and PARALL.

MISSING Subcommand

PROBIT always deletes cases having a missing value for any variable. In the output, PROBIT indicates how many cases it rejected because of missing data. This information is displayed with the DATA Information that prints at the beginning of the output. You can use the MISSING subcommand to control the treatment of user-missing values.

EXCLUDE *Delete cases with user-missing values.* This is the default. You can also make it explicit by using the keyword DEFAULT.

INCLUDE *Include user-missing values.* PROBIT treats user-missing values as valid. Only cases with system-missing values are rejected.

PROCEDURE OUTPUT

```
PROCEDURE OUTPUT OUTFILE=file.
```

Example

```
PROCEDURE OUTPUT OUTFILE=CELLDATA.
```

Overview

PROCEDURE OUTPUT specifies the files to which CROSSTABS and SURVIVAL (included in the Advanced Models option) can write procedure output. PROCEDURE OUTPUT has no other applications.

Basic Specification

The only specification is OUTFILE and the file specification. PROCEDURE OUTPUT must precede the command to which it applies.

Operations

Commands with the WRITE subcommand or keyword write to the output file that is specified on the most recent PROCEDURE OUTPUT command. If only one output file has been specified, the output from the last such procedure overwrites all previous ones.

Examples

Using PROCEDURE OUTPUT with CROSSTABS

```
PROCEDURE OUTPUT OUTFILE=CELLDATA.
CROSSTABS VARIABLES=FEAR SEX (1,2)
  /TABLES=FEAR BY SEX
  /WRITE=ALL.
```

- PROCEDURE OUTPUT precedes CROSSTABS and specifies *CELLDATA* as the file to receive the cell frequencies.
- The WRITE subcommand on CROSSTABS is required for writing cell frequencies to a procedure output file.

Using PROCEDURE OUTPUT with SURVIVAL

```
PROCEDURE OUTPUT OUTFILE=SURVTBL.
SURVIVAL  TABLES=ONSSURV,RECSURV BY TREATMNT(1,3)
  /STATUS = RECURSIT(1,9) FOR RECSURV
  /STATUS = STATUS(3,4) FOR ONSSURV
  /INTERVAL=THRU 50 BY 5 THRU 100 BY 10/PLOTS/COMPARE
  /CALCULATE=CONDITIONAL PAIRWISE
  /WRITE=TABLES.
```

- `PROCEDURE OUTPUT` precedes `SURVIVAL` and specifies *SURVTBL* as the file to receive the survival tables.
- The `WRITE` subcommand on `SURVIVAL` is required for writing survival tables to a procedure output file.

PROXIMITIES

```
PROXIMITIES  varlist  [/VIEW={CASE**  }]
                            {VARIABLE}

 [/STANDARDIZE=[{VARIABLE}] [{NONE** }]]
                {CASE    }   {Z      }

            {PATTERN[(p[,np])] }
            {BSEUCLID[(p[,np])]}
            {BSHAPE[(p[,np])]  }
            {DISPER[(p[,np])]  }
            {VARIANCE[(p[,np])]}
            {BLWMN[(p[,np])]   }
            {NONE              }

 [/PRINT=[{PROXIMITIES**}]]  [/ID=varname]
         {NONE          }

 [/MISSING=[EXCLUDE**]  [INCLUDE]]

 [/MATRIX=[IN({'savfile'|'dataset'})] [OUT({'savfile'|'dataset'})]]
             {*                  }        {*                  }
```

**Default if subcommand or keyword is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
PROXIMITIES A B C.
```

Overview

PROXIMITIES computes a variety of measures of similarity, dissimilarity, or distance between pairs of cases or pairs of variables for moderate-sized datasets (see "Limitations" below). PROXIMITIES matrix output can be used as input to procedures ALSCAL, CLUSTER, and FACTOR.

Options

Standardizing Data. With the STANDARDIZE subcommand, you can use several different methods to standardize the values for each variable or for each case.

Proximity Measures. You can use the MEASURE subcommand to compute a variety of similarity, dissimilarity, and distance measures. (Similarity measures increase with greater similarity; dissimilarity and distance measures decrease.) MEASURE can compute measures for interval data, frequency-count data, and binary data. Only one measure can be requested in any one PROXIMITIES procedure. With the VIEW subcommand, you can control whether proximities are computed between variables or between cases.

Output. You can use the PRINT subcommand to display a computed matrix.

Matrix Input and Output. You can use the MATRIX subcommand to write a computed proximities matrix to an SPSS-format data file. This matrix can be used as input to procedures CLUSTER, ALSCAL, and FACTOR. You can also use MATRIX to read a similarity, dissimilarity, or distance matrix. This option lets you rescale or transform existing proximity matrices.

Basic Specification

The basic specification is a variable list, which obtains Euclidean distances between cases based on the values of each specified variable.

Subcommand Order

- The variable list must be first.
- Subcommands can be named in any order.

Operations

- PROXIMITIES ignores case weights when computing coefficients.

Limitations

- PROXIMITIES keeps the raw data for the current split-file group in memory. Storage requirements increase rapidly with the number of cases and the number of items (cases or variables) for which PROXIMITIES computes coefficients.

Example

```
PROXIMITIES A B C.
```

- PROXIMITIES computes Euclidean distances between cases based on the values of variables *A*, *B*, and *C*.

Variable Specification

- The variable list must be specified first.
- The variable list can be omitted when an input matrix data file is specified. A slash must then be specified before the first subcommand to indicate that the variable list is omitted.

STANDARDIZE Subcommand

Use STANDARDIZE to standardize data values for either cases or variables before computing proximities. One of two options can be specified to control the direction of standardization:

VARIABLE	*Standardize the values for each variable.* This setting is the default.
CASE	*Standardize the values within each case.*

Several standardization methods are available. These methods allow you to equalize selected properties of the values. All methods can be used with either VARIABLE or CASE. Only one standardization method can be specified.

- If STANDARDIZE is omitted, proximities are computed by using the original values (keyword NONE).
- If STANDARDIZE is used without specifications, proximities are computed by using *Z* scores (keyword Z).
- STANDARDIZE cannot be used with binary measures.

NONE	*Do not standardize.* Proximities are computed by using the original values. This setting is the default if STANDARDIZE is omitted.
Z	*Standardize values to Z scores, with a mean of 0 and a standard deviation of 1.* PROXIMITIES subtracts the mean value for the variable or case from each value that is being standardized, and then PROXIMITIES divides by the standard deviation. If the standard deviation is 0, PROXIMITIES sets all values for the case or variable to 0. This setting is the default if STANDARDIZE is used without specifications.
RANGE	*Standardize values to have a range of 1.* PROXIMITIES divides each value that is being standardized by the range of values for the variable or case. If the range is 0, PROXIMITIES leaves all values unchanged.
RESCALE	*Standardize values to have a range from 0 to 1.* From each value that is being standardized, PROXIMITIES subtracts the minimum value and then divides by the range for the variable or case. If a range is 0, PROXIMITIES sets all values for the case or variable to 0.50.
MAX	*Standardize values to a maximum magnitude of 1.* PROXIMITIES divides each value that is being standardized by the maximum value for the variable or case. If the maximum of the values is 0, PROXIMITIES divides each value by the absolute magnitude of the smallest value and adds 1.

MEAN *Standardize values to a mean of 1.* PROXIMITIES divides each value that is being standardized by the mean of the values for the variable or case. If the mean is 0, PROXIMITIES adds 1 to all values for the case or variable to produce a mean of 1.

SD *Standardize values to unit standard deviation.* PROXIMITIES divides each value that is being standardized by the standard deviation of the values for the variable or case. PROXIMITIES does not change the values if their standard deviation is 0.

Example

```
PROXIMITIES A B C
  /STANDARDIZE=CASE RANGE.
```

- Within each case, values are standardized to have ranges of 1.

VIEW Subcommand

VIEW indicates whether proximities are computed between cases or between variables.

CASE *Compute proximity values between cases.* This is the default.

VARIABLE *Compute proximity values between variables.*

MEASURE Subcommand

MEASURE specifies the similarity, dissimilarity, or distance measure that PROXIMITIES computes. Three transformations are available:

ABSOLUTE *Take the absolute values of the proximities.* Use ABSOLUTE when the sign of the values indicates the direction of the relationship (as with correlation coefficients) but only the magnitude of the relationship is of interest.

REVERSE *Transform similarity values into dissimilarities, or vice versa.* Use this specification to reverse the ordering of the proximities by negating the values.

RESCALE *Rescale the proximity values to a range of 0 to 1.* RESCALE standardizes the proximities by first subtracting the value of the smallest proximity and then dividing by the range. You would not usually use RESCALE with measures that are already standardized on meaningful scales, as are correlations, cosines, and many binary coefficients.

PROXIMITIES can compute any one of a number of measures between items. You can choose among measures for interval data, frequency-count data, or binary data. Available keywords for each type of measures are defined in the following sections.

- Only one measure can be specified. However, each measure can be specified with any of the transformations ABSOLUTE, REVERSE, or RESCALE. To apply a transformation to an existing matrix of proximity values without computing any measures, use keyword NONE (see Transforming Measures in Proximity Matrix on p. 1492).
- If more than one transformation is specified, PROXIMITIES handles them in the order listed above: ABSOLUTE, REVERSE, and then RESCALE (regardless of the order in which they are specified).
- Each entry in the resulting proximity matrix represents a pair of items. The items can be either cases or variables, whichever is specified on the VIEW subcommand.

- When the items are cases, the computation for each pair of cases involves pairs of values for the specified variables.
- When the items are variables, the computation for each pair of variables involves pairs of values for the variables across all cases.

Example

```
PROXIMITIES A B C
  /MEASURE=EUCLID REVERSE.
```

- `MEASURE` specifies a `EUCLID` measure and a `REVERSE` transformation.

Measures for Interval Data

To obtain proximities for interval data, use one of the following keywords on `MEASURE`:

EUCLID *Euclidean distance.* The distance between two items, *x* and *y*, is the square root of the sum of the squared differences between the values for the items. This setting is the default.

$$EUCLID(x,y) = \sqrt{\Sigma_i (x_i - y_i)^2}$$

SEUCLID *Squared Euclidean distance.* The distance between two items is the sum of the squared differences between the values for the items.

$$SEUCLID(x,y) = \Sigma_i (x_i - y_i)^2$$

CORRELATION *Correlation between vectors of values.* This measure is a pattern-similarity measure.

$$CORRELATION(x,y) = \frac{\Sigma_i (Z_{xi} Z_{yi})}{N-1}$$

where Z_{xi} is the *Z*-score (standardized) value of *x* for the *i*th case or variable, and *N* is the number of cases or variables.

COSINE *Cosine of vectors of values.* This measure is a pattern-similarity measure.

$$COSINE(x,y) = \frac{\Sigma_i (x_i y_i)}{\sqrt{(\Sigma_i x_i^2)(\Sigma_i y_i^2)}}$$

CHEBYCHEV *Chebychev distance metric.* The distance between two items is the maximum absolute difference between the values for the items.

$$CHEBYCHEV(x,y) = \max_i |x_i - y_i|$$

BLOCK *City-block or Manhattan distance.* The distance between two items is the sum of the absolute differences between the values for the items.

$$BLOCK(x,y) = \Sigma_i |x_i - y_i|$$

MINKOWSKI(p) *Distance in an absolute Minkowski power metric.* The distance between two items is the *p*th root of the sum of the absolute differences to the *p*th power between the values for the items. Appropriate selection of the integer parameter *p* yields Euclidean and many other distance metrics.

$$MINKOWSKI(x,y) = (\Sigma_i |x_i - y_i|^p)^{1/p}$$

POWER(p,r) *Distance in an absolute power metric.* The distance between two items is the *r*th root of the sum of the absolute differences to the *p*th power between the values for the items. Appropriate selection of the integer parameters *p* and *r* yields Euclidean, squared Euclidean, Minkowski, city-block, and many other distance metrics.

$$POWER(x,y) = (\Sigma_i |x_i - y_i|^p)^{1/r}$$

Measures for Frequency-Count Data

To obtain proximities for frequency-count data, use either of the following keywords on MEASURE:

CHISQ *Based on the chi-square test of equality for two sets of frequencies.* The magnitude of this dissimilarity measure depends on the total frequencies of the two cases or variables whose dissimilarity is computed. Expected values are from the model of independence of cases or variables *x* and *y*.

$$CHISQ(x,y) = \sqrt{\frac{\Sigma_i (x_i - E(x_i))^2}{E(x_i)} + \frac{\Sigma_i (y_i - E(y_i))^2}{E(y_i)}}$$

PH2 *Phi-square between sets of frequencies.* This measure is the CHISQ measure normalized by the square root of the combined frequency. Therefore, its value does not depend on the total frequencies of the two cases or variables whose dissimilarity is computed.

$$PH2(x,y) = \sqrt{\frac{\frac{\Sigma_i (x_i - E(x_i))^2}{E(x_i)} + \frac{\Sigma_i (y_i - E(y_i))^2}{E(y_i)}}{N}}$$

Measures for Binary Data

Different binary measures emphasize different aspects of the relationship between sets of binary values. However, all measures are specified in the same way. Each measure has two optional integer-valued parameters, *p* (present) and *np* (not present).

- If both parameters are specified, PROXIMITIES uses the value of the first parameter as an indicator that a characteristic is present, and PROXIMITIES uses the value of the second parameter as an indicator that a characteristic is absent. PROXIMITIES skips all other values.
- If only the first parameter is specified, PROXIMITIES uses that value to indicate presence and uses all other values to indicate absence.
- If no parameters are specified, PROXIMITIES assumes that 1 indicates presence and 0 indicates absence.

Using the indicators for presence and absence within each item (case or variable), PROXIMITIES constructs a 2×2 contingency table for each pair of items and uses this table to compute a proximity measure for the pair.

	Item 2 characteristics	
	Present	Absent
Item 1 characteristics		
Present	*a*	*b*
Absent	*c*	*d*

PROXIMITIES computes all binary measures from the values of *a*, *b*, *c*, and *d*. These values are tallied across variables (when the items are cases) or cases (when the items are variables). For example, if variables *V*, *W*, *X*, *Y*, *Z* have values 0, 1, 1, 0, 1 for case 1 and have values 0, 1, 1, 0, 0 for case 2 (where 1 indicates presence and 0 indicates absence), the contingency table is as follows:

	Case 2 characteristics	
	Present	Absent
Case 1 characteristics		
Present	2	1
Absent	0	2

The contingency table indicates that both cases are present for two variables (*W* and *X*), both cases are absent for two variables (*V* and *Y*), and case 1 is present and case 2 is absent for one variable (*Z*). There are no variables for which case 1 is absent and case 2 is present.

The available binary measures include matching coefficients, conditional probabilities, predictability measures, and other measures.

Matching Coefficients. The following table shows a classification scheme for PROXIMITIES matching coefficients. In this scheme, *matches* are joint presences (value *a* in the contingency table) or joint absences (value *d*). *Nonmatches* are equal in number to value *b* plus value *c*. Matches and nonmatches may be weighted equally or not. The three coefficients JACCARD, DICE, and SS2 are related monotonically, as are SM, SS1, and RT. All coefficients in the table are similarity measures, and all coefficients exceptK1 and SS3 range from 0 to 1. K1 and SS3 have a minimum value of 0 and have no upper limit.

Table 182-1
Binary matching coefficients in PROXIMITIES

	Joint absences excluded from numerator	**Joint absences included in numerator**
All matches included in denominator		
Equal weight for matches and nonmatches	RR	SM
Double weight for matches		SS1
Double weight for nonmatches		RT
Joint absences excluded from denominator		
Equal weight for matches and nonmatches	JACCARD	
Double weight for matches	DICE	

	Joint absences excluded from numerator	**Joint absences included in numerator**
Double weight for nonmatches	SS2	
All matches excluded from denominator		
Equal weight for matches and nonmatches	K1	SS3

RR[(p[,np])] *Russell and Rao similarity measure.* This measure is the binary dot product.

$$RR(x,y) = \frac{a}{a+b+c+d}$$

SM[(p[,np])] *Simple matching similarity measure.* This measure is the ratio of the number of matches to the total number of characteristics.

$$SM(x,y) = \frac{a+d}{a+b+c+d}$$

JACCARD[(p[,np])] *Jaccard similarity measure.* This measure is also known as the *similarity ratio*.

$$JACCARD(x,y) = \frac{a}{a+b+c}$$

DICE[(p[,np])] *Dice (or Czekanowski or Sorenson) similarity measure.*

$$DICE(x,y) = \frac{2a}{2a+b+c}$$

SS1[(p[,np])] *Sokal and Sneath similarity measure 1.*

$$SS1(x,y) = \frac{2(a+d)}{2(a+d)+b+c+d}$$

RT[(p[,np])] *Rogers and Tanimoto similarity measure.*

$$RT(x,y) = \frac{a+d}{a+d+2(b+c)}$$

SS2[(p[,np])] *Sokal and Sneath similarity measure 2.*

$$SS2(x,y) = \frac{a}{a+2(b+c)}$$

K1[(p[,np])] *Kulczynski similarity measure 1.* This measure has a minimum value of 0 and no upper limit. The measure is undefined when there are no nonmatches (*b*=0 and *c*=0).

$$K1(x,y) = \frac{a}{b+c}$$

SS3[(p[,np])] *Sokal and Sneath similarity measure 3.* This measure has a minimum value of 0 and no upper limit. The measure is undefined when there are no nonmatches (*b*=0 and *c*=0).

$$SS3(x,y) = \frac{a+d}{b+c}$$

Conditional Probabilities. The following binary measures yield values that can be interpreted in terms of conditional probability. All three measures are similarity measures.

K2[(p[,np])] *Kulczynski similarity measure 2.* This measure yields the average conditional probability that a characteristic is present in one item given that the characteristic is present in the other item. The measure is an average over both items that are acting as predictors. The measure has a range of 0 to 1.

$$K2(x,y) = \frac{a/(a+b)+a/(a+c)}{2}$$

SS4[(p[,np])] *Sokal and Sneath similarity measure 4.* This measure yields the conditional probability that a characteristic of one item is in the same state (presence or absence) as the characteristic of the other item. The measure is an average over both items that are acting as predictors. The measure has a range of 0 to 1.

$$SS4(x,y) = \frac{a/(a+b)+a/(a+c)+d/(b+d)+d/(c+d)}{4}$$

HAMANN[(p[,np])] *Hamann similarity measure.* This measure gives the probability that a characteristic has the same state in both items (present in both or absent from both) minus the probability that a characteristic has different states in the two items (present in one and absent from the other). HAMANN has a range of −1 to +1 and is monotonically related to SM, SS1, and RT.

$$HAMANN(x,y) = \frac{(a+d)-(b+c)}{a+b+c+d}$$

Predictability Measures. The following four binary measures assess the association between items as the predictability of one item given the other item. All four measures yield similarities.

LAMBDA[(p[,np])] *Goodman and Kruskal's lambda (similarity).* This coefficient assesses the predictability of the state of a characteristic on one item (present or absent) given the state on the other item. Specifically, LAMBDA measures the proportional reduction in error, using one item to predict the other item when the directions of prediction are of equal importance. LAMBDA has a range of 0 to 1.

$$LAMBDA(x,y) = \frac{t_1-t_2}{2(a+b+c+d)-t_2}$$

where

t_1 = max(a, b) + max(c, d) + max(a, c) + max(b,d)

t_2 = max(a + c, b + d) + max(a + d, c + d).

D[(p[,np])] *Anderberg's* D *(similarity).* This coefficient assesses the predictability of the state of a characteristic on one item (present or absent) given the state on the other item. D measures the actual reduction in the error probability when one item is used to predict the other item. The range of D is 0 to 1.

$$D(x,y) = \frac{t_1-t_2}{2(a+b+c+d)}$$

where

t_1 = max(a, b) + max(c, d) + max(a, c) + max(b,d)

t_2 = max(a + c, b + d) + max(a + d, c + d)

Y[(p[,np])] *Yule's* Y *coefficient of colligation (similarity).* This measure is a function of the cross ratio for a 2×2 table and has a range of −1 to +1.

$$Y(x,y) = \frac{\sqrt{ad}-\sqrt{bc}}{\sqrt{ad}+\sqrt{bc}}$$

Q[(p[,np])] *Yule's* Q *(similarity).* This measure is the 2×2 version of Goodman and Kruskal's ordinal measure *gamma.* Like Yule's *Y*, Q is a function of the cross ratio for a 2×2 table and has a range of −1 to +1.

Other Binary Measures. The remaining binary measures that are available in PROXIMITIES are either binary equivalents of association measures for continuous variables or measures of special properties of the relationship between items.

OCHIAI[(p[,np])] *Ochiai similarity measure.* This measure is the binary form of the cosine and has a range of 0 to 1.

$$OCHIAI(x,y) = \sqrt{\frac{a}{a+b}\ \frac{a}{a+c}}$$

SS5[(p[,np])] *Sokal and Sneath similarity measure 5.* The range is 0 to 1.

$$SS5(x,y) = \frac{ad}{\sqrt{(a+b)(a+c)(b+d)(c+d)}}$$

PHI[(p[,np])] *Fourfold point correlation (similarity).* This measure is the binary form of the Pearson product-moment correlation coefficient.

$$PHI(x,y) = \frac{ad-bc}{\sqrt{(a+b)(a+c)(b+d)(c+d)}}$$

BEUCLID[(p[,np])] *Binary Euclidean distance.* This measure is a distance measure. Its minimum value is 0, and it has no upper limit.

$$BEUCLID(x,y) = \sqrt{b+c}$$

BSEUCLID[(p[,np])] *Binary squared Euclidean distance.* This measure is a distance measure. Its minimum value is 0, and it has no upper limit.

$$BSEUCLID(x,y) = b+c$$

SIZE[(p[,np])] *Size difference.* This measure is a dissimilarity measure with a minimum value of 0 and no upper limit.

$$SIZE(x,y) = \frac{(b-c)^2}{(a+b+c+d)^2}$$

PATTERN[(p[,np])] *Pattern difference.* This measure is a dissimilarity measure. The range is 0 to 1.

$$PATTERN(x,y) = \frac{bc}{(a+b+c+d)^2}$$

BSHAPE[(p[,np])] *Binary shape difference.* This dissimilarity measure has no upper limit or lower limit.

$$BSHAPE(x,y) = \frac{(a+b+c+d)(b+c)-(b-c)^2}{(a+b+c+d)^2}$$

DISPER[(p[,np])] *Dispersion similarity measure.* The range is −1 to +1.

$$DISPER(x,y) = \frac{ad-bc}{(a+b+c+d)^2}$$

VARIANCE[(p[,np])] *Variance dissimilarity measure.* This measure has a minimum value of 0 and no upper limit.

$$VARIANCE(x,y) = \frac{b+c}{4(a+b+c+d)}$$

BLWMN[(p[,np])] *Binary Lance-and-Williams nonmetric dissimilarity measure.* This measure is also known as the Bray-Curtis nonmetric coefficient. The range is 0 to 1.

$$BLWMN(x,y) = \frac{b+c}{2a+b+c}$$

Example

```
PROXIMITIES A B C
  /MEASURE=RR(1,2).
```

- MEASURE computes Russell and Rao coefficients from data in which 1 indicates the presence of a characteristic and 2 indicates the absence. Other values are ignored.

Example

```
PROXIMITIES A B C
  /MEASURE=SM(2).
```

- MEASURE computes simple matching coefficients from data in which 2 indicates presence and all other values indicate absence.

Transforming Measures in Proximity Matrix

Use keyword NONE to apply the ABSOLUTE, REVERSE, and/or RESCALE transformations to an existing matrix of proximity values without computing any proximity measures.

NONE *Do not compute proximity measures.* Use NONE only if you have specified an existing proximity matrix on keyword IN on the MATRIX subcommand.

PRINT Subcommand

PROXIMITIES always prints the name of the measure that it computes and the number of cases. Use PRINT to control printing of the proximity matrix.

PROXIMITIES *Print the matrix of the proximities between items.* This setting is the default. The matrix may have been either read or computed. When the number of cases or variables is large, this specification produces a large volume of output and uses significant CPU time.

NONE *Do not print the matrix of proximities.*

ID Subcommand

By default, PROXIMITIES identifies cases by case number alone. Use ID to specify an identifying string variable for cases.

- Any string variable in the active dataset can be named as the identifier. PROXIMITIES uses the first eight characters of this variable to identify cases in the output.
- When used with the MATRIX IN subcommand, the variable that is specified on the ID subcommand identifies the labeling variable in the matrix file.

MISSING Subcommand

MISSING controls the treatment of cases with missing values.

- PROXIMITIES deletes cases with missing values listwise. By default, PROXIMITIES excludes user-missing values from the analysis.

EXCLUDE *Exclude cases with user-missing values.* This setting is the default.

INCLUDE *Include cases with user-missing values.* Only cases with system-missing values are deleted.

MATRIX Subcommand

MATRIX reads and writes matrix data files.

- Either IN or OUT and the matrix file in parentheses are required. When both IN and OUT are used on the same PROXIMITIES command, they can be specified on separate MATRIX subcommands or on the same subcommand.

OUT ('savfile'|'dataset') *Write a matrix data file or dataset.* Specify either a filename, a previously declared dataset name, or an asterisk, enclosed in parentheses. Filenames should be enclosed in quotes and are stored in the working directory unless a path is included as part of the file specification. If you specify an asterisk (*), the matrix data file replaces the active dataset. If you specify an asterisk or a dataset name, the file is not stored on disk unless you use SAVE or XSAVE.

IN ('savfile'|'dataset') *Read a matrix data file or dataset.* Specify either a filename, dataset name created during the current session, or an asterisk enclosed in parentheses. An asterisk reads the matrix data from the active dataset. Filenames should be enclosed in quotes and are read from the working directory unless a path is included as part of the file specification.

When a matrix is produced by using the MATRIX OUT subcommand, the matrix corresponds to a unique dataset. All subsequent analyses that are performed on this matrix would match the corresponding analysis on the original data. However, if the data file is altered in any way, this matching process would no longer occur.

For example, if the original file is edited or rearranged it would no longer correspond to the initially produced matrix. You need to make sure that the data match the matrix whenever inferring the results from the matrix analysis. Specifically, when the cluster membership is saved into an active dataset in the CLUSTER procedure, the proximity matrix in the MATRIX IN statement must match the current active dataset.

Matrix Output

- PROXIMITIES writes a variety of proximity matrices, each matrix with *ROWTYPE_* values of PROX. PROXIMITIES neither reads nor writes additional statistics with its matrix materials. See Format of the Matrix Data File on p. 1495 for a description of the file.
- The matrices that PROXIMITIES writes can be used by PROXIMITIES or other procedures. Procedures CLUSTER and ALSCAL can read a proximity matrix directly. Procedure FACTOR can read a correlation matrix that is written by PROXIMITIES, but RECODE must first be used to change the *ROWTYPE_* value PROX to *ROWTYPE_* value CORR. Also, the ID subcommand cannot be used on PROXIMITIES if the matrix will be used in FACTOR.
- If VIEW=VARIABLE, the variables in the matrix file will have the names and labels of the original variables.
- If VIEW=CASE (the default), the variables in the matrix file are named *VAR1, VAR2, ...VARn*, where *n* is the sequential number of the variable in the new file. The numeric suffix *n* is consecutive and does not necessarily match the number of the actual case. If there are no split files, the case number appears in the variable label in the form *CASE m*. The numeric suffix *m* is the actual case number and may not be consecutive (for example, if cases were selected before PROXIMITIES was executed).
- If VIEW=CASE, a numeric variable *CASENO_* is added to the matrix file. Values of *CASENO_* are the case numbers in the original file.
- The new file preserves the names and values of any split-file variables that are in effect. When split-file processing is in effect, no labels are generated for variables in the new file. The actual case number is retained by the variable *ID*.
- Any documents that are contained in the active dataset are not transferred to the matrix file.

Matrix Input

- PROXIMITIES can read a matrix file that is written by a previous PROXIMITIES procedure.
- Values for split-file variables should precede values for *ROWTYPE_*. *CASENO_* and the labeling variable (if present) should come after *ROWTYPE_* and before *VARNAME_*.
- If *CASENO_* is of type string rather than numeric, it is considered unavailable and a warning is issued.
- If *CASENO_* appears on a variable list, a syntax error results.
- PROXIMITIES ignores unrecognized *ROWTYPE_* values. In addition, PROXIMITIES ignores variables that are present in the matrix file that are not specified (or used by default) on the PROXIMITIES variable list.
- The program reads variable names, variable and value labels, and print and write formats from the dictionary of the matrix data file.
- MATRIX=IN cannot be used unless an active dataset has already been defined. To read an existing matrix data file at the beginning of a session, use GET to retrieve the matrix file, and then specify IN(*) on MATRIX.
- When you read a matrix that is created with MATRIX DATA, you should supply a value label for PROX of either *SIMILARITY* or *DISSIMILARITY* so that the matrix is correctly identified. If you do not supply a label, PROXIMITIES assumes *DISSIMILARITY*. See Format of the Matrix Data File on p. 1495.

- The variable list on PROXIMITIES can be omitted when a matrix file is used as input. When the variable list is omitted, all variables in the matrix data file are used in the analysis. If a variable list is specified, the specified variables can be a subset of the variables in the matrix file.
- With a large number of variables, the matrix data file will wrap when displayed (as with LIST) and will be difficult to read. Nonetheless, the matrix values are accurate and can be used as matrix input.

Format of the Matrix Data File

- The matrix data file includes three special variables created by the program: *ROWTYPE_*, *VARNAME_*, and *CASENO_*. Variable *ROWTYPE_* is a short string variable with value PROX (for proximity measure). PROX is assigned value labels containing the distance measure that is used to create the matrix and either *SIMILARITY* or *DISSIMILARITY* as an identifier. Variable *VARNAME_* is a short string variable whose values are the names of the new variables. Variable *CASENO_* is a numeric variable with values equal to the original case numbers.
- The matrix file includes the string variable that is named on the ID subcommand. This variable is used to identify cases. Up to 20 characters can be displayed for the identifier variable; longer values are truncated. The identifier variable is present only when VIEW=CASE (the default) and when the ID subcommand is used.
- The remaining variables in the matrix file are the variables that are used to form the matrix.

Split Files

- When split-file processing is in effect, the first variables in the matrix system file are the split variables, followed by *ROWTYPE_*, the case-identifier variable (if VIEW=CASE and ID are used), *VARNAME_*, and the variables that form the matrix.
- A full set of matrix materials is written for each split-file group that is defined by the split variables.
- A split variable cannot have the same name as any other variable that is written to the matrix data file.
- If split-file processing is in effect when a matrix is written, the same split file must be in effect when that matrix is read by any procedure.

Example: Matrix Output to SPSS-format External File

```
PROXIMITIES  V1 TO V20
  /MATRIX=OUT(DISTOUT).
```

- PROXIMITIES produces a default Euclidean distance matrix for cases by using variables *V1* through *V20* and saves the matrix in the SPSS-format file *DISTOUT*.
- The names of the variables on the matrix file will be *VAR1*, *VAR2, ...VARn*.

Example: Matrix Output to External File

```
GET FILE='/data/crime.sav'.
PROXIMITIES MURDER TO MOTOR
  /ID=CITY
  /MEASURE=EUCLID
  /MATRIX=OUT(PROXMTX).
```

- PROXIMITIES reads data from the SPSS-format data file *crime.sav* and writes one set of matrix materials to file *PROXMTX*.
- The active dataset is still *crime.sav*. Subsequent commands are executed on this file.

Example: Matrix Output to Working File

```
GET FILE='/data/crime.sav'.
PROXIMITIES MURDER TO MOTOR
  /ID=CITY
  /MEASURE=EUCLID
  /MATRIX=OUT(*).
LIST.
```

- PROXIMITIES writes the same matrix as in the example above. However, the matrix data file replaces the active dataset. The LIST command is executed on the matrix file, not on the *crime.sav* file.

Example: Matrix Input from External File

```
GET FILE PRSNNL.
FREQUENCIES VARIABLE=AGE.

PROXIMITIES CASE1 TO CASE8
  /ID=CITY
  /MATRIX=IN(PROXMTX).
```

- This example performs a frequencies analysis on file *PRSNNL* and then uses a different file that contains matrix data for PROXIMITIES.
- MATRIX=IN specifies the matrix data file *PROXMTX*. *PROXMTX* does not replace *PRSNNL* as the active dataset.

Example: Matrix Input from Working File

```
GET FILE PROXMTX.
PROXIMITIES CASE1 TO CASE8
  /ID=CITY
  /MATRIX=IN(*).
```

- This example assumes that you are starting a new session and want to read an existing matrix data file. GET retrieves the matrix file *PROXMTX*.
- MATRIX=IN specifies an asterisk because the matrix data file is the active dataset. If MATRIX=IN(PROXMTX) is specified, the program issues an error message.
- If the GET command is omitted, the program issues an error message.

Example: Matrix Output to and Then Input from Working File

```
GET FILE='/data/crime.sav'.
PROXIMITIES MURDER TO MOTOR
  /ID=CITY
  /MATRIX=OUT(*).
PROXIMITIES
  /MATRIX=IN(*)
  /STANDARDIZE.
```

- GET retrieves the SPSS-format data file *crime.sav*.
- The first PROXIMITIES command specifies variables for the analysis and reads data from file *crime.sav*. ID specifies *CITY* as the case identifier. MATRIX writes the resulting matrix to the active dataset.
- The second PROXIMITIES command uses the matrix file that is written by the first PROXIMITIES command as input. The asterisk indicates that the matrix file is the active dataset. The variable list is omitted, indicating that all variables in the matrix are to be used.
- The slash preceding the MATRIX subcommand on the second PROXIMITIES command is required. Without the slash, PROXIMITIES attempts to interpret MATRIX as a variable name rather than as a subcommand.

Example: Q-factor Analysis

In this example, PROXIMITIES and FACTOR are used for a *Q*-factor analysis, in which factors account for variance shared among observations rather than among variables. Procedure FACTOR does not perform *Q*-factor analysis without some preliminary transformation such as what is provided by PROXIMITIES. Because the number of cases exceeds the number of variables, the model is not of full rank, and FACTOR will print a warning. This result is a common occurrence when case-by-case matrices from PROXIMITIES are used as input to FACTOR.

```
* Recoding a PROXIMITIES matrix for procedure FACTOR.

GET FILE='/data/crime.sav'.
PROXIMITIES   MURDER TO MOTOR
  /MEASURE=CORR
  /MATRIX=OUT('/data/tempfile.sav').
GET FILE='/data/tempfile.sav' /DROP=ID.
RECODE ROWTYPE_ ('PROX' = 'CORR').
FACTOR MATRIX IN(COR=*).
```

- The MATRIX subcommand on PROXIMITIES writes the correlation matrix to the active dataset. Because the matrix materials will be used in procedure FACTOR, the ID subcommand is not specified.
- RECODE recodes *ROWTYPE_* value PROX to CORR so that procedure FACTOR can read the matrix.
- When FACTOR reads matrix materials, it reads all variables in the file. The MATRIX subcommand on FACTOR indicates that the matrix is a correlation matrix and that data are in the active dataset.

```

** Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Overview

PROXSCAL performs multidimensional scaling of proximity data to find a least-squares representation of the objects in a low-dimensional space. Individual differences models are allowed for multiple sources. A majorization algorithm guarantees monotone convergence for optionally transformed metric and nonmetric data under a variety of models and constraints.

Options

Data Input. You can read one or more square matrices of proximities that can either be symmetrical or asymmetrical. Alternatively, you can provide specifications with the TABLE subcommand for matrices with proximities in a stacked format. You can read proximity matrices created by PROXIMITIES and CLUSTER with the MATRIX subcommand. Additionally, you can read weights, initial configurations, fixed coordinates, and independent variables.

Methodological Assumptions. You can specify transformations considering all sources (unconditional) or separate transformations for each source (matrix-conditional) on the CONDITION subcommand. You can treat proximities as nonmetric (ordinal) or as metric (numerical or splines) using the TRANSFORMATION subcommand. Ordinal transformations can treat tied observations as tied (discrete) and untied (continuous). You can specify whether your proximities are similarities or dissimilarities on the PROXIMITIES subcommand.

Model Selection. You can specify multidimensional scaling models by selecting a combination of PROXSCAL subcommands, keywords, and criteria. The subcommand MODEL offers, besides the identity model, three individual differences models. You can specify other selections on the CRITERIA subcommand.

Constraints. You can specify fixed coordinates or independent variables to restrict the configuration(s) on the RESTRICTIONS subcommand. You can specify transformations (numerical, nominal, ordinal, and splines) for the independent variables on the same subcommand.

Output. You can produce output that includes the original and transformed proximities, history of iterations, common and individual configurations, individual space weights, distances, and decomposition of the stress. Plots can be produced of common and individual configurations, individual space weights, transformations, and residuals.

Basic Specification

The basic specification is PROXSCAL followed by a variable list. By default, PROXSCAL produces a two-dimensional metric Euclidean multidimensional scaling solution (identity model). Input is expected to contain one or more square matrices with proximities that are dissimilarities. The ratio transformation of the proximities is matrix-conditional. The analysis uses a simplex start as an initial configuration. By default, output includes fit and stress values, the coordinates of the common space, and a chart of the common space configuration.

Syntax Rules

- The number of dimensions (both minimum and maximum) may not exceed the number of proximities minus one.
- Dimensionality reduction is omitted if combined with multiple random starts.
- If there is only one source, then the model is always assumed to be identity.

Limitations

- PROXSCAL needs at least three objects, which means that at least three variables must be specified in the variable list. In the case of the TABLE subcommand, the minimum value for rowid and columnid must be at least three.
- PROXSCAL recognizes data weights created by the WEIGHT command but only in combination with the TABLE subcommand.
- Split-file has no implications for PROXSCAL.

Variable List Subcommand

The variable list identifies the columns in the proximity matrix or matrices that PROXSCAL reads. Each variable identifies one column of the proximity matrix, with each case in the active dataset representing one row, unless specified otherwise with the TABLE subcommand. In this case, the variable list identifies whole matrices or sources.

- Only numeric variables can be specified.
- The total number of cases must be divisible by the number of variables. This is not applicable when the TABLE subcommand is used.
- PROXSCAL reads data row by row; the columns are represented by the variables on the variable list. The order of the variables on the list is crucial.

Example

```
DATA LIST
  /object01 object02 object03 object04.

BEGIN DATA
  0 2 6 3
  2 0 5 4
  6 5 0 1
  3 4 1 0
END DATA.
```

```
PROXSCAL VARIABLES=object01 TO object04.
```

- This example specifies an analysis on a 4×4 proximity matrix.
- The total number of cases must be divisible by 4.

TABLE Subcommand

The TABLE subcommand specifies the row identifier rowid and the column identifier columnid. Using TABLE, the proximities of separate sources are given in separate variables on the PROXSCAL variable list.

In the same manner, sources are identified by sourceid. In combination with rowid and columnid, the proximities are stacked in one single variable, containing the proximities of all sources, where sources are distinguished by the values of sourceid.

Using sourceid as the only variable on the TABLE subcommand indicates the use of stacked matrices, where individual stacked matrices are recognized by different values of sourceid.

- Rowid, columnid, and sourceid should not be specified on the variable list.
- When specifying both upper- and lower-triangular parts of the matrix, the SHAPE subcommand will determine the handling of the data.
- If a cell's value is specified multiple times, the final specification is used.
- Rowid, columnid, and sourceid must appear in that order.
- Omitting sourceid causes PROXSCAL to use the sources specified on the PROXSCAL variable list. Each variable is assumed to contain the proximities of one source.
- Specifying multiple sources on the PROXSCAL variable list in conjunction with specifying rowid, columnid, and sourceid is not possible and causes PROXSCAL to ignore sourceid.

rowid *Row identifying variable.* The values of this variable specify the row object of a proximity. The values must be integers between 1 and the number of objects, inclusive.

columnid *Column identifying variable.* The values specify the column object of a proximity. The values must be integers between 1 and the number of objects, inclusive.

sourceid *Source identifying variable.* The values specify the source number and must be integers between 1 and the number of sources, inclusive. The value labels of this variable are used to identify sources on other subcommands. These value labels must comply with variable name conventions. Omitting a value label causes PROXSCAL to use the default label *SRC_n*, where *n* is the number of the source.

Example

```
DATA LIST
  /r_id c_id men women.

BEGIN DATA
2 1 1.08 1.14
3 1 0.68 1.12
3 2 0.95 0.75
4 1 0.96 0.32
```

```
4 2 0.76 0.98
4 3 0.47 0.69
. . .... ....
.. .. .... ....
13 10 0.55 0.86
13 11 0.61 0.97
13 12 0.46 0.83
END DATA.

PROXSCAL men women
  /TABLE=r_id BY c_id
  /PLOT = INDIVIDUAL (women).
```

- PROXSCAL reads two proximity matrices (*men* and *women*), where the row objects are specified by *r_id* and the column objects by *c_id*.
- A chart of the individual space for *women* is plotted.

This is one way to proceed. Another way is to add the proximities of the additional source below the proximities of the first source and specify sourceid on the TABLE subcommand, containing values distinguishing the first and the additional source (see the next example).

Example

```
DATA LIST
  /r_id c_id s_id prox.

BEGIN DATA
2 1 1 1.08
3 1 1 0.68
3 2 1 0.95
4 1 1 0.96
4 2 1 0.76
4 3 1 0.47
. . . ....
.. .. . ....
13 10 1 0.55
13 11 1 0.61
13 12 1 0.46
2 1 2 1.14
3 1 2 1.12
3 2 2 0.75
4 1 2 0.32
4 2 2 0.98
4 3 2 0.69
. . . ....
.. .. . ....
13 10 2 0.86
13 11 2 0.97
13 12 2 0.83
END DATA.

VALUE LABELS s_id 1 'men' 2 'women'.

PROXSCAL prox
  /TABLE=r_id BY c_id BY s_id
  /PLOT = INDIVIDUAL (women).
```

- PROXSCAL reads two proximity matrices. The row objects are identified by *r_id* and the column objects, by *c_id*. The proximity matrices are gathered in one variable, *source01*, where each source is distinguished by a value of the source identifying variable *s_id*.
- A chart of the individual space for *women* is plotted.

Example

```
DATA LIST LIST
  /obj_1 obj_2 obj_3 obj_4 s_id

BEGIN DATA
0  0  0  0 1
1  0  0  0 1
2  3  0  0 1
4  5  6  0 1
7  0  0  0 2
0  0  0  0 2
8  9  0  0 2
12 11 12 0 2
END DATA.

VALUE LABELS s_id 1 'women' 2 'men'.

PROXSCAL obj_1 obj_2 obj_3 obj_4
  /TABLE = s_id
  /MODEL = WEIGHTED
  /PLOT = INDIVIDUAL (women).
```

- PROXSCAL reads two proximity matrices. The objects are given on the PROXSCAL variable list. Each source is distinguished by a value of the source identifying variable *s_id*, which is also used for labeling.
- A chart of the individual space for *women* is plotted.

SHAPE Subcommand

The SHAPE subcommand specifies the structure of the proximity matrix.

LOWER *Lower-triangular data matrix.* For a lower-triangular matrix, PROXSCAL expects a square matrix of proximities of which the lower-triangular elements are used under the assumption that the full matrix is symmetric. The diagonal is ignored but must be included.

UPPER *Upper-triangular data matrix.* For an upper-triangular matrix, PROXSCAL expects a square matrix of proximities of which the upper-triangular elements are used under the assumption that the full matrix is symmetric. The diagonal is ignored but must be included.

BOTH *Full data matrix.* The values in the corresponding cells in the upper and lower triangles may be different. PROXSCAL reads the complete square matrix and, after obtaining symmetry, continues with the lower-triangular elements. The diagonal is ignored but must be included.

- System or other missing values on the (virtual) diagonal are ignored.

Example

```
PROXSCAL object01 TO object07
  /SHAPE=UPPER.
```

- PROXSCAL reads square matrices of seven columns per matrix of which the upper-triangular parts are used in computations.
- Although specified, the diagonal and lower-triangular part of the matrix are not used.

INITIAL Subcommand

INITIAL defines the initial or starting configuration of the common space for the analysis. When a reduction in dimensionality is specified on the CRITERIA subcommand, a derivation of coordinates in the higher dimensionality is used as a starting configuration in the lower dimensionality.

- You can specify one of the three keywords listed below.
- You can specify a variable list containing the initial configuration.

SIMPLEX *Simplex start.* This specification is the default. PROXSCAL starts by placing the objects in the configuration all at the same distance of each other and taking one iteration to improve this high-dimensional configuration, followed by a dimension-reduction operation to obtain the user-provided maximum dimensionality specified in the CRITERIA subcommand with the keyword DIMENSIONS.

TORGERSON *Torgerson start.* A classical scaling solution is used as initial configuration.

RANDOM *(Multiple) random start.* You can specify the number of random starts (*n*). *n* is any positive integer. The random sequence can be controlled by the RANDOM SEED command and not by a subcommand within the PROXSCAL command. Each analysis starts with a different random configuration. In the output, all *n* final stress values are reported, as well as the initial seeds of each analysis (for reproduction purposes), followed by the full output of the analysis with the lowest stress value. The default number of random starts is 1. Reduction of dimensionality—that is, using a maximum dimensionality that is larger than the minimum dimensionality—is not allowed within this option and the minimum dimensionality is used, if reduction is specified anyway.

Instead of these keywords, a parenthesized SPSS data file can be specified containing the coordinates of the initial configuration. If the variable list is omitted, the first MAXDIM variables are automatically selected, where MAXDIM is the maximum number of dimensions requested for the analysis on the CRITERIA subcommand. Only nonmissing values are allowed as initial coordinates.

Example

```
PROXSCAL object01 TO object17
  /INITIAL=RANDOM(100).
```

- This example performs 100 analyses each, starting with different random configurations. The results of the analysis with the lowest final stress are displayed in the output.

WEIGHTS Subcommand

The WEIGHTS subcommand specifies non-negative weights on the proximities included in the active dataset.

- The number and order of the variables in the variable list is important. The first variable on the WEIGHTS variable list corresponds to the first variable on the PROXSCAL variable list. This is repeated for all variables on the variable lists. Every proximity has its own weight. The number of variables on the WEIGHTS subcommand must therefore be equal to the number of variables on the PROXSCAL variable list.
- Negative weights are not allowed. If specified, a warning will be issued and the procedure will abort.

Example

```
DATA LIST FILE='cola.dat' FREE
  /object01 TO object14 weight01 TO weight14.

PROXSCAL object01 TO object14
  /WEIGHTS=weight01 TO weight14.
```

- In this example, the VARIABLES subcommand indicates that there are 14 columns per matrix of which the weights can be found in *weight01* to *weight14*.
- *weight01* contains the weights for *object01*, etc.

CONDITION Subcommand

CONDITION specifies how transformations among sources are compared. The TRANSFORMATION subcommand specifies the type of transformation.

MATRIX	*Matrix conditional.* Only the proximities within each source are compared with each other. This is the default.
UNCONDITIONAL	*Unconditional.* This specification is appropriate when the proximities in all sources can be compared with each other and result in a single transformation of all sources simultaneously.

- Note that if there is only one source, then MATRIX and UNCONDITIONAL give the same results.

Example

```
PROXSCAL object01 TO object15
  /CONDITION=UNCONDITIONAL
  /TRANSFORMATION=ORDINAL(UNTIE).
```

- In this example, the proximities are ordinally transformed, where tied proximities are allowed to be untied. The transformations are performed simultaneously over all possible sources.

TRANSFORMATION Subcommand

TRANSFORMATION offers four different options for optimal transformation of the original proximities. The resulting values are called transformed proximities. The distances between the objects in the configuration should match these transformed proximities as closely as possible.

RATIO *No transformation.* Omitting the entire subcommand is equivalent to using this keyword. In both cases, the transformed proximities are proportional to the original proximities. This "transformation" is only allowed for positive dissimilarities. In all other cases, a warning is issued and the transformation is set to INTERVAL.

INTERVAL *Numerical transformation.* In this case, the transformed proximities are proportional to the original proximities, including free estimation of the intercept. The inclusion of the intercept assures that all transformed proximities are positive.

ORDINAL *Ordinal transformation.* The transformed proximities have the same order as the original proximities. In parentheses, the approach to tied proximities can be specified. Keeping tied proximities tied, also known as secondary approach to ties, is default. Specification may be implicit, ORDINAL, or explicit, ORDINAL(KEEPTIES). Allowing tied proximities to be untied, also known as the primary approach to ties, is specified as ORDINAL (UNTIE).

SPLINE *Monotone spline transformation.* The transformed proximities are a smooth nondecreasing piecewise polynomial transformation of the original proximities of the chosen degree. The pieces are specified by the number and placement of the interior knots.

SPLINE Keyword

SPLINE has the following keywords:

DEGREE *The degree of the polynomial.* If DEGREE is not specified, the degree is assumed to be 2. The range of DEGREE is between 1 and 3 (inclusive).

INKNOT *The number of interior knots.* If INKNOT is not specified, the number of interior knots is assumed to be 1. The range of INKNOT is between 1 and the number of different proximities.

Example

```
PROXSCAL object01 TO object05
  /TRANSFORMATION=ORDINAL(UNTIE).
```

- In this example, the proximities are ordinally transformed, where tied proximities are allowed to be untied.
- The default conditionality (MATRIX) implies that the transformation is performed for each source separately.

PROXIMITIES Subcommand

The PROXIMITIES subcommand specifies the type of proximities used in the analysis. The term proximity is used for either similarity or dissimilarity data.

DISSIMILARITIES	*Dissimilarity data.* This specification is the default when PROXIMITIES is not specified. Small dissimilarities correspond to small distances, and large dissimilarities correspond to large distances.
SIMILARITIES	*Similarity data.* Small similarities correspond to large distances and large similarities correspond to small distances.

Example

```
PROXSCAL object01 TO object12
  /PROXIMITIES=SIMILARITIES.
```

- In this example, PROXSCAL expects the proximities to be similarities.

MODEL Subcommand

MODEL defines the scaling model for the analysis if more than one source is present. IDENTITY is the default model. The three other models are individual differences models.

IDENTITY	*Identity model.* All sources have the same configuration. This is the default model, and it is not an individual differences model.
WEIGHTED	*Weighted Euclidean model.* This model is an individual differences model and equivalent to the INDSCAL model in the ALSCAL procedure. Each source has an individual space, in which every dimension of the common space is weighted differentially.
GENERALIZED	*Generalized Euclidean model.* This model is equivalent to the GEMSCAL model in the ALSCAL procedure. Each source has an individual space that is equal to a rotation of the common space, followed by a differential weighting of the dimensions.
REDUCED	*Reduced rank model.* This model is similar to GENERALIZED, but the rank of the individual space is equal to n. This number is always smaller than the maximum number of dimensions and equal to or greater than 1. The default is 2.

- If IDENTITY is specified for only one source, this subcommand is silently ignored.
- If an individual differences model is specified for only one source, a warning is issued, and the model is set to IDENTITY.

Example

```
PROXSCAL object01 TO object07
  /MODEL=WEIGHTED.
```

- A weighted Euclidean model is fitted, but only when the number of cases in the active dataset is a multiple of 7, starting from 14 (14, 21, 28, and so on). Otherwise, there is only one source, and the model is set to IDENTITY.

RESTRICTIONS Subcommand

PROXSCAL provides two types of restrictions for the user to choose from. The first type fixes (some) coordinates in the configuration. The second type specifies that the common space is a weighted sum of independent variables.

COORDINATES *Fixed coordinates.* A parenthesized SPSS data filename must be specified containing the fixed coordinates for the common space. A variable list may be given, if some specific variables need to be selected from the external file. If the variable list is omitted, the procedure automatically selects the first MAXDIM variables in the external file, where MAXDIM is the maximum number of dimensions requested for the analysis on the CRITERIA subcommand. A missing value indicates that a coordinate on a dimension is free. The coordinates of objects with nonmissing values are kept fixed during the analysis. The number of cases for each variable must be equal to the number of objects.

VARIABLES *Independent variables.* The common space is restricted to be a linear combination of the independent variables in the variable list. A parenthesized SPSS data file must be specified containing the independent variables. If the variable list is omitted, the procedure automatically selects all variables in the external file. Instead of the variable list, the user may specify the keyword FIRST(n), where n is a positive integer, to select the first *n* variables in the external file. The number of cases for each variable must be equal to the number of objects. After the variable selection specification, we may provide a list of keywords (in number equal to the number of the independent variables) indicating the transformations for the independent variables.

VARIABLES Keyword

The following keywords may be specified:

INTERVAL *Numerical transformation.* In this case, the transformed values of a variable are proportional to the original values of the variable, including free estimation of the intercept.

NOMINAL *Nominal transformation.* The values are treated as unordered. The same values will obtain the same transformed values.

ORDINAL *Ordinal transformation.* The values of the transformed variable have the same order as the values of the original variable. In parenthesis, the approach to tied values can be specified. Keeping tied values tied, also known as secondary approach to ties, is default. Specification may be implicit, ORDINAL, or explicit, ORDINAL(KEEPTIES). Allowing tied values to be untied, also known as the primary approach to ties, is specified as ORDINAL (UNTIE).

SPLINE *Monotone spline transformation.* The transformed values of the variable are a smooth nondecreasing piecewise polynomial transformation of the original values of the chosen degree. The pieces are specified by the number and placement of the interior knots.

SPLINE Keyword

SPLINE has the following keywords:

DEGREE *The degree of the polynomial.* If DEGREE is not specified, the degree is assumed to be 2. The range of DEGREE is between 1 and 3 (inclusive).

INKNOT *The number of interior knots.* If INKNOT is not specified, the number of interior knots is assumed to be 1. The range of INKNOT is between 0 and the number of different values of the variable.

Example

```
PROXSCAL aunt TO uncle
  /RESTRICTIONS=VARIABLES(ivars.sav) degree generation gender
                          (ORDINAL ORDINAL NOMINAL).
```

- In this example, there are three independent variables specified: *degree*, *generation*, and *gender*.
- The variables are specified in the data file *ivars.sav*.
- On both *degree* and *generation*, ordinal transformations are allowed. By default, tied values in ordinal variables are kept tied. *Gender* is allowed to be nominally transformed.

ACCELERATION Subcommand

By default, a fast majorization method is used to minimize stress.

NONE *The standard majorization update.* This turns off the fast method.

- If the subcommand RESTRICTION is used with fixed coordinates or independent variables, ACCELERATION=NONE is in effect.
- If an individual differences model is specified on the MODEL subcommand, ACCELERATION=NONE is in effect.

Example

```
PROXSCAL VARIABLES=object01 TO object12
  /ACCELERATION=NONE.
```

- Here, relaxed updates are switched off through the specification of the keyword NONE after ACCELERATION.

CRITERIA Subcommand

Use CRITERIA to set the dimensionality and criteria for terminating the algorithm, or minimization process. You can specify one or more of the following keywords:

DIMENSIONS *Minimum and maximum number of dimensions.* By default, PROXSCAL computes a solution in two dimensions (min=2 and max=2). The minimum and maximum number of dimensions can be any integers inclusively between 1 and the number of objects minus 1, as long as the minimum is less than or equal to the maximum. PROXSCAL starts computing a solution in the largest dimensionality and reduces the dimensionality in steps, until the lowest dimensionality is reached. Specifying a single value represents both minimum and maximum number of dimensions, thus DIMENSIONS(4) is equivalent to DIMENSIONS(4,4).

MAXITER *Maximum number of iterations.* By default, *n*=100, specifying the maximum number of iterations that is performed while one of the convergence criterion below (CONVERGENCE and STRESSMIN) is not yet reached. Decreasing this number might give less accurate results but will take less time. *N* must have a positive integer value.

DIFFSTRESS *Convergence criterion.* PROXSCAL minimizes the goodness-of-fit index normalized raw stress. By default, PROXSCAL stops iterating when the difference in consecutive stress values is less than 0.0001 (*n*=0.0001). To obtain a more precise solution, you can specify a smaller value. The value specified must lie between 0.0 and 1.0, inclusively.

MINSTRESS *Minimum stress value.* By default, PROXSCAL stops iterating when the stress value itself is small, that is, less than 0.0001 (*n*=0.0001). To obtain an even more precise solution, you can specify a smaller value. The value specified must lie between 0.0 and 1.0, inclusively.

Example

```
PROXSCAL VARIABLES=object01 TO object24
  /CRITERIA=DIMENSIONS(2,4) MAXITER(200) DIFFSTRESS(0.00001).
```

- The maximum number of dimensions equals 4 and the minimum number of dimensions equals 2. PROXSCAL computes a four-, three-, and two-dimensional solution, respectively.
- The maximum number of iteration is raised to 200.
- The convergence criterion is sharpened to 0.00001.

PRINT Subcommand

PRINT specifies the optional output. By default, PROXSCAL displays the stress and fit values for each analysis, the coordinates of the common space, and, with appropriate specification on corresponding subcommands, the individual space weights and transformed independent variables, corresponding regression weights, and correlations.

- Omitting the PRINT subcommand or specifying PRINT without keywords is equivalent to specifying COMMON, WEIGHTS, and VARIABLES.
- If a keyword(s) is specified, only the output for that particular keyword(s) is displayed.
- In the case of duplicate or contradicting keyword specification, the last keyword applies.

- Inapplicable keywords are silently ignored. That is, specifying a keyword for which no output is available (for example, specifying `INDIVIDUAL` with only one source) will silently ignore this keyword.

NONE	*No output.* Display only the normalized raw stress and corresponding fit values.
INPUT	*Input data.* The display includes the original proximities, and, if present, the data weights, the initial configuration, and the fixed coordinates or the independent variables.
RANDOM	*Multiple random starts.* Displays the random number seed and stress value of each random start.
HISTORY	*History of iterations.* Displays the history of iterations of the main algorithm.
STRESS	*Stress measures.* Displays different stress values. The table contains values for normalized raw stress, Stress-I, Stress-II, S-Stress, dispersion accounted for (D.A.F.), and Tucker's coefficient of congruence. This is specified by default.
DECOMPOSITION	*Decomposition of stress.* Displays an object and source decomposition of stress, including row and column totals.
COMMON	*Common space.* Displays the coordinates of the common space. This is specified by default.
DISTANCES	*Distances.* Displays the distances between the objects in the configuration.
WEIGHTS	*Individual space weights.* Displays the individual space weights, only if one of the individual differences models is specified on the `MODEL` subcommand. Depending on the model, the space weights are decomposed in rotation weights and dimension weights, which are also displayed. This is specified by default.
INDIVIDUAL	*Individual spaces.* The coordinates of the individual spaces are displayed, only if one of the individual differences models is specified on the `MODEL` subcommand.
TRANSFORMATION	*Transformed proximities.* Displays the transformed proximities between the objects in the configuration.
VARIABLES	*Independent variables.* If `VARIABLES` was specified on the `RESTRICTIONS` subcommand, this keyword triggers the display of the transformed independent variables and the corresponding regression weights. This is specified by default.
CORRELATIONS	*Correlations.* The correlations between the independent variables and the dimensions of the common space are displayed. This is specified by default.

Example

```
PROXSCAL VARIABLES=source01 TO source02
  /TABLE=row_id BY col_id
  /MODEL=WEIGHTED
  /PRINT=HISTORY COMMON STRESS.
```

- Here, a weighted Euclidean model is specified with two sources.
- The output consists of the history of iterations of the main algorithm, the coordinates of the common space, the individual space weights, and several measures of fit.

PLOT Subcommand

PLOT controls the display of plots. By default, PROXSCAL produces a scatterplot of object coordinates of the common space, the individual space weights, and the correlations between the independent variables (that is, equivalent to specifying COMMON, WEIGHTS, and CORRELATIONS).

- Specifying a keyword overrides the default output and only output is generated for that keyword.
- Duplicate keywords are silently ignored.
- In case of contradicting keywords, only the last keyword is considered.
- Inapplicable keywords (for example, stress with equal minimum and maximum number of dimensions on the CRITERIA subcommand) are silently ignored.
- Multiple variable lists are allowed for TRANSFORMATIONS and RESIDUALS. For each variable list, a separate plot will be displayed.

NONE	*No plots.* PROXSCAL does not produce any plots.
STRESS	*Stress plot.* A plot is produced of stress versus dimensions. This plot is only produced if the maximum number of dimensions is larger than the minimum number of dimensions.
COMMON	*Common space.* A scatterplot matrix of coordinates of the common space is displayed.
WEIGHTS	*Individual space weights.* A scatterplot is produced of the individual space weights. This is only possible if one of the individual differences models is specified on the MODEL subcommand. For the weighted Euclidean model, the weights are printed in plots with one dimension on each axis. For the generalized Euclidean model, one plot is produced per dimension, indicating both rotation and weighting of that dimension. The reduced rank model produces the same plot as the generalized Euclidean model does but reduces the number of dimensions for the individual spaces.
INDIVIDUAL	*Individual spaces.* For each source specified on the variable list, the coordinates of the individual spaces are displayed in scatterplot matrices. This is only possible if one of the individual differences models is specified on the MODEL subcommand.
TRANSFORMATIONS	*Transformation plots.* Plots are produced of the original proximities versus the transformed proximities. On the variable list, the sources can be specified of which the plot is to be produced.
RESIDUALS	*Residuals plots.* The transformed proximities versus the distances are plotted. On the variable list, the sources can be specified of which the plot is to be produced.
VARIABLES	*Independent variables.* Transformation plots are produced for the independent variables specified on the variable list.
CORRELATIONS	*Correlations.* A plot of correlations between the independent variables and the dimensions of the common space is displayed.

Example

```
PROXSCAL VARIABLES=source01 TO source02
  /TABLE=row_id BY col_id
  /MODEL=WEIGHTED
  /CRITERIA=DIMENSIONS(3)
  /PLOT=COMMON INDIVIDUAL(source02).
```

- Here, the syntax specifies a weighted Euclidean model with two sources in three dimensions.
- COMMON produces a scatterplot matrix defined by dimensions 1, 2, and 3.
- For the individual spaces, a scatterplot matrix with 3 dimensions is only produced for the individual space of *source02*.

OUTFILE Subcommand

OUTFILE saves coordinates of the common space, individual space weights, distances, transformed proximities, and transformed independent variables to an SPSS data file or previously declared dataset. The only specification required is a name for the output file.

COMMON *Common space coordinates.* The coordinates of the common space are written to an SPSS data file. The columns (variables) represent the dimensions *DIM_1*, *DIM_2*, ..., *DIM_n* of the common space. The number of cases (rows) in the SPSS data file equals the number of objects.

WEIGHTS *Individual space weights.* The individual space weights are written to an SPSS data file. The columns represent the dimensions *DIM_1*, *DIM_2*, ..., *DIM_n* of the space weights. The number of cases depends on the individual differences model specified on the MODEL subcommand. The weighted Euclidean model uses diagonal weight matrices. Only the diagonals are written to file and the number of cases is equal to the number of dimensions. The generalized Euclidean model uses full-rank nonsingular weight matrices. The matrices are written to the SPSS data file row by row. The reduced rank model writes matrices to the SPSS data file in the same way as the generalized Euclidean model does but does not write the reduced part.

DISTANCES *Distances.* The matrices containing the distances for each source are stacked beneath each other and written to an SPSS data file. The number of variables in the data file are equal to the number of objects (*OBJ_1*, *OBJ_2*, ..., *OBJ_n*) and the number of cases in the data file are equal to the number of objects times the number of sources.

TRANSFORMATION *Transformed proximities.* The matrices containing the transformed proximities for each source are stacked beneath each other and written to an SPSS data file. The number of variables in the file are equal to the number of objects (*OBJ_1*, *OBJ_2*, ..., *OBJ_n*) and the number of cases in the data file are equal to the number of objects times the number of sources.

VARIABLES *Independent variables.* The transformed independent variables are written to an SPSS data file. The variables are written to the columns (*VAR_1*, *VAR_2*, ..., *VAR_n*). The number of variables in the data file are equal to the number of independent variables and the number of cases are equal to the number of objects.

Example

```
PROXSCAL VARIABLES=source01 TO source04
  /TABLE=row_id BY col_id
  /OUTFILE=COMMON('/data/start.sav').
```

- Here, the coordinates of the common space are written to the SPSS data file *start.sav*.
- Filenames should be enclosed in quotes and are stored in the working directory unless a path is included as part of the file specification. datasets are available during the current session but are not available in subsequent sessions unless you explicitly save them as data files.

MATRIX Subcommand

MATRIX reads matrix data files. It can read a matrix written by either PROXIMITIES or CLUSTER.

- The specification on MATRIX is the keyword IN and the matrix file in parentheses.
- Generally, data read by PROXSCAL are already in matrix form, whether in square format, or in stacked format using the TABLE subcommand.
- The proximity matrices PROXSCAL reads have ROWTYPE_ values of PROX.
- Using MATRIX=IN, PROXSCAL will ignore variables specified on the main variable list. All numerical variables from the matrix data file are processed.
- PROXSCAL ignores variables specified in the WEIGHTS subcommand in combination with the use of MATRIX=IN.
- With MATRIX=IN, only a source identifying variable can be specified on the TABLE subcommand. The sources are created as a result of a split file action.

IN('file'|'dataset') *Read a matrix data file.* Specify a quoted file specification or previously declared dataset name, enclosed in parentheses. Data read through the MATRIX subcommand does not replace the active dataset.

Example

```
GET FILE = '/data/proxmtx.SAV'.

PROXSCAL
  /MATRIX=IN('/data/matrix.sav').
```

- MATRIX=IN specifies an external matrix data file called *matrix.sav*, of which all numerical variables are used for the current analysis.

QUICK CLUSTER

```
QUICK CLUSTER {varlist}
              {ALL    }

 [/MISSING=[{LISTWISE**}] [INCLUDE]]
           {PAIRWISE  }
           {DEFAULT   }

 [/FILE='savfile'|'dataset']

 [/INITIAL=(value list)]

 [/CRITERIA=[CLUSTER({2**})][NOINITIAL][MXITER({10**})] [CONVERGE({0**})]]
                    {n  }                      {n   }             {n  }

 [/METHOD=[{KMEANS[(NOUPDATE)]**}]
          {KMEANS(UPDATE)}     }
          {CLASSIFY            }

 [/PRINT=[INITIAL**] [CLUSTER] [ID(varname)] [DISTANCE] [ANOVA] [NONE]]

 [/OUTFILE='savfile'|'dataset']

 [/SAVE=[CLUSTER[(varname)]] [DISTANCE[(varname)]]]
```

**Default if subcommand or keyword is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
QUICK CLUSTER V1 TO V4
  /CRITERIA=CLUSTER(4)
  /SAVE=CLUSTER(GROUP).
```

Overview

When the desired number of clusters is known, QUICK CLUSTER groups cases efficiently into clusters. It is not as flexible as CLUSTER, but it uses considerably less processing time and memory, especially when the number of cases is large.

Options

Algorithm Specifications. You can specify the number of clusters to form with the CRITERIA subcommand. You can also use CRITERIA to control initial cluster selection and the criteria for iterating the clustering algorithm. With the METHOD subcommand, you can specify how to update cluster centers, and you can request classification only when working with very large data files.

Initial Cluster Centers. By default, QUICK CLUSTER chooses the initial cluster centers. Alternatively, you can provide initial centers on the INITIAL subcommand. You can also read initial cluster centers from an SPSS-format data file using the FILE subcommand.

Optional Output. With the PRINT subcommand, you can display the cluster membership of each case and the distance of each case from its cluster center. You can also display the distances between the final cluster centers and a univariate analysis of variance between clusters for each clustering variable.

Saving Results. You can write the final cluster centers to an SPSS-format data file using the OUTFILE subcommand. In addition, you can save the cluster membership of each case and the distance from each case to its classification cluster center as new variables in the active dataset using the SAVE subcommand.

Basic Specification

The basic specification is a list of variables. By default, QUICK CLUSTER produces two clusters. The two cases that are farthest apart based on the values of the clustering variables are selected as initial cluster centers and the rest of the cases are assigned to the nearer center. The new cluster centers are calculated as the means of all cases in each cluster, and if neither the minimum change nor the maximum iteration criterion is met, all cases are assigned to the new cluster centers again. When one of the criteria is met, iteration stops, the final cluster centers are updated, and the distance of each case is computed.

Subcommand Order

- The variable list must be specified first.
- Subcommands can be named in any order.

Operations

The procedure generally involves four steps:

- First, initial cluster centers are selected, either by choosing one case for each cluster requested or by using the specified values.
- Second, each case is assigned to the nearest cluster center, and the mean of each cluster is calculated to obtain the new cluster centers.
- Third, the maximum change between the new cluster centers and the initial cluster centers is computed. If the maximum change is not less than the minimum change value and the maximum iteration number is not reached, the second step is repeated and the cluster centers are updated. The process stops when either the minimum change or maximum iteration criterion is met. The resulting clustering centers are used as classification centers in the last step.
- In the last step, all cases are assigned to the nearest classification center. The final cluster centers are updated and the distance for each case is computed.

When the number of cases is large, directly clustering all cases may be impractical. As an alternative, you can cluster a sample of cases and then use the cluster solution for the sample to classify the entire group. This can be done in two phases:

- The first phase obtains a cluster solution for the sample. This involves all four steps of the QUICK CLUSTER algorithm. OUTFILE then saves the final cluster centers to an SPSS-format data file.

- The second phase requires only one pass through the data. First, the FILE subcommand specifies the file containing the final cluster centers from the first analysis. These final cluster centers are used as the initial cluster centers for the second analysis. CLASSIFY is specified on the METHOD subcommand to skip the second and third steps of the clustering algorithm, and cases are classified using the initial cluster centers. When all cases are assigned, the cluster centers are updated and the distance of each case is computed. This phase can be repeated until final cluster centers are stable.

Example

```
QUICK CLUSTER V1 TO V4
  /CRITERIA=CLUSTERS(4)
  /SAVE=CLUSTER(GROUP).
```

- This example clusters cases based on their values for all variables between and including *V1* and *V4* in the active dataset.
- Four clusters, rather than the default two, will be formed.
- Initial cluster centers are chosen by finding four widely spaced cases. This is the default.
- The cluster membership of each case is saved in variable *GROUP* in the active dataset. *GROUP* has integer values from 1 to 4, indicating the cluster to which each case belongs.

Variable List

The variable list identifies the clustering variables.

- The variable list is required and must be the first specification on QUICK CLUSTER.
- You can use keyword ALL to refer to all user-defined variables in the active dataset.
- QUICK CLUSTER uses squared Euclidean distances, which equally weight all clustering variables. If the variables are measured in units that are not comparable, the procedure will give more weight to variables with large variances. Therefore, you should standardize variables measured on different scales using procedure DESCRIPTIVES before performing QUICK CLUSTER.

CRITERIA Subcommand

CRITERIA specifies the number of clusters to form and controls options for the clustering algorithm. You can use any or all of the keywords below.

- The NOINITIAL option followed by the remaining steps of the default QUICK CLUSTER algorithm makes QUICK CLUSTER equivalent to MacQueen's *n*-means clustering method.

CLUSTER(n) *Number of clusters.* QUICK CLUSTER assigns cases to *n* clusters. The default is 2.

NOINITIAL *No initial cluster center selection.* By default, initial cluster centers are formed by choosing one case (with valid data for the clustering variables) for each cluster requested. The initial selection requires a pass through the data to ensure that the centers are well separated from one another. If NOINITIAL is specified, QUICK CLUSTER selects the first *n* cases without missing values as initial cluster centers.

MXITER(n) *Maximum number of iterations for updating cluster centers.* The default is 10. Iteration stops when the maximum number of iterations has been reached. MXITER is ignored when METHOD=CLASSIFY.

CONVERGE(n) *Convergence criterion controlling minimum change in cluster centers.* The default value for *n* is 0. The minimum change value equals the convergence value (*n*) times the minimum distance between initial centers. Iteration stops when the largest change of any cluster center is less than or equal to the minimum change value. CONVERGE is ignored when METHOD=CLASSIFY.

METHOD Subcommand

By default, QUICK CLUSTER recalculates cluster centers after assigning all the cases and repeats the process until one of the criteria is met. You can use the METHOD subcommand to recalculate cluster centers after each case is assigned or to suppress recalculation until after classification is complete. When METHOD=KMEANS is specified, QUICK CLUSTER displays the iteration history table.

KMEANS(NOUPDATE) *Recalculate cluster centers after all cases are assigned for each iteration.* This is the default.

KMEANS(UPDATE) *Recalculate a cluster center each time a case is assigned.* QUICK CLUSTER calculates the mean of cases currently in the cluster and uses this new cluster center in subsequent case assignment.

CLASSIFY *Do not recalculate cluster centers.* QUICK CLUSTER uses the initial cluster centers for classification and computes the final cluster centers as the means of all the cases assigned to the same cluster. When CLASSIFY is specified, the CONVERGE or MXITER specifications on CRITERIA are ignored.

INITIAL Subcommand

INITIAL specifies the initial cluster centers. Initial cluster centers can also be read from an SPSS-format data file (see FILE Subcommand on p. 1520).

- One value for each clustering variable must be included for each cluster requested. Values are specified in parentheses cluster by cluster.

Example

```
QUICK CLUSTER  A B C D
  /CRITERIA = CLUSTER(3)
  /INITIAL = (13 24  1  8
               7 12  5  9
              10 18 17 16).
```

- This example specifies four clustering variables and requests three clusters. Thus, twelve values are supplied on INITIAL.
- The initial center of the first cluster has a value of 13 for variable *A*, 24 for variable *B*, 1 for *C*, and 8 for *D*.

FILE Subcommand

Use FILE to obtain initial cluster centers from an SPSS-format data file or previously declared dataset (DATASET DECLARE command).

- The only specification is the quoted file specification or dataset name.

Example

```
QUICK CLUSTER  A B C D
  /FILE='/data/init.sav'
  /CRITERIA = CLUSTER(3).
```

- In this example, the initial cluster centers are read from file *init.sav*. The file must contain cluster centers for the same four clustering variables specified (*A*, *B*, *C*, and *D*).

PRINT Subcommand

QUICK CLUSTER always displays in a Final Cluster Centers table listing the centers used to classify cases and the mean values of the cases in each cluster and a Number of Cases in Each Cluster table listing the number of weighted (if weighting is on) and unweighted cases in each cluster. Use PRINT to request other types of output.

- If PRINT is not specified or is specified without keywords, the default is INITIAL.

INITIAL *Initial cluster centers.* When SPLIT FILES is in effect, the initial cluster center for each split file is displayed. This is the default.

CLUSTER *Cluster membership.* Each case displays an identifying number or value, the number of the cluster to which it was assigned, and its distance from the center of that cluster. This output is extensive when the number of cases is large.

ID(varname) *Case identification.* The value of the specified variable is used in addition to the case numbers to identify cases in output. Case numbers may not be sequential if cases have been selected.

DISTANCE *Pairwise distances between all final cluster centers.* This output can consume a great deal of processing time when the number of clusters requested is large.

ANOVA *Descriptive univariate* F *tests for the clustering variables.* Since cases are systematically assigned to clusters to maximize differences on the clustering variables, these tests are descriptive only and should not be used to test the null hypothesis that there are no differences between clusters. Statistics after clustering are also available through procedure DISCRIMINANT or GLM (GLM is available in the Advanced Models option).

NONE *No additional output.* Only the default output is displayed. NONE overrides any other specifications on PRINT.

Example

```
QUICK CLUSTER A B C D E
  /CRITERIA=CLUSTERS(6)
  /PRINT=CLUSTER ID(CASEID) DISTANCE.
```

- Six clusters are formed on the basis of the five variables *A*, *B*, *C*, *D*, and *E*.

- For each case in the file, cluster membership and distance from cluster center are displayed. Cases are identified by the values of the variable *CASEID*.
- Distances between all cluster centers are printed.

OUTFILE Subcommand

OUTFILE saves the final cluster centers in an SPSS-format data file or dataset. You can later use these final cluster centers as initial cluster centers for a different sample of cases that use the same variables. You can also cluster the final cluster centers themselves to obtain clusters of clusters.

- The only specification is a filename or previously declared dataset name for the file. Filenames should be enclosed in quotes and are stored in the working directory unless a path is included as part of the file specification. Datasets are available during the current session but are not available in subsequent sessions unless you explicitly save them as data files.
- The program displays the name of the saved file in the procedure information notes.

Example

```
QUICK CLUSTER A B C D
  /CRITERIA = CLUSTER(3)
  /OUTFILE = '/data/QC1.sav'.
```

- QUICK CLUSTER writes the final cluster centers to the file *QC1.sav*.

SAVE Subcommand

Use SAVE to save results of cluster analysis as new variables in the active dataset.

- You can specify a variable name in parentheses following either keyword. If no variable name is specified, QUICK CLUSTER forms unique variable names by appending an underscore and a sequential number to the rootname *QCL*. The number increments with each new variable saved.
- The program displays the new variables and a short description of each in the procedure information notes.

CLUSTER[(varname)]	*The cluster number of each case.* The value of the new variable is set to an integer from 1 to the number of clusters.
DISTANCE[(varname)]	*The distance of each case from its classification cluster center.*

Example

```
QUICK CLUSTER A B C D
  /CRITERIA=CLUSTERS(6)
  /SAVE=CLUSTER DISTANCE.
```

- Six clusters of cases are formed on the basis of the variables *A*, *B*, *C*, and *D*.

- A new variable *QCL_1* is created and set to an integer between 1 and 6 to indicate cluster membership for each case.
- Another new variable *QCL_2* is created and set to the Euclidean distance between a case and the center of the cluster to which it is assigned.

MISSING Subcommand

MISSING controls the treatment of cases with missing values.

- LISTWISE, PAIRWISE, and DEFAULT are alternatives. However, each can be used with INCLUDE.

LISTWISE *Delete cases with missing values listwise.* A case with a missing value for any of the clustering variables is deleted from the analysis and will not be assigned to a cluster. This is the default.

PAIRWISE *Assign each case to the nearest cluster on the basis of the clustering variables for which the case has nonmissing values.* Only cases with missing values for *all* clustering variables are deleted.

INCLUDE *Treat user-missing values as valid.*

DEFAULT *Same as LISTWISE.*

RANK

```
RANK VARIABLES= varlist [({A**})] [BY varlist]
                        {D  }

  [/TIES={MEAN**  }]
         {LOW     }
         {HIGH    }
         {CONDENSE}

  [/FRACTION={BLOM**}]
             {TUKEY }
             {VW    }
             {RANKIT}

  [/PRINT={YES**}]
          {NO   }

  [/MISSING={EXCLUDE**}]
            {INCLUDE  }
```

The following function subcommands can each be specified once:

```
  [/RANK**] [/NTILES(k)] [/NORMAL] [/PERCENT]

  [/RFRACTION] [/PROPORTION] [/N] [/SAVAGE]
```

The following keyword can be used with any function subcommand:

```
  [INTO varname]
```

**Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
RANK VARIABLES=SALARY JOBTIME.
```

Overview

RANK produces new variables containing ranks, normal scores, and Savage and related scores for numeric variables.

Options

Methods. You can rank variables in ascending or descending order by specifying A or D on the VARIABLES subcommand. You can compute different rank functions and also name the new variables using the function subcommands. You can specify the method for handling ties on the TIES subcommand, and you can specify how the proportion estimate is computed for the NORMAL and PROPORTIONAL functions on the FRACTION subcommand.

Format. You can suppress the display of the summary table that lists the ranked variables and their associated new variables in the active dataset using the PRINT subcommand.

Basic Specification

The basic specification is VARIABLES and at least one variable from the active dataset. By default, the ranking function is RANK. Direction is ascending, and ties are handled by assigning the mean rank to tied values. A summary table that lists the ranked variables and the new variables into which computed ranks have been stored is displayed.

Subcommand Order

- VARIABLES must be specified first.
- The remaining subcommands can be specified in any order.

Operations

- RANK does not change the way the active dataset is sorted.
- If new variable names are not specified with the INTO keyword on the function subcommand, RANK creates default names.
- RANK automatically assigns variable labels to the new variables. The labels identify the source variables. For example, the label for a new variable with the default name *RSALARY* is *RANK of SALARY*.

Example

```
RANK VARIABLES=SALARY JOBTIME.
```

- RANK ranks *SALARY* and *JOBTIME* and creates two new variables in the active dataset, *RSALARY* and *RJOBTIME*, which contain the ranks.

VARIABLES Subcommand

VARIABLES specifies the variables to be ranked.

- VARIABLES is required and must be the first specification on RANK. The minimum specification is a single numeric variable. To rank more than one variable, specify a variable list.
- After the variable list, you can specify the direction for ranking in parentheses. Specify A for ascending (smallest value gets smallest rank) or D for descending (largest value gets smallest rank). A is the default.
- To rank some variables in ascending order and others in descending order, use both A and D in the same variable list. A or D applies to all preceding variables in the list up to the previous A or D specification.
- To organize ranks into subgroups, specify keyword BY followed by the variable whose values determine the subgroups. The active dataset does not have to be sorted by this variable.
- String variables cannot be specified. Use AUTORECODE to recode string variables for ranking.

Examples

```
RANK VARIABLES=MURDERS ROBBERY (D).
```

- RANK ranks *MURDERS* and *ROBBERY* and creates two new variables in the active dataset: *RMURDERS* and *RROBBERY*.
- D specifies descending order of rank. D applies to both *MURDERS* and *ROBBERY*.

```
RANK VARIABLES=MURDERS (D) ROBBERY (A) BY ETHNIC.
```

- Ranks are computed within each group defined by *ETHNIC*. *MURDERS* is ranked in descending order and *ROBBERY* in ascending order within each group of *ETHNIC*. The active dataset does not have to be sorted by *ETHNIC*.

Function Subcommands

The optional function subcommands specify different rank functions. RANK is the default function.

- Any combination of function subcommands can be specified for a RANK procedure, but each function can be specified only once.
- Each function subcommand must be preceded by a slash.
- The functions assign default names to the new variables unless keyword INTO is specified.

RANK *Simple ranks.* The values for the new variable are the ranks. Rank can either be ascending or descending, as indicated on the VARIABLES subcommand. Rank values can be affected by the specification on the TIES subcommand.

RFRACTION *Fractional ranks.* The values for the new variable equal the ranks divided by the sum of the weights of the nonmissing cases. If HIGH is specified on TIES, fractional rank values are an empirical cumulative distribution.

NORMAL *Normal scores*(Lehmann, 1975). The new variable contains the inverse of the standard normal cumulative distribution of the proportion estimate defined by the FRACTION subcommand. The default for FRACTION is BLOM.

PERCENT *Fractional ranks as a percentage.* The new variable contains fractional ranks multiplied by 100.

PROPORTION *Proportion estimates.* The estimation method is specified by the FRACTION subcommand. The default for FRACTION is BLOM.

N *Sum of case weights.* The new variable is a constant.

SAVAGE *Savage scores*(Lehmann et al., 1975). The new variable contains Savage (exponential) scores.

NTILES(k) *Percentile groups.* The new variable contains values from 1 to *k*, where *k* is the number of groups to be generated. Each case is assigned a group value, which is the integer part of $1+rk/(w+1)$, where *r* is the rank of the case, *k* is the number of groups specified on NTILES, and *w* is the sum of the case weights. Group values can be affected by the specification on TIES. There is no default for *k*.

INTO Keyword

INTO specifies variable names for the new variable(s) added to the active dataset. INTO can be used with any of the function subcommands.

- INTO must follow a function subcommand. You must specify the INTO subcommand to assign names to the new variables created by the function.
- You can specify multiple variable names on INTO. The names are assigned to the new variables in the order they are created (the order the variables are specified on the VARIABLES subcommand).
- If you specify fewer names than the new variables, default names are used for the remaining new variables. If you specify more names, the program issues a message and the command is not executed.

If INTO is not specified on a function, RANK creates default names for the new variables according to the following rules:

- The first letter of the ranking function is added to the first seven characters of the original variable name.
- New variable names cannot duplicate variable names in the active dataset or names specified after INTO or generated by default.
- If a new default name is a duplicate, the scheme *XXXnnn* is used, where *XXX* represents the first three characters of the function and *nnn* is a three-digit number starting with 001 and increased by 1 for each variable. (If the ranking function is N, *XXX* is simply *N*.) If this naming scheme generates duplicate names, the duplicates are named *RNKXXnn*, where *XX* is the first two characters of the function and *nn* is a two-digit number starting with 01 and increased by 1 for each variable.
- If it is not possible to generate unique names, an error results.

Example

```
RANK VARIABLES=SALARY
 /NORMAL INTO SALNORM
 /SAVAGE INTO SALSAV
 /NTILES(4) INTO SALQUART.
```

- RANK generates three new variables from variable *SALARY*.
- NORMAL produces the new variable *SALNORM*. *SALNORM* contains normal scores for *SALARY* computed with the default formula BLOM.
- SAVAGE produces the new variable *SALSAV*. *SALSAV* contains Savage scores for *SALARY*.
- NTILES(4) produces the new variable *SALQUART*. *SALQUART* contains the value 1, 2, 3, or 4 to represent one of the four percentile groups of *SALARY*.

TIES Subcommand

TIES determines the way tied values are handled. The default method is MEAN.

MEAN	*Mean rank of tied values is used for ties.* This is the default.
LOW	*Lowest rank of tied values is used for ties.*
HIGH	*Highest rank of tied values is used for ties.*
CONDENSE	*Consecutive ranks with ties sharing the same value.* Each distinct value of the ranked variable is assigned a consecutive rank. Ties share the same rank.

Example

```
RANK VARIABLES=BURGLARY /RANK INTO RMEAN /TIES=MEAN.
RANK VARIABLES=BURGLARY /RANK INTO RCONDS /TIES=CONDENSE.
RANK VARIABLES=BURGLARY /RANK INTO RHIGH /TIES=HIGH.
RANK VARIABLES=BURGLARY /RANK INTO RLOW /TIES=LOW.
```

- The values of *BURGLARY* and the four new ranking variables are shown below:

```
BURGLARY   RMEAN   RCONDS   RHIGH   RLOW
   0         3        1       5       1
   0         3        1       5       1
   0         3        1       5       1
   0         3        1       5       1
   0         3        1       5       1
   1         6.5      2       7       6
   1         6.5      2       7       6
   3         8        3       8       8
```

FRACTION Subcommand

FRACTION specifies the way to compute a proportion estimate *P* for the NORMAL and PROPORTION rank functions.

- FRACTION can be used only with function subcommands NORMAL or PROPORTION. If it is used with other function subcommands, FRACTION is ignored and a warning message is displayed.
- Only one formula can be specified for each RANK procedure. If more than one is specified, an error results.

In the following formulas, *r* is the rank and *w* is the sum of case weights.

BLOM	*Blom's transformation, defined by the formula (r – 3/8) / (w + 1/4).* (Blom, 1958) This is the default.
RANKIT	*The formula is (r – 1/2) / w.* (Chambers, Cleveland, Kleiner, and Tukey, 1983)
TUKEY	*Tukey's transformation, defined by the formula (r – 1/3) / (w + 1/3).* (Tukey, 1962)
VW	*Van der Waerden's transformation, defined by the formula r / (w +1).* (Lehmann et al., 1975)

Example

```
RANK VARIABLES=MORTGAGE VALUE /FRACTION=BLOM
  /NORMAL INTO MORTNORM VALNORM.
```

- RANK generates new variables *MORTNORM* and *VALNORM*. *MORTNORM* contains normal scores for *MORTGAGE*, and *VALNORM* contains normal scores for *VALUE*.

PRINT Subcommand

PRINT determines whether the summary tables are displayed. The summary table lists the ranked variables and their associated new variables in the active dataset.

YES *Display the summary tables.* This is the default.

NO *Suppress the summary tables.*

MISSING Subcommand

MISSING controls the treatment of user-missing values.

INCLUDE *Include user-missing values.* User-missing values are treated as valid values.

EXCLUDE *Exclude all missing values.* User-missing values are treated as missing. This is the default.

Example

```
MISSING VALUE SALARY (0).
RANK VARIABLES=SALARY /RANK INTO SALRANK /MISSING=INCLUDE.
```

- RANK generates the new variable *SALRANK*.
- INCLUDE causes the user-missing value 0 to be included in the ranking process.

RATIO STATISTICS

```
RATIO STATISTICS numerator varname WITH denominator varname
  [BY group varname[({ASCENDING**})]]
                     {DESCENDING }
                     {NOSORT     }

 [/MISSING = {EXCLUDE**}]
             {INCLUDE  }

  [/OUTFILE('file'|'dataset') = [AAD] [BCOC((low,high) [(low,high)] ...)] [CIN[({95   })]]
                                                                          {value}
                          [COD] [MAX] [MDCOV] [MEAN] [MEDIAN] [MIN] [MNCOV] [PRD]
                          [RANGE] [STDDEV] [WCOC(value list)] [WGTMEAN]]

  [/PRINT = [AAD] [BCOC(low,high)...] [CIN[({95   })]]
                                      {value}
            [COD] [MAX] [MDCOV] [MEAN] [MEDIAN] [MIN] [MNCOV] [PRD]
            [RANGE] [STDDEV] [WCOC(value list)] [WGTMEAN]]
```

** Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
RATIO STATISTICS appraise WITH price
  /PRINT = AAD BCOC((1,2) (3,4)) MEAN.
```

Overview

RATIO STATISTICS provides a variety of descriptive statistics for the ratio between two variables.

Basic Specification

The minimum specification is a numerator variable and a denominator variable, and either an OUTFILE subcommand or a PRINT subcommand.

Subcommand Order

- The variable list must be specified first.
- Subcommands can be specified in any order.

Syntax Rules

- Empty subcommands are silently ignored.
- All subcommands should be specified only once. If a subcommand is repeated, only the last specification will be used.
- The following words are reserved as keywords in this procedure: BY and WITH.

Case Frequency

- If a WEIGHT variable is specified, its values are used as frequency weights by this procedure.
- Cases with missing or nonpositive weights are not used for computing the ratio statistics.
- The weight values are rounded to the nearest whole numbers before use. For example, 0.5 is rounded to 1, and 2.4 is rounded to 2.

Variable List

The variable list specifies the numerator variable, denominator variable, and optional group variable.

- The numerator variable must be the first specification after the procedure name.
- The denominator variable must be preceded by the keyword WITH.
- The group variable, if specified, must be preceded by the keyword BY.
- Both the numerator and the denominator variables must be numeric.
- The group variable can be of any type (numeric or string).
- By default or when the keyword ASCENDING is specified, values of the group variable are displayed in ascending order. Specify the keyword DESCENDING to display in descending order. Specify NOSORT to preserve the appearance order in the data.
- Only cases with no (system- or user-) missing values in both the numerator and the denominator variables will be used. Please note that this rule does not apply to the group variable.

Example

```
RATIO STATISTICS appraise WITH price
  /PRINT = AAD BCOC((1,2) (3,4)) MEAN.
```

- This is a typical analysis where *appraise* is the appraised value and *price* is the transaction price. The ratio is computed by dividing *appraise* by *price*.

Example

```
RATIO STATISTICS appraise WITH price BY county
  /PRINT = CIN(90) MEDIAN.
```

- The ratio is still computed by dividing *appraise* by *price*. However, separate ratio statistics are requested for each category of *county*.

MISSING Subcommand

MISSING specifies the way to handle cases with user-missing values.

- A case is never used if it contains system-missing values in the numerator and/or the denominator variables.

- If this subcommand is not specified, the default is EXCLUDE.
- Keywords EXCLUDE and INCLUDE are mutually exclusive. Only one of them can be specified once.

EXCLUDE *Exclude both user-missing and system-missing values.* This is the default.

INCLUDE *User-missing values are treated as valid.* System-missing values cannot be included in the analysis.

OUTFILE Subcommand

OUTFILE saves the requested statistics to an SPSS-format data file or a previously declared dataset (DATASET DECLARE command).

- The requested statistics are saved in a single record in the external file.
- If a group variable has been specified, the requested statistics at each category of the group variable will also be saved as additional records in the external file.
- The file specification or dataset name should be quoted and enclosed in quotes.

The following statistics are available.

AAD *Average absolute deviation.* The result of summing the absolute deviations of the ratios about the median and dividing the result by the total number of ratios.

BCOC (low,high) …) *Coefficient of concentration.* The percentage of ratios that fall into an interval. Pairs of low and high values enclosed in parentheses specify the intervals.

CIN(a) *Confidence interval.* Specifying this keyword displays confidence intervals for the mean, median, and weighted mean (if those statistics are requested). Specify a value greater than or equal to 0 and less than 100 as the confidence level.

COD *Coefficient of dispersion.* The result of expressing the average absolute deviation as a percentage of the median.

MAX *Maximum.* The largest ratio.

MDCOV *Median-centered coefficient of variation.* The result of expressing the root mean squares of deviation from the median as a percentage of the median.

MEAN *Mean.* The result of summing the ratios and dividing the result by the total number ratios.

MEDIAN *Median.* The value such that number of ratios less than this value and the number of ratios greater than this value are the same.

MIN *Minimum.* The smallest ratio.

MNCOV *Mean-centered coefficient of variation.* The result of expressing the standard deviation as a percentage of the mean.

PRD *Price-related differential.* Also known as the index of regressivity, the result of dividing the mean by the weighted mean.

RANGE *Range.* The result of subtracting the minimum ratio from the maximum ratio.

STDDEV *Standard deviation.* The result of summing the squared deviations of the ratios about the mean, dividing the result by the total number of ratios minus one, and taking the positive square root.

WCOC(value list) *Coefficient of concentration.* The percentage of ratios that fall within the specified percent of the median. Specify a list of values that are greater than 0 and less than 100.

WGTMEAN *Weighted mean.* The result of dividing the mean of the numerator by the mean of the denominator. It is also the mean of the ratios weighted by the denominator.

Example

```
RATIO STATISTICS appraise WITH price BY county
  /OUTFILE('/PropertyTax/Ratio.sav') = CIN(90) MEDIAN.
```

- The median ratios and their 90% confidence intervals at each category of *county* are saved to */PropertyTax/Ratio.sav*.
- The overall median ratio and its 90% confidence intervals are also saved.

PRINT Subcommand

PRINT displays optional output. If no PRINT subcommand is specified, only a case processing summary table is displayed by default.

AAD *Average absolute deviation.* The result of summing the absolute deviations of the ratios about the median and dividing the result by the total number of ratios.

BCOC(low,high) …) *Coefficient of concentration.* The percentage of ratios that fall into an interval. Pairs of low and high values enclosed in parentheses specify the intervals.

CIN(a) *Confidence interval.* Specifying this keyword displays confidence intervals for the mean, median, and weighted mean (if those statistics are requested). Specify a value greater than or equal to 0 and less than 100 as the confidence level.

COD *Coefficient of dispersion.* The result of expressing the average absolute deviation as a percentage of the median.

MAX *Maximum.* The largest ratio.

MDCOV *Median-centered coefficient of variation.* The result of expressing the root mean squares of deviation from the median as a percentage of the median.

MEAN *Mean.* The result of summing the ratios and dividing the result by the total number ratios.

MEDIAN *Median.* The value such that number of ratios less than this value and the number of ratios greater than this value are the same.

MIN *Minimum.* The smallest ratio.

MNCOV *Mean-centered coefficient of variation.* The result of expressing the standard deviation as a percentage of the mean.

PRD *Price-related differential.* Also known as the index of regressivity, the result of dividing the mean by the weighted mean.

RANGE *Range.* The result of subtracting the minimum ratio from the maximum ratio.

STDDEV *Standard deviation.* The result of summing the squared deviations of the ratios about the mean, dividing the result by the total number of ratios minus one, and taking the positive square root.

WCOC(value list) *Coefficient of concentration.* The percentage of ratios that fall within the specified percentage of the median. Specify a list of values that are greater than 0 and less than 100.

WGTMEAN *Weighted mean.* The result of dividing the mean of the numerator by the mean of the denominator. It is also the mean of the ratios weighted by the denominator.

Example

```
RATIO STATISTICS appraise WITH price BY county
  /PRINT = BCOC((0.5,0.9) (1.3,1.5)) WCOC(15 30 45) MEDIAN PRD.
```

- The median ratios and priced related differentials at each category of *county* are displayed. The overall median ratio and the overall price-related differential are also displayed.
- Five coefficients of concentration are also displayed. The first two `COC` are percentages of ratios that fall into the intervals: (0.5, 0.9) and (1.3, 1.5). The next three `COC` are percentages of ratios that fall within 15% of the median, 30% of the median, and 45% of the median.

RBF

RBF is available in the Neural Networks option.

```
RBF dependent variable [(MLEVEL = {S})] [dependent variable...]
                                  {O}
                                  {N}

    [BY factor list] [WITH covariate list]

[/EXCEPT VARIABLES = varlist]

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Release History

Release 16.0

- Command introduced.

Example

```
RBF dep_var BY A B C WITH X Y Z.
```

Overview

Neural networks are a data mining tool for finding unknown patterns in databases. Neural networks can be used to make business decisions by forecasting demand for a product as a function of price and other variables or by categorizing customers based on buying habits and demographic characteristics. The RBF procedure fits a radial basis function neural network, which is a feedforward, supervised learning network with an input layer, a hidden layer called the radial basis function layer, and an output layer. The hidden layer transforms the input vectors into radial basis functions. Like the MLP (multilayer perceptron) procedure, the RBF procedure performs prediction and classification.

The RBF procedure trains the network in two stages:

1. The procedure determines the radial basis functions using clustering methods. The center and width of each radial basis function are determined.
2. The procedure estimates the synaptic weights given the radial basis functions. The sum-of-squares error function with identity activation function for the output layer is used for both prediction and classification. Ordinary least squares regression is used to minimize the sum-of-squares error.

   Because of this two-stage training approach, the RBF network is in general trained much faster than MLP.

Options

Prediction or classification. One or more dependent variables may be specified, and they may be scale, categorical, or a combination. If a dependent variable has scale measurement level, then the neural network predicts continuous values that approximate the "true" value of some continuous function of the input data. If a dependent variable is categorical, then the neural network is used to classify cases into the "best" category based on the input predictors.

Rescaling. RBF optionally rescales covariates (predictors with scale measurement level) or scale dependent variables before training the neural network. There are three rescaling options: standardization, normalization, and adjusted normalization.

Training, testing, and holdout data. RBF optionally divides the dataset into training, testing, and holdout data. The neural network is trained using the training data. The testing data can be used to determine the "best" number of hidden units for the network. The holdout data is completely excluded from the training process and is used for independent assessment of the final network.

Architecture selection. The RBF procedure creates a neural network with one hidden layer and can perform automatic architecture selection to find the "best" number of hidden units. By default, the procedure automatically computes a reasonable range and finds the "best" number within the range. However, you can override these computations by providing your own range or a specific number of hidden units.

Activation functions. Units in the hidden layer can use the normalized radial basis function or the ordinary radial basis function.

Missing values. The RBF procedure has an option for treating user-missing values of categorical variables as valid. User-missing values of scale variables are always treated as invalid.

Output. RBF displays pivot table output but offers an option for suppressing most such output. Graphical output includes a network diagram (default) and a number of optional charts: predicted by observed values, residual by predicted values, ROC (Receiver Operating Characteristic) curves, cumulative gains, lift, and independent variable importance. The procedure also optionally saves predicted values in the active dataset. Hidden unit center and width vectors and synaptic weight estimates can be saved in XML files.

Basic Specification

The basic specification is the RBF command followed by one or more dependent variables, the BY keyword and one or more factors, and the WITH keyword and one or more covariates.

By default, the RBF procedure standardizes covariates and scale dependent variables and selects a training sample before training the neural network. Automatic architecture selection is used to find the "best" neural network architecture. User-missing values are excluded and default pivot table output is displayed.

Syntax Rules

- All subcommands are optional.
- Subcommands may be specified in any order.
- Only a single instance of each subcommand is allowed.
- An error occurs if a keyword is specified more than once within a subcommand.
- Parentheses, equals signs, and slashes shown in the syntax chart are required.
- The command name, subcommand names, and keywords must be spelled in full.
- Empty subcommands are not allowed.
- Any split variable defined on the SPLIT FILE command may not be used as a dependent variable, factor, covariate, or partition variable.

Limitations

Frequency weights specified on the WEIGHT command are ignored with a warning by the RBF procedure.

Categorical Variables

The RBF procedure temporarily recodes categorical predictors and dependent variables using one-of-*c* coding for the duration of the procedure. If there are *c* categories of a variable, then the variable is stored as c vectors, with the first category denoted (1,0,...,0), the next category, (0,1,0,...,0), ..., and the final category, (0,0,...,0,1).

Because of the one-of-*c* coding, the total number of input units is the number of scale predictors plus the number of categories across all categorical predictors. However, unlike the multilayer perceptron (MLP), this coding scheme does not increase the number of syntaptic weights for categorical predictors and hence should not significantly increase the training time.

All one-of-*c* coding is based on the training data, even if a testing or holdout sample is defined (see PARTITION Subcommand). Thus, if the testing or holdout samples contain cases with predictor categories that are not present in the training data, then those cases are not used

by the procedure or in scoring. If the testing or holdout samples contain cases with dependent variable categories that are not present in the training data, then those cases are not used by the procedure but they may be scored.

Replicating Results

The RBF procedure uses random number generation during random assignment of partitions. To reproduce the same randomized results in the future, use the SET command to set the initialization value for the random number generator before each run of the RBF procedure.

RBF results are also dependent on data order because the two-step cluster algorithm is used to determine the radial basis functions. To minimize data order effects, randomly order the cases before running the RBF procedure. To verify the stability of a given solution, you may want to obtain several different solutions with cases sorted in different random orders. In situations with extremely large file sizes, multiple runs can be performed with a sample of cases sorted in different random orders.

In summary, if you want to exactly replicate RBF results in the future, use the same initialization value for the random number generator and the same data order, in addition to using the same RBF procedure settings.

Examples

Basic specification with default neural network settings

```
RBF DepVar BY A B C WITH X Y Z.
```

- The RBF procedure treats *DepVar* as the dependent variable. Predictors *A*, *B*, and *C* are factors, and *X*, *Y*, and *Z* are covariates.
- By default, covariates and the dependent variable (if it has scale measurement level) are standardized before training. Also, the active dataset is partitioned into training and testing data samples, with 70% going to the training data and 30% to the testing data sample.
- Automatic architecture selection is used to find the "best" neural network architecture.
- User-missing values are excluded and default output is displayed.

User-specified neural network with three hidden units

```
RBF DepVar BY A B C WITH X Y Z
  /ARCHITECTURE
     NUMUNITS=3
     HIDDENFUNCTION=ORBF.
```

- The RBF procedure treats *DepVar* as the dependent variable. Predictors *A*, *B*, and *C* are factors, and *X*, *Y*, and *Z* are covariates.
- By default, covariates and the dependent variable (if it has scale measurement level) are standardized before training. Also, the active dataset is partitioned into training and testing data samples, with 70% going to the training data and 30% to the testing data sample.

- The ARCHITECTURE subcommand specifies a neural network with three hidden units, thereby overriding automatic architecture selection. In addition, the hidden layer uses the ordinary radial basis function.
- User-missing values are excluded and default output is displayed.

Nominal dependent variable; user-specified rescaling and partitions

```
*Radial Basis Function Network.
RBF custcat (MLEVEL=N) BY marital ed retire gender WITH age address
    income employ reside
  /RESCALE COVARIATE=ADJNORMALIZED
  /PARTITION  TRAINING=6  TESTING=2  HOLDOUT=1
  /ARCHITECTURE MINUNITS=AUTO MAXUNITS=AUTO HIDDENFUNCTION=NRBF
  /CRITERIA OVERLAP=AUTO
  /PRINT CPS NETWORKINFO SUMMARY CLASSIFICATION
  /PLOT ROC GAIN LIFT PREDICTED
  /SAVE PREDVAL PSEUDOPROB
  /MISSING USERMISSING=EXCLUDE .
```

- The procedure constructs a network to predict the nominal-level variable *custcat*, using *marital*, *ed*, *retire*, and *gender* as factors and *age*, *address*, *income*, *employ*, and *reside* as covariates.
- The RESCALE subcommand specifies that covariates should be rescaled using the adjusted normalized method.
- The PARTITION subcommand specifies that the relative number of cases assigned to the training:testing:holdout samples should be 6:2:1. This assigned 2/3 of the cases to training, 2/9 to testing, and 1/9 to holdout.
- The PLOT subcommand does not request the default graphical output (the network diagram), but instead an ROC curve, cumulative gains chart, lift chart, and predicted-by-residuals chart will be produced.
- The SAVE subcommand requests that the predicted values and predicted pseudo-probabilities of *custcat* be saved to the active dataset.
- All other options are set to their default values.

Variable Lists

The command line variable lists specify the dependent variables, any categorical predictors (also known as factors), and any scale predictors (also known as covariates).

Dependent Variables

- A list of one or more dependent variables must be the first specification on the RBF command.
- Each dependent variable may be followed by the measurement level specification, which contains, in parentheses, the MLEVEL keyword followed by an equals sign and then S for scale, O for ordinal, or N for nominal. RBF treats ordinal and nominal dependent variables equivalently as categorical.
- If a measurement level is specified, then it temporarily overrides a dependent variable's setting in the data dictionary.

- If no measurement level is specified, then RBF defaults to the dictionary setting.
- If a measurement level is not specified and no setting is recorded in the data dictionary, then a numeric variable is treated as scale and a string variable is treated as categorical.
- Dependent variables can be numeric or string.
- A string variable may be defined as ordinal or nominal only.

Predictor Variables

- The names of the factors, if any, must be preceded by the keyword BY.
- If the keyword BY is specified with no factors, then a warning is issued and BY is ignored.
- The names of the covariates, if any, must be preceded by the keyword WITH.
- If the keyword WITH is specified with no covariates, then a warning is issued and WITH is ignored.
- If the dependent variable is specified within a factor list or a covariate list, then it is ignored in the list.
- All variables specified within a factor or covariate list must be unique. If duplicate variables are specified within a list, then the duplicates are ignored.
- If duplicate variables are specified across the factor and covariate lists, then an error is issued.
- Factor variables can be numeric or string.
- Covariates must be numeric.
- At least one predictor must be specified.

EXCEPT Subcommand

The EXCEPT subcommand lists any variables that the RBF procedure should exclude from the factor or covariate lists on the command line. This subcommand is useful if the factor or covariate lists contain a large number of variables—specified using the TO or ALL keyword, for example—but there are a few variables (for example, Case ID) that should be excluded.

The EXCEPT subcommand is introduced strictly for the purpose of simplifying syntax. Missing values on factors or covariates specified on EXCEPT do not affect whether a case is included in the analysis. For example, the following two RBF commands are equivalent. In both commands, listwise deletion is based on the dependent variable and factors *A*, *B*, and *C*.

```
RBF DepVar BY A B C.

RBF DepVar BY A B C D   /EXCEPT VARIABLES=D.
```

- The EXCEPT subcommand ignores duplicate variables and variables that are not specified on the command line's factor or covariate lists.
- There is no default variable list on the EXCEPT subcommand.

RESCALE Subcommand

The RESCALE subcommand is used to rescale covariates or scale dependent variables.

All rescaling is performed based on the training data, even if a testing or holdout sample is defined (see PARTITION Subcommand). That is, depending on the type of rescaling, the mean, standard deviation, minimum value, or maximum value of a covariate or dependent variable is computed using only the training data. It is important that these covariates or dependent variables have similar distributions across the training, testing, and holdout samples. If the data are partitioned by specifying percentages on the PARTITION subcommand, then the RBF procedure attempts to ensure this similarity by random assignment. However, if you use the PARTITION subcommand VARIABLE keyword to assign cases to the training, testing, and holdout samples, then we recommend that you confirm that the distributions are similar across samples before running the RBF procedure.

COVARIATE Keyword

The COVARIATE keyword specifies the rescaling method to use for covariates specified following WITH on the command line.

If no covariates are specified on the command line, then the COVARIATE keyword is ignored.

STANDARDIZED	*Subtract the mean and divide by the standard deviation, (x-mean)/s.* This is the default rescaling method for covariates.
NORMALIZED	*Subtract the minimum and divide by the range, (x-min)/(max-min).*
ADJNORMALIZED	*Adjusted version of subtracting the minimum and dividing by the range, [2*(x-min)/(max-min)]-1 .*
NONE	*No rescaling of covariates.*

DEPENDENT Keyword

The DEPENDENT keyword specifies the rescaling method to use for the dependent variables.

This keyword is applied only for scale dependent variables; that is, either MLEVEL=S is specified on the command line or the variable has a scale measurement level based on its data dictionary setting. If a dependent variable is not scale, then the DEPENDENT keyword is ignored for that variable.

STANDARDIZED	*Subtract the mean and divide by the standard deviation, (x-mean)/s.* This is the default rescaling method for scale dependent variables.
NORMALIZED	*Subtract the minimum and divide by the range, (x-min)/(max-min).*
ADJNORMALIZED	*Adjusted version of subtracting the minimum and dividing by the range, [2*(x-min)/(max-min)]-1.*
NONE	*No rescaling of scale dependent variables.*

PARTITION Subcommand

The PARTITION subcommand specifies the method of partitioning the active dataset into training, testing, and holdout samples. The training sample comprises the data records used to train the neural network. The testing sample is an independent set of data records used to track prediction error during training in order to prevent overtraining. The holdout sample is another independent set of data records used to assess the final neural network.

- The partition can be defined by specifying the ratio of cases randomly assigned to each sample (training, testing, and holdout) or by a variable that assigns each case to the training, testing, or holdout sample.
- If the PARTITION subcommand is not specified, then the default partition randomly assigns 70% of the cases to the training sample, 30% to the testing sample, and 0% to the holdout sample. If you want to specify a different random assignment, then you must specify new values for the TRAINING, TESTING, and HOLDOUT keywords. The value specified on each keyword gives the relative number of cases in the active dataset to assign to each sample. For example, /PARTITION TRAINING = 50 TESTING = 30 HOLDOUT = 20 is equivalent to /PARTITION TRAINING = 5 TESTING = 3 HOLDOUT = 2; both subcommands randomly assign 50% of the cases to the training sample, 30% to the testing sample, and 20% to the holdout sample.
- If you want to be able to reproduce results based on the TRAINING, TESTING, and HOLDOUT keywords later, use the SET command to set the initialization value for the random number generator before running the RBF procedure.
- Be aware of the relationship between rescaling and partitioning. For more information, see RESCALE Subcommand on p. 1539.
- All partitioning is performed after listwise deletion of any cases with invalid data for any variable used by the procedure. See MISSING Subcommand for details about valid and invalid data.

TRAINING Keyword

The TRAINING keyword specifies the relative number of cases in the active dataset to randomly assign to the training sample. The value must be an integer greater than 0. The default (if the PARTITION subcommand is not specified) is 70.

TESTING Keyword

The TESTING keyword specifies the relative number of cases in the active dataset to randomly assign to the testing sample. The value must be an integer greater than 0. The default (if the PARTITION subcommand is not specified) is 30.

HOLDOUT Keyword

The HOLDOUT keyword specifies the relative number of cases in the active dataset to randomly assign to the holdout sample. The value must be an integer greater than 0. The default (if the PARTITION subcommand is not specified) is 0.

VARIABLE Keyword

The VARIABLE keyword specifies a variable that assigns each case in the active dataset to the training, testing, or holdout sample. Cases with a positive value on the variable are assigned to the training sample, cases with a value of 0, to the testing sample, and cases with a negative value, to the holdout sample. Cases with a system-missing value are excluded from the analysis. (Any user-missing values for the partition variable are always treated as valid.)

The variable may not be the dependent variable or any variable specified on the command line factor or covariate lists. The variable must be numeric.

ARCHITECTURE Subcommand

The ARCHITECTURE subcommand is used to specify the neural network architecture. RBF creates a neural network with one hidden layer. There are three ways of choosing the number of hidden units:

1. By default, RBF uses automatic architecture selection to find the "best" number of hidden units within a range. The procedure automatically computes the minimum and maximum and finds the best number of hidden units within the range.

   If a testing sample is defined; that is, if /PARTITION TESTING is specified with a number greater than zero or via /PARTITION VARIABLE, then the procedure uses the testing data criterion: The best number of hidden units is the one that yields the smallest error in the testing data. If a testing sample is not defined, then the procedure uses the Bayesian information criterion (BIC): The best number of hidden units is the one that yields the smallest BIC based on the training data.

2. You can provide your own range by specifying the MINUNITS and MAXUNITS keywords with integers, and the procedure will find the "best" number of hidden units within that range. It is invalid to specify only MINUNITS or only MAXUNITS; both must be given. The best number of hidden units from the range is determined using the testing data criterion or the BIC.

3. You can override the use of a range and specify a particular number of units directly using the NUMUNITS keyword. It is invalid to specify NUMUNITS with either the MINUNITS or MAXUNITS keyword.

MINUNITS Keyword

The MINUNITS keyword specifies the minimum number of units to use in the range. Value AUTO indicates that the number should be computed automatically. Alternatively, a positive integer may be specified. The integer must be less than the number specified on the MAXUNITS keyword.

The default value is AUTO.

MAXUNITS Keyword

The MAXUNITS keyword specifies the maximum number of units to use in the range. Value AUTO indicates that the number should be computed automatically. Alternatively, a positive integer may be specified. The integer must be greater than the number specified on the MINUNITS keyword.

The default value is AUTO.

NUMUNITS Keyword

The NUMUNITS keyword specifies a particular number of hidden units instead of a range. A positive integer may be specified.

- If NUMUNITS is specified when testing data are defined (see PARTITION Subcommand), then the testing data are not used in determining the network architecture and a warning is issued.
- There is no default value.

HIDDENFUNCTION Keyword

The HIDDENFUNCTION keyword specifies the Gaussian radial basis function used in the hidden layer.

NRBF *Normalized radial basis function.* Uses the softmax activation function so the activations of all hidden units are normalized to sum to 1. This is the default activation function for all units in the hidden layer.

ORBF *Ordinary radial basis function.* Uses the exponential activation function so the activation of the hidden unit is a Gaussian "bump" as a function of the inputs.

CRITERIA Subcommand

The CRITERIA subcommand specifies computational settings for the RBF procedure.

OVERLAP Keyword

The OVERLAP keyword specifies the hidden-unit overlapping factor that controls how much overlap occurs among the hidden units.

- Specify AUTO to automatically compute the overlapping factor 1+0.1*d*, where *d* is the number of input units. (The number of input units equals the sum of the number of categories across all factors and the number of covariates.) This is the default.
- Alternatively, specify a number greater than 0 to request a particular overlapping factor.

MISSING Subcommand

The MISSING subcommand is used to control whether user-missing values for categorical variables; that is, factors and categorical dependent variables, are treated as valid values.

- By default, user-missing values for categorical variables are treated as invalid.
- User-missing values for scale variables are always treated as invalid. System-missing values for any variables are always treated as invalid.

USERMISSING=EXCLUDE

User-missing values for categorical variables are treated as invalid. This is the default.

USERMISSING=INCLUDE

User-missing values for categorical variables are treated as valid values.

PRINT Subcommand

The PRINT subcommand indicates the tabular output to display and can be used to request a sensitivity analysis. If PRINT is not specified, then the default tables are displayed. If PRINT is specified, then only the requested PRINT output is displayed.

CPS Keyword

The CPS keyword displays the case processing summary table, which summarizes the number of cases included and excluded in the analysis, in total and by training, testing, and holdout samples. This table is shown by default.

NETWORKINFO Keyword

The NETWORKINFO keyword displays information about the neural network, including the dependent variables, number of input and output units, number of hidden units, and activation functions. This table is shown by default.

SUMMARY Keyword

The SUMMARY keyword displays a summary of the neural network results, including the error, the relative error or percentage of incorrect predictions, and the training time.

- The error is the sum-of-squares error. In addition, relative errors or percentages of incorrect predictions are displayed, depending on the dependent variable measurement levels. If any dependent variable has scale measurement level, then the average overall relative error (relative to the mean model) is displayed. If all dependent variables are categorical, then the average percentage of incorrect predictions is displayed. Relative errors or percentages of incorrect predictions are also displayed for individual dependent variables.
- Summary results are given for the training data, and for testing and holdout data if they exist.
- This table is shown by default.

CLASSIFICATION Keyword

The CLASSIFICATION keyword displays a classification table for each categorical dependent variable. The table gives the number of cases classified correctly and incorrectly for each dependent variable category.

- In addition to classification tables, the CLASSIFICATION keyword reports the percentage of the total cases that were correctly classified. A case is correctly classified if its highest predicted probabilities correspond to the observed categories for that case.
- Classification results are given for the training data, and for testing and holdout data if they exist.
- Classification results are shown by default.
- The CLASSIFICATION keyword is ignored for scale dependent variables.

SOLUTION Keyword

The SOLUTION keyword displays the center and width vectors for each hidden unit, and the synaptic weight estimates (that is, the coefficient estimates) from the hidden units to the output units. These results are based on the training sample even if the active dataset is partitioned into training, testing, and holdout data.

This table is not shown by default because the number of synaptic weight estimates may be large, and these weights are generally not used for interpretation.

IMPORTANCE Keyword

The IMPORTANCE keyword performs a sensitivity analysis, which computes the importance of each predictor in determining the neural network. The analysis is based on the combined training and testing samples, or only the training sample if there is no testing sample. This keyword creates a table and a chart displaying importance and normalized importance for each predictor.

Sensitivity analysis is not performed by default because it is computationally expensive and time-consuming if there are a large number of predictors or cases.

NONE Keyword

The NONE keyword suppresses all PRINT output. This keyword may not be specified with any other PRINT keywords.

PLOT Subcommand

The PLOT subcommand indicates the chart output to display. If PLOT is not specified, then the default chart (the network diagram) is displayed. If PLOT is specified, then only the requested PLOT output is displayed.

NETWORK Keyword

The NETWORK keyword displays the network diagram. This chart is shown by default.

PREDICTED Keyword

The PREDICTED keyword displays a predicted-by-observed-value chart for each dependent variable. For categorical dependent variables, a boxplot of predicted pseudo-probabilities is displayed. For scale dependent variables, a scatterplot is displayed.

- Charts are based on the combined training and testing samples, or only the training sample if there is no testing sample.

RESIDUAL Keyword

The RESIDUAL keyword displays a residual-by-predicted-value chart for each scale dependent variable.

- This chart is available only for scale dependent variables. The RESIDUAL keyword is ignored for categorical dependent variables.
- Charts are based on the combined training and testing samples, or only the training sample if there is no testing sample.

ROC Keyword

The ROC keyword displays an ROC (Receiver Operating Characteristic) chart for each categorical dependent variable. It also displays a table giving the area under each curve in the chart.

- For a given dependent variable, the ROC chart displays one curve for each category. If the dependent variable has two categories, then each curve treats the category at issue as the positive state versus the other category. If the dependent variable has more than two categories, then each curve treats the category at issue as the positive state versus the aggregate of all other categories.
- This chart is available only for categorical dependent variables. The ROC keyword is ignored for scale dependent variables.
- Charts are based on the combined training and testing samples, or only the training sample if there is no testing sample.

GAIN Keyword

The GAIN keyword displays a cumulative gains chart for each categorical dependent variable.

- The display of one curve for each dependent variable category is the same as for the ROC keyword.
- This chart is available only for categorical dependent variables. The GAIN keyword is ignored for scale dependent variables.
- Charts are based on the combined training and testing samples, or only the training sample if there is no testing sample.

LIFT Keyword

The LIFT keyword displays a lift chart for each categorical dependent variable.

- The display of one curve for each dependent variable category is the same as for the ROC keyword.
- This chart is available only for categorical dependent variables. The LIFT keyword is ignored for scale dependent variables.
- Charts are based on the combined training and testing samples, or only the training sample if there is no testing sample.

NONE Keyword

The NONE keyword suppresses all PLOT output. This keyword may not be specified with any other PLOT keywords.

SAVE Subcommand

The SAVE subcommand writes optional temporary variables to the active dataset.

PREDVAL(varname varname…)

Predicted value or category. If a dependent variable has scale measurement level, then this is the predicted value. If a dependent variable is categorical, then this is the predicted category.

Specify one or more unique, valid variable names. There should be as many variable names specified as there are dependent variables, and the names should be listed in the order of the dependent variables on the command line. If you do not specify enough variable names, then default names are used for any remaining variables. If you specify too many variable names, then any remaining names are ignored.

If there is only one dependent variable, then the default variable name is *RBF_PredictedValue*. If there are multiple dependent variables, then the default variable names are *RBF_PredictedValue_1*, *RBF_PredictedValue_2*, etc., corresponding to the order of the dependent variables on the command line.

PSEUDOPROB(rootname:n rootname…)

Predicted pseudo-probability. If a dependent variable is categorical, then this keyword saves the predicted pseudo-probabilities of the first *n* categories of that dependent variable.

Specify one or more unique, valid variable names. There should be as many variable names specified as there are categorical dependent variables, and the names should be listed in the order of the categorical dependent variables on the command line. The specified names are treated as rootnames. Suffixes are added to each rootname to get a group of variable names corresponding to the categories for a given dependent variable. If you do not specify enough variable names, then default names are used for any remaining categorical dependent variables. If you specify too many variable names, then any remaining names are ignored.

A colon and a positive integer giving the number of probabilities to save for a dependent variable can follow the rootname.

If there is only one dependent variable, then the default rootname is *RBF_PseudoProbability*. If there are multiple dependent variables, then the default rootnames are *RBF_PseudoProbability_1*, *RBF_PseudoProbability_2*, etc., corresponding to the order of the categorical dependent variables on the command line and taking into account the position of any scale dependent variables.

The default *n* is 25.

This keyword is ignored for scale dependent variables.

Probabilities and Pseudo-Probabilities

Predicted pseudo-probabilities cannot be interpreted as probabilities because the RBF procedure uses the sum-of-squares error and identity activation function for the output layer. The SAVE subcommand saves these predicted pseudo-probabilities even if any are less than 0 or greater than 1, or the sum for a given dependent variable is not 1.

The ROC, cumulative gains, and lift charts (see /PLOT ROC, GAIN, and LIFT, respectively) are created based on pseudo-probabilities. In the event that any of the pseudo-probabilities are less than 0 or greater than 1, or the sum for a given variable is not 1, they are first rescaled to be between 0 and 1 and to sum to 1. The SAVE subcommand saves the original pseudo-probabilities, but the charts are based on rescaled pseudo-probabilities.

Pseudo-probabilities are rescaled by dividing by their sum. For example, if a case has predicted pseudo-probabilities of 0.50, 0.60, and 0.40 for a three-category dependent variable, then each pseudo-probability is divided by the sum 1.50 to get 0.33, 0.40, and 0.27.

If any of the pseudo-probabilities are negative, then the absolute value of the lowest is added to all pseudo-probabilities before the above rescaling. For example, if the pseudo-probabilities are –0.30, 0.50, and 1.30, then first add 0.30 to each value to get 0.00, 0.80, and 1.60. Next, divide each new value by the sum 2.40 to get 0.00, 0.33, and 0.67.

OUTFILE Subcommand

The `OUTFILE` subcommand saves XML-format (PMML) files containing the hidden unit center and width vectors, and the synaptic weight estimates. SmartScore and SPSS Server (a separate product) can use this file to apply the model information to other data files for scoring purposes.

- Filenames must be specified in full. The `RBF` procedure does not supply extensions.
- The `MODEL` keyword is not honored if split-file processing is in effect (see SPLIT FILE). If this keyword is specified when split-file processing is on, then a warning is displayed.

MODEL = 'file' 'file'…

Writes the hidden unit center and width vectors and synaptic weight estimates to XML (PMML) files. Specify one or more unique, valid filenames. There should be as many filenames as there are dependent variables, and the names should be listed in the order of the dependent variables on the command line. If you do not specify enough filenames, then an error is issued. If you specify too many filenames, then any remaining names are ignored.

If any `'file'` specification refers to an existing file, then the file is overwritten. If any `'file'` specifications refer to the same file, then only the last instance of this `'file'` specification is honored.

READ MODEL

```
READ MODEL FILE='filename'

 [/KEEP={ALL**      }]
        {model names}
        {procedures }

 [/DROP={model names}]
        {procedures }

 [/TYPE={MODEL**}]
        {COMMAND}

 [/TSET={CURRENT**}]
        {RESTORE  }
```

**Default if the subcommand is omitted.

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Example

```
READ MODEL FILE='ACFMOD.DAT'.
```

Overview

READ MODEL reads a model file that has been previously saved on the SAVE MODEL command (see SAVE MODEL).

Options

You can restore a subset of models from the model file by using the DROP and KEEP subcommands. You can use the TYPE subcommand to control whether models are specified by model name or by the name of the procedure that generated them. With the TSET subcommand, you can restore the TSET settings that were in effect when the model file was created.

Basic Specification

The basic specification is the FILE subcommand, specifying the name of a previously saved model file.

- By default, all models that are contained in the specified file are restored, replacing all models that are currently active. The restored models have their original *MOD_n* default names or names that are assigned by the MODEL NAME command.

Subcommand Order

- Subcommands can be specified in any order.

Syntax Rules

- If a subcommand is specified more than once, only the last subcommand is executed.

Operations

- READ MODEL is executed immediately.
- Models that are currently active are erased when READ MODEL is executed. To save these models for later use, specify the SAVE MODEL command before READ MODEL.
- Model files are designed to be read by specific procedures and should not be edited.
- DATE specifications are not saved in model files. Therefore, the DATE specifications from the current session are applied to the restored models.
- The following procedures can generate models that can be read by the READ MODEL command: AREG, ARIMA, EXSMOOTH, SEASON, and SPECTRA in the Trends module; ACF, CASEPLOT, CCF, CURVEFIT, PACF, PPLOT, and TSPLOT in the Base system; and WLS and 2SLS in Regression Models.

Limitations

- A maximum of one filename can be specified.
- The READ MODEL command can only read models created by a SAVE MODEL command on the same operating system/platform.

Example

```
READ MODEL FILE='ACFMOD.DAT'
  /DROP=MOD_1.
```

- In this example, all models are restored except *MOD_1* in the model file *ACFMOD.DAT*.

FILE Subcommand

FILE names the model file to be read and is the only required subcommand.

- The only specification on FILE is the name of the model file.
- The filename should be enclosed in quotes.
- Only one filename can be specified.
- Only files that are saved with the SAVE MODEL command can be read.
- You can specify files residing in other directories by supplying a fully qualified filename.

KEEP and DROP Subcommands

KEEP and DROP allow you to restore a subset of models. By default, all models in the model file are restored.

- KEEP specifies the models to be restored.
- DROP specifies the models to be excluded.

- Models can be specified by using individual model names or the names of the procedures that created them. To use procedure names, you must specify COMMAND on the TYPE subcommand.
- Model names are either the default *MOD_n* names or the names that are assigned with MODEL NAME.
- If a procedure name is specified on KEEP, all models that are created by that procedure are restored; on DROP, all models that are created by the procedure are dropped.
- Model names and procedure names cannot be mixed on a single READ MODEL command.
- If more than one KEEP or DROP subcommand is specified, only the last subcommand is executed.
- You can specify the keyword ALL on KEEP to restore all models in the model file. This setting is the default.
- The stored model file is not affected by the KEEP or DROP specification on READ MODEL.

Example

```
READ MODEL FILE='ACFCCF.DAT'
  /KEEP=ACF1 ACF2.
```

- In this example, only models *ACF1* and *ACF2* are restored from model file *ACFCCF.DAT*.

TYPE Subcommand

TYPE indicates whether models are specified by model name or procedure name on DROP and KEEP.

- One keyword, MODEL or COMMAND, can be specified after TYPE.
- MODEL is the default and indicates that models are specified as model names.
- COMMAND indicates that models are specified by procedure name.
- TYPE has no effect if KEEP or DROP is not specified.
- The TYPE specification applies only to the current READ MODEL command.

Example

```
READ MODEL FILE='CURVE1.DAT'
  /KEEP=CURVEFIT
  /TYPE=COMMAND.
```

- In this example, all models that are created by CURVEFIT are restored from model file *CURVE1.DAT*.

TSET Subcommand

TSET allows you to restore the TSET settings that were in effect when the model was created.

- The specification on TSET is either CURRENT or RESTORE.

- CURRENT (the default) indicates that you want to continue to use the current TSET settings.
- RESTORE indicates that you want to restore the TSET settings that were in effect when the model file was saved. The current TSET settings are replaced with the model file settings when the file is restored.

RECODE

For numeric variables:

```
RECODE varlist (value list=value)...(value list=value) [INTO varlist]
       [/varlist...]
```

Input keywords:

```
LO, LOWEST, HI, HIGHEST, THRU, MISSING, SYSMIS, ELSE
```

Output keywords:

```
COPY, SYSMIS
```

For string variables:

```
RECODE varlist [('string',['string'...]='string')][INTO varlist]
       [/varlist...]
```

Input keywords:

```
CONVERT, ELSE
```

Output keyword:

```
COPY
```

This command does not read the active dataset. It is stored, pending execution with the next command that reads the dataset. For more information, see Command Order on p. 36.

Examples

```
RECODE V1 TO V3 (0=1) (1=0) (2,3=-1) (9=9) (ELSE=SYSMIS).
RECODE STRNGVAR ('A','B','C'='A')('D','E','F'='B')(ELSE=' ').
```

Overview

RECODE changes, rearranges, or consolidates the values of an existing variable. RECODE can be executed on a value-by-value basis or for a range of values. Where it can be used, RECODE is much more efficient than the series of IF commands that produce the same transformation.

With RECODE, you must specify the new values. Use AUTORECODE to automatically recode the values of string or numeric variables to consecutive integers.

Options

You can generate a new variable as the recoded version of an existing variable using the keyword INTO. You can also use INTO to recode a string variable into a new numeric variable for more efficient processing, or to recode a numeric variable into a new string variable to provide more descriptive values.

Basic Specification

The basic specification is a variable name and, within parentheses, the original values followed by a required equals sign and a new value. RECODE changes the values to the left of the equals sign into the single value to the right of the equals sign.

Syntax Rules

- The variables to be recoded must already exist and must be specified before the value specifications.
- Value specifications are enclosed in parentheses. The original value or values must be specified to the left of an equals sign. A single new value is specified to the right of the equals sign.
- Multiple values can be consolidated into a single recoded value by specifying, to the left of the equals sign, a list of values separated by blanks or commas. Only one recoded value per set is allowed to the right of the equals sign.
- Multiple sets of value specifications are permitted. Each set must be enclosed in parentheses and can result in only one new value.
- To recode multiple variables using the same set of value specifications, specify a variable list before the value specifications. Each variable in the list is recoded identically.
- To recode variables using different value specifications, separate each variable (or variable list) and its specifications from the others by a slash.
- Original values that are not specified remain unchanged unless the keyword ELSE or INTO is used to recode into a new variable. ELSE refers to all original values not previously mentioned, including the system-missing value. ELSE should be the last specification for the variable. When recoding INTO another variable, unspecified values are set to system-missing or blank for strings.
- COPY replicates original values without recoding them.
- INTO is required to recode a string variable into a numeric variable or a numeric variable into a string variable.

Numeric Variables

- Keywords that can be used in the list of original values are LO (or LOWEST), HI (or HIGHEST), THRU, MISSING, SYSMIS, and ELSE. Keywords that can be used in place of a new value are COPY and SYSMIS.
- THRU specifies a value range and includes the specified end values.
- LOWEST and HIGHEST (LO and HI) specify the lowest and highest values encountered in the data. LOWEST and HIGHEST include user-missing values but not the system-missing value.

- MISSING specifies user-missing and system-missing values for recoding. MISSING can be used in the list of original values only.
- SYSMIS specifies the system-missing value and can be used as both an original value and a new value.

String Variables

- Keywords that can be used in the list of original values are CONVERT and ELSE. The only keyword that can be used in place of a new value is COPY.
- Values must be enclosed in quotes.
- Blanks are significant characters.

Operations

- Value specifications are scanned left to right.
- A value is recoded only once per RECODE command.
- Invalid specifications on a RECODE command that result in errors stop all processing of that RECODE command. No variables are recoded.

Numeric Variables

- Blank fields for numeric variables are handled according to the SET BLANKS specification prior to recoding.
- When you recode a value that was previously defined as user-missing on the MISSING VALUE command, the new value is not missing.

String Variables

- If the original or new value specified is shorter than the format width defined for the variable, the string is right-padded with blanks.
- If the original or recoded value specified is longer than the format width defined for that variable, the program issues an error message and RECODE is not executed.

Examples

Recoding Numeric Variables

```
RECODE V1 TO V3 (0=1) (1=0) (2,3=-1) (9=9) (ELSE=SYSMIS)
  /QVAR(1 THRU 5=1)(6 THRU 10=2)(11 THRU HI=3)(ELSE=0).
```

- The numeric variables between and including *V1* and *V3* are recoded: original values 0 and 1 are switched respectively to 1 and 0; 2 and 3 are changed to −1; 9 remains 9; and any other value is changed to the system-missing value.
- Variable *QVAR* is also recoded: original values 1 through 5 are changed to 1; 6 through 10 are changed to 2; 11 through the highest value in the data are changed to 3; and any other value, including system-missing, is changed to 0.

Recoding String Variables

```
RECODE STRNGVAR ('A','B','C'='A')('D','E','F'='B')(ELSE=' ').
RECODE PET ('IGUANA', 'SNAKE ' = 'WILD  ').
```

- Values A, B, and C are changed to value A. Values D, E, and F are changed to value B. All other values are changed to a blank.
- Values IGUANA and SNAKE are changed to value WILD. The defined width of the variable *PET* is 6. Thus, values SNAKE and WILD include trailing blanks for a total of six characters. If blanks are not specified, the values are right-padded. In this example, the results will be the same.
- Each string value is enclosed within quotes.

INTO Keyword

`INTO` specifies a **target** variable to receive recoded values from the original, or **source**, variable. Source variables remain unchanged after being recoded.

- `INTO` must follow the value specifications for the source variables that are being recoded into the target variables.
- The number of target variables must equal the number of source variables.

Numeric Variables

- Target variables can be existing or new variables. For existing variables, cases with values not mentioned in the value specifications are not changed. For new variables, cases with values not mentioned are assigned the system-missing value.
- New numeric variables have default print and write formats of `F8.2` (or the format specified on `SET FORMAT`).

Recoding a Single Variable Into a Target Variable

```
RECODE AGE (MISSING=9) (18 THRU HI=1) (0 THRU 18=0) INTO VOTER.
```

- The recoded *AGE* values are stored in target variable *VOTER*, leaving *AGE* unchanged.
- Value 18 and higher values are changed to value 1. Values between 0 and 18, but not including 18, are recoded to 0. If the specification `0 THRU 18` preceded the specification `18 THRU HI`, value 18 would be recoded to 0.

Recording Multiple Variables Into Target Variables

```
RECODE V1 TO V3 (0=1) (1=0) (2=-1) INTO DEFENSE WELFARE HEALTH.
```

- Values for *V1* through *V3* are recoded and stored in *DEFENSE*, *WELFARE*, and *HEALTH*. *V1*, *V2,* and *V3* are not changed.

String Variables

- Target variables must already exist. To create a new string variable, declare the variable with the STRING command before specifying it on RECODE.
- The new string values cannot be longer than the defined width of the target variable.
- If the new values are shorter than the defined width of the target variable, the values are right-padded with blanks.
- Multiple target variables are allowed. The target variables must all be the same defined width; the source variables can have different widths.
- If the source and target variables have different widths, the criterion for the width of the original values is the width defined for the source variable; the criterion for the width of the recoded values is the width defined for the target variable.

Using Keyword COPY With Target Variables

```
STRING STATE1 (A2).
RECODE STATE ('IO'='IA') (ELSE=COPY) INTO STATE1.
```

- STRING declares the variable *STATE1* so that it can be used as a target variable on RECODE.
- RECODE specifies *STATE* as the source variable and *STATE1* as the target variable. The original value IO is recoded to IA. The keywords ELSE and COPY copy all other state codes over unchanged. Thus, *STATE* and *STATE1* are identical except for cases with the original value IO.

Recoding a String Variable Into a Numeric Target

```
RECODE SEX ('M'=1) ('F'=2) INTO NSEX.
```

- RECODE recodes the string variable *SEX* into the numeric variable *NSEX*. Any value other than M or F becomes system-missing.
- The program can process a large number of cases more efficiently with the numeric variable *NSEX* than it can with the string variable *SEX*.

CONVERT Keyword

CONVERT recodes the string representation of numbers to their numeric representation.

- If the keyword CONVERT precedes the value specifications, cases with numbers are recoded immediately and blanks are recoded to the system-missing value, even if you specifically recode blanks into a value.
- To recode blanks to a value other than system-missing or to recode a string value to a noncorresponding numeric value (for example, '0' to 10), you must specify a recode specification *before* the keyword CONVERT.
- RECODE converts numbers as if the variable were being reread using the F format.
- If RECODE encounters a value that cannot be converted, it scans the remaining value specifications. If there is no specific recode specification for that value, the target variable will be system-missing for that case.

Examples

```
RECODE #JOB (CONVERT) ('-'=11) ('&'=12) INTO JOB.
```

- RECODE first recodes all numbers in the string variable #*JOB* to numbers. The target variable is *JOB*.
- RECODE then specifically recodes the minus sign (the "eleven" punch) to 11 and the ampersand (or "twelve" punch in EBCDIC) to 12. The keyword CONVERT is specified first as an efficiency measure to recode cases with numbers immediately. Blanks are recoded to the system-missing value.

```
RECODE #JOB (' '=-99) (CONVERT) ('-'=11) ('&'=12) INTO JOB.
```

- The result is the same as in the above example except that blanks are changed to −99.

RECORD TYPE

For mixed file types:

```
RECORD TYPE {value list} [SKIP]
            {OTHER     }
```

For grouped file types:

```
RECORD TYPE {value list} [SKIP] [CASE=col loc]
            {OTHER     }

 [DUPLICATE={WARN   }] [MISSING={WARN   }]
            {NOWARN }            {NOWARN }
```

For nested file types:

```
RECORD TYPE {value list} [SKIP] [CASE=col loc]
            {OTHER     }

 [SPREAD={YES}] [MISSING={WARN   }]
         {NO }           {NOWARN }
```

Example

```
FILE TYPE  MIXED RECORD=RECID 1-2.
RECORD TYPE 23.
DATA LIST   /SEX 5 AGE 6-7 DOSAGE 8-10 RESULT 12.
END FILE TYPE.
```

Overview

RECORD TYPE is used with DATA LIST within a FILE TYPE–END FILE TYPE structure to define any one of the three types of complex raw data files: **mixed files**, which contain several types of records that define different types of cases; **hierarchical** or **nested files**, which contain several types of records with a defined relationship among the record types; or **grouped files**, which contain several records for each case with some records missing or duplicated (see FILE TYPE for more complete information). A fourth type of complex file, files with **repeating groups** of information, can be read with the REPEATING DATA command. REPEATING DATA can also be used to read mixed files and the lowest level of nested files.

Each type of complex file has varying types of records. One set of RECORD TYPE and DATA LIST commands is used to define each type of record in the data. The specifications available for RECORD TYPE vary according to whether MIXED, GROUPED, or NESTED is specified on FILE TYPE.

Basic Specification

For each record type being defined, the basic specification is the value of the record type variable defined on the RECORD subcommand on FILE TYPE.

- RECORD TYPE must be followed by a DATA LIST command defining the variables for the specified records, unless SKIP is used.

- One pair of RECORD TYPE and DATA LIST commands must be used for each defined record type.

Syntax Rules

- A list of values can be specified if a set of different record types has the same variable definitions. Each value must be separated by a space or comma.
- String values must be enclosed in quotes.
- For mixed files, each DATA LIST can specify variables with the same variable name, since each record type defines a separate case. For grouped and nested files, the variable names on each DATA LIST must be unique, since a case is built by combining all record types together onto a single record.
- For mixed files, if the same variable is defined for more than one record type, the format type and width of the variable should be the same on all DATA LIST commands. The program refers to the first DATA LIST command that defines a variable for the print and write formats to include in the dictionary of the active dataset.
- For nested files, the order of the RECORD TYPE commands defines the hierarchical structure of the file. The first RECORD TYPE defines the highest-level record type, the next RECORD TYPE defines the next highest-level record, and so forth. The last RECORD TYPE command defines a case in the active dataset.

Operations

- If a record type is specified on more than one RECORD TYPE command, the program uses the DATA LIST command associated with the first specification and ignores all others.
- For NESTED files, the first record in the file should be the type specified on the first RECORD TYPE command—the highest-level record of the hierarchy. If the first record in the file is not the highest-level type, the program skips all records until it encounters a record of the highest-level type. If the MISSING or DUPLICATE subcommands have been specified on the FILE TYPE command, these records may produce warning messages but will not be used to build a case in the active dataset.

Examples

Reading a Single Record Type From a Mixed File

```
FILE TYPE  MIXED RECORD=RECID 1-2.
RECORD TYPE 23.
DATA LIST   /SEX 5 AGE 6-7 DOSAGE 8-10 RESULT 12.
END FILE TYPE.

BEGIN DATA
21  145010 1
22  257200 2
25  235  250  2
35  167          300    3
24  125150 1
23  272075 1
21  149050 2
25  134  035  3
30  138          300    3
```

```
32  229          500    3
END DATA.
```

- FILE TYPE begins the file definition, and END FILE TYPE indicates the end of file definition. FILE TYPE specifies a mixed file type. Since the data are included between BEGIN DATA–END DATA, the FILE subcommand is omitted. The record identification variable *RECID* is located in columns 1 and 2.
- RECORD TYPE indicates that records with value 23 for variable *RECID* will be copied into the active dataset. All other records are skipped. The program does not issue a warning when it skips records in mixed files.
- DATA LIST defines variables on records with the value 23 for variable *RECID*.

Reading Multiple Record Types From a Mixed File

```
FILE TYPE  MIXED FILE=TREATMNT RECORD=RECID 1-2.
+ RECORD TYPE 21,22,23,24.
+ DATA LIST   /SEX 5 AGE 6-7 DOSAGE 8-10 RESULT 12.
+ RECORD TYPE 25.
+ DATA LIST   /SEX 5 AGE 6-7 DOSAGE 10-12 RESULT 15.
END FILE TYPE.
```

- Variable *DOSAGE* is read from columns 8–10 for record types 21, 22, 23, and 24 and from columns 10–12 for record type 25. *RESULT* is read from column 12 for record types 21, 22, 23, and 24 and from column 15 for record type 25.
- The active dataset contains values for all variables defined on the DATA LIST commands for record types 21 through 25. All other record types are skipped.

Working With Nested Files

```
* A nested file of accident records.

FILE TYPE NESTED RECORD=6 CASE=ACCID 1-4.
RECORD TYPE 1.
DATA LIST /ACC_ID 9-11 WEATHER 12-13 STATE 15-16 (A) DATE 18-24 (A).
RECORD TYPE 2.
DATA LIST /STYLE 11 MAKE 13 OLD 14 LICENSE 15-16(A) INSURNCE 18-21 (A).
RECORD TYPE 3.
DATA LIST /PSNGR_NO 11 AGE 13-14 SEX 16 (A) INJURY 18 SEAT 20-21 (A)
          COST 23-24.
END FILE TYPE.

BEGIN DATA
0001 1  322 1 IL 3/13/88   /* Type 1:  accident record
0001 2    1 44MI 134M      /* Type 2:    vehicle record
0001 3    1 34 M 1 FR  3   /* Type 3:      person record
0001 2    2 16IL 322F      /*            vehicle record
0001 3    1 22 F 1 FR 11   /*              person record
0001 3    2 35 M 1 FR  5   /*              person record
0001 3    3 59 M 1 BK  7   /*              person record
0001 2    3 21IN 146M      /*            vehicle record
0001 3    1 46 M 0 FR  0   /*              person record
END DATA.
```

- FILE TYPE specifies a nested file type. The record identifier, located in column 6, is not assigned a variable name, so the default scratch variable name *####RECD* is used. The case identification variable *ACCID* is located in columns 1–4.

- Because there are three record types, there are three RECORD TYPE commands. For each RECORD TYPE, there is a DATA LIST command to define variables on that record type. The order of the RECORD TYPE commands defines the hierarchical structure of the file.
- END FILE TYPE signals the end of file definition.
- The program builds a case for each lowest-level (type 3) record, representing each person in the file. There can be only one type 1 record for each type 2 record, and one type 2 record for each type 3 record. Each vehicle can be in only one accident, and each person can be in only one vehicle. The variables from the type 1 and type 2 records are spread to their corresponding type 3 records.

OTHER Keyword

OTHER specifies all record types that have not been mentioned on previous RECORD TYPE commands.

- OTHER can be specified only on the last RECORD TYPE command in the file definition.
- OTHER can be used with SKIP to skip all undefined record types.
- For nested files, OTHER can be used only with SKIP. Neither can be used separately.
- If WILD=WARN is in effect for the FILE TYPE command, OTHER cannot be specified on the RECORD TYPE command.

Using Keyword OTHER With a Mixed File

```
FILE TYPE  MIXED FILE=TREATMNT RECORD=RECID 1-2.
RECORD TYPE 21,22,23,24.
DATA LIST   /SEX 5 AGE 6-7 DOSAGE 8-10 RESULT 12.
RECORD TYPE 25.
DATA LIST   /SEX 5 AGE 6-7 DOSAGE 10-12 RESULT 15.
RECORD TYPE OTHER.
DATA LIST   /SEX 5 AGE 6-7 DOSAGE 18-20 RESULT 25.
END FILE TYPE.
```

- The first two RECORD TYPE commands specify record types 21–25. All other record types are specified by the third RECORD TYPE.

Using Keyword OTHER With a Nested File

```
FILE TYPE NESTED FILE=ACCIDENT RECORD=#RECID 6 CASE=ACCID 1-4.
RECORD TYPE 1.        /* Accident record
DATA LIST   /WEATHER 12-13.
RECORD TYPE 2.        /* Vehicle record
DATA LIST /STYLE 16.
RECORD TYPE OTHER SKIP.
END FILE TYPE.
```

- The third RECORD TYPE specifies OTHER SKIP. Type 2 records are therefore the lowest-level records included in the active dataset. These commands build one case for each vehicle record. The person records are skipped.
- Because the data are in a nested file, OTHER can be specified only with SKIP.

SKIP Subcommand

SKIP specifies record types to skip.

- To skip selected record types, specify the values for the types you want to skip and then specify SKIP. To skip all record types other than those specified on previous RECORD TYPE commands, specify OTHER and then SKIP.
- For nested files, SKIP can be used only with OTHER. Neither can be used separately.
- For grouped files, OTHER cannot be specified on SKIP if WILD=WARN (the default) is in effect for FILE TYPE.
- For mixed files, all record types that are not specified on a RECORD TYPE command are skipped by default. No warning is issued (WILD=NOWARN on FILE TYPE is the default for mixed files).
- For grouped files, a warning message is issued by default for all record types not specified on a RECORD TYPE command (WILD=WARN on FILE TYPE is the default for grouped files). If the record types are explicitly specified on SKIP, no warning is issued.

Examples

```
FILE TYPE GROUPED FILE=HUBDATA RECORD=#RECID 80 CASE=ID 1-5
                               WILD=NOWARN.
RECORD TYPE 1.
DATA LIST   /MOHIRED YRHIRED 12-15 DEPT79 TO DEPT82 SEX 16-20.
RECORD TYPE OTHER SKIP.
END FILE TYPE.
```

- The program reads variables from type 1 records and skips all other types.
- WILD=NOWARN on the FILE TYPE command suppresses the warning messages that is issued by default for undefined record types for grouped files. Keyword OTHER cannot be used when the default WILD=WARN specification is in effect.

```
FILE TYPE GROUPED FILE=HUBDATA RECORD=#RECID 80 CASE=ID 1-5.
RECORD TYPE 1.
DATA LIST   /MOHIRED YRHIRED 12-15 DEPT79 TO DEPT82 SEX 16-20.
RECORD TYPE 2,3 SKIP.
END FILE TYPE.
```

- Record type 1 is defined for each case, and record types 2 and 3 are skipped.
- WILD=WARN (the default) on FILE TYPE GROUPED is in effect. The program therefore issues a warning message for any record types it encounters other than types 1, 2, and 3. No warning is issued for record types 2 and 3 because they are explicitly specified on a RECORD TYPE command.

CASE Subcommand

CASE specifies the column locations of the case identification variable when that variable is not in the location defined by the CASE subcommand on FILE TYPE.

- CASE on RECORD TYPE applies only to those records specified by that RECORD TYPE command. The identifier for record types without CASE on RECORD TYPE must be in the location specified by CASE on FILE TYPE.

- CASE can be used for nested and grouped files only. CASE cannot be used for mixed files.
- CASE can be used on RECORD TYPE only if a CASE subcommand is specified on FILE TYPE.
- The format type of the case identification variable must be the same on all records, and the same format must be assigned on the RECORD TYPE and FILE TYPE commands. For example, if the case identification variable is defined as a string on FILE TYPE, it cannot be defined as a numeric variable on RECORD TYPE.

Example

```
* Specifying case on the record type command for a grouped file.

FILE TYPE GROUPED FILE=HUBDATA RECORD=#RECID 80 CASE=ID 1-5.
RECORD TYPE 1.
DATA LIST   /MOHIRED YRHIRED 12-15 DEPT79 TO DEPT82 SEX 16-20.
RECORD TYPE 2.
DATA LIST   /SALARY79 TO SALARY82 6-25
             HOURLY81 HOURLY82 40-53 (2)
             PROMO81 72  AGE 54-55 RAISE82 66-70.
RECORD TYPE 3  CASE=75-79.
DATA LIST   /JOBCAT 6 NAME 25-48 (A).
END FILE TYPE.
```

- CASE on FILE TYPE indicates that the case identification variable is located in columns 1–5. On the third RECORD TYPE command, the CASE subcommand overrides the identifier location for type 3 records. For type 3 records, the case identification variable is located in columns 75–79.

MISSING Subcommand

MISSING controls whether the program issues a warning when it encounters a missing record type for a case. Regardless of whether the program issues the warning, it builds the case in the active dataset with system-missing values for the variables defined on the missing record.

- The only specification is a single keyword. NOWARN is the default for nested files. WARN is the default for grouped files. MISSING cannot be used with MIXED files.
- MISSING on RECORD TYPE applies only to those records specified by that RECORD TYPE command. The treatment of missing records for record types without the MISSING specification on RECORD TYPE is determined by the MISSING subcommand on FILE TYPE.
- For grouped files, the program checks whether there is a record for each case identification number. For nested files, the program verifies that each defined case includes one record of each type.

WARN *Issue a warning message when a record type is missing for a case.* This is the default for grouped files.

NOWARN *Suppress the warning message when a record type is missing for a case.* This is the default for nested files.

Example

```
FILE TYPE GROUPED FILE=HUBDATA RECORD=#RECID 80 CASE=ID 1-5.
RECORD TYPE 1.
DATA LIST   /MOHIRED YRHIRED 12-15 DEPT79 TO DEPT82 SEX 16-20.
```

```
RECORD TYPE 2  MISSING=NOWARN.
DATA LIST   /SALARY79 TO SALARY82 6-25
  HOURLY81 HOURLY82 40-53 (2) PROMO81 72 AGE 54-55 RAISE82 66-70.
RECORD TYPE 3.
DATA LIST   /JOBCAT 6 NAME 25-48 (A).
END FILE TYPE.
```

- MISSING is not specified on FILE TYPE. Therefore the default MISSING=WARN is in effect for all record types.
- MISSING=NOWARN is specified on the second RECORD TYPE, overriding the default setting for type 2 records. WARN is still in effect for type 1 and type 3 records.

DUPLICATE Subcommand

DUPLICATE controls whether the program issues a warning when it encounters more than one record of each type for a single case.

- DUPLICATE on RECORD TYPE can be used for grouped files only. DUPLICATE cannot be used for mixed or nested files.
- The only specification is a single keyword. WARN is the default.
- DUPLICATE on RECORD TYPE applies only to those records specified by that RECORD TYPE command. The treatment of duplicate records for record types without DUPLICATE specification is determined by the DUPLICATE subcommand on FILE TYPE.
- Regardless of the specification on DUPLICATE, only the last record from a set of duplicates is included in the active dataset.

WARN *Issue a warning message.* The program issues a message and the first 80 characters of the last record of the duplicate set of record types. This is the default.

NOWARN *Suppress the warning message.*

Example

```
* Specifying DUPLICATE on RECORD TYPE for a grouped file.

FILE TYPE GROUPED FILE=HUBDATA RECORD=#RECID 80 CASE=ID 1-5.
RECORD TYPE 1.
DATA LIST   /MOHIRED YRHIRED 12-15 DEPT79 TO DEPT82 SEX 16-20.
RECORD TYPE 2  DUPLICATE=NOWARN.
DATA LIST   /SALARY79 TO SALARY82 6-25
  HOURLY81 HOURLY82 40-53 (2) PROMO81 72  AGE 54-55 RAISE82 66-70.
RECORD TYPE 3.
DATA LIST   /JOBCAT 6 NAME 25-48 (A).
END FILE TYPE.
```

- DUPLICATE is not specified on FILE TYPE. Therefore the default DUPLICATE=WARN is in effect for all record types.
- DUPLICATE=NOWARN is specified on the second RECORD TYPE, overriding the FILE TYPE setting for type 2 records. WARN is still in effect for type 1 and type 3 records.

SPREAD Subcommand

SPREAD controls whether the values for variables defined for a record type are spread to all related cases.

- SPREAD can be used for nested files only. SPREAD cannot be used for mixed or grouped files.
- The only specification is a single keyword. YES is the default.
- SPREAD=NO applies only to the record type specified on that RECORD TYPE command. The default YES is in effect for all other defined record types.

YES *Spread the values from the specified record type to all related cases.* This is the default.

NO *Spread the values from the specified type only to the first related case.* All other cases built from the same record are assigned the system-missing value for the variables defined on the record type.

Example

```
* A nested file.

FILE TYPE NESTED RECORD=#RECID 6 CASE=ACCID 1-4.
RECORD TYPE 1.
DATA LIST   /ACC_NO 9-11 WEATHER 12-13
             STATE 15-16 (A) DATE 18-24 (A).
RECORD TYPE 2  SPREAD=NO.
DATA LIST /STYLE 11 MAKE 13 OLD 14
           LICENSE 15-16 (A) INSURNCE 18-21 (A).
RECORD TYPE 3.
DATA LIST /PSNGR_NO 11 AGE 13-14 SEX 16 (A)
       INJURY 18 SEAT 20-21 (A) COST 23-24.
END FILE TYPE.

BEGIN DATA
0001 1  322 1 IL 3/13/88   /* Type 1:  accident record
0001 2    1 44MI 134M      /* Type 2:    vehicle record
0001 3    1 34 M 1 FR  3   /* Type 3:       person record
0001 2    2 16IL 322F      /*            vehicle record
0001 3    1 22 F 1 FR 11   /*               person record
0001 3    2 35 M 1 FR  5   /*               person record
0001 3    3 59 M 1 BK  7   /*               person record
0001 2    3 21IN 146M      /*            vehicle record
0001 3    1 46 M 0 FR  0   /*               person record
END DATA.
```

- The accident record (type 1) is spread to all related cases (in this example, all cases).
- The first vehicle record has one related person record. The values for *STYLE, MAKE, OLD, LICENSE*, and *INSURNCE* are spread to the case built for the person record.
- The second vehicle record has three related person records. The values for *STYLE, MAKE, OLD, LICENSE,* and *INSURNCE* are spread only to the case built from the first person record. The other two cases have the system-missing values for *STYLE, MAKE, OLD, LICENSE,* and *INSURNCE*.
- The third vehicle record has one related person record, and the values for type 2 records are spread to that case.

REFORMAT

```
REFORMAT  {ALPHA  } = varlist [/...]
          {NUMERIC}
```

Example

```
REFORMAT ALPHA=STATE /NUMERIC=HOUR1 TO HOUR6.
```

Overview

REFORMAT converts variables from BMDP files to variables for SPSS-format data files. It also converts very old versions of SPSS-format data files to current SPSS-format data files. REFORMAT can change the print formats, write formats, and missing-value specifications for variables from alphanumeric to numeric, or from numeric to alphanumeric.

Basic Specification

The basic specification is ALPHA and a list of variables or NUMERIC and a list of variables.

- The ALPHA subcommand declares variables as string variables. The NUMERIC subcommand declares variables as numeric variables.
- If both ALPHA and NUMERIC are specified, they must be separated by a slash.

Operations

- REFORMAT always assigns the print and write format F8.2 (or the format specified on the SET command) to variables specified after NUMERIC and format A4 to variables specified after ALPHA.
- Formats cannot be specified on REFORMAT. To define different formats for numeric variables, use the PRINT FORMATS, WRITE FORMATS, or FORMATS commands. To declare new format widths for string variables, use the STRING and COMPUTE commands to perform data transformations.
- Missing-value specifications for variables named with both ALPHA and NUMERIC are also changed to conform to the new formats.
- The SAVE or XSAVE commands can be used to save the reformatted variables in an SPSS-format data file. This avoids having to reformat the variables each time the SPSS-format or BMDP dataset is used.

Example

```
* Convert an old SPSS-format file to a new SPSS-format data file.

GET FILE R9FILE.
REFORMAT ALPHA=STATE /NUMERIC=HOUR1 TO HOUR6.
STRING XSTATE (A2) /NAME1 TO NAME6 (A15).
COMPUTE XSTATE=STATE.
```

```
FORMATS HOUR1 TO HOUR6 (F2.0).
SAVE OUTFILE=NEWFILE /DROP=STATE
    /RENAME=(XSTATE=STATE).
```

- GET accesses the old SPSS-format data file.
- REFORMAT converts variable STATE to a string variable with an A4 format and variables *HOUR1* to *HOUR6* to numeric variables with F8.2 formats.
- STRING declares *XSTATE* as a string variable with two positions.
- COMPUTE transfers the information from the variable *STATE* to the new string variable *XSTATE*.
- FORMATS changes the F8.2 formats for *HOUR1* to *HOUR6* to F2.0 formats.
- SAVE saves a new SPSS-format data file. The DROP subcommand drops the old variable *STATE*. RENAME renames the new string variable *XSTATE* to the original variable name *STATE*.

REGRESSION

```
REGRESSION [MATRIX=[IN({file})]  [OUT({file})]]
                      {*   }         {*   }

 [/CASEWISE=[DEFAULTS]  [{OUTLIERS({3    })}] [PLOT({ZRESID })]
                          {        {value} }       {tempvar}
                          {ALL             }

       [{DEPENDENT PRED RESID}]]
        {tempvars           }

 [/SCATTERPLOT [varname,varname]...[

 [/PARTIALPLOT=[{ALL    }]
               {varlist}
```

```
[/OUTFILE={COVB ('savfile'|'dataset')}]  [{MODEL('file')    }]
          {CORB ('savfile'|'dataset')}    {PARAMETER('file')}

[/SAVE=tempvar[(newname)]  [tempvar[(newname)]...]  [FITS]]
```

**Default if the subcommand is omitted.

Temporary residual variables are:

PRED, ADJPRED, SRESID, MAHAL, RESID, ZPRED, SDRESID, COOK, DRESID, ZRESID, SEPRED, LEVER, DFBETA, SDBETA, DFFIT, SDFFIT, COVRATIO, MCIN, ICIN

SAVE FITS saves:

DFFIT, SDFIT, DFBETA, SDBETA, COVRATIO

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Release History

Release 13.0

- PARAMETER keyword introduced on OUTFILE subcommand.

Example

```
REGRESSION VARIABLES=POP15,POP75,INCOME,GROWTH,SAVINGS
 /DEPENDENT=SAVINGS
 /METHOD=ENTER POP15,POP75,INCOME
 /METHOD=ENTER GROWTH.
```

Overview

REGRESSION calculates multiple regression equations and associated statistics and plots. REGRESSION also calculates collinearity diagnostics, predicted values, residuals, measures of fit and influence, and several statistics based on these measures.

Options

Input and Output Control Subcommands. DESCRIPTIVES requests descriptive statistics on the variables in the analysis. SELECT estimates the model based on a subset of cases. REGWGT specifies a weight variable for estimating weighted least-squares models. MISSING specifies the treatment of cases with missing values. MATRIX reads and writes matrix data files.

Equation-Control Subcommands. These optional subcommands control the calculation and display of statistics for each equation. STATISTICS controls the statistics displayed for the equation(s) and the independent variable(s), CRITERIA specifies the criteria used by the variable selection method, and ORIGIN specifies whether regression is through the origin.

Analysis of Residuals, Fit, and Influence. REGRESSION creates temporary variables containing predicted values, residuals, measures of fit and influence, and several statistics based on these measures. These temporary variables can be analyzed within REGRESSION in Casewise Diagnostics tables (CASEWISE subcommand), scatterplots (SCATTERPLOT subcommand), histograms and normal probability plots (RESIDUALS subcommand), and partial regression plots (PARTIALPLOT subcommand). Any of the residuals subcommands can be specified to obtain descriptive statistics for the predicted values, residuals, and their standardized versions. Any of the temporary variables can be added to the active dataset with the SAVE subcommand.

Basic Specification

The basic specification is DEPENDENT, which initiates the equation(s) and defines at least one dependent variable, followed by METHOD, which specifies the method for selecting independent variables.

- By default, all variables named on DEPENDENT and METHOD are used in the analysis.
- The default display for each equation includes a Model Summary table showing R^2, an ANOVA table, a Coefficients table displaying related statistics for variables in the equation, and an Excluded Variables table displaying related statistics for variables not yet in the equation.
- By default, all cases in the active dataset with valid values for all selected variables are used to compute the correlation matrix on which the regression equations are based. The default equations include a constant (intercept).
- All residuals analysis subcommands are optional. Most have defaults that can be requested by including the subcommand without any further specifications. These defaults are described in the discussion of each subcommand below.

Subcommand Order

The standard subcommand order for REGRESSION is

```
REGRESSION MATRIX=...
   /VARIABLES=...
   /DESCRIPTIVES=...
   /SELECT=...
   /MISSING=...
   /REGWGT=...

              --Equation Block--
   /STATISTICS=...
   /CRITERIA=...
   /ORIGIN
   /DEPENDENT=...

              --Method Block(s)--
   /METHOD=...
   [/METHOD=...]

              --Residuals Block--
   /RESIDUALS=...
   /SAVE=...
   /CASEWISE=...
   /SCATTERPLOT=...
   /PARTIALPLOT=...
```

```
/OUTFILE=...
```

- When used, MATRIX must be specified first.
- Subcommands listed before the equation block must be specified before any subcommands within the block.
- Only one equation block is allowed per REGRESSION command.
- An equation block can contain multiple METHOD subcommands. These methods are applied, one after the other, to the estimation of the equation for that block.
- The STATISTICS, CRITERIA, and ORIGIN/NOORIGIN subcommands must precede the DEPENDENT subcommand.
- The residuals subcommands RESIDUALS, CASEWISE, SCATTERPLOT, and PARTIALPLOT follow the last METHOD subcommand of any equation for which residuals analysis is requested. Statistics are based on this final equation.
- Residuals subcommands can be specified in any order. All residuals subcommands must follow the DEPENDENT and METHOD subcommands.

Syntax Rules

- VARIABLES can be specified only once. If omitted, VARIABLES defaults to COLLECT.
- The DEPENDENT subcommand can be specified only once and must be followed immediately by one or more METHOD subcommands.
- CRITERIA, STATISTICS, and ORIGIN must be specified before DEPENDENT and METHOD. If any of these subcommands are specified more than once, only the last specified is in effect for all subsequent equations.
- More than one variable can be specified on the DEPENDENT subcommand. An equation is estimated for each.
- If no variables are specified on METHOD, all variables named on VARIABLES but not on DEPENDENT are considered for selection.

Operations

- This procedure uses the multithreaded options specified by SET THREADS and SET MCACHE.

Operations

- REGRESSION calculates a correlation matrix that includes all variables named on VARIABLES. All equations requested on the REGRESSION command are calculated from the same correlation matrix.
- The MISSING, DESCRIPTIVES, and SELECT subcommands control the calculation of the correlation matrix and associated displays.
- If multiple METHOD subcommands are specified, they operate in sequence on the equations defined by the preceding DEPENDENT subcommand.
- Only independent variables that pass the tolerance criterion are candidates for entry into the equation. For more information, see CRITERIA Subcommand on p. 1579.

- The temporary variables *PRED* (unstandardized predicted value), *ZPRED* (standardized predicted value), *RESID* (unstandardized residual), and *ZRESID* (standardized residual) are calculated and descriptive statistics are displayed whenever any residuals subcommand is specified. If any of the other temporary variables are referred to on the command, they are also calculated.
- Predicted values and statistics based on predicted values are calculated for every observation that has valid values for all variables in the equation. Residuals and statistics based on residuals are calculated for all observations that have a valid predicted value and a valid value for the dependent variable. The missing-values option therefore affects the calculation of residuals and predicted values.
- No residuals or predictors are generated for cases deleted from the active dataset with `SELECT IF`, a temporary `SELECT IF`, or `SAMPLE`.
- All variables are standardized before plotting. If the unstandardized version of a variable is requested, the standardized version is plotted.
- Residuals processing is not available when the active dataset is a matrix file or is replaced by a matrix file with `MATRIX OUT(*)` on `REGRESSION`. If `RESIDUALS`, `CASEWISE`, `SCATTERPLOT`, `PARTIALPLOT`, or `SAVE` are used when `MATRIX IN(*)` or `MATRIX OUT(*)` is specified, the `REGRESSION` command is not executed.

For each analysis, `REGRESSION` can calculate the following types of temporary variables:

PRED	*Unstandardized predicted values*.
RESID	*Unstandardized residuals*.
DRESID	*Deleted residuals*.
ADJPRED	*Adjusted predicted values*.
ZPRED	*Standardized predicted values*.
ZRESID	*Standardized residuals*.
SRESID	*Studentized residuals*.
SDRESID	*Studentized deleted residuals*. (Hoaglin and Welsch, 1978)
SEPRED	*Standard errors of the predicted values*.
MAHAL	*Mahalanobis distances*.
COOK	*Cook's distances*. (Cook, 1977)
LEVER	*Centered leverage values*. (Velleman and Welsch, 1981)
DFBETA	*Change in the regression coefficient that results from the deletion of the* i*th case.* A `DFBETA` value is computed for each case for each regression coefficient generated by a model. (Belsley, Kuh, and Welsch, 1980)
SDBETA	*Standardized DFBETA*. An `SDBETA` value is computed for each case for each regression coefficient generated by a model. (Belsley et al., 1980)
DFFIT	*Change in the predicted value when the* i*th case is deleted.*(Belsley et al., 1980)
SDFIT	*Standardized DFFIT.*(Belsley et al., 1980)
COVRATIO	*Ratio of the determinant of the covariance matrix with the* i*th case deleted to the determinant of the covariance matrix with all cases included.* (Belsley et al., 1980)

MCIN *Lower and upper bounds for the prediction interval of the mean predicted response.* A lowerbound *LMCIN* and an upperbound *UMCIN* are generated. The default confidence interval is 95%. The confidence interval can be reset with the CIN subcommand. (Dillon and Goldstein, 1984)

ICIN *Lower and upper bounds for the prediction interval for a single observation.* A lowerbound *LICIN* and an upperbound *UICIN* are generated. The default confidence interval is 95%. The confidence interval can be reset with the CIN subcommand. (Dillon et al., 1984)

Examples

```
REGRESSION VARIABLES=POP15,POP75,INCOME,GROWTH,SAVINGS
 /DEPENDENT=SAVINGS
 /METHOD=ENTER POP15,POP75,INCOME
 /METHOD=ENTER GROWTH.
```

- VARIABLES calculates a correlation matrix of five variables for use by REGRESSION.
- DEPENDENT defines a single equation, with *SAVINGS* as the dependent variable.
- The first METHOD subcommand enters *POP15, POP75,* and *INCOME* into the equation.
- The second METHOD subcommand adds *GROWTH* to the equation containing *POP15* to *INCOME*.

Example: Specifying Residual Output

```
REGRESSION VARIABLES=SAVINGS INCOME POP15 POP75
  /DEPENDENT=SAVINGS
  /METHOD=ENTER
  /RESIDUALS
  /CASEWISE
  /SCATTERPLOT (*ZRESID *ZPRED)
  /PARTIALPLOT
  /SAVE ZRESID(STDRES) ZPRED(STDPRED).
```

- REGRESSION requests a single equation in which *SAVINGS* is the dependent variable and *INCOME*, *POP15*, and *POP75* are independent variables.
- RESIDUALS requests the default residuals output.
- Because residuals processing has been requested, statistics for predicted values, residuals, and standardized versions of predicted values and residuals are displayed in a Residuals Statistics table.
- CASEWISE requests a Casewise Diagnostics table for cases whose absolute value of *ZRESID* is greater than 3. Values of the dependent variable, predicted value, and residual are listed for each case.
- SCATTERPLOT requests a plot of the standardized predicted value and the standardized residual.
- PARTIALPLOT requests partial regression plots for all independent variables.
- SAVE adds the standardized residual and the standardized predicted value to the active dataset as new variables named *STDRES* and *STDPRED*.

VARIABLES Subcommand

VARIABLES names all the variables to be used in the analysis.

- The minimum specification is a list of two variables or the keyword ALL or COLLECT. COLLECT, which must be specified in parentheses, is the default.
- Only one VARIABLES subcommand is allowed, and it must precede any DEPENDENT or METHOD subcommands.
- You can use keyword TO to refer to consecutive variables in the active dataset.
- The order of variables in the correlation matrix constructed by REGRESSION is the same as their order on VARIABLES. If (COLLECT) is used, the order of variables in the correlation matrix is the order in which they are first listed on the DEPENDENT and METHOD subcommands.

ALL *Include all user-defined variables in the active dataset.*

(COLLECT) *Include all variables named on the DEPENDENT and METHOD subcommands.* COLLECT is the default if the VARIABLES subcommand is omitted. COLLECT must be specified in parentheses. If COLLECT is used, the METHOD subcommands must specify variable lists.

Example

```
REGRESSION VARIABLES=(COLLECT)
 /DEPENDENT=SAVINGS
 /METHOD=STEP POP15 POP75 INCOME
 /METHOD=ENTER GROWTH.
```

- COLLECT requests that the correlation matrix include *SAVINGS, POP15, POP75, INCOME,* and *GROWTH*. Since COLLECT is the default, the VARIABLES subcommand could have been omitted.
- The DEPENDENT subcommand defines a single equation in which *SAVINGS* is the dependent variable.
- The first METHOD subcommand requests that the block of variables *POP15, POP75,* and *INCOME* be considered for inclusion using a stepwise procedure.
- The second METHOD subcommand adds variable *GROWTH* to the equation.

DEPENDENT Subcommand

DEPENDENT specifies a list of variables and requests that an equation be built for each. DEPENDENT is required.

- The minimum specification is a single variable. There is no default variable list.
- Only one DEPENDENT subcommand can be specified. It must be followed by at least one METHOD subcommand.
- Keyword TO on a DEPENDENT subcommand refers to the order in which variables are specified on the VARIABLES subcommand. If VARIABLES=(COLLECT), TO refers to the order of variables in the active dataset.
- If DEPENDENT names more than one variable, an equation is built for each using the same independent variables and methods.

METHOD Subcommand

METHOD specifies a variable selection method and names a block of variables to be evaluated using that method. METHOD is required.

- The minimum specification is a method keyword and, for some methods, a list of variables. The actual keyword METHOD can be omitted.
- When more than one METHOD subcommand is specified, each METHOD subcommand is applied to the equation that resulted from the previous METHOD subcommands.
- The default variable list for methods FORWARD, BACKWARD, STEPWISE, and ENTER consists of all variables named on VARIABLES that are not named on the DEPENDENT subcommand. If VARIABLES=(COLLECT), the variables must be specified for these methods.
- There is no default variable list for the REMOVE and TEST methods.
- Keyword TO in a variable list on METHOD refers to the order in which variables are specified on the VARIABLES subcommand. If VARIABLES=(COLLECT), TO refers to the order of variables in the active dataset.

The available stepwise methods are as follows:

BACKWARD [varlist] *Backward elimination.* Variables in the block are considered for removal. At each step, the variable with the largest probability-of-*F* value is removed, provided that the value is larger than POUT. For more information, see CRITERIA Subcommand on p. 1579. If no variables are in the equation when BACKWARD is specified, all independent variables in the block are first entered.

FORWARD [varlist] *Forward entry.* Variables in the block are added to the equation one at a time. At each step, the variable not in the equation with the smallest probability of *F* is entered if the value is smaller than PIN. For more information, see CRITERIA Subcommand on p. 1579.

STEPWISE [varlist] *Stepwise selection.* If there are independent variables already in the equation, the variable with the largest probability of *F* is removed if the value is larger than POUT. The equation is recomputed without the variable and the process is repeated until no more independent variables can be removed. Then, the independent variable not in the equation with the smallest probability of *F* is entered if the value is smaller than PIN. All variables in the equation are again examined for removal. This process continues until no variables in the equation can be removed and no variables not in the equation are eligible for entry, or until the maximum number of steps has been reached. For more information, see CRITERIA Subcommand on p. 1579.

The methods that enter or remove the entire variable block in a single step are as follows:

ENTER [varlist]	*Forced entry.* All variables specified are entered in a single step in order of decreasing tolerance. You can control the order in which variables are entered by specifying the variables on multiple METHOD=ENTER subcommands.
REMOVE varlist	*Forced removal.* All variables specified are removed in a single step. REMOVE requires a variable list.
TEST (varlist) (varlist)	R^2 *change and its significance for sets of independent variables.* This method first adds all variables specified on TEST to the current equation. It then removes in turn each subset from the equation and displays requested statistics. Specify test subsets in parentheses. A variable can be used in more than one subset, and each subset can include any number of variables. Variables named on TEST remain in the equation when the method is completed.

Example

```
REGRESSION VARIABLES=POP15 TO GROWTH, SAVINGS
 /DEPENDENT=SAVINGS
 /METHOD=STEPWISE
 /METHOD=ENTER.
```

- STEPWISE applies the stepwise procedure to variables *POP15* to *GROWTH*.
- All variables not in the equation when the STEPWISE method is completed will be forced into the equation with ENTER.

Example

```
REGRESSION VARIABLES=(COLLECT)
 /DEPENDENT=SAVINGS
 /METHOD=TEST(MEASURE3 TO MEASURE9)(MEASURE3,INCOME)
 /METHOD=ENTER GROWTH.
```

- The VARIABLES=(COLLECT) specification assembles a correlation matrix that includes all variables named on the DEPENDENT and METHOD subcommands.
- REGRESSION first builds the full equation of all the variables named on the first METHOD subcommand: *SAVINGS* regressed on *MEASURE3* to *MEASURE9* and *INCOME*. For each set of test variables (MEASURE3 to MEASURE9, and MEASURE3 and INCOME), the R^2 change, *F*, probability, sums of squares, and degrees of freedom are displayed.
- *GROWTH* is added to the equation by the second METHOD subcommand. Variables *MEASURE3* to *MEASURE9* and *INCOME* are still in the equation when this subcommand is executed.

STATISTICS Subcommand

STATISTICS controls the display of statistics for the equation and for the independent variables.

- If STATISTICS is omitted or if it is specified without keywords, R, ANOVA, COEFF, and OUTS are displayed (see below).

- If any statistics are specified on STATISTICS, only those statistics specifically requested are displayed.
- STATISTICS must be specified before DEPENDENT and METHOD subcommands. The last specified STATISTICS affects all equations.

Global Statistics

DEFAULTS *R, ANOVA, COEFF, and OUTS.* These are displayed if STATISTICS is omitted or if it is specified without keywords.

ALL *All statistics except F.*

Equation Statistics

R *Multiple R.* R includes R^2, adjusted R^2, and standard error of the estimate displayed in the Model Summary table.

ANOVA *Analysis of variance table.* This option includes regression and residual sums of squares, mean square, *F*, and probability of *F* displayed in the ANOVA table.

CHA *Change in* R^2. This option includes the change in R^2 between steps, along with the corresponding *F* and its probability, in the Model Summary table. For each equation, *F* and its probability are also displayed.

BCOV *Variance-covariance matrix for unstandardized regression coefficients.* The statistics are displayed in the Coefficient Correlations table.

XTX *Swept correlation matrix*.

COLLIN *Collinearity diagnostics*(Belsley et al., 1980). COLLIN includes the variance-inflation factors (VIF) displayed in the Coefficients table, and the eigenvalues of the scaled and uncentered cross-products matrix, condition indexes, and variance-decomposition proportions displayed in the Collinearity Diagnostics table.

SELECTION *Selection statistics.* This option includes Akaike information criterion (AIK), Ameniya's prediction criterion (PC), Mallows conditional mean squared error of prediction criterion (C_p), and Schwarz Bayesian criterion (SBC) (Judge, Griffiths, Hill, Lutkepohl, and Lee, 1980). The statistics are displayed in the Model Summary table.

Statistics for the Independent Variables

COEFF *Regression coefficients.* This option includes regression coefficients (B), standard errors of the coefficients, standardized regression coefficients (beta), *t*, and two-tailed probability of *t*. The statistics are displayed in the Coefficients table.

OUTS *Statistics for variables not yet in the equation that have been named on METHOD subcommands for the equation.*OUTS displays the Excluded Variables table showing beta, *t,* two-tailed probability of *t,* and minimum tolerance of the variable if it were the only variable entered next.

ZPP *Zero-order, part, and partial correlation*. The statistics are displayed in the Coefficients table.

CI *95% confidence interval for the unstandardized regression coefficients.* The statistics are displayed in the Coefficients table.

SES *Approximate standard error of the standardized regression coefficients.*(Meyer and Younger, 1976) The statistics are displayed in the Coefficients table.

TOL *Tolerance.* This option displays tolerance for variables in the equation in the Coefficients table. For variables not yet entered into the equation, TOL displays in the Excluded Variables table the tolerance each variable would have if it were the only variable entered next.

F *F value for B and its probability.* This is displayed instead of the *t* value in the Coefficients or Excluded Variables table.

CRITERIA Subcommand

CRITERIA controls the statistical criteria used to build the regression equations. The way in which these criteria are used depends on the method specified on METHOD. The default criteria are noted in the description of each CRITERIA keyword below.

- The minimum specification is a criterion keyword and its arguments, if any.
- If CRITERIA is omitted or included without specifications, the default criteria are in effect.
- The CRITERIA subcommand must be specified before DEPENDENT and METHOD subcommands. The last specified CRITERIA affects all equations.

Tolerance and Minimum Tolerance Tests

Variables must pass both tolerance and minimum tolerance tests in order to enter and remain in a regression equation. Tolerance is the proportion of the variance of a variable in the equation that is not accounted for by other independent variables in the equation. The minimum tolerance of a variable not in the equation is the smallest tolerance any variable already in the equation would have if the variable being considered were included in the analysis.

If a variable passes the tolerance criteria, it is eligible for inclusion based on the method in effect.

Criteria for Variable Selection

- The ENTER, REMOVE, and TEST methods use only the TOLERANCE criterion.
- BACKWARD removes variables according to the probability of *F*-to-remove (keyword POUT). Specify FOUT to use *F*-to-remove instead.
- FORWARD enters variables according to the probability of *F*-to-enter (keyword PIN). Specify FIN to use *F*-to-enter instead.
- STEPWISE uses both PIN and POUT (or FIN and FOUT) as criteria. If the criterion for entry (PIN or FIN) is less stringent than the criterion for removal (POUT or FOUT), the same variable can cycle in and out until the maximum number of steps is reached. Therefore, if PIN is larger than POUT or FIN is smaller than FOUT, REGRESSION adjusts POUT or FOUT and issues a warning.

- The values for these criteria are specified in parentheses. If a value is not specified, the default values are used.

DEFAULTS *PIN(0.05), POUT(0.10), and TOLERANCE(0.0001).* These are the defaults if CRITERIA is omitted. If criteria have been changed, DEFAULTS restores these defaults.

PIN[(value)] *Probability of* F-*to-enter*. The default value is 0.05. Either PIN or FIN can be specified. If more than one is used, the last one specified is in effect.

FIN[(value)] F-*to-enter*. The default value is 3.84. Either PIN or FIN can be specified. If more than one is used, the last one specified is in effect.

POUT[(value)] *Probability of* F-*to-remove*. The default value is 0.10. Either POUT or FOUT can be specified. If more than one is used, the last one specified is in effect.

FOUT[(value)] F-*to-remove*. The default value is 2.71. Either POUT or FOUT can be specified. If more than one is used, the last one specified is in effect.

TOLERANCE[(value)] *Tolerance*. The default value is 0.0001. If the specified tolerance is very low, REGRESSION issues a warning.

MAXSTEPS[(n)] *Maximum number of steps*. The value of MAXSTEPS is the sum of the maximum number of steps for each method for the equation. The default values are, for the BACKWARD or FORWARD methods, the number of variables meeting PIN/POUT or FIN/FOUT criteria, and for the STEPWISE method, twice the number of independent variables.

Confidence Intervals

CIN[(value)] *Reset the value of the percent for confidence intervals.* The default is 95%. The specified value sets the percentage interval used in the computation of temporary variable types MCIN and ICIN.

Example

```
REGRESSION VARIABLES=POP15 TO GROWTH, SAVINGS
 /CRITERIA=PIN(.1) POUT(.15)
 /DEPENDENT=SAVINGS
 /METHOD=FORWARD.
```

- The CRITERIA subcommand relaxes the default criteria for entry and removal for the FORWARD method. Note that the specified PIN is less than POUT.

ORIGIN and NOORIGIN Subcommands

ORIGIN and NOORIGIN control whether or not the constant is suppressed. By default, the constant is included in the model (NOORIGIN).

- The specification is either the ORIGIN or NOORIGIN subcommand.
- ORIGIN and NOORIGIN must be specified before the DEPENDENT and METHOD subcommands. The last specified remains in effect for all equations.
- ORIGIN requests regression through the origin. The constant term is suppressed.
- If you specify ORIGIN, statistics requested on the DESCRIPTIVES subcommand are computed as if the mean were 0.

- ORIGIN and NOORIGIN affect the way the correlation matrix is built. If matrix materials are used as input to REGRESSION, the keyword that was in effect when the matrix was written should be in effect when that matrix is read.

Example

```
REGRESSION VAR=(COL)
 /ORIGIN
 /DEP=HOMICIDE
 /METHOD=ENTER POVPCT.
```

- The REGRESSION command requests an equation that regresses *HOMICIDE* on *POVPCT* and suppresses the constant (ORIGIN).

REGWGT Subcommand

The only specification on REGWGT is the name of the variable containing the weights to be used in estimating a weighted least-squares model. With REGWGT, the default display is the usual REGRESSION display.

- REGWGT is a global subcommand.
- If more than one REGWGT subcommand is specified on a REGRESSION procedure, only the last one is in effect.
- REGWGT can be used with MATRIX OUT but not with MATRIX IN.
- Residuals saved from equations using the REGWGT command are not weighted. To obtain weighted residuals, multiply the residuals created with SAVE by the square root of the weighting variable in a COMPUTE statement.
- REGWGT is in effect for all equations and affects the way the correlation matrix is built. Thus, if REGWGT is specified on a REGRESSION procedure that writes matrix materials to a matrix data file, subsequent REGRESSION procedures using that file will be automatically weighted.

Example

```
REGRESSION VARIABLES=GRADE GPA STARTLEV TREATMNT
 /DEPENDENT=GRADE
 /METHOD=ENTER
 /SAVE PRED(P).
COMPUTE WEIGHT=1/(P*(1-P)).
REGRESSION VAR=GRADE GPA STARTLEV TREATMNT
 /REGWGT=WEIGHT
 /DEP=GRADE
 /METHOD=ENTER.
```

- VARIABLES builds a correlation matrix that includes *GRADE*, *GPA*, *STARTLEV*, and *TREATMNT*.
- DEPENDENT identifies *GRADE* as the dependent variable.
- METHOD regresses *GRADE* on *GPA*, *STARTLEV*, and *TREATMNT*.
- SAVE saves the predicted values from the regression equation as variable *P* in the active dataset. For more information, see SAVE Subcommand on p. 1590.
- COMPUTE creates the variable *WEIGHT* as a transformation of *P*.

- The second REGRESSION procedure performs a weighted regression analysis on the same set of variables using *WEIGHT* as the weighting variable.

Example

```
REGRESSION VAR=GRADE GPA STARTLEV TREATMNT
 /REGWGT=WEIGHT
 /DEP=GRADE
 /METHOD=ENTER
 /SAVE RESID(RGRADE).
COMPUTE WRGRADE=RGRADE * SQRT(WEIGHT).
```

- This example illustrates the use of COMPUTE with SAVE to weight residuals.
- REGRESSION performs a weighted regression analysis of *GRADE* on *GPA*, *STARTLEV*, and *TREATMNT*, using *WEIGHT* as the weighting variable.
- SAVE saves the residuals as *RGRADE*. These residuals are not weighted.
- COMPUTE creates variable *WRGRADE*, which contains the weighted residuals.

DESCRIPTIVES Subcommand

DESCRIPTIVES requests the display of correlations and descriptive statistics. By default, descriptive statistics are not displayed.

- The minimum specification is simply the subcommand keyword DESCRIPTIVES, which obtains MEAN, STDDEV, and CORR.
- If DESCRIPTIVES is specified with keywords, only those statistics specifically requested are displayed.
- Descriptive statistics are displayed only once for all variables named or implied on VARIABLES.
- Descriptive statistics are based on all valid cases for each variable if PAIRWISE or MEANSUBSTITUTION has been specified on MISSING. Otherwise, only cases with valid values for all variables named or implied on the VARIABLES subcommand are included in the calculation of descriptive statistics.
- If regression through the origin has been requested (subcommand ORIGIN), statistics are computed as if the mean were 0.

NONE	*No descriptive statistics.* This is the default if the subcommand is omitted.
DEFAULTS	*MEAN, STDDEV, and CORR*. This is the same as specifying DESCRIPTIVES without specifications.
MEAN	*Display variable means in the Descriptive Statistics table*.
STDDEV	*Display variable standard deviations in the Descriptive Statistics table.*
VARIANCE	*Display variable variances in the Descriptive Statistics table*.
CORR	*Display Pearson correlation coefficients in the Correlations table*.
SIG	*Display one-tailed probabilities of the correlation coefficients in the Correlations table*.
BADCORR	*Display the correlation coefficients only if some coefficients cannot be computed.*
COV	*Display covariance in the Correlations table*.

XPROD	*Display sum of squares and cross-product deviations from the mean in the Correlations table.*
N	*Display numbers of cases used to compute correlation coefficients in the Correlations table.*
ALL	*All descriptive statistics.*

Example

```
REGRESSION DESCRIPTIVES=DEFAULTS SIG COV
 /VARIABLES=AGE,FEMALE,YRS_JOB,STARTPAY,SALARY
 /DEPENDENT=SALARY
 /METHOD=ENTER STARTPAY
 /METHOD=ENTER YRS_JOB.
```

- The variable means, standard deviations, and number of cases are displayed in the Descriptive Statistics table and the correlation coefficients, one-tailed probabilities of the correlation coefficients, and covariance are displayed in the Correlations table.
- Statistics are displayed for all variables named on VARIABLES, even though only variables *SALARY, STARTPAY*, and *YRS_JOB* are used to build the equations.
- *STARTPAY* is entered into the equation by the first METHOD subcommand. *YRS_JOB* is entered by the second METHOD subcommand.

SELECT Subcommand

By default, all cases in the active dataset are considered for inclusion on REGRESSION. Use SELECT to include a subset of cases in the correlation matrix and resulting regression statistics.

- The required specification on SELECT is a logical expression.
- The syntax for the SELECT subcommand is as follows:

```
/SELECT=varname relation value
```

- The variable named on SELECT should not be specified on the VARIABLES subcommand.
- The relation can be EQ, NE, LT, LE, GT, or GE.
- Only cases for which the logical expression on SELECT is true are included in the calculation of the correlation matrix and regression statistics.
- All other cases, including those with missing values for the variable named on SELECT, are not included in the computations.
- If SELECT is specified, residuals and predicted values are calculated and reported separately for both selected and unselected cases by default. For more information, see RESIDUALS Subcommand on p. 1586.
- Cases deleted from the active dataset with SELECT IF, a temporary SELECT IF, or SAMPLE are not passed to REGRESSION and are not included among either the selected or unselected cases.
- You should not use a variable from a temporary transformation as a selection variable, since REGRESSION reads the data file more than once if any residuals subcommands are specified. A variable created from a temporary transformation (with IF and COMPUTE statements)

will disappear when the data are read a second time, and a variable that is the result of a temporary RECODE will change.

Example

```
REGRESSION SELECT SEX EQ 'M'
 /VARIABLES=AGE,STARTPAY,YRS_JOB,SALARY
 /DEPENDENT=SALARY
 /METHOD=STEP
 /RESIDUALS=NORMPROB.
```

- Only cases with the value M for *SEX* are included in the correlation matrix calculated by REGRESSION.
- Separate normal P_P plots are displayed for cases with *SEX* equal to M and for other cases. For more information, see RESIDUALS Subcommand on p. 1586.

MATRIX Subcommand

MATRIX reads and writes matrix data files. It can read matrix data files or datasets written by previous REGRESSION procedures or data files or datasets written by other procedures such as CORRELATIONS. The matrix materials REGRESSION writes also include the mean, standard deviation, and number of cases used to compute each coefficient. This information immediately precedes the correlation matrix in the matrix file.

- Either IN or OUT and a matrix file or previously declared dataset name in parentheses are required on MATRIX.
- When used, MATRIX must be the first subcommand specified in a REGRESSION procedure.
- ORIGIN and NOORIGIN affect the way the correlation matrix is built. If matrix materials are used as input to REGRESSION, the keyword that was in effect when the matrix was written should be in effect when that matrix is read.

OUT ('savfile'|'dataset') *Write a matrix data file or dataset.* Specify either a filename, a previously declared dataset name, or an asterisk, enclosed in parentheses. Filenames should be enclosed in quotes and are stored in the working directory unless a path is included as part of the file specification. If you specify an asterisk (*), the matrix data file replaces the active dataset. If you specify an asterisk or a dataset name, the file is not stored on disk unless you use SAVE or XSAVE.

IN ('savfile'|'dataset') *Read a matrix data file or dataset.* Specify either a filename, dataset name created during the current session, or an asterisk enclosed in parentheses. An asterisk reads the matrix data from the active dataset. Filenames should be enclosed in quotes and are read from the working directory unless a path is included as part of the file specification.

Format of the Matrix Data File

- The file has two special variables created by the program: *ROWTYPE_* and *VARNAME_*.
- *ROWTYPE_* is a short string variable with values MEAN, STDDEV, N, and CORR (for Pearson correlation coefficient).

- *VARNAME_* is a short string variable whose values are the names of the variables used to form the correlation matrix. When *ROWTYPE_* is CORR, *VARNAME_* gives the variable associated with that row of the correlation matrix.
- The remaining variables in the file are the variables used to form the correlation matrix.
- To suppress the constant term when ORIGIN is used in the analysis, value OCORR (rather than value CORR) is written to the matrix system file. OCORR indicates that the regression passes through the origin.

Split Files

- When split-file processing is in effect, the first variables in the matrix data file are the split variables, followed by *ROWTYPE_*, the independent variable, *VARNAME_*, and the dependent variables.
- A full set of matrix materials is written for each subgroup defined by the split variable(s).
- A split variable cannot have the same variable name as any other variable written to the matrix data file.
- If a split file is in effect when a matrix is written, the same split file must be in effect when that matrix is read.

Missing Values

- With PAIRWISE treatment of missing values, the matrix of N's used to compute each coefficient is included with the matrix materials.
- With LISTWISE treatment (the default) or MEANSUBSTITUTION, a single N used to calculate all coefficients is included.

Example

```
REGRESSION MATRIX IN('/data/pay_data.sav') OUT(*)
 /VARIABLES=AGE,STARTPAY,YRS_JOB,SALARY
 /DEPENDENT=SALARY
 /METHOD=STEP.
```

- MATRIX IN reads the matrix data file *pay_data.sav*.
- A stepwise regression analysis of *SALARY* is performed using *AGE*, *STARTPAY*, and *YRS_JOB*.
- MATRIX OUT replaces the active dataset with the matrix data file that was previously stored in the *pay_data.sav* file.

MISSING Subcommand

MISSING controls the treatment of cases with missing values. By default, a case that has a user-missing or system-missing value for any variable named or implied on VARIABLES is omitted from the computation of the correlation matrix on which all analyses are based.

- The minimum specification is a keyword specifying a missing-value treatment.

LISTWISE *Delete cases with missing values listwise.* Only cases with valid values for all variables named on the current VARIABLES subcommand are used. If INCLUDE is also specified, only cases with system-missing values are deleted listwise. LISTWISE is the default if the MISSING subcommand is omitted.

PAIRWISE *Delete cases with missing values pairwise*. Each correlation coefficient is computed using cases with complete data for the pair of variables correlated. If INCLUDE is also specified, only cases with system-missing values are deleted pairwise.

MEANSUBSTITUTION *Replace missing values with the variable mean*. All cases are included and the substitutions are treated as valid observations. If INCLUDE is also specified, user-missing values are treated as valid and are included in the computation of the means.

INCLUDE *Includes cases with user-missing values*. All user-missing values are treated as valid values. This keyword can be specified along with the methods LISTWISE, PAIRWISE, or MEANSUBSTITUTION.

Example

```
REGRESSION  VARIABLES=POP15,POP75,INCOME,GROWTH,SAVINGS
 /DEPENDENT=SAVINGS
 /METHOD=STEP
 /MISSING=MEANSUBSTITUTION.
```

- System-missing and user-missing values are replaced with the means of the variables when the correlation matrix is calculated.

RESIDUALS Subcommand

RESIDUALS controls the display and labeling of summary information on outliers as well as the display of the Durbin-Watson statistic and histograms and normal probability plots for the temporary variables.

- If RESIDUALS is specified without keywords, it displays a histogram of residuals, a normal probability plot of residuals, the values of *$CASENUM* and *ZRESID* for the 10 cases with the largest absolute value of *ZRESID*, and the Durbin-Watson test statistic. The histogram and the normal plot are standardized.
- If any keywords are specified on RESIDUALS, only the requested information and plots are displayed.

DEFAULTS *DURBIN, NORMPROB(ZRESID), HISTOGRAM(ZRESID), OUTLIERS(ZRESID).* These are the defaults if RESIDUALS is used without specifications.

HISTOGRAM(tempvars) *Histogram of the temporary variable or variables*. The default is *ZRESID*. You can request histograms for *PRED*, *RESID*, *ZPRED*, *DRESID*, *ADJPRED*, *SRESID*, *SDRESID*, *SEPRED*, *MAHAL*, *COOK*, and *LEVER*. The specification of any other temporary variable will result in an error.

NORMPROB(tempvars) *Normal probability (P-P) plot*. The default is *ZRESID*. The other temporary variables for which normal probability plots are available are *PRED*, *RESID*, *ZPRED*, *DRESID*, *SRESID*, and *SDRESID*. The specification of any other temporary variable will result in an error. Normal probability plots are always displayed in standardized form; therefore, when *PRED*, *RESID*, or *DRESID* is requested, the standardized equivalent *ZPRED*, *ZRESID* or *SDRESID* is displayed.

OUTLIERS(tempvars) *The 10 cases with the largest absolute values of the specified temporary variables.* The default is *ZRESID*. The output includes the values of *$CASENUM* and of the temporary variables for the 10 cases. The other temporary variables available for OUTLIERS are *RESID*, *SRESID*, *SDRESID*, *DRESID*, *MAHAL*, and *COOK*. The specification of any temporary variable other than these will result in an error.

DURBIN *Display Durbin-Watson test statistic in the Model Summary table*.

ID(varname) *ID variable providing case labels for use with point selection mode in the Chart Editor*. Applicable to scatterplots produced by SCATTERPLOT, PARTIALPLOT, and RESIDUALS. Any variable in the active dataset can be named.

SEPARATE *Separate reporting of residuals statistics and plots for selected and unselected cases.* This is the default.

POOLED *Pooled plots and statistics using all cases in the working file when the SELECT subcommand is in effect.* This is an alternative to SEPARATE.

Example

```
/RESID=DEFAULT ID(SVAR)
```

- DEFAULT produces the default residuals statistics: Durbin-Watson statistic, a normal probability plot and histogram of *ZRESID*, and an outlier listing for *ZRESID*.
- Descriptive statistics for *ZRESID, RESID, PRED,* and *ZPRED* are automatically displayed.
- *SVAR* is specified as the case identifier on the outlier output.

CASEWISE Subcommand

CASEWISE requests a Casewise Diagnostics table of residuals. You can specify a temporary residual variable for casewise listing (via the PLOT keyword). You can also specify variables to be listed in the table for each case.

- If CASEWISE is used without any additional specifications, it displays a Casewise Diagnostics table of *ZRESID* for cases whose absolute value of *ZRESID* is at least 3. By default, the values of the case sequence number, *DEPENDENT*, *PRED*, and *RESID* are listed for each case.
- Defaults remain in effect unless specifically altered.

DEFAULTS *OUTLIERS(3), PLOT(ZRESID), DEPENDENT, PRED, and RESID.* These are the defaults if the subcommand is used without specifications.

OUTLIERS(value) *List only cases for which the absolute standardized value of the listed variable is at least as large as the specified value.* The default value is 3. Keyword OUTLIERS is ignored if keyword ALL is also present.

ALL *Include all cases in the Casewise Diagnostic table.* ALL is the alternative to keyword OUTLIERS.

PLOT(tempvar)	*List the values of the temporary variable in the Casewise Diagnostics table*. The default temporary variable is *ZRESID*. Other variables that can be listed are *RESID*, *DRESID*, *SRESID*, and *SDRESID*. The specification of any temporary variable other than these will result in an error. When requested, *RESID* is standardized and *DRESID* is Studentized in the output.
tempvars	*Display the values of these variables next to the casewise list entry for each case.* The default variables are *DEPENDENT* (the dependent variable), *PRED*, and *RESID*. Any of the other temporary variables can be specified. If an `ID` variable is specified on `RESIDUALS`, the `ID` variable is also listed.

Example

```
/CASEWISE=DEFAULT ALL SRE MAH COOK SDR
```

- This example requests a Casewise Diagnostics table of the standardized residuals for all cases.
- *ZRESID*, the dependent variable, and the temporary variables *PRED*, *RESID*, *SRESID*, *MAHAL*, *COOK*, and *SDRESID* are for all cases.

SCATTERPLOT Subcommand

`SCATTERPLOT` names pairs of variables for scatterplots.

- The minimum specification for `SCATTERPLOT` is a pair of variables in parentheses. There are no default specifications.
- You can specify as many pairs of variables in parentheses as you want.
- The first variable named in each set of parentheses is plotted along the vertical axis, and the second variable is plotted along the horizontal axis.
- Plotting symbols are used to represent multiple points occurring at the same position.
- You can specify any variable named on the `VARIABLES` subcommand.
- You can specify *PRED*, *RESID*, *ZPRED*, *ZRESID*, *DRESID*, *ADJPRED, SRESID*, *SDRESID*, *SEPRED*, *MAHAL*, *COOK*, and *LEVER*. The specification of any other temporary variables will result in an error.
- Specify an asterisk before temporary variable names to distinguish them from user-defined variables. For example, use **PRED* to specify *PRED*.

Example

```
/SCATTERPLOT (*RES,*PRE)(*RES,SAVINGS)
```

- This example specifies two scatterplots: residuals against predicted values and residuals against the values of the variable *SAVINGS*.

PARTIALPLOT Subcommand

PARTIALPLOT requests partial regression plots. Partial regression plots are scatterplots of the residuals of the dependent variable and an independent variable when both of these variables are regressed on the rest of the independent variables.

- If PARTIALPLOT is included without any additional specifications, it produces a partial regression plot for every independent variable in the equation. The plots appear in the order the variables are specified or implied on the VARIABLES subcommand.
- If variables are specified on PARTIALPLOT, only the requested plots are displayed. The plots appear in the order the variables are listed on the PARTIALPLOT subcommand.
- At least two independent variables must be in the equation for partial regression plots to be produced.

ALL	*Plot all independent variables in the equation.* This is the default.
varlist	*Plot the specified variables.* Any variable entered into the equation can be specified.

Example

```
REGRESSION VARS=PLOT15 TO SAVINGS
  /DEP=SAVINGS
  /METH=ENTER
  /RESID=DEFAULTS
  /PARTIAL.
```

- A partial regression plot is produced for every independent variable in the equation.

OUTFILE Subcommand

OUTFILE saves in an SPSS-format data file the parameter covariance or correlation matrix with parameter estimates, standard errors, significance values, and residual degrees of freedom for each term in the final equation. It also saves model information in XML format.

- The OUTFILE subcommand must follow the last METHOD subcommand.
- Only one OUTFILE subcommand is allowed. If you specify more than one, only the last one is executed.
- You must specify at least one keyword and a quoted file specification , enclosed in parentheses. For COVB and CORB, you can specify a previously declared dataset (DATASET DECLARE command) instead of a file.
- You cannot save the parameter statistics as the active dataset.
- COVB and CORB are mutually exclusive.
- MODEL cannot be used if split file processing is on (SPLIT FILE command) or if more than one dependent (DEPENDENT subcommand) variable is specified.

- If you specify an external file name, you should include the .sav extension in the specification. There is no default extension.

COVB ('savfile'|'dataset') *Write the parameter covariance matrix with other statistics.*

CORB ('savfile'|'dataset') *Write the parameter correlation matrix with other statistics.*

MODEL ('file') *Write model information to an XML file.* SmartScore and SPSS Server (a separate product) can use this model file to apply the model information to other data files for scoring purposes.

PARAMETER('file') *Write parameter estimates only to an XML file.* SmartScore and SPSS Server (a separate product) can use this model file to apply the model information to other data files for scoring purposes.

Example

```
REGRESSION DEPENDENT=Y
 /METHOD=ENTER X1 X2
 /OUTFILE CORB ('/data/covx1x2y.sav').
```

- The OUTFILE subcommand saves the parameter correlation matrix, and the parameter estimates, standard errors, significance values, and residual degrees of freedom for the constant term, *X1* and *X2*.

SAVE Subcommand

Use SAVE to add one or more residual or fit variables to the active dataset.

- The specification on SAVE is one or more of the temporary variable types, each followed by an optional name in parentheses for the new variable.
- New variable names must be unique.
- If new names are not specified, REGRESSION generates a rootname using a shortened form of the temporary variable name with a suffix to identify its creation sequence.
- If you specify DFBETA or SDBETA on the SAVE subcommand, the number of new variables saved is the total number of variables in the equation.

FITS *Save all influence statistics.* FITS saves *DFFIT, SDFIT, DFBETA, SDBETA,* and *COVRATIO*. You cannot specify new variable names when using this keyword. Default names are generated.

Example

```
 /SAVE=PRED(PREDVAL) RESID(RESIDUAL) COOK(CDISTANC)
```

- This subcommand adds three variables to the end of the active dataset: *PREDVAL*, containing the unstandardized predicted value for each case; *RESIDUAL*, containing the unstandardized residual; and *CDISTANC*, containing Cook's distance.

Example

```
/SAVE=PRED RESID
```

- This subcommand adds two variables named *PRE_1* and *RES_1* to the end of the active dataset.

Example

```
REGRESSION DEPENDENT=Y
 /METHOD=ENTER X1 X2
 /SAVE DFBETA(DFBVAR).
```

- The SAVE subcommand creates and saves three new variables with the names *DFBVAR0*, *DFBVAR1*, and *DFBVAR2*.

Example

```
REGRESSION VARIABLES=SAVINGS INCOME POP15 POP75 GROWTH
 /DEPENDENT=SAVINGS
 /METHOD=ENTER INCOME POP15 POP75
 /SAVE=PRED(PREDV) SDBETA(BETA) ICIN.
```

- The SAVE subcommand adds seven variables to the end of the file: *PREDV*, containing the unstandardized predicted value for the case; *BETA0*, the standardized *DFBETA* for the intercept; *BETA1*, *BETA2*, and *BETA3*, the standardized *DFBETA*'s for the three independent variables in the model; *LICI_1*, the lower bound for the prediction interval for an individual case; and *UICI_1*, the upper bound for the prediction interval for an individual case.

               {'savfile'|'dataset'}        {'savfile'|'dataset'}
```

**Default if the subcommand or keyword is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
RELIABILITY  VARIABLES=SCORE1 TO SCORE10
  /SCALE (OVERALL) = ALL
  /MODEL = ALPHA
  /SUMMARY = MEANS TOTAL.
```

Overview

RELIABILITY estimates reliability statistics for the components of multiple-item additive scales. It uses any one of five models for reliability analysis and offers a variety of statistical displays. RELIABILITY can also be used to perform a repeated measures analysis of variance, a two-way factorial analysis of variance with one observation per cell, Tukey's test for additivity, Hotelling's *T*-square test for equality of means in repeated measures designs, and Friedman's two-way analysis of variance on ranks. For more complex repeated measures designs, use the GLM procedure (available in the Advanced Models option).

Options

Model Type. You can specify any one of five models on the MODEL subcommand.

Statistical Display. Statistics available on the STATISTICS subcommand include descriptive statistics, correlation and covariance matrices, a repeated measures analysis of variance table, Hotelling's *T*-square, Tukey's test for additivity, Friedman's chi-square for the analysis of ranked data, and Cochran's *Q*.

Computational Method. You can force RELIABILITY to use the covariance method, even when you are not requesting any output that requires it, by using the METHOD subcommand.

Matrix Input and Output. You can read data in the form of correlation matrices and you can write correlation-type matrix materials to a data file using the MATRIX subcommand.

Basic Specification

The basic specification is VARIABLES and a variable list. By default, RELIABILITY displays the number of cases, number of items, and Cronbach's alpha. Whenever possible, it uses an algorithm that does not require the calculation of the covariance matrix.

Subcommand Order

- VARIABLES must be specified first.
- The remaining subcommands can be named in any order.

Operations

- STATISTICS and SUMMARY are cumulative. If you enter them more than once, all requested statistics are produced for each scale.
- If you request output that is not available for your model or for your data, RELIABILITY ignores the request.
- RELIABILITY uses an economical algorithm whenever possible but calculates a covariance matrix when necessary (see METHOD Subcommand on p. 1597).

Limitations

- Maximum 1 VARIABLES subcommand.
- Maximum 1 SCALE subcommand.
- Maximum 500 variables on the VARIABLES subcommand.
- Maximum 500 variables on the SCALE subcommand.

Example

```
RELIABILITY  VARIABLES=SCORE1 TO SCORE10.
```

- This example analyzes a scale (labeled *ALL* in the display output) that includes all 10 items.
- Because there is no SUMMARY subcommand, no summary statistics are displayed.

VARIABLES Subcommand

VARIABLES specifies the variables to be used in the analysis. Only numeric variables can be used.

- VARIABLES is required and must be specified first.
- You can use keyword ALL to refer to all user-defined variables in the active dataset.

SCALE Subcommand

SCALE defines a scale for analysis, providing a label for the scale and specifying its component variables. If SCALE is omitted, all variables named on VARIABLES are used, and the label for the scale is *ALL*.

- The label is specified in parentheses after SCALE. It can have a maximum of 255 bytes before being truncated.
- RELIABILITY does not add any new variables to the active dataset. The label is used only to identify the output. If the analysis is satisfactory, use COMPUTE to create a new variable containing the sum of the component items.
- Variables named on SCALE must have been named on the VARIABLES subcommand. Use the keyword ALL to refer to all variables named on the VARIABLES subcommand.

Example

```
RELIABILITY VARIABLES = ITEM1 TO ITEM20
  /SCALE (A) = ITEM1 TO ITEM10.

RELIABILITY VARIABLES = ITEM1 TO ITEM20
  /SCALE (B) = ITEM1 TO ITEM20.
```

- Analyses for scales A and B both use only cases that have complete data for items 1 through 20.

MODEL Subcommand

MODEL specifies the type of reliability analysis for the scale named on the SCALE subcommand.

ALPHA	*Cronbach's* α. Standardized item α is displayed. This is the default.
SPLIT [(n)]	*Split-half coefficients.* You can specify a number in parentheses to indicate how many items should be in the second half. For example, MODEL SPLIT (6) uses the last six variables for the second half and all others for the first. By default, each half has an equal number of items, with the odd item, if any, going to the first half.
GUTTMAN	*Guttman's lower bounds for true reliability.*
PARALLEL	*Maximum-likelihood reliability estimate under parallel assumptions.* This model assumes that items have the same variance but not necessarily the same mean.
STRICTPARALLEL	*Maximum-likelihood reliability estimate under strictly parallel assumptions.* This model assumes that items have the same means, the same true score variances over a set of objects being measured, and the same error variance over replications.

STATISTICS Subcommand

STATISTICS displays optional statistics. There are no default statistics.

- STATISTICS is cumulative. If you enter it more than once, all requested statistics are produced for each scale.

DESCRIPTIVES	*Item means and standard deviations.*
COVARIANCES	*Inter-item variance-covariance matrix.*
CORRELATIONS	*Inter-item correlation matrix.*
SCALE	*Scale means and scale variances.*
TUKEY	*Tukey's test for additivity.* This helps determine whether a transformation of the items is needed to reduce nonadditivity. The test displays an estimate of the power to which the items should be raised in order to be additive.
HOTELLING	*Hotelling's* T-*square.* This is a test for equality of means among the items.
ANOVA	*Repeated measures analysis of variance table.*
FRIEDMAN	*Friedman's chi-square and Kendall's coefficient of concordance.* These apply to ranked data. You must request ANOVA in addition to FRIEDMAN; Friedman's chi-square appears in place of the usual *F* test. If the ANOVA keyword is not specified, the FRIEDMAN keyword is silently ignored.
COCHRAN	*Cochran's* Q. This applies when all items are dichotomies. You must request ANOVA in addition to COCHRAN; the *Q* statistic appears in place of the usual *F* test. If the ANOVA keyword is not specified, the COCHRAN keyword is silently ignored.
ALL	*All applicable statistics.*

ICC Subcommand

ICC displays intraclass correlation coefficients for single measure and average measure. Single measure applies to single measurements—for example, the rating of judges, individual item scores, or the body weights of individuals. Average measure, however, applies to average measurements, for example, the average rating of *k* judges, or the average score for a *k*-item test.

MODEL	*Model.* You can specify the model for the computation of ICC. There are three keywords for this option. ONEWAY is the one-way random effects model (people effects are random). RANDOM is the two-way random effect model (people effects and the item effects are random). MIXED is the two-way mixed (people effects are random and the item effects are fixed). MIXED is the default. Only one model can be specified.
TYPE	*Type of definition.* When the model is RANDOM or MIXED, one of the two TYPE keywords may be given. CONSISTENCY is the consistency definition and ABSOLUTE is the absolute agreement definition. For the consistency coefficient, the between measures variance is excluded from the denominator variance, and for absolute agreement, it is not.
CIN	*The value of the percent for confidence interval and significance level of the hypothesis testing.*
TESTVAL	*The value with which an estimate of ICC is compared.* The value should be between 0 and 1.

SUMMARY Subcommand

SUMMARY displays summary statistics for each individual item in the scale.

- SUMMARY is cumulative. If you enter it more than once, all requested statistics are produced for the scale.
- You can specify one or more of the following:

MEANS	*Statistics on item means.* The average, minimum, maximum, range, ratio of maximum to minimum, and variance of the item means.
VARIANCE	*Statistics on item variances.* This displays the same statistics as for MEANS.
COVARIANCES	*Statistics on item covariances.* This displays the same statistics as for MEANS.
CORRELATIONS	*Statistics on item correlations.* This displays the same statistics as for MEANS.
TOTAL	*Statistics comparing each individual item to the scale composed of the other items.* The output includes the scale mean, variance, and Cronbach's α without the item, and the correlation between the item and the scale without it.
ALL	*All applicable summary statistics.*

METHOD Subcommand

By default, RELIABILITY uses a computational method that does not require the calculation of a covariance matrix wherever possible. METHOD forces RELIABILITY to calculate the covariance matrix. Only a single specification applies to METHOD:

COVARIANCE	*Calculate and use the covariance matrix, even if it is not needed.*

If METHOD is not specified, RELIABILITY computes the covariance matrix for all variables on each VARIABLES subcommand only if any of the following is true:

- You specify a model other than ALPHA or SPLIT.
- You request COV, CORR, FRIEDMAN, or HOTELLING on the STATISTICS subcommand.
- You request anything other than TOTAL on the SUMMARY subcommand.
- You write the matrix to a matrix data file, using the MATRIX subcommand.

MISSING Subcommand

MISSING controls the deletion of cases with user-missing data.

- RELIABILITY deletes cases from analysis if they have a missing value for any variable named on the VARIABLES subcommand. By default, both system-missing and user-missing values are excluded.

EXCLUDE	*Exclude user-missing and system-missing values.* This is the default.
INCLUDE	*Treat user-missing values as valid.* Only system-missing values are excluded.

MATRIX Subcommand

MATRIX reads and writes SPSS-format matrix data files.

- Either IN or OUT and the matrix file in parentheses are required. When both IN and OUT are used on the same RELIABILITY procedure, they can be specified on separate MATRIX subcommands or on the same subcommand.
- If both IN and OUT are used on the same RELIABILITY command and there are grouping variables in the matrix input file, these variables are treated as if they were split variables. Values of the grouping variables in the input matrix are passed on to the output matrix (see Split Files on p. 1599).

OUT ('savfile'|'dataset') *Write a matrix data file or dataset.* Specify either a filename, a previously declared dataset name, or an asterisk, enclosed in parentheses. Filenames should be enclosed in quotes and are stored in the working directory unless a path is included as part of the file specification. If you specify an asterisk (*), the matrix data file replaces the active dataset. If you specify an asterisk or a dataset name, the file is not stored on disk unless you use SAVE or XSAVE.

IN ('savfile'|'dataset') *Read a matrix data file or dataset.* Specify either a filename, dataset name created during the current session, or an asterisk enclosed in parentheses. An asterisk reads the matrix data from the active dataset. Filenames should be enclosed in quotes and are read from the working directory unless a path is included as part of the file specification.

Matrix Output

- RELIABILITY writes correlation-type matrices that include the number of cases, means, and standard deviations with the matrix materials (see Format of the Matrix Data File below for a description of the file). These matrix materials can be used as input to RELIABILITY or other procedures.
- Any documents contained in the active dataset are not transferred to the matrix file.
- RELIABILITY displays the scale analysis when it writes matrix materials. To suppress the display of scale analysis, specify keyword NOPRINT on MATRIX.

Matrix Input

- RELIABILITY can read a matrix data file created by a previous RELIABILITY command or by another procedure. The matrix input file must have records of type N, MEAN, STDDEV, and CORR for each split-file group. For more information, see the Universals section.
- Variable names, variable and value labels, and print and write formats are read from the dictionary of the matrix data file.
- MATRIX=IN cannot be used unless an active dataset has already been defined. To read an existing matrix data file at the beginning of a session, use GET to retrieve the matrix file and then specify IN(*) on MATRIX.

Format of the Matrix Data File

- The matrix data file includes two special variables: *ROWTYPE_* and *VARNAME_*. Variable *ROWTYPE_* is a short string variable having values N, MEAN, STDDEV, and CORR. Variable *VARNAME_* is a short string variable whose values are the names of the variables used to form the correlation matrix.
- When *ROWTYPE_* is CORR, *VARNAME_* gives the variable associated with that row of the correlation matrix.
- The remaining variables in the matrix file are the variables used to form the correlation matrix.

Split Files

- When split-file processing is in effect, the first variables in the matrix data file will be the split variables, followed by *ROWTYPE_*, *VARNAME_*, and the dependent variable(s).
- If grouping variables are in the matrix input file, their values are between *ROWTYPE_* and *VARNAME_*. The grouping variables are treated like split-file variables.
- A full set of matrix materials is written for each split-file group defined by the split variables.
- A split variable cannot have the same variable name as any other variable written to the matrix data file.
- If split-file processing is in effect when a matrix is written, the same split file must be in effect when that matrix is read by any procedure.

Missing Values

Missing-value treatment affects the values written to a matrix data file. When reading a matrix data file, be sure to specify a missing-value treatment on `RELIABILITY` that is compatible with the treatment that was in effect when the matrix materials were generated.

Example: Matrix Output to External File

```
DATA LIST / TIME1 TO TIME5 1-10.
BEGIN DATA
 0 0 0 0 0
 0 0 1 1 0
 0 0 1 1 1
 0 1 1 1 1
 0 0 0 0 1
 0 1 0 1 1
 0 0 1 1 1
 1 0 0 1 1
 1 1 1 1 1
 1 1 1 1 1
END DATA.
RELIABILITY  VARIABLES=TIME1 TO TIME5
  /MATRIX=OUT('/data/relmtx.sav').
LIST.
```

- `RELIABILITY` reads data from the active dataset and writes one set of matrix materials to file *relmtx.sav*.

- The active dataset is still the file defined by DATA LIST. Subsequent commands are executed in this file.

Example: Matrix Output to Active Dataset

```
DATA LIST  / TIME1 TO TIME5 1-10.
BEGIN DATA
 0 0 0 0 0
 0 0 1 1 0
 0 0 1 1 1
 0 1 1 1 1
 0 0 0 0 1
 0 1 0 1 1
 0 0 1 1 1
 1 0 0 1 1
 1 1 1 1 1
 1 1 1 1 1
END DATA.
RELIABILITY  VARIABLES=TIME1 TO TIME5
  /MATRIX=OUT(*) NOPRINT.
LIST.
```

- RELIABILITY writes the same matrix as in the previous example. However, the matrix data file replaces the active dataset. The LIST command is executed in the matrix file, not in the file defined by DATA LIST.
- Because NOPRINT is specified on MATRIX, scale analyses are not displayed.

Example: Matrix Output to Active Dataset

```
GET FILE='/data/relmtx.sav'.
RELIABILITY VARIABLES=ALL
  /MATRIX=IN(*).
```

- This example assumes that you are starting a new session and want to read an existing matrix data file. GET retrieves the matrix data file *relmtx.sav*.
- MATRIX=IN specifies an asterisk because the matrix data file is the active dataset. If MATRIX=IN('/data/relmtx.sav') is specified, an error message is issued.
- If the GET command is omitted, an error message is issued.

Example: Matrix Input from External File

```
GET FILE='/data/personnel.sav'.
FREQUENCIES VARIABLE=AGE.

RELIABILITY VARIABLES=ALL
  /MATRIX=IN('/data/relmtx.sav').
```

- This example performs a frequencies analysis on file *personnel.sav* and then uses a different file containing matrix data for RELIABILITY. The file is an existing matrix data file. In order for this to work, the analysis variables named in *relmtx.sav* must also exist in *personnel.sav*.
- *relmtx.sav* must have records of type N, MEAN, STDDEV, and CORR for each split-file group.
- *relmtx.sav* does not replace *personnel.sav* as the active dataset.

Example: Matrix Input from Working File

```
GET FILE='/data/personnel.sav'.
CORRELATIONS VARIABLES=V1 TO V5
  /MATRIX=OUT(*).
RELIABILITY VARIABLES=V1 TO V5
  /MATRIX=IN(*).
```

- RELIABILITY uses matrix input from procedure CORRELATIONS. An asterisk is used to specify the active dataset for both the matrix output from CORRELATIONS and the matrix input for RELIABILITY.

RENAME VARIABLES

```
RENAME VARIABLES {(varname=varname)  [(varname ...)]}
                 {(varnames=varnames)               }
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Example

```
RENAME VARIABLES (JOBCAT=TITLE).
```

Overview

RENAME VARIABLES changes the names of variables in the active dataset while preserving their original order, values, variable labels, value labels, missing values, and print and write formats.

Basic Specification

- The basic specification is an old variable name, an equals sign, and the new variable name. The equals sign is required.

Syntax Rules

- Multiple sets of variable specifications are allowed. Each set can be enclosed in parentheses.
- You can specify a list of old variable names followed by an equals sign and a list of new variable names. The same number of variables must be specified on both lists. A single set of parentheses enclosing the entire specification is required for this method.
- Keyword TO can be used on the left side of the equals sign to refer to variables in the active dataset, and on the right side of the equals sign to generate new variable names.
- Old variable names do not need to be specified according to their order in the active dataset.
- Name changes take place in one operation. Therefore, variable names can be exchanged between two variables (see the Examples on p. 1602).
- Multiple RENAME VARIABLES commands are allowed.
- RENAME VARIABLES cannot follow either a TEMPORARY or a MODEL PROGRAM command.

Examples

Renaming Multiple Variables

```
RENAME VARIABLES (MOHIRED=MOSTART) (YRHIRED=YRSTART).
```

- MOHIRED is renamed to MOSTART and YRHIRED to YRSTART. The parentheses are optional.

```
RENAME VARIABLES (MOHIRED YRHIRED=MOSTART YRSTART).
```

- The same name changes are specified as in the previous example. The parentheses are required, since variable lists are used.

Exchanging Variable Names

```
RENAME VARIABLES (A=B) (B=A).
```

- Variable names are exchanged between two variables: `A` is renamed to `B`, and `B` is renamed to `A`.

Mixed Case Variable Names

You can use the `RENAME VARIABLES` command to change the case of any characters in a variable name.

Example

```
RENAME VARIABLES (newvariable = NewVariable).
```

- For the existing variable name specification, case is ignored. Any combination of upper and lower case will work.
- For the new variable name, case will be preserved as entered for display purposes.

REPEATING DATA

```
REPEATING DATA [FILE=file]

 [/ENCODING='encoding specification']

 /STARTS=beg col[-end col] /OCCURS={value  }
                                   {varname}

 [/LENGTH={value  }] [/CONTINUED[=beg col[-end col]]]
          {varname}

 [/ID={col loc}=varname] [/{TABLE  }]
      {format }           {NOTABLE}

 /DATA=variable specifications
```

Release History

Release 16.0

- ENCODING subcommand added for Unicode support.

Example

```
INPUT PROGRAM.
DATA LIST / SEQNUM 2-4 NUMPERS 6-7 NUMVEH 9-10.
REPEATING DATA STARTS=12 /OCCURS=NUMVEH
 /DATA=MAKE 1-8 (A) MODEL 9 (A) NUMCYL 10.
END INPUT PROGRAM.
```

Overview

REPEATING DATA reads input cases whose records contain repeating groups of data. For each repeating group, REPEATING DATA builds one output case in the active dataset. All of the repeating groups in the data must contain the same type of information, although the number of groups for each input case may vary. Information common to the repeating groups for each input case can be recorded once for that case and then spread to each resulting output case. In this respect, a file with a repeating data structure is like a hierarchical file with both levels of information recorded on a single record rather than on separate record types. For information on reading hierarchical files, see FILE TYPE–END FILE TYPE.

REPEATING DATA must be used within an INPUT PROGRAM structure or within a FILE TYPE structure with mixed or nested data. In an INPUT PROGRAM structure, REPEATING DATA must be preceded by a DATA LIST command. In a FILE TYPE structure, DATA LIST is needed only if there are variables to be spread to each resulting output case.

Options

Length of Repeating Groups. If the length of the repeating groups varies across input cases, you can specify a variable that indicates the length on the LENGTH subcommand. You can also use LENGTH if you do not want to read all the data in each repeating group.

Continuation Records. You can use the CONTINUED subcommand to indicate that the repeating groups for each input case are contained on more than one record. You can check the value of an identification variable across records for the same input case using the ID subcommand.

Summary Tables. You can suppress the display of the table that summarizes the names, locations, and formats of the variables specified on the DATA subcommand using the NOTABLE subcommand.

Basic Specification

The basic specification requires three subcommands: STARTS, OCCURS, and DATA.

- STARTS specifies the beginning column of the repeating data segments. When there are continuation records, STARTS can specify the ending column of the last repeating group on the first record of each input case.
- OCCURS specifies the number of repeating groups on each input case. OCCURS can specify a number if the number of repeating groups is the same for all input cases. Otherwise, OCCURS should specify the name of a variable whose value for each input case indicates the number of repeating groups for that case.
- DATA specifies names, location within the repeating segment, and format for each variable to be read from the repeated groups.

Subcommand Order

- DATA must be the last subcommand specified on REPEATING DATA.
- The remaining subcommands can be named in any order.

Syntax Rules

- REPEATING DATA can be specified only within an INPUT PROGRAM structure, or within a FILE TYPE structure with mixed or nested data. DATA LIST, REPEATING DATA, and any transformation commands used to build the output cases must be placed within the INPUT PROGRAM or FILE TYPE structure. Transformations that apply to the output cases should be specified after the END INPUT PROGRAM or END FILE TYPE command.
- LENGTH must be used if the last variable specified on the DATA subcommand is not read from the last position of each repeating group or if the length of the repeating groups varies across input cases.
- CONTINUED must be used if repeating groups for each input case are continued on successive records.
- The DATA LIST command used with REPEATING DATA must define all fixed-format data for the records.
- Repeating groups are usually recorded at the end of the fixed-format records, but fixed-format data may follow the repeating data in data structures such as IBM SMF and RMF records. Use the following sequence in such cases.

```
DATA LIST .../* Read the fixed-format data before repeating data
REREAD COLUMNS= .../* Skip repeating data
DATA LIST .../* Read the fixed-format data after repeating data
REPEATING DATA ... /*Read repeating data
```

Operations

- Fixed-location data specified on the DATA LIST are spread to each output case.
- If LENGTH is not specified, the program uses the default length for repeating data groups, which is determined from specifications on the DATA subcommand. For more information on the default length, see the LENGTH subcommand.

Cases Generated

- The number of output cases generated is the number specified on the OCCURS subcommand. Physical record length or whether fields are non-blank does not affect the number of cases generated.
- If the number specified for OCCURS is nonpositive or missing, no cases are generated.

Records Read

- If CONTINUED is not specified, all repeating groups are read from the first record of each input case.
- If CONTINUED is specified, the first continuation record is read when the first record for the input case is exhausted, that is, when the next repeating group would extend past the end of the record. The ending column for the first record is defined on STARTS. If the ending column is not specified on STARTS, the logical record length is used.
- Subsequent continuation records are read when the current continuation record is exhausted. Exhaustion of the current continuation record is detected when the next repeating group would extend past the end of the record. The ending column for continuation records is defined on CONTINUED. If the ending column is not specified on CONTINUED, the logical record length is used.
- For inline data, the record length is always 80. For data stored in a file, the record length is generally whatever was specified on the FILE HANDLE command or the default of 1024. Shorter records are extended with blanks when they are read. For IBM implementations, the physical record length is available and is used.

Reading Past End of Record

If one or more fields extend past the end of the actual record, or if CONTINUED is specified and the ending column specified on either STARTS or CONTINUED is beyond the end of the actual record, the program takes the following action:

- For string data with format A, the data record is considered to be extended logically with blanks. If the entire field lies past the end of the record, the resulting value will be all blanks.
- For numeric data, a warning is issued and the resulting value is system-missing.

Examples

Basic Example

```
* Build a file with each case representing one vehicle and
```

```
  spread information about the household to each case.

INPUT PROGRAM.
DATA LIST / SEQNUM 2-4 NUMPERS 6-7 NUMVEH 9-10.
REPEATING DATA STARTS=12 /OCCURS=NUMVEH
 /DATA=MAKE 1-8 (A) MODEL 9 (A) NUMCYL 10.
END INPUT PROGRAM.

BEGIN DATA
1001 02 02 FORD    T8PONTIAC C6
1002 04 01 CHEVY   C4
1003 02 03 CADILAC C8FORD    T6VW      C4
END DATA.
LIST.
```

- Data are extracted from a file representing household records. Each input case is recorded on a single record; there are no continuation records.
- The total number of persons living in the house and number of vehicles owned by the household is recorded on each record. The first field of numbers (columns 1–4) for each record is an identification number unique to each record. The next two fields of numbers are number of persons in household and number of vehicles. The remainder of the record contains repeating groups of information about each vehicle: the make of vehicle, model, and number of cylinders.
- `INPUT PROGRAM` indicates the beginning of the input program and `END INPUT PROGRAM` indicates the end of the input program.
- `DATA LIST` reads the variables from the household portion of the record. All fixed-format variables are defined on `DATA LIST`.
- `REPEATING DATA` reads the information from the repeating groups and builds the output cases. Repeating groups start in column 12. The number of repeating groups for each input case is given by the value of variable *NUMVEH*. Three variables are defined for each repeating group: *MAKE*, *MODEL*, and *NUMCYL*.
- The first input record contains two repeating groups, producing two output cases in the active dataset. One output case is built from the second input record which contains information on one vehicle, and three output cases are built from the third record. The values of the fixed-format variables defined on `DATA LIST` are spread to every new case built in the active dataset. Six cases result, as shown below.

```
SEQNUM NUMPERS NUMVEH MAKE     MODEL NUMCYL

    1      2      2   FORD     T         8
    1      2      2   PONTIAC  C         6
    2      4      1   CHEVY    C         4
    3      2      3   CADILAC  C         8
    3      2      3   FORD     T         6
    3      2      3   VW       C         4

 NUMBER OF CASES READ =       6    NUMBER OF CASES LISTED =       6
```

Using REPEATING DATA With Mixed File Types

```
* Use REPEATING DATA with FILE TYPE MIXED: read only type 3 records.

FILE TYPE  MIXED RECORD=#SEQNUM 2-4.
RECORD TYPE 003.
REPEATING DATA STARTS=12 /OCCURS=3
 /DATA=MAKE 1-8(A) MODEL 9(A) NUMCYL 10.
```

```
END FILE.
END FILE TYPE.

BEGIN DATA
1001 02 02 FORD    T8PONTIAC C6
1002 04 01 CHEVY   C4
1003 02 03 CADILAC C8FORD    T6VW      C4
END DATA.
LIST.
```

- The task in this example is to read only the repeating data for records with value 003 for variable *#SEQNUM*.
- REPEATING DATA is used within a FILE TYPE structure, which specifies a mixed file type. The record identification variable *#SEQNUM* is located in columns 2–4.
- RECORD TYPE specifies that only records with value 003 for *#SEQNUM* are copied into the active dataset. All other records are skipped.
- REPEATING DATA indicates that the repeating groups start in column 12. The OCCURS subcommand indicates there are three repeating groups on each input case, and the DATA subcommand specifies names, locations, and formats for the variables in the repeating groups.
- The DATA LIST command is not required in this example, since none of the information on the input case is being spread to the output cases. However, if there were multiple input cases with value 003 for *#SEQNUM* and they did not all have three repeating groups, DATA LIST would be required to define a variable whose value for each input case indicated the number of repeating groups for that case. This variable would then be specified on the OCCURS subcommand.

Using Transformations With REPEATING DATA

```
INPUT PROGRAM.
DATA LIST / PARENTID 1 DATE 3-6 NCHILD 8.
REPEATING DATA STARTS=9 /OCCURS=NCHILD
 /DATA=BIRTHDAY 2-5 VACDATE 7-10.
END INPUT PROGRAM.

COMPUTE AGE=DATE - BIRTHDAY.
COMPUTE VACAGE=VACDATE - BIRTHDAY.

DO IF PARENTID NE LAG(PARENTID,1) OR $CASENUM EQ 1.
COMPUTE CHILD=1.
ELSE.
COMPUTE CHILD=LAG(CHILD,1)+1.
END IF.
FORMAT AGE VACAGE CHILD (F2).

BEGIN DATA
1 1987 2 1981 1983 1982 1984
2 1988 1 1979 1984
3 1988 3 1978 1981 1981 1986 1983 1986
4 1988 1 1984 1987
END DATA.
LIST.
```

- Data are from a file that contains information on parents within a school district. Each input case is recorded on a single record; there are no continuation records.
- Each record identifies the parents by a number and indicates how many children they have. The repeating groups give the year of birth and year of vaccination for each child.

- REPEATING DATA indicates that the repeating groups begin in column 9. The value of *NCHILD* indicates how many repeating groups there are for each record.
- The first two COMPUTE commands compute the age for each child and age at vaccination. These transformation commands are specified outside the input program.
- Because the repeating groups do not have descriptive values, the DO IF structure computes variable *CHILD* to distinguish between the first-born child, second-born child, and so forth. The value for *CHILD* will be 1 for the first-born, 2 for the second-born, and so forth. The LIST output is shown below.

```
PARENTID DATE NCHILD BIRTHDAY VACDATE AGE VACAGE CHILD

    1    1987    2     1981     1983    6    2      1
    1    1987    2     1982     1984    5    2      2
    2    1988    1     1979     1984    9    5      1
    3    1988    3     1978     1981   10    3      1
    3    1988    3     1981     1986    7    5      2
    3    1988    3     1983     1986    5    3      3
    4    1988    1     1984     1987    4    3      1

NUMBER OF CASES READ =       7    NUMBER OF CASES LISTED =       7
```

STARTS Subcommand

STARTS indicates the beginning location of the repeating data segment on the first record of each input case. STARTS is required and can specify either a number or a variable name.

- If the repeating groups on the first record of each input case begin in the same column, STARTS specifies a column number.
- If the repeating groups on the first record of each input case do not begin in the same column, STARTS specifies the name of a variable whose value for each input case indicates the beginning location of the repeating groups on the first record. The variable can be defined on DATA LIST or created by transformation commands that precede REPEATING DATA.
- When repeating groups are continued on multiple records for each input case, STARTS must also specify an ending location if there is room on the logical record length for more repeating groups than are contained on the first record of each input case. The ending column applies only to the first record of each input case. See the CONTINUED subcommand for an example.
- The ending column can be specified as a number or a variable name. Specifications for the beginning column and the ending column are separated by a hyphen. The values of the variable used to define the ending column must be valid values and must be larger than the starting value.
- If the variable specified for the ending column is undefined or missing for an input case, the program displays a warning message and builds no output cases from that input case. If the variable specified for the ending column on STARTS has a value that is less than the value specified for the starting column, the program issues a warning and builds output cases only from the continuation records of that input case; it does not build cases from the first record of the case.
- If the ending location is required but not supplied, the program generates output cases with system-missing values for the variables specified on the DATA subcommand and may misread all data after the first or second record in the data file (see the CONTINUED subcommand).

Repeating Groups in the Same Location

```
INPUT PROGRAM.
DATA LIST FILE=VEHICLE / SEQNUM 2-4 NUMPERS 6-7 NUMVEH 9-10.
REPEATING DATA STARTS=12 /OCCURS=NUMVEH
 /DATA=MAKE 1-8 (A) MODEL 9 (A) NUMCYL 10.
END INPUT PROGRAM.
```

- STARTS specifies column number 12. The repeating groups must therefore start in column 12 of the first record of each input case.

Repeating Groups in Varying Locations

```
INPUT PROGRAM.
DATA LIST FILE=VEHICLE / SEQNUM 2-4 NUMPERS 6-7 NUMVEH 9-10.
+    DO IF   (SEQNUM LE 100).
+    COMPUTE FIRST=12.
+    ELSE.
+    COMPUTE FIRST=15.
+    END IF.
REPEATING DATA STARTS=FIRST /OCCURS=NUMVEH
 /DATA=MAKE 1-8 (A) MODEL 9 (A) NUMCYL 10.
END INPUT PROGRAM.
```

- This example assumes that each input case is recorded on a single record and that there are no continuation records. Repeating groups begin in column 12 for all records with sequence numbers 1 through 100 and in column 15 for all records with sequence numbers greater than 100.
- The sequence number for each record is defined as variable *SEQNUM* on the DATA LIST command. The DO IF–END IF structure creates the variable *FIRST* with value 12 for records with sequence numbers through 100 and value 15 for records with sequence numbers greater than 100.
- Variable *FIRST* is specified on the STARTS subcommand.

OCCURS Subcommand

OCCURS specifies the number of repeating groups for each input case. OCCURS is required and specifies a number if the number of groups is the same for all input cases or a variable if the number of groups varies across input cases. The variable must be defined on a DATA LIST command or created with transformation commands.

Specifying the Number of Repeating Groups Using a Data Field

```
INPUT PROGRAM.
DATA LIST / SEQNUM 2-4 NUMPERS 6-7 NUMVEH 9-10.
REPEATING DATA STARTS=12 /OCCURS=NUMVEH
 /DATA=MAKE 1-8 (A) MODEL 9 (A) NUMCYL 10.
END INPUT PROGRAM.

BEGIN DATA
1001 02 02 FORD    T8PONTIAC C6
1002 04 01 CHEVY   C4
1003 02 03 CADILAC C8FORD    T6VW      C4
END DATA.
LIST.
```

- Data for each input case are recorded on a single record; there are no continuation records.
- The value for variable *NUMVEH* in columns 9 and 10 indicates the number of repeating groups on each record. One output case is built in the active dataset for each occurrence of a repeating group.
- In the data, *NUMVEH* has the value 2 for the first case, 1 for the second, and 3 for the third. Thus, six cases are built from these records. If the value of *NUMVEH* is 0, no cases are built from that record.

Specifying a Fixed Number of Repeating Groups

```
* Read only the first repeating group from each record.

INPUT PROGRAM.
DATA LIST FILE=VEHICLE / SEQNUM 2-4 NUMPERS 6-7 NUMVEH 9-10.
REPEATING DATA STARTS=12 /OCCURS=1
 /DATA=MAKE 1-8 (A) MODEL 9 (A) NUMCYL 10.
END INPUT PROGRAM.
LIST.
```

- Since OCCURS specifies that there is only one repeating group for each input case, only one output case is built from each input case regardless of the actual number of repeating groups.

DATA Subcommand

DATA specifies a name, location within each repeating segment, and format for each variable to be read from the repeating groups. DATA is required and must be the last subcommand on REPEATING DATA.

- The specifications for DATA are the same as for the DATA LIST command.
- The specified location of the variables on DATA is their location within each repeating group—*not* their location within the record.
- Any input format available on the DATA LIST command can be specified on the DATA subcommand. Both FORTRAN-like and the column-style specifications can be used.

Example

```
INPUT PROGRAM.
DATA LIST FILE=VEHICLE / SEQNUM 2-4 NUMPERS 6-7 NUMVEH 9-10.
REPEATING DATA STARTS=12 /OCCURS=NUMVEH
 /DATA=MAKE 1-8 (A) MODEL 9 (A) NUMCYL 10.
END INPUT PROGRAM.
LIST.
```

- Variable *MAKE* is a string variable read from positions 1 through 8 of each repeating group; *MODEL* is a single-character string variable read from position 9; and *NUMCYL* is a one-digit numeric variable read from position 10.
- The DATA LIST command defines variables *SEQNUM, NUMPERS*, and *NUMVEH*. These variables are spread to each output case built from the repeating groups.

FILE Subcommand

REPEATING DATA always reads the file specified on its associated DATA LIST or FILE TYPE command. The FILE subcommand on REPEATING DATA explicitly specifies the name of the file.

- FILE must specify the same file as its associated DATA LIST or FILE TYPE command.

Example

```
INPUT PROGRAM.
DATA LIST FILE=VEHICLE / SEQNUM 2-4 NUMPERS 6-7 NUMVEH 9-10.
REPEATING DATA FILE=VEHICLE /STARTS=12 /OCCURS=NUMVEH
 /DATA=MAKE 1-8 (A) MODEL 9 (A) NUMCYL 10.
END INPUT PROGRAM.
LIST.
```

- FILE on REPEATING DATA specifically identifies the *VEHICLE* file, which is also specified on the DATA LIST command.

ENCODING Subcommand

ENCODING specifies the encoding format of the file. The keyword is followed by an equals sign and a quoted encoding specification.

- In Unicode mode, the default is UTF8. For more information, see SET command, UNICODE subcommand.
- In code page mode, the default is the current locale setting. For more information, see SET command, LOCALE subcommand.
- The quoted encoding value can be: Locale (the current locale setting), UTF8, UTF16, UTF16BE (big endian), UTF16LE (little endian), a numeric Windows code page value (for example, '1252'), or an IANA code page value (for example, 'iso8859-1' or cp1252).
- In Unicode mode, the defined width of string variables is tripled for code page and UTF-16 text data files. Use ALTER TYPE to automatically adjust the defined width of string variables.

LENGTH Subcommand

LENGTH specifies the length of each repeating data group. The default length is the number of columns between the beginning column of the repeating data groups and the ending position of the last variable specified on DATA. (For the first record of each input case, STARTS specifies the beginning column of the repeating groups. For continuation records, repeating groups are read from column 1 by default or from the column specified on CONTINUED.)

- The specification on LENGTH can be a number or the name of a variable.
- LENGTH must be used if the last variable specified on the DATA subcommand is not read from the last position of each repeating group, or if the length of the repeating groups varies across input cases.
- If the length of the repeating groups varies across input cases, the specification must be a variable whose value for each input case is the length of the repeating groups for that case. The variable can be defined on DATA LIST or created with transformation commands.

- If the value of the variable specified on LENGTH is undefined or missing for an input case, the program displays a warning message and builds only one output case for that input case.

Example

```
* Read only the variable MAKE for each vehicle.

* The data contain two values that are not specified on the
  DATA subcommand.  The first is in position 9 of the repeating
  groups, and the second is in position 10.

INPUT PROGRAM.
DATA LIST FILE=VEHICLE / SEQNUM 2-4 NUMPERS 6-7 NUMVEH 9-10.
REPEATING DATA STARTS=12 /OCCURS=NUMVEH /LENGTH=10
 /DATA=MAKE 1-8 (A).
END INPUT PROGRAM.
```

- LENGTH indicates that each repeating group is 10 columns long. LENGTH is required because *MAKE* is not read from the last position of each repeating group. As illustrated in previous examples, each repeating group also includes variable *MODEL* (position 9) and *NUMCYL* (position 10).
- DATA specifies that *MAKE* is in positions 1 through 8 of each repeating group. Positions 9 and 10 of each repeating group are skipped.

CONTINUED Subcommand

CONTINUED indicates that the repeating groups are contained on more than one record for each input case.

- Each repeating group must be fully recorded on a single record: a repeating group cannot be split across records.
- The repeating groups must begin in the same column on all continuation records.
- If CONTINUED is specified without beginning and ending columns, the program assumes that the repeating groups begin in column 1 of continuation records and searches for repeating groups by scanning to the end of the record or to the value specified by OCCURS. For more information, see Operations on p. 1606.
- If the repeating groups on continuation records do not begin in column 1, CONTINUED must specify the column in which the repeating groups begin.
- If there is room on the logical record length for more repeating groups than are contained on the first record of each input case, the STARTS subcommand must indicate an ending column for the records. The ending column on STARTS applies only to the first record of each input case.
- If there is room on the logical record length for more repeating groups than are contained on the continuation records of each input case, the CONTINUED subcommand must indicate an ending column. The ending column on CONTINUED applies to all continuation records.

Basic Example

```
* This example assumes the logical record length is 80.

INPUT PROGRAM.
DATA LIST / ORDERID 1-5 NITEMS 7-8.
```

```
REPEATING DATA STARTS=10 /OCCURS=NITEMS /CONTINUED=7
 /DATA=ITEM 1-9 (A) QUANTITY 11-13 PRICE (DOLLAR7.2,1X).
END INPUT PROGRAM.

BEGIN DATA
10020 07 01-923-89 001  25.99 02-899-56 100 101.99 03-574-54 064  61.29
10020 04-780-32 025  13.95 05-756-90 005  56.75 06-323-47 003  23.74
10020 07-350-95 014  11.46
20030 04 01-781-43 010  10.97 02-236-54 075 105.95 03-655-83 054  22.99
20030 04-569-38 015  75.00
END DATA.
LIST.
```

- Data are extracted from a mail-order file. Each input case represents one complete order. The data show two complete orders recorded on a total of five records.
- The order number is recorded in columns 1 through 5 of each record. The first three records contain information for order 10020; the next two records contain information for order 20030. The second field of numbers on the first record of each order indicates the total number of items ordered. The repeating groups begin in column 10 on the first record and in column 7 on continuation records. Each repeating data group represents one item ordered and contains three variables—the item inventory number, the quantity ordered, and the price.
- `DATA LIST` defines variables *ORDERID* and *NITEMS* on the first record of each input case.
- `STARTS` on `REPEATING DATA` indicates that the repeating groups on the first record of each input case begin in column 10.
- `OCCURS` indicates that the total number of repeating groups for each input case is the value of *NITEMS*.
- `CONTINUED` must be used because the repeating groups are continued on more than one record for each input case. `CONTINUED` specifies a beginning column because the repeating groups begin in column 7 rather than in column 1 on the continuation records.
- `DATA` defines variables *ITEM*, *QUANTITY*, and *PRICE* for each repeating data group. *ITEM* is in positions 1–9, *QUANTITY* is in positions 11–13, and *PRICE* is in positions 14–20 and is followed by one blank column. The length of the repeating groups is therefore 21 columns. The `LIST` output is shown below.

```
ORDERID NITEMS ITEM      QUANTITY      PRICE

 10020      7   01-923-89      1       $25.99
 10020      7   02-899-56    100      $101.99
 10020      7   03-574-54     64       $61.29
 10020      7   04-780-32     25       $13.95
 10020      7   05-756-90      5       $56.75
 10020      7   06-323-47      3       $23.74
 10020      7   07-350-95     14       $11.46
 20030      4   01-781-43     10       $10.97
 20030      4   02-236-54     75      $105.95
 20030      4   03-655-83     54       $22.99
 20030      4   04-569-38     15       $75.00

NUMBER OF CASES READ =      11    NUMBER OF CASES LISTED =      11
```

Specifying an Ending Column on the STARTS Subcommand

```
* This example assumes the logical record length is 80.

INPUT PROGRAM.
DATA LIST / ORDERID 1-5 NITEMS 7-8.
REPEATING DATA STARTS=10-55 /OCCURS=NITEMS /CONTINUED=7
```

```
 /DATA=ITEM 1-9 (A) QUANTITY 11-13 PRICE (DOLLAR7.2,1X).
END INPUT PROGRAM.

BEGIN DATA
10020 07 01-923-89 001  25.99 02-899-56 100 101.99
10020 03-574-54 064  61.29 04-780-32 025  13.95 05-756-90 005  56.75
10020 06-323-47 003  23.74 07-350-95 014  11.46
20030 04 01-781-43 010  10.97 02-236-54 075 105.95
20030 03-655-83 054  22.99 04-569-38 015  75.00
END DATA.
LIST.
```

- Data are the same as in the previous example; however, records are entered differently. The first record for each input case contains only two repeating groups.
- DATA LIST defines variables *ORDERID* and *NITEMS* in columns 1–8 on the first record of each input case. Column 9 is blank. DATA defines variables *ITEM*, *QUANTITY*, and *PRICE* in positions 1–20 of each repeating group, followed by a blank. Thus, each repeating group is 21 columns wide. The length of the first record of each input case is therefore 51 columns: 21 columns for each of two repeating groups, plus the eight columns defined on DATA LIST, plus column 9, which is blank. The operating system's logical record length is 80, which allows room for one more repeating group on the first record of each input case. STARTS must therefore specify an ending column that does not provide enough columns for another repeating group; otherwise, the program creates an output case with missing values for the variables specified on DATA.
- STARTS specifies that the program is to scan only columns 10–55 of the first record of each input case looking for repeating data groups. It will scan continuation records beginning in column 7 until the value specified on the OCCURS subcommand is reached.

Specifying an Ending Column on the CONTINUED Subcommand

```
* This example assumes the logical record length is 80.

INPUT PROGRAM.
DATA LIST / ORDERID 1-5 NITEMS 7-8.
REPEATING DATA STARTS=10-55 /OCCURS=NITEMS /CONTINUED=7-55
 /DATA=ITEM 1-9 (A) QUANTITY 11-13 PRICE (DOLLAR7.2,1X).
END INPUT PROGRAM.

BEGIN DATA
10020 07 01-923-89 001  25.99 02-899-56 100 101.99
10020 03-574-54 064  61.29 04-780-32 025  13.95
10020 05-756-90 005  56.75 06-323-47 003  23.74
10020 07-350-95 014  11.46
20030 04 01-781-43 010  10.97 89-236-54 075 105.95
20030 03-655-83 054  22.99 04-569-38 015  75.00
END DATA.
LIST.
```

- The data are the same as in the previous two examples, but records are entered differently. The first record and the continuation records for each input case store only two repeating groups each.
- The operating system's logical record length is 80, which allows room for more repeating groups on all records.

- STARTS specifies that the program is to scan only columns 10-55 of the first record of each input case looking for repeating data groups.
- CONTINUED specifies that the program is to scan only columns 7–55 of all continuation records.

ID Subcommand

ID compares the value of an identification variable across records of the same input case. ID can be used only when CONTINUED is specified. The identification variable must be defined on a DATA LIST command and must be recorded on all records in the file.

- The ID subcommand has two specifications: the location of the variable on the continuation records and the name of the variable (as specified on the DATA LIST command). The specifications must be separated from each other by an equals sign.
- The format specified on the ID subcommand must be the same as the format specified for the variable on DATA LIST. However, the location can be different on the continuation records.
- If the values of the identification variable are not the same on all records for a single input case, the program displays an error message and stops reading data.

Example

```
INPUT PROGRAM.
DATA LIST / ORDERID 1-5 NITEMS 7-8.
REPEATING DATA STARTS=10-50 /OCCURS=NITEMS
 /CONTINUED=7 /ID=1-5=ORDERID
 /DATA=ITEM 1-9 (A) QUANTITY 11-13 PRICE 15-20 (2).
END INPUT PROGRAM.

BEGIN DATA
10020 04 45-923-89 001  25.9923-899-56 100 101.99
10020 63-780-32 025  13.9554-756-90 005  56.75
20030 03 45-781-43 010  10.9789-236-54 075 105.95
20030 32-569-38 015  75.00
END DATA.
LIST.
```

- The order number in the data is recorded in columns 1–5 of each record.
- *ORDERID* is defined on the DATA LIST command as a five-column integer variable. The first specification on the ID subcommand must therefore specify a five-column integer variable. The location of the variable can be different on continuation records.

TABLE and NOTABLE Subcommands

TABLE displays a table summarizing all variables defined on the DATA subcommand. The summary table lists the names, locations, and formats of the variables and is identical in format to the summary table displayed by the DATA LIST command. NOTABLE suppresses the table. TABLE is the default.

Example

```
INPUT PROGRAM.
```

```
DATA LIST FILE=VEHICLE / SEQNUM 2-4 NUMPERS 6-7 NUMVEH 9-10.
REPEATING DATA STARTS=12 /OCCURS=NUMVEH /NOTABLE
 /DATA=MAKE 1-8 (A) MODEL 9 (A) NUMCYL 10.
END INPUT PROGRAM.
```

- NOTABLE suppresses the display of the summary table.

REPORT

```
REPORT [/FORMAT=[{MANUAL   }] [{NOLIST   }] [ALIGN({LEFT  })] [TSPACE({1})]
                {AUTOMATIC}   {LIST[(n)]}         {CENTER}           {n}
                                                  {RIGHT }
        [CHDSPACE({1})] [FTSPACE({1})] [SUMSPACE({1})] [COLSPACE({4})]
                 {n}             {n}            {n}            {n}
        [BRKSPACE({ 1 })][LENGTH({1,length})] [MARGINS({1,width})]
                 { n }          {t,b     }            {l,r    }

                                 {format††}
```

**Default if the keyword is omitted.

†Default if FORMAT=AUTOMATIC.

††Any printable output format is valid. See FORMATS.

Aggregate functions:

VALIDN	VARIANCE	PLT(n)
SUM	KURTOSIS	PIN(min,max)
MIN	SKEWNESS	FREQUENCY(min,max)
MAX	MEDIAN(min,max)	PERCENT(min,max)
MEAN	MODE(min,max)	
STDDEV	PGT(n)	

Composite functions:

DIVIDE(arg_1 arg_2 [factor])
MULTIPLY(arg_1...arg_n)
PCT(arg_1 arg_2)
SUBTRACT(arg_1 arg_2)
ADD(arg_1...arg_n)
GREAT(arg_1...arg_n)
LEAST(arg_1...arg_n)
AVERAGE(arg_1...arg_n)

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
REPORT FORMAT=LIST
  /VARIABLES=PRODUCT (LABEL) ' ' 'Retail' 'Products'
            SALES 'Annual' 'Sales' '1981'
  /BREAK=DEPT 'Department' (LABEL)
  /SUMMARY=VALIDN (PRODUCT) MEAN (SALES).
```

Overview

REPORT produces case listings and summary statistics and gives you considerable control over the appearance of the output. REPORT calculates all the univariate statistics available in DESCRIPTIVES and the statistics and subpopulation means available in MEANS. In addition, REPORT calculates statistics not directly available in any other procedure, such as computations involving aggregated statistics.

REPORT provides complete report format defaults but also lets you customize a variety of table elements, including column widths, titles, footnotes, and spacing. Because REPORT is so flexible and the output has so many components, it is often efficient to preview report output using a small number of cases until you find the format that best suits your needs.

Basic Specification

The basic specification depends on whether you want a listing report or a summary report. A listing report without subgroup classification requires FORMAT and VARIABLES. A listing report with subgroup classification requires FORMAT, VARIABLES, and BREAK. A summary report requires VARIABLES, BREAK, and SUMMARY.

Listing Reports. FORMAT=LIST and VARIABLES with a variable list are required. Case listings are displayed for each variable named on VARIABLES. There are no break groups or summary statistics unless BREAK or SUMMARY is specified.

Summary Reports. VARIABLES, BREAK, and SUMMARY are required. The report is organized according to the values of the variable named on BREAK. The variable named on BREAK must be named on a preceding SORT CASES command. Specified statistics are computed for the variables specified on VARIABLES for each subgroup defined by the break variables.

Subcommand Order

The following order must be observed among subcommands when they are used:

- FORMAT must precede all other subcommands.
- VARIABLES must precede BREAK.
- OUTFILE must precede BREAK.
- Each SUMMARY subcommand must immediately follow its associated BREAK. Multiple SUMMARY subcommands associated with the same BREAK must be specified consecutively.
- TITLE and FOOTNOTE can appear anywhere after FORMAT except between BREAK and SUMMARY.
- MISSING must follow VARIABLES and precede the first BREAK.
- STRING must precede VARIABLES.

Syntax Rules

- Only one each of the FORMAT, STRING, VARIABLES, and MISSING subcommands is allowed.
- To obtain multiple break groups, use multiple BREAK subcommands.
- To obtain multiple summaries for a break level, specify multiple SUMMARY subcommands for the associated BREAK.
- Keywords on REPORT subcommands have default specifications that are in effect if the keyword is not specified. Specify keywords only when you wish to change a default.
- Keywords are enclosed in parentheses if the subcommand takes variable names as arguments.

Operations

- REPORT processes cases sequentially. When the value of a break variable changes, REPORT displays a statistical summary for cases processed since the last set of summary statistics was displayed. Thus, the file must be sorted in order on the break variable or variables.
- The maximum width and page length of the report are determined by the SET command.

- If a column is not wide enough to display numeric values, REPORT first rounds decimal digits, then converts to scientific notation if possible, and then displays asterisks. String variables that are wider than the column are truncated.
- The format used to display values in case listings is controlled by the dictionary format of the variable. Each statistical function in REPORT has a default format.

Limitations

- Maximum 500 variables per VARIABLES subcommand. You can specify more than 500 variables if you stack them. For more information, see VARIABLES Subcommand on p. 1627.
- Maximum 10 dummy variables per VARIABLES subcommand.
- Maximum 20 MODE and MEDIAN requests per SUMMARY subcommand.
- Maximum 20 PGT, PLT, and PIN requests per SUMMARY subcommand.
- Maximum 50 strings per STRING subcommand.
- The length of titles and footnotes cannot exceed the report width.
- The length of string variables created on STRING cannot exceed the page width.
- There is no fixed limit on the number of BREAK and SUMMARY subcommands. However, the page width limits the number of variables that can be displayed and thereby limits the number of break variables.
- The maximum width of a report is 255 characters.
- The number of report variables that can be specified depends upon the width of the report, the width of the variable columns, and the number of BREAK subcommands.
- Maximum 50 variables for the FREQUENCY or PERCENT functions.
- Memory requirements significantly increase if FREQUENCY, PERCENT, MEDIAN, or MODE is requested for variables with a wide range of values. The amount of workspace required is 20 + 8*(max − min + 1) bytes per variable per function per break. If the same range is used for different statistics for the same variable, only one set of cells is collected. For example, FREQUENCY(1,100)(VARA) PERCENT(1,100)(VARA) requires only 820 bytes.
- If TOTAL is in effect, workspace requirements are almost doubled.
- Memory requirements also increase if value labels are displayed for variables with many value labels. The amount of workspace required is 4 + 24*n bytes per variable, where n is the number of value labels specified for the variable.

Examples

```
SORT CASES BY DEPT.
REPORT FORMAT=LIST
  /VARIABLES=PRODUCT (LABEL) ' ' 'Retail' 'Products'
            SALES 'Annual' 'Sales' '1981'
  /BREAK=DEPT 'Department' (LABEL)
  /SUMMARY=VALIDN (PRODUCT) MEAN (SALES) 'No.Sold,Mean Sales'.
```

- This report is a listing of products and sales by department. A summary of the total number of products sold and the average sales by department is also produced.

- Cases are first sorted by *DEPT* so that cases are grouped by department for the case listing and for the calculation of statistics.
- FORMAT requests a report that lists individual cases within each break group.
- VARIABLES specifies *PRODUCT* and *SALES* as the report variables. Keyword LABEL requests that the case listings for *PRODUCT* display value labels instead of values. Three-line column headings are provided for each report column. The first line of the column heading is blank for the variable *PRODUCT*.
- BREAK identifies *DEPT* as the break variable and provides a one-line column title for the break column. LABEL displays the value label instead of the value itself.
- SUMMARY calculates the valid number of cases for *PRODUCT* and the mean of *SALES* for each value of *DEPT*. A title is provided for the summary line to override the default title, *VALIDN*.

Defaults

Column Heads. REPORT uses variable labels as default column heads; if no variable labels have been specified, variable names are used. If ONEBREAKCOLUMN is ON, the default head for the first BREAK subcommand is used.

Column Widths. Default column widths are determined by REPORT, using the maximum of the following for each column:

- The widest print format in the column, whether it is a variable print format or a summary print format.
- The width of any temporary variable defined with the STRING subcommand on REPORT.
- If a column heading is assigned, the length of the longest title line in the heading when CHWRAP is off, and the longest word in the title when CHWRAP is on. Underscores, which are removed on printing, can be used to create longer words in the title.
- When no column heading is specified, the length of the longest word in the variable label, or the length of the variable name.
- If you specify LABEL on VARIABLES or BREAK, the length of the variable's longest value label. If FORMAT=MANUAL is in effect, 20 is the maximum value used for this criterion.
- The minimum column width is 8 when FORMAT=MANUAL; it can be less when FORMAT=AUTOMATIC.

Automatic Fit. When the above criteria for column width result in a report that is too wide for the report margins, FORMAT=AUTOMATIC shrinks the report. AUTOMATIC performs the following two steps sequentially, stopping as soon as the report fits within the margins:

1. AUTOMATIC reduces intercolumn spacing incrementally until it reaches a minimum intercolumn space of 1. It will never reduce it to 0.

2. AUTOMATIC shortens widths for strings specified on the STRING subcommand or for value label strings when the LABEL option is specified. It begins with the longest string if that string is at least 15 characters wide and shortens the column width as much as needed (up to 40% of its length), wrapping the string within the new width. If necessary, it repeats the step, using different defined strings. It will not shorten the column width of the same string twice.

REPORT does *not* implement the automatic fit unless AUTOMATIC is specified on the FORMAT subcommand.

AUTOMATIC versus MANUAL Defaults. Many default settings depend on whether you specify AUTOMATIC or MANUAL on FORMAT. The following table shows the defaults according to either of the specifications.

Table 196-1
Keyword default settings

Subcommand	Keyword	Default for AUTOMATIC	Default for MANUAL
FORMAT	ALIGN	left	left
	BRKSPACE		
	summary report	1	1
	listing report	–1	1
	CHALIGN	bottom	top
	CHDSPACE	1	1
	COLSPACE	4	4
	FTSPACE	1	1
	LENGTH	1,system length	1,system length
	LIST|NOLIST	NOLIST	NOLIST
	MARGINS	1,system width	1,system width
	MISSING	.	.
	PAGE1	1	1
	SUMSPACE	1	1
	TSPACE	1	1
	UNDERSCORE	on	off
	ONEBREAKCOLUMN	off	off
	INDENT[1]	2	2
	CHWRAP	off	off
	PREVIEW	off	off
VARIABLES	LABEL|VALUE|DUMMY	VALUE	VALUE
	LEFT|CENTER|RIGHT	CENTER[2]	RIGHT for numbers LEFT for strings
	OFFSET	CENTER	0
BREAK	LABEL|VALUE	LABEL	VALUE
	LEFT|CENTER|RIGHT	CENTER[2]	RIGHT for numbers LEFT for strings
	NAME|NONAME	NONAME	NONAME
	OFFSET	CENTER[3]	0
	PAGE	off	off

Subcommand	Keyword	Default for AUTOMATIC	Default for MANUAL
	SKIP	1	1
	TOTAL|NOTOTAL	NOTOTAL	NOTOTAL
	UNDERSCORE	off	off
SUMMARY	PREVIOUS	1	1
	SKIP	0	0

[1] No effect when ONEBREAKCOLUMN is on.

[2] LEFT when ONEBREAKCOLUMN is on.

[3] 0 when ONEBREAKCOLUMN is on.

Options

Format. REPORT provides full format defaults and offers you optional control over page length, vertical spacing, margin and column widths, page titles, footnotes, and labels for statistics. The maximum width and length of the report are controlled by specifications on the SET command. The FORMAT subcommand on REPORT controls how the report is laid out on a page and whether case listings are displayed. The VARIABLES subcommand specifies the variables that are listed or summarized in the report (**report variables**) and controls the titles, width, and contents of report columns. The BREAK subcommand specifies the variables that define groups (**break variables**) and controls the titles, width, and contents of break columns. SUMMARY specifies statistics and controls the titles and spacing of summary lines. The TITLE and FOOTNOTE subcommands control the specification and placement of multiple-line titles and footnotes. STRING concatenates variables to create temporary variables that can be specified on VARIABLES or BREAK.

Output File. You can direct reports to a file separate from the file used for the rest of the output from your session using the OUTFILE subcommand.

Statistical Display. The statistical display is controlled by the SUMMARY subcommand. Statistics can be calculated for each category of a break variable and for the group as a whole. Available statistics include mean, variance, standard deviation, skewness, kurtosis, sum, minimum, maximum, mode, median, and percentages. Composite functions perform arithmetic operations using two or more summary statistics calculated on single variables.

Missing Values. You can override the default to include user-missing values in report statistics and listings with the MISSING subcommand. You can also use FORMAT to define a missing-value symbol to represent missing data.

FORMAT Subcommand

FORMAT controls the overall width and length of the report and vertical spacing. Keywords and their arguments can be specified in any order.

- MANUAL and AUTOMATIC are alternatives. The default is MANUAL.
- LIST and NOLIST are alternatives. The default is NOLIST.

MANUAL *Default settings for manual format.* MANUAL displays values for break variables, right-justifies numeric values and their column headings, left-justifies value labels and string values and their column headings, top-aligns and does not underscore column headings, extends column widths to accommodate the variable's longest value label (but not the longest word in the variable label) up to a width of 20, and generates an error message when a report is too wide for its margins. MANUAL is the default.

AUTOMATIC *Default settings for automatic format.* AUTOMATIC displays labels for break variables, centers all data, centers column headings but left-justifies column headings if value labels or string values exceed the width of the longest word in the heading, bottom-aligns and underscores column headings, extends column widths to accommodate the longest word in a variable label or the variable's longest value label, and shrinks a report that is too wide for its margins.

LIST(n) *Individual case listing.* The values of all variables named on VARIABLES are displayed for each case. The optional *n* inserts a blank line after each *n* cases. By default, no blank lines are inserted. Values for cases are listed using the default formats for the variables.

NOLIST *No case listing.* This is the default.

PAGE(n) *Page number for the first page of the report.* The default is 1.

LENGTH(t,b) *Top and bottom line numbers of the report.* You can specify any numbers to define the report page length. By default, the top of the report begins at line 1, and the bottom of the report is the last line of the system page. You can use an asterisk for *t* or *b* to indicate a default value. If the specified length does not allow even one complete line of information to be displayed, REPORT extends the length specification and displays a warning.

MARGINS(l,r) *Columns for the left and right margins.* The right column cannot exceed 255. By default, the left margin is display column 1 and the right margin is the rightmost display column of the system page. You can use an asterisk for *l* or *r* to indicate a default value.

ALIGN *Placement of the report relative to its margins.* LEFT, CENTER, or RIGHT can be specified in the parentheses following the keyword. LEFT left-justifies the report. CENTER centers the report between its margins. RIGHT right-justifies the report. The default is LEFT.

COLSPACE(n) *Number of spaces between each column.* The default is 4 or the average number of spaces that will fit within report margins, whichever is less. When AUTOMATIC is in effect, REPORT overrides the specified column spacing if necessary to fit the report between its margins.

CHALIGN *Alignment of column headings.* Either TOP or BOTTOM can be specified in the parentheses following the keyword. TOP aligns all column headings with the first, or top, line of multiple-line headings. BOTTOM aligns headings with the last, or bottom, line of multiple-line headings. When AUTOMATIC is in effect, the default is BOTTOM; when MANUAL is in effect, the default is TOP.

UNDERSCORE *Underscores for column headings.* Either ON or OFF can be specified in the parentheses following the keyword. ON underscores the bottom line of each column heading for the full width of the column. OFF does not underscore column headings. The default is ON when AUTOMATIC is in effect and OFF when MANUAL is in effect.

TSPACE(n) *Number of blank lines between the report title and the column heads.* The default is 1.

CHDSPACE(n) *Number of blank lines beneath the longest column head.* The default is 1.

BRKSPACE(n) *Number of blank lines between the break head and the next line.* The next line is a case if LIST is in effect or the first summary line if NOLIST is in effect. BRKSPACE(−1) places the first summary statistic or the first case listing on the same line as the break value. When a summary line is placed on the same line as the break value, the summary title is suppressed. When AUTOMATIC is in effect, the default is −1; when MANUAL is in effect, it is 1.

SUMSPACE(n) *Number of blank lines between the last summary line at the lower break level and the first summary line at the higher break level when they break simultaneously.* SUMSPACE also controls spacing between the last listed case and the first summary line if LIST is in effect. The default is 1.

FTSPACE(n) *Minimum number of blank lines between the last listing on the page and the footnote.* The default is 1.

MISSING 's' *Missing-value symbol.* The symbol can be only one character and represents both system- and user-missing values. The default is a period.

ONEBREAKCOLUMN *Display subgroups defined on multiple BREAK subcommands in a single column.* You can specify OFF or ON in parentheses after the keyword. The default is OFF. When ONEBREAKCOLUMN is ON, it applies to all BREAK subcommands. For more information, see BREAK Subcommand on p. 1630.

INDENT(n) *Indention of break values and summary titles of each successive subgroup defined by one BREAK subcommand in a single break column.* INDENT is effective only when ONEBREAKCOLUMN is on. Multiple variables specified on one BREAK subcommand are indented as a block. The default specification is 2. When ONEBREAKCOLUMN is OFF, specification on INDENT is ignored.

CHWRAP *Automatically wrap user-specified column heads.* You can specify OFF or ON in parentheses after the keyword. The default is OFF. When CHWRAP is ON, user-specified heads for either break or variable columns are wrapped. If multiple lines are specified for a head, each line is wrapped, if necessary, independent of other lines. To prevent wrapping at blanks, use the underscore character (_) to signify a hard blank in your head specification. The underscore serves as a hard blank only in user-specified heads and only when CHWRAP is ON. The underscore does not appear in the printed heading.

PREVIEW *Display the first page of output only.* You can specify OFF or ON either in parentheses or with one blank space separating the specification from the keyword. The default is OFF. When PREVIEW is ON, the program stops processing after the first page for you to quickly check the format of your report.

OUTFILE Subcommand

OUTFILE directs the report to a file separate from the file used for the rest of the output from your session. This allows you to print the report without having to delete the extraneous material that would be present in the output.

- OUTFILE must follow FORMAT and must precede BREAK.
- You can append multiple reports to the same file by naming the same file on the OUTFILE subcommand for each REPORT command.

Example

```
REPORT FORMAT=AUTOMATIC LIST
  /OUTFILE=PRSNLRPT
  /VARIABLES=LNAME AGE TENURE JTENURE SALARY
  /BREAK=DIVISION
  /SUMMARY=MEAN.
```

```
REPORT FORMAT=AUTOMATIC
  /OUTFILE=PRSNLRPT
  /VARIABLES=LNAME AGE TENURE JTENURE SALARY
  /BREAK=DIVISION
  /SUMMARY=MEAN
  /SUMMARY=MIN
  /SUMMARY=MAX.
```

- Both a listing report and a summary report are written to file *PRSNLRPT*.

VARIABLES Subcommand

The required VARIABLES subcommand names the variables to be listed and summarized in the report. You can also use VARIABLES to control column titles, column widths, and the contents of report columns.

- The minimum specification on VARIABLES is a list of report variables. The number of variables that can be specified is limited by the system page width.
- Each report variable defines a report column. The value of the variable or an aggregate statistic calculated for the variable is displayed in that variable's report column.
- Variables are assigned to columns in the order in which they are named on VARIABLES.
- Variables named on BREAK can also be named on VARIABLES.
- When FORMAT=LIST, variables can be stacked in a single column by linking them with plus signs (+) on the VARIABLES subcommand. If no column heading is specified, REPORT uses the default heading from the first variable on the list. Only values from the first variable in the column are used to calculate summaries.
- Optional specifications apply only to the immediately preceding variable or list of variables implied by the TO keyword. Options can be specified in any order.
- All optional specifications except column headings must be enclosed in parentheses; column headings must be enclosed in quotes.

Column Contents

The following options can be used to specify the contents of the report column for each variable:

(VALUE)	*Display the values of the variable.* This is the default.
(LABEL)	*Display value labels*. If value labels are not defined, values are displayed.
(DUMMY)	*Display blank spaces.* DUMMY defines a report column for a variable that does not exist in the active dataset. Dummy variables are used to control spacing or to reserve space for statistics computed for other variables. Do not name an existing variable as a dummy variable.

- VALUE and LABEL have no effect unless LIST has been specified on the FORMAT subcommand.
- When AUTOMATIC is in effect, value labels or string values are centered in the column based on the length of the longest string or label; numeric values are centered based on the width of the widest value or summary format. When MANUAL is in effect, value labels or string values are left-justified in the column and numeric values are right-justified. (See the OFFSET keyword.)

Column Heading

The following option can be used to specify a heading for the report column:

'column heading' *Column heading for the preceding variable.* The heading must be enclosed in quotes. If no column heading is specified, the default is the variable label or, if no variable label has been specified, the variable name.

- To specify multiple-line headings, enclose each line in quotes, using the conventions for strings. The specifications for title lines should be separated by at least one blank.
- Default column headings wrap for as many lines as are required to display the entire label. If AUTOMATIC is in effect, user-specified column headings appear exactly as specified, even if the column width must be extended. If MANUAL is in effect, user-specified titles wrap to fit within the column width.

Column Heading Alignment

The following options can be used to specify how column headings are aligned:

(LEFT) *Left-aligned column heading.*

(CENTER) *Centered column heading.*

(RIGHT) *Right-aligned column heading.*

- If AUTOMATIC is in effect, column headings are centered within their columns by default. If value labels or string values exceed the width of the longest word in the heading, the heading is left-justified.
- If MANUAL is in effect, column headings are left-justified for value labels or string values and right-justified for numeric values by default.

Column Format

The following options can be used to specify column width and adjust the position of the column contents:

(width) *Width for the report column.* If no width is specified for a variable, REPORT determines a default width using the criteria described under Defaults. If you specify a width that is not wide enough to display numeric values, REPORT first rounds decimal digits, then converts to scientific notation if possible, and then displays asterisks. Value labels or string values that exceed the width are wrapped.

(OFFSET) *Position of the report column contents.* The specification is either *n* or CENTER specified in parentheses. OFFSET(*n*) indicates the number of spaces to offset the contents from the left for value labels or string values, and from the right for numeric values. OFFSET(CENTER) centers contents within the center of the column. If AUTOMATIC is in effect, the default is CENTER. If MANUAL is in effect, the default is 0. Value labels and string values are left-justified and numeric values are right-justified.

Example

```
/VARIABLES=V1 TO V3(LABEL) (15)
  V4 V5 (LABEL)(OFFSET (2))(10)
  SEP1 (DUMMY) (2) ''
  V6 'Results using' "Lieben's Method" 'of Calculation'
```

- The width of the columns for variables *V1* through *V3* is 15 each. Value labels are displayed for these variables in the case listing.
- The column for variable *V4* uses the default width. Values are listed in the case listing.
- Value labels are displayed for variable *V5*. The column width is 10. Column contents are offset two spaces from the left.
- *SEP1* is a dummy variable. The column width is 2, and there is at least one space on each side of *SEP1*. Thus, there are at least four blanks between the columns for *V5* and *V6*. *SEP1* is given a null title to override the default column title *SEP1*.
- *V6* has a three-line title. Its column uses the default width, and values are listed in the case listing.

STRING Subcommand

STRING creates a temporary string variable by concatenating variables and user-specified strings. These variables exist only within the REPORT procedure.

- The minimum specification is a name for the string variable followed by a variable name or a user-specified string enclosed in parentheses.
- The name assigned to the string variable must be unique.
- Any combination of string variables, numeric variables, and user-specified strings can be used in the parentheses to define the string.
- Keyword TO cannot be used within the parentheses to imply a variable list.
- More than one string variable can be defined on STRING.
- If a case has a missing value for a variable within the parentheses, the variable passes the missing value to the temporary variable without affecting other elements specified.
- A string variable defined in REPORT cannot exceed the system page width.
- String variables defined on STRING can be used on VARIABLES or BREAK.

The following options can be used to specify how components are to be concatenated:

(width)	*Width of the preceding variable within the string.* The default is the dictionary width of the variable. The maximum width for numeric variables within the string definition is 16. The maximum width for a string variable is the system page width. If the width specified is less than that required by the value, numeric values are displayed as asterisks and string values are truncated. If the width exceeds the width of a value, numeric values are padded with zeros on the left and string values are padded with blanks on the right.
(BLANK)	*Left-pad values of the preceding numeric variable with blanks.* The default is to left-pad values of numeric variables with zeros. If a numeric variable has a dollar or comma format, it is automatically left-padded with blanks.
'literal'	*User-specified string.* Any combination of characters can be specified within quotes.

Example

```
/STRING=JOB1(AVAR NVAR)
        JOB2(AVAR(2) NVAR(3))
        JOB3(AVAR(2) NVAR(BLANK) (4))
```

- STRING defines three string variables to be used within the report.
- Assume that *AVAR* is a string variable read from a four-column field using keyword FIXED on DATA LIST and that *NVAR* is a computed numeric variable with the default format of eight columns with two implied decimal places.
- If a case has value KJ for *AVAR* and value 241 for *NVAR*, *JOB1* displays the value 'KJ 00241.00', *JOB2* the value 'KJ241', and *JOB3* the value 'KJ 241'. If *NVAR* has the system-missing value for a case, *JOB1* displays the value 'KJ'.

Example

```
/STRING=SOCSEC(S1 '-' S2 '-' S3)
```

- STRING concatenates the three variables *S1*, *S2*, and *S3*, each of which contains a segment of the social security number.
- Hyphens are inserted between the segments when the values of *SOCSEC* are displayed.
- This example assumes that the variables *S1*, *S2*, and *S3* were read from three-column, two-column, and four-column fields respectively, using the keyword FIXED on DATA LIST. These variables would then have default format widths of 3, 2, and 4 columns and would not be left-padded with zeros.

BREAK Subcommand

BREAK specifies the variables that define the subgroups for the report, or it specifies summary totals for reports with no subgroups. BREAK also allows you to control the titles, width, and contents of break columns and to begin a new page for each level of the break variable.

- A break occurs when any one of the variables named on BREAK changes value. Cases must be sorted by the values of all BREAK variables on all BREAK subcommands.

- The BREAK subcommand must precede the SUMMARY subcommand that defines the summary line for the break.
- A break column is reserved for each BREAK subcommand if ONEBREAKCOLUMN is OFF (the default).
- To obtain multiple break levels, specify multiple break variables on a BREAK subcommand.
- If more than one variable is specified on a BREAK subcommand, a single break column is used. The value or value label for each variable is displayed on a separate line in the order in which the variables are specified on BREAK. The first variable specified changes most slowly. The default column width is the longest of the default widths for any of the break variables.
- To obtain summary totals without any break levels, use keyword TOTAL in parentheses on BREAK without listing any variables. TOTAL must be specified on the first BREAK subcommand.
- When MISSING=VAR is specified, user-missing values are displayed in case listings but are not included in summary statistics. When NONE is specified, user-missing values are ignored. System-missing values are displayed as missing in case and break listings.
- Optional specifications apply to all variables in the break column and to the break column as a whole. Options can be specified in any order following the last variable named.
- All optional specifications except column headings must be enclosed in parentheses; column headings must be enclosed in quotes.

Column Contents

The following can be used to specify the contents of the break column:

(VALUE) *Display values of the break variables.*

(LABEL) *Display value labels*. If no value labels have been defined, values are displayed.

- The value or label is displayed only once for each break change but it is repeated at the top of the page in a multiple-page break group.
- When AUTOMATIC is in effect, the default is LABEL; when MANUAL is in effect, the default is VALUE.
- When AUTOMATIC is in effect, the value or label is centered in the column. When MANUAL is in effect, value labels and string values are left-justified and numeric values are right-justified. Keywords OFFSET, ONEBREAKCOLUMN, and INDENT can also affect positioning.

Column Heading

The following option specifies headings used for the break column.

'column heading' *Column heading for the break column.* The heading must be included in quotes. The default heading is the variable label of the break variable or, if no label has been defined, the variable name. If the break column is defined by more than one variable, the label or name of the first variable is used. If ONEBREAKCOLUMN is ON, the specified or implied column heading for the first BREAK subcommand is used.

- To specify multiple-line headings, enclose each line in a set of quotes, following the conventions for strings. Separate the specifications for heading lines with at least one blank.
- Default column headings wrap for as many lines as are required to display the entire label.
- User-specified column headings appear exactly as specified if CHWRAP is OFF (the default). If CHWRAP is ON, any user-defined line longer than the specified or default column width is automatically wrapped.

Column Heading Alignment

The following options can be used to specify how column headings are aligned:

(LEFT)	*Left-aligned column heading.*
(CENTER)	*Centered column heading.*
(RIGHT)	*Right-aligned column heading.*

- When AUTOMATIC is in effect, column headings are centered within their columns by default. If value labels or string values exceed the width of the longest word in the heading, the heading is left-justified.
- When MANUAL is in effect, column headings are left-justified for value labels or string values and right-justified for numeric values.
- When ONEBREAKCOLUMN is ON, all column contents are left aligned. Specifications of CENTER and RIGHT on BREAK are ignored.

Column Format

The following options can be used to format break columns:

(width)	*Column width for the break column.* If no width is specified for a variable, REPORT determines a default width using the criteria described under Defaults. If ONEBREAKCOLUMN is ON, the column width specified or implied by the first BREAK subcommand is used. If you specify a width that is not wide enough to display numeric values, REPORT first rounds decimal digits, then converts them to scientific notation if possible, and then displays asterisks. Value labels or string values that exceed the width are wrapped.
(OFFSET)	*Position of the break column contents.* The specification is either *n* or CENTER specified in parentheses. OFFSET(*n*) indicates the number of spaces to offset the contents from the left for value labels or string values, and from the right for numeric values. OFFSET(CENTER) centers contents within the column. If AUTOMATIC is in effect, the default is CENTER. If MANUAL is in effect, the default is 0: value labels and string values are left-justified and numeric values are right-justified. If ONEBREAKCOLUMN is ON, the offset is applied along with the indentation specified on INDENT, always from the left. The specification of CENTER on OFFSET is ignored.
(UNDERSCORE)	*Use underscores below case listings.* Case listing columns produced by FORMAT LIST are underscored before summary statistics are displayed. You can optionally specify the names of one or more report variables after UNDERSCORE; only the specified columns are underscored.

(TOTAL)	*Display the summary statistics requested on the next SUMMARY subcommand for all the cases in the report.* TOTAL must be specified on the first BREAK subcommand and applies only to the next SUMMARY subcommand specified.
(NOTOTAL)	*Display summary statistics only for each break.* This is the default.
(SKIP(n))	*Skip* n *lines after the last summary line for a break before beginning the next break.* The default for *n* is 1.
(PAGE)	*Begin each break on a new page.* If RESET is specified on PAGE, the page counter resets to the PAGE1 setting on the FORMAT subcommand every time the break value changes for the specified variable. PAGE cannot be specified for listing reports with no break levels.
(NAME)	*Display the name of the break variable next to each value or value label of the break variable.* NAME requires enough space for the length of the variable name plus two additional characters (for a colon and a blank space) in addition to the space needed to display break values or value labels. NAME is ignored if the break column width is insufficient.
(NONAME)	*Suppress the display of break variable names.* This is the default.

Example

```
SORT DIVISION BRANCH DEPT.
REPORT FORMAT=AUTOMATIC MARGINS (1,70) BRKSPACE(-1)

  /VARIABLES=SPACE(DUMMY) ' ' (4)
             SALES 'Annual' 'Sales' '1981' (15) (OFFSET(2))
             EXPENSES 'Annual' 'Expenses' '1981' (15) (OFFSET(2))

  /BREAK=DIVISION
         BRANCH (10) (TOTAL) (OFFSET(1))
  /SUMMARY=MEAN

  /BREAK=DEPT 'Department' (10)
  /SUMMARY=MEAN.
```

- This example creates a report with three break variables. *BRANCH* breaks within values of *DIVISION*, and *DEPT* breaks within values of *BRANCH*.
- FORMAT sets margins to a maximum of 70 columns and requests that summary lines be displayed on the same line as break values. Because LIST is not specified on FORMAT, only summary statistics are displayed.
- VARIABLES defines three report columns, each occupied by a report variable: *SPACE*, *SALES*, and *EXPENSES*.
- The variable *SPACE* is a dummy variable that exists only within REPORT. It has a null heading and a width of 4. It is used as a space holder to separate the break columns from the report columns.
- *SALES* has a three-line heading and a width of 15. The values of *SALES* are offset two spaces from the right.
- *EXPENSES* is the third report variable and has the same width and offset specifications as *SALES*.
- The leftmost column in the report is reserved for the first two break variables, *DIVISION* and *BRANCH*. Value labels are displayed, since this is the default for AUTOMATIC. The break column has a width of 10 and the value labels are offset one space from the left. Value labels

more than nine characters long are wrapped. The default column heading is used. TOTAL requests a summary line at the end of the report showing the mean of all cases in the report.

- The first SUMMARY subcommand displays the mean of each report variable in its report column. This line is displayed each time the value of *DIVISION* or *BRANCH* changes.
- The third break variable, *DEPT*, occupies the second column from the left in the report. The break column has a width of 10 and has a one-line heading. Value labels are displayed in the break column, and those exceeding 10 characters are wrapped.
- The second SUMMARY subcommand displays the mean for each report variable when the value of *DEPT* changes.

SUMMARY Subcommand

SUMMARY calculates a wide range of aggregate and composite statistics.

- SUMMARY must be specified if LIST is not specified on FORMAT.
- The minimum specification is an aggregate or a composite function and its arguments. This must be the first specification on SUMMARY.
- Each SUMMARY subcommand following a BREAK subcommand specifies a new summary line.
- The default location of the summary title is the column of the break variable to which the summary applies. When more than one function is named on SUMMARY, the default summary title is that of the function named first. Both the title and its default column location can be altered. For more information, see Summary Titles on p. 1638.
- The default format can be altered for any function. (For more information, see Summary Print Formats on p. 1639.)
- SUMMARY subcommands apply only to the preceding BREAK subcommand. If there is no SUMMARY subcommand after a BREAK subcommand, no statistics are displayed for that break level.
- To use the summary specifications from a previous BREAK subcommand for the current BREAK subcommand, specify keyword PREVIOUS on SUMMARY. For more information, see Other Summary Keywords on p. 1641.
- Summary statistics are displayed in report columns. With aggregate functions, you can compute summary statistics for all report variables or for a subset. For more information, see Aggregate Functions on p. 1635. With composite functions, you can compute summaries for all or a subset of report variables and you have additional control over the placement of summary statistics in particular report columns. For more information, see Composite Functions on p. 1637.
- Multiple summary statistics requested on one SUMMARY subcommand are all displayed on the same line. More than one function can be specified on SUMMARY as long as you do not attempt to place two results in the same report column (REPORT will not be executed if you do). To place results of more than one function in the same report column, use multiple SUMMARY subcommands.

- Any composite and aggregate functions except FREQUENCY and PERCENT can be specified on the same summary line.
- To insert blank lines between summaries when more than one summary line is requested for a break, use keyword SKIP followed by the number of lines to skip in parentheses. The default is 0. For more information, see Other Summary Keywords on p. 1641.

Aggregate Functions

Use the aggregate functions to request descriptive statistics for report variables.

- If no variable names are specified as arguments to an aggregate function, the statistic is calculated for all variables named on VARIABLES (all report variables).
- To request an aggregate function for a subset of report variables, specify the variables in parentheses after the function keyword.
- All variables specified for an aggregate function must have been named on VARIABLES.
- Keyword TO cannot be used to specify a list of variables for an aggregate function.
- The result of an aggregate function is always displayed in the report column reserved for the variable for which the function was calculated.
- To use several aggregate functions for the same report variable, specify multiple SUMMARY subcommands. The results are displayed on different summary lines.
- The aggregate functions FREQUENCY and PERCENT have special display formats and cannot be placed on the same summary line with other aggregate or composite functions. They can be specified only once per SUMMARY subcommand.
- Aggregate functions use only cases with valid values.

VALIDN	*Valid number of cases.* This is the only function available for string variables.
SUM	*Sum of values.*
MIN	*Minimum value.*
MAX	*Maximum value.*
MEAN	*Mean.*
STDDEV	*Standard deviation.* Aliases are SD and STDEV.
VARIANCE	*Variance.*
KURTOSIS	*Kurtosis.*
SKEWNESS	*Skewness.*
MEDIAN(min,max)	*Median value for values within the range.* MEDIAN sets up integer-valued bins for counting all values in the specified range. Noninteger values are truncated when the median is calculated.
MODE(min,max)	*Modal value for values within the range.* MODE sets up integer-valued bins for counting all values in the specified range. Noninteger values are truncated when the mode is calculated.
PGT(n)	*Percentage of cases with values greater than* n. Alias PCGT.
PLT(n)	*Percentage of cases with values less than* n. Alias PCLT.
PIN(min,max)	*Percentage of cases within the inclusive value range specified.* Alias PCIN.

FREQUENCY(min,max) *Frequency counts for values within the inclusive range.* FREQUENCY sets up integer-valued bins for counting all values in the specified range. Noninteger values are truncated when the frequency is computed. FREQUENCY cannot be mixed with other aggregate statistics on a summary line.

PERCENT(min,max) *Percentages for values within the inclusive range.* PERCENT sets up integer-valued bins for counting all values in the specified range. Noninteger values are truncated when the percentages are computed. PERCENT cannot be mixed with other aggregate statistics on a summary line.

Example

```
SORT CASES BY BVAR AVAR.
REPORT FORMAT=AUTOMATIC LIST /VARIABLES=XVAR YVAR ZVAR

  /BREAK=BVAR
    /SUMMARY=SUM
    /SUMMARY=MEAN (XVAR YVAR ZVAR)
    /SUMMARY=VALIDN(XVAR)

  /BREAK=AVAR
    /SUMMARY=PREVIOUS.
```

- FORMAT requests a case listing, and VARIABLES establishes a report column for variables *XVAR*, *YVAR*, and *ZVAR*. The report columns have default widths and titles.
- Both break variables, *BVAR* and *AVAR*, have default widths and headings.
- Every time the value of *BVAR* changes, three summary lines are displayed. The first line contains the sums for variables *XVAR*, *YVAR*, and *ZVAR*. The second line contains the means of all three variables. The third line displays the number of valid cases for *XVAR* in the report column for *XVAR*.
- Every time the value of *AVAR* changes within each value of *BVAR*, the three summary lines requested for *BVAR* are displayed. These summary lines are based on cases with the current values of *BVAR* and *AVAR*.

Example

```
SORT CASES BY DEPT.
REPORT FORMAT=AUTOMATIC
  /VARIABLES=WAGE BONUS TENURE
  /BREAK=DEPT (23)
  /SUMMARY=SUM(WAGE BONUS) MEAN(TENURE) 'Sum Income: Mean Tenure'.
```

- SUMMARY defines a summary line consisting of the sums of *WAGE* and *BONUS* and the mean of TENURE. The result of each aggregate function is displayed in the report column of the variable for which the function is calculated.
- A title is assigned to the summary line. A width of 23 is defined for the break column to accommodate the title for the summary line.

Composite Functions

Use composite functions to obtain statistics based on aggregated statistics, to place a summary statistic in a column other than that of the report variable for which it was calculated, or to manipulate variables not named on VARIABLES.

- Composite functions can be computed for the following aggregate functions: VALIDN, SUM, MIN, MAX, MEAN, STDEV, VARIANCE, KURTOSIS, SKEWNESS, PGT, PLT, and PIN. Constants can also be arguments to composite functions.
- When used within composite functions, aggregate functions can have only one variable as an argument.
- A composite function and its arguments cannot be separated by other SUMMARY specifications.
- The result of a composite function can be placed in any report column, including columns of dummy or string variables, by specifying a target column. To specify a target column, enclose the variable name of the column in parentheses after the composite function and its arguments. By default, the results of a composite function are placed in the report column of the first variable specified on the composite function that is also specified on VARIABLES.
- The format for the result of a composite function can be specified in parentheses after the name of the column location, within the parentheses that enclose the column-location specification.

DIVIDE(arg arg	*Divide the first argument by the second and then multiply the result by the factor if it is specified.*
MULTIPLY(arg	*Multiply the arguments.*
PCT(arg	*The percentage of the first argument over the second.*
SUBTRACT(arg	*Subtract the second argument from the first.*
ADD(arg	*Add the arguments.*
GREAT(arg	*The maximum of the arguments.*
LEAST(arg	*The minimum of the arguments.*
AVERAGE(arg	*The average of the arguments.*

Example

```
SORT CASES BY DEPT.
REPORT FORMAT=AUTOMATIC BRKSPACE(-1)
  /VARIABLES=WAGE BONUS SPACE1 (DUMMY) '' BNFT1 BNFT2 SPACE2 (DUMMY)''
  /BREAK=DEPT

  /SUMMARY=MEAN(WAGE BONUS BNFT1 BNFT2)
       ADD(VALIDN(WAGE)) (SPACE2)

  /SUMMARY=ADD(SUM(WAGE) SUM(BONUS))
        ADD(SUM(BNFT1) SUM(BNFT2)) 'Totals' SKIP(1)

  /SUMMARY=DIVIDE(MEAN(WAGE) MEAN(BONUS)) (SPACE1 (COMMA)(2))
        DIVIDE(MEAN(BNFT1) MEAN(BNFT2)) (SPACE2 (COMMA)(2)) 'Ratios'
        SKIP(1).
```

- VARIABLES defines six report columns. The columns for *WAGE, BONUS, BNFT1,* and *BNFT2* contain aggregate statistics based on those variables. The variables *SPACE1* and *SPACE2* are dummy variables that are created for use as space holders; each is given a blank heading to suppress the default column heading.

- The first SUMMARY computes the means of the variables *WAGE, BONUS, BNFT1,* and *BNFT2*. Because BRKSPACE=-1, this summary line will be placed on the same line as the break value and will have no summary title. The means are displayed in the report column for each variable. SUMMARY also computes the valid number of cases for *WAGE* and places the result in the *SPACE2* column.
- The second SUMMARY adds the sum of *WAGE* to the sum of *BONUS*. Since no location is specified, the result is displayed in the *WAGE* column. In addition, the sum of *BNFT1* is added to the sum of *BNFT2* and the result is placed in the *BNFT1* column. The title for the summary line is *Totals*. One line is skipped before the summary line requested by this SUMMARY subcommand is displayed.
- The third summary line divides the mean of *WAGE* by the mean of *BONUS* and places the result in *SPACE1*. The ratio of the mean of *BNFT1* to the mean of *BNFT2* is displayed in the *SPACE2* column. The results are displayed with commas and two decimal places. The title for the summary line is *Ratios*. One line is skipped before the summary line requested by this SUMMARY subcommand is displayed.

Summary Titles

- You can specify a summary title enclosed in quotes, following the conventions for strings.
- The summary title must be specified after the first function and its arguments. It cannot separate any function from its arguments.
- A summary title can be only one line long.
- A summary title wider than the break column extends into the next break column to the right. If the title is wider than all of the available break columns, it is truncated.
- Only one summary title can be specified per summary line. If more than one is specified, the last is used.
- The summary title is left- or right-justified depending upon whether the break title is left- or right-justified.
- The default location for the summary title is the column of the BREAK variable to which the summary applies. With multiple breaks, you can override the default placement of the title by specifying, in parentheses following the title, the number of the break column in which you want the summary title to be displayed.
- In a report with no break levels, REPORT displays the summary title above the summary line at the left margin.

Table 196-2
Default title for summary lines

Function	Title
VALIDN	N
VARIANCE	Variance
SUM	Sum
MEAN	Mean
STDDEV	StdDev
MIN	Minimum

Function	Title
MAX	Maximum
SKEWNESS	Skewness
KURTOSIS	Kurtosis
PGT(n)	>n
PLT(n)	<n
PIN(min,max)	In n_1 to n_2
FREQUENCY(min,max)	Total
PERCENT(min,max)	Total
MEDIAN(min,max)	Median
MODE(min,max)	Mode

Summary Print Formats

All functions have default formats that are used to display results. You can override these defaults by specifying a format keyword and/or the number of decimal places.

- Any printable formats or the PLAIN keyword can be specified. Format specifications must be enclosed in parentheses.
- For aggregate functions, the format and/or number of decimal places is specified after the variable name, within the parentheses that enclose the variable name. The variable must be explicitly named as an argument.
- For composite functions, the format and/or number of decimal places is specified after the variable name of the column location, within the parentheses that enclose the variable name. The column location must be explicitly specified.
- If the report column is wide enough, SUM, MEAN, STDDEV, MIN, MAX, MEDIAN, MODE, and VARIANCE use DOLLAR or COMMA format if a DOLLAR or COMMA format has been declared for the variable on either the FORMATS or PRINT FORMATS command.
- If the column is not wide enough to display the decimal digits for a given function, REPORT displays fewer decimal places. If the column is not wide enough to display the integer portion of the number, REPORT uses scientific notation if possible, or, if not, displays asterisks.
- An exact value of 0 is displayed with one 0 to the left of the decimal point and as many 0 digits to the right as specified by the format. A number less than 1 in absolute value is displayed without a 0 to the left of the decimal point, except with DOLLAR and COMMA formats.

(PLAIN) *Uses the setting on SET DECIMAL for the thousands separator and decimal delimiter.* PLAIN overrides dictionary formats. This is the default for all functions except SUM, MEAN, STDDEV, MIN, MAX, MEDIAN, MODE, and VARIANCE. For these functions, the default is the dictionary format of the variable for which the function is computed.

(d) *Number of decimal places.*

Example

```
/SUMMARY=MEAN(INCOME (DOLLAR)(2))
```

```
ADD(SUM(INCOME)SUM(WEALTH)) (WEALTH(DOLLAR(2))
```

- SUMMARY displays the mean of *INCOME* with dollar format and two decimal places. The result is displayed in the *INCOME* column.
- The sums of *INCOME* and *WEALTH* are added, and the result is displayed in the *WEALTH* column with dollar format and two decimal places.

Table 196-3
Default print formats for functions

Function	Format type	Width	Decimal places
VALIDN	F	5	0
SUM	Dictionary	Dictionary + 2	Dictionary
MEAN	Dictionary	Dictionary	Dictionary
STDDEV	Dictionary	Dictionary	Dictionary
VARIANCE	Dictionary	Dictionary	Dictionary
MIN	Dictionary	Dictionary	Dictionary
MAX	Dictionary	Dictionary	Dictionary
SKEWNESS	F	5	2
KURTOSIS	F	5	2
PGT	PCT	6	1
PLT	PCT	6	1
PIN	PCT	6	1
MEDIAN	Dictionary	Dictionary	Dictionary
MODE	Dictionary	Dictionary	Dictionary
PERCENT	F	6	1
FREQUENCY	F	5	0
DIVIDE	F	Dictionary	0
PCT	PCT	6	2
SUBTRACT	F	Dictionary	0
ADD	F	Dictionary	0
GREAT	F	Dictionary	0
LEAST	F	Dictionary	0
AVERAGE	F	Dictionary	0
MULTIPLY	F	Dictionary	0

Where DATE formats are specified, functions with the dictionary format type display the DATE formats, using the column width as the display width.

Other Summary Keywords

The following additional keywords can be specified on SUMMARY. These keywords are not enclosed in parentheses.

SKIP(n) *Blank lines before the summary line.* The default is 0. If SKIP is specified for the first SUMMARY subcommand for a BREAK, it skips the specified lines after skipping the number of lines specified for BRKSPACE on FORMAT. Similarly, with case listings SKIP skips *n* lines after the blank line at the end of the listing.

PREVIOUS(n) *Use the SUMMARY subcommands specified for the* n*th BREAK.* If *n* is not specified, PREVIOUS refers to the set of SUMMARY subcommands for the previous BREAK. If an integer is specified, the SUMMARY subcommands from the *n*th BREAK are used. If PREVIOUS is specified, no other specification can be used on that SUMMARY subcommand.

TITLE and FOOTNOTE Subcommands

TITLE and FOOTNOTE provide titles and footnotes for the report.

- TITLE and FOOTNOTE are optional and can be placed anywhere after FORMAT except between the BREAK and SUMMARY subcommands.
- The specification on TITLE or FOOTNOTE is the title or footnote in quotes. To specify a multiple-line title or footnote, enclose each line in quotes and separate the specifications for each line by at least one blank.
- The default REPORT title is the title specified on the TITLE command. If there is no TITLE command specified in your session, the default REPORT title is the first line of the header.
- Titles begin on the first line of the report page. Footnotes end on the last line of the report page.
- Titles and footnotes are repeated on each page of a multiple-page report.
- The positional keywords LEFT, CENTER, and RIGHT can each be specified once. The default is CENTER.
- If the total width needed for the combined titles or footnotes for a line exceeds the page width, REPORT generates an error message.

LEFT *Left-justify titles or footnotes within the report page margins.*

RIGHT *Right-justify titles or footnotes within the report page margins.*

CENTER *Center titles and footnotes within the report page width.*

The following can be specified as part of the title or footnote.

)PAGE *Display the page number right-justified in a five-character field.*

)DATE *Display the current date in the form* dd/mmm/yy, *right-justified in a nine-character field.*

)var *Display this variable's value label at this position.* If you specify a variable that has no value label, the value is displayed, formatted according to its print format. You cannot specify a scratch or system variable or a variable created with the STRING subcommand. If you want to use a variable named *DATE* or *PAGE* in the file, change the variable's name with the RENAME VARIABLES command before you use it on the TITLE or FOOTNOTE subcommands, to avoid confusion with the)PAGE and)DATE keywords.

-)PAGE,)DATE, and)var are specified within quotes and can be mixed with string segments within the quotes.
- A variable specified on TITLE or FOOTNOTE must be defined in the active dataset, but does not need to be included as a column on the report.
- One label or value from each variable specified on TITLE or FOOTNOTE is displayed on every page of the report. If a new page starts with a case listing, REPORT takes the value label from the first case listed. If a new page starts with a BREAK line, REPORT takes the value label from the first case of the new break group. If a new page starts with a summary line, REPORT takes the value label from the last case of the break group being summarized.

Example

```
/TITLE=LEFT 'Personnel Report' 'Prepared on )DATE'
    RIGHT 'Page: )PAGE'
```

- TITLE specifies two lines for a left-justified title and one line for a right-justified title. These titles are displayed at the top of each page of the report.
- The second line of the left-justified title contains the date on which the report was processed.
- The right-justified title displays the page number following the string *Page:* on the same line as the first line of the left-justified title.

MISSING Subcommand

MISSING controls the treatment of cases with missing values.

- MISSING specifications apply to variables named on VARIABLES and SUMMARY and to strings created with the STRING subcommand.
- Missing-value specifications are ignored for variables named on BREAK when MISSING=VAR or NONE. There is one break category for system-missing values and one for each user-missing value.
- The character used to indicate missing values is controlled by the FORMAT subcommand.

VAR — *Missing values are treated separately for each variable.* Missing values are displayed in case listings but are not included in the calculation of summary statistics on a function-by-function basis. This is the default.

NONE — *User-missing values are treated as valid values.* This applies to all variables named on VARIABLES.

LIST[([varlist][n])] — *Cases with the specified number of missing values across the specified list of variables are not used.* The variable list and *n* are specified in parentheses. If *n* is not specified, the default is 1. If no variables are specified, all variables named on VARIABLES are assumed.

Example

```
/MISSING= LIST (XVAR,YVAR,ZVAR 2)
```

- Any case with two or more missing values across the variables *XVAR, YVAR,* and *ZVAR* is omitted from the report.

REREAD

```
REREAD [FILE=file]
       [COLUMN=expression]
```

Example

```
INPUT PROGRAM.
DATA LIST /KIND 10-14 (A).

DO IF (KIND EQ 'FORD').
REREAD.
DATA LIST /PARTNO 1-2 PRICE 3-6 (DOLLAR,2) QUANTITY 7-9.
END CASE.

ELSE IF (KIND EQ 'CHEVY').
REREAD.
DATA LIST /PARTNO 1-2 PRICE 15-18 (DOLLAR,2) QUANTITY 19-21.
END CASE.
END IF.

END INPUT PROGRAM.

BEGIN DATA
111295100FORD
11       CHEVY 295015
END DATA.
```

Overview

REREAD instructs the program to reread a record in the data. It is available only within an INPUT PROGRAM structure and is generally used to define data using information obtained from a previous reading of the record. REREAD is usually specified within a conditional structure, such as DO IF—END IF, and is followed by a DATA LIST command. When it receives control for a case, REREAD places the pointer back to the column specified for the current case and begins reading data as defined by the DATA LIST command that follows.

Options

Data Source. You can use inline data or data from an external file specified on the FILE subcommand. Using external files allows you to open multiple files and merge data.

Beginning Column. You can specify a beginning column other than column 1 using the COLUMN subcommand.

Basic Specification

The basic specification is the command keyword REREAD. The program rereads the current case according to the data definitions specified on the following DATA LIST.

Subcommand Order

Subcommands can be specified in any order.

Syntax Rules

- REREAD is available only within an INPUT PROGRAM structure.
- Multiple REREAD commands can be used within the input program. Each must be followed by an associated DATA LIST command.

Operations

- REREAD causes the next DATA LIST command to reread the most recently processed record in the specified file.
- When it receives control for a case, REREAD places the pointer back to column 1 for the current case and begins reading data as defined by the DATA LIST that follows. If the COLUMN subcommand is specified, the pointer begins reading in the specified column and uses it as column 1 for data definition.
- REREAD can be used to read part of a record in FIXED format and the remainder in LIST format. Mixing FIXED and FREE formats yields unpredictable results.
- Multiple REREAD commands specified without an intervening DATA LIST do not have a cumulative effect. All but the last are ignored.

Examples

Using REREAD to Process Different Record Formats

```
INPUT PROGRAM.
DATA LIST /PARTNO 1-2 KIND 10-14 (A).

DO IF (KIND EQ 'FORD').
REREAD.
DATA LIST /PRICE 3-6 (DOLLAR,2) QUANTITY 7-9.
END CASE.

ELSE IF (KIND EQ 'CHEVY').
REREAD.
DATA LIST /PRICE 15-18 (DOLLAR,2) QUANTITY 19-21.
END CASE.
END IF.
END INPUT PROGRAM.

BEGIN DATA
111295100FORD      CHAPMAN AUTO SALES
121199005VW    MIDWEST VOLKSWAGEN SALES
11 395025FORD      BETTER USED CARS
11       CHEVY 195005        HUFFMAN SALES & SERVICE
11       VW    595020        MIDWEST VOLKSWAGEN SALES
11       CHEVY 295015        SAM'S AUTO REPAIR
11       CHEVY 210 20        LONGFELLOW CHEVROLET
 9555032 VW                  HYDE PARK IMPORTS
END DATA.
LIST.
```

- Data are extracted from an inventory of automobile parts. The automobile part number always appears in columns 1 and 2, and the automobile type always appears in columns 10 through 14. The location of other information such as price and quantity depends on both the part number and the type of automobile.
- The first DATA LIST extracts the part number and type of automobile.
- Depending on the information from the first DATA LIST, the records are reread using one of two DATA LIST commands, pulling the price and quantity from different places.
- The two END CASE commands limit the active dataset to only those cases with part 11 and automobile type Ford or Chevrolet. Without the END CASE commands, cases would be created for other part numbers and automobile types, with missing values for price, quantity, and buyer.

The output from the LIST command is as follows:

```
PARTNO KIND   PRICE QUANTITY

  11   FORD  $12.95    100
  11   FORD   $3.95     25
  11   CHEVY  $1.95      5
  11   CHEVY  $2.95     15
  11   CHEVY  $2.10     20
```

Multiple REREAD Commands for the Same Record

```
INPUT PROGRAM.
DATA LIST      NOTABLE/ CDIMAGE 1-20(A).
REREAD         COLUMN = 6.  /* A, C, and E are in column 6
REREAD         COLUMN = 11. /* B, D, and F are in column 11
DATA LIST      NOTABLE/ INFO 1(A).
END INPUT PROGRAM.
BEGIN DATA
1    A    B
2    C    D
3    E    F
END DATA.
LIST.
```

- Multiple REREAD commands are used without an intervening DATA LIST. Only the last one is used. Thus, the starting column comes from the last REREAD specified and the pointer is reset to column 11.

The output from the LIST command is as follows:

```
CDIMAGE             INFO

1    A    B         B
2    C    D         D
3    E    F         F
```

FILE Subcommand

FILE specifies an external raw data file from which the next DATA LIST command reads data.

- The default file is the file specified on the immediately preceding DATA LIST command.

- If the file specified on FILE is not the default file, the same file must be specified on the next DATA LIST. Otherwise, the FILE subcommand is ignored and the DATA LIST command reads the next record from the file specified on it or, if no file is specified, from the file specified on the previous DATA LIST command.

Example

```
INPUT PROGRAM.
DATA LIST FILE=UPDATE END=#EOF NOTABLE
     /#ID 1-3.                    /*Get rep ID in new sales file.
DATA LIST FILE = SALESREP NOTABLE
     /ID 1-3 SALES 4-11(F,2)
      NEWSALE 12-19(F,2).       /*Get rep record from master file.

LOOP IF #EOF OR (#ID GT ID).  /*If UPDATE ends or no new sales made.
+  COMPUTE NEWSALE = 0.      /*Set NEWSALE to 0
+  END CASE.                 /*Build a case.
+  DATA LIST FILE = SALESREP NOTABLE
     /ID 1-3 SALES 4-11(F,2)
      NEWSALE 12-19(F,2).           /*Continue reading masterfile.
END LOOP

DO IF NOT #EOF.                        /*If new sales made.
+  REREAD FILE=UPDATE COLUMN = 4.      /*Read new sales from UPDATE.
+  DATA LIST FILE=UPDATE
     /NEWSALE 1-8(F,2).
+  COMPUTE SALES=SALES+NEWSALE.      /*Update master file.
END IF.
END CASE.                            /*Build a case.
END INPUT PROGRAM.

LIST.
```

- This example uses REREAD to merge two raw data files (*SALESREP* and *UPDATE*).
- Both files are sorted by sales representative ID number. The *UPDATE* file contains only records for sales representatives who have made new sales, with variables *ID* and *NEWSALE*. The master file *SALESREP* contains records for all sales representatives, with variables *SALES* (which contains year-to-date sales) and *NEWSALE* (which contains the update values each time the file is updated).
- If a sales representative has made no new sales, there is no matching ID in the *UPDATE* file. When *UPDATE* is exhausted or when the ID's in the two files do not match, the loop structure causes the program to build a case with *NEWSALE* equal to 0 and then continue reading the master file.
- When the ID's match (and the *UPDATE* file is not yet exhausted), the REREAD command is executed. The following DATA LIST rereads the record in *UPDATE* that matches the *ID* variable. *NEWSALE* is read from the *UPDATE* file starting from column 4 and *SALES* is updated. Note that the following DATA LIST specifies the same file.
- When the updated base is built, the program returns to the first DATA LIST command in the input program and reads the next ID from the *UPDATE* file. If the *UPDATE* file is exhausted (*#EOF*=1), the loop keeps reading records from the master file until it reaches the end of the file.
- The same task can be accomplished using MATCH FILES. With MATCH FILES, the raw data must be read and saved as SPSS-format data files first.

COLUMN Subcommand

COLUMN specifies a beginning column for the REREAD command to read data. The default is column 1. You can specify a numeric expression for the column.

Specifying a Numeric Expression for the Column

```
INPUT PROGRAM.
DATA LIST /KIND 10-14 (A).
COMPUTE #COL=1.
IF (KIND EQ 'CHEVY') #COL=13.

DO IF (KIND EQ 'CHEVY' OR KIND EQ 'FORD').
REREAD COLUMN #COL.
DATA LIST /PRICE 3-6 (DOLLAR,2) QUANTITY 7-9.
END CASE.
END IF.
END INPUT PROGRAM.
BEGIN DATA
111295100FORD      CHAPMAN AUTO SALES
121199005VW    MIDWEST VOLKSWAGEN SALES
11 395025FORD      BETTER USED CARS
11       CHEVY 195005        HUFFMAN SALES & SERVICE
11       VW    595020        MIDWEST VOLKSWAGEN SALES
11       CHEVY 295015        SAM'S AUTO REPAIR
12       CHEVY 210 20        LONGFELLOW CHEVROLET
 9555032 VW                  HYDE PARK IMPORTS
END DATA.
LIST.
```

- The task in this example is to read *PRICE* and *QUANTITY* for Chevrolets and Fords only. A scratch variable is created to indicate the starting column positions for *PRICE* and *QUANTITY*, and a single DATA LIST command is used to read data for both types of automobiles.
- Scratch variable *#COL* is set to 13 for Chevrolets and 1 for all other automobiles. For Fords, the data begin in column 1. Variable *PRICE* is read from columns 3–6 and *QUANTITY* is read from columns 7–9. When the record is a Chevrolet, the data begins in column 13. Variable *PRICE* is read from columns 15–18 (15 is 3, 16 is 4, and so forth), and *QUANTITY* is read from columns 19–21.

Reading Both FIXED and LIST Input With REREAD

```
INPUT PROGRAM.
DATA LIST    NOTABLE FIXED/ A 1-14(A).  /*Read the FIXED portion
REREAD       COLUMN = 15.
DATA LIST    LIST/ X Y Z.              /*Read the LIST portion
END INPUT PROGRAM.

*  The value 1 on the first record is in column 15.

BEGIN DATA
FIRST RECORD  1 2 3 -1 -2 -3
NUMBER 2      4 5
THE THIRD     6 7 8
#4
FIFTH AND LAST9 10 11
END DATA.
LIST.
```

- Columns 1–14 are read in `FIXED` format. `REREAD` then resets the pointer to column 15. Thus, beginning in column 15, values are read in `LIST` format.
- The second `DATA LIST` specifies only three variables. Thus, the values –1, –2, and –3 on the first record are not read.
- The program generates a warning for the missing value on record 2 and a second warning for the three missing values on record 4.
- On the fifth and last record there is no delimiter between value LAST and value 9. `REREAD` can still read the 9 in `LIST` format.

RESTORE

```
RESTORE
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Overview

RESTORE restores SET specifications that were stored by a previous PRESERVE command. RESTORE and PRESERVE are especially useful when using the macro facility. PRESERVE–RESTORE sequences can be nested up to five levels.

Basic Specification

The only specification is the command keyword. RESTORE has no additional specifications.

Limitations

RESTORE does not restoreSET THREADS and SET MCACHE settings.

Example

```
GET FILE='/data/personnel.sav'.
FREQUENCIES VAR=DIVISION /STATISTICS=ALL.
PRESERVE.
SET WIDTH=90 UNDEFINED=NOWARN BLANKS=000 CASE=UPLOW.
SORT CASES BY DIVISION.
REPORT FORMAT=AUTO LIST /VARS=LNAME FNAME DEPT SOCSEC SALARY
  /BREAK=DIVISION /SUMMARY=MEAN.
RESTORE.
```

- GET reads SPSS-format data file *personnel.sav*.
- FREQUENCIES requests a frequency table and all statistics for variable *DIVISION*.
- PRESERVE stores all current SET specifications.
- SET changes several subcommand settings.
- REPORT requests a report organized by variable *DIVISION*.
- RESTORE reestablishes all the SET specifications that were in effect when PRESERVE was specified.

RMV

```
RMV new variables={LINT (varlist)           }
                  {MEAN (varlist [{,2 }])   }
                  {                {,n }    }
                  {                {ALL}    }
                  {MEDIAN (varlist [{,2 }])}
                  {                 {,n }   }
                  {                 {ALL}   }
                  {SMEAN (varlist)          }
                  {TREND (varlist)          }

   [/new variables=function (varlist [,span])]
```

Table 199-1
Function keywords

LINT	Linear interpolation
MEAN	Mean of surrounding values
MEDIAN	Median of surrounding values
SMEAN	Variable mean
TREND	Linear trend at that point

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
RMV NEWVAR1=LINT(OLDVAR1).
```

Overview

RMV produces new variables by copying existing variables and replacing any system- or user-missing values with estimates computed by one of several methods. You can also use RMV to replace the values of existing variables. The estimated values are computed from valid data in the existing variables. The new or revised variables can be used in any procedure and can be saved in an SPSS-format data file.

Basic Specification

The basic specification is one or more new variable names, an equals sign, a function, and an equal number of existing variables. RMV displays a list of the new variables, the number of missing values replaced, the case numbers of the first and last nonmissing cases, the number of valid cases, and the function used to produce the variables.

Syntax Rules

- The existing variables (and span, if specified) must be enclosed in parentheses.
- The equals sign is required.

- You can specify more than one equation on RMV.
- Equations are separated by slashes.
- You can specify only one function per equation.
- You can create more than one new variable per equation by specifying more than one new variable name on the left and an equal number of existing variables on the right.

Operations

- Each new variable is added to the active dataset.
- If the new variable named already exists, its values are replaced.
- If the new variable named does not already exist, it is created.
- If the same variable is named on both sides of the equation, the new variable will replace the existing variable. Valid values from the existing variable are copied into the new variable, and missing values are replaced with estimates.
- Variables are created in the order in which they are specified on the RMV command.
- If multiple variables are created on a single equation, the first new variable is based on the first existing variable, the second new variable is based on the second existing variable, and so forth.
- RMV automatically generates a variable label for each new variable describing the function and variable used to create it and the date and time of creation.
- The format of a new variable depends on the function specified and on the format of the existing variable.
- RMV honors the TSET MISSING setting that is currently in effect.
- RMV does not honor the USE command.

Limitations

- Maximum 1 function per equation.
- There is no limit on the number of variables created by an equation.
- There is no limit on the number of equations per RMV command.

LINT Function

LINT replaces missing values using linear interpolation. The last valid value before the missing value and the first valid value after the missing value are used for the interpolation.

- The only specification on LINT is a variable or variable list in parentheses.
- LINT will not replace missing values at the endpoints of variables.

Example

```
RMV NEWVAR1=LINT(OLDVAR1).
```

- This example produces a new variable called *NEWVAR1*.
- *NEWVAR1* will have the same values as *OLDVAR1* but with missing values replaced by linear interpolation.

MEAN Function

MEAN replaces missing values with the mean of valid surrounding values. The number of surrounding values used to compute the mean depends on the span.

- The specification on MEAN is a variable or variable list and a span, in parentheses.
- The span specification is optional and can be any positive integer or keyword ALL.
- A span of *n* uses *n* valid cases before and after the missing value.
- If span is not specified, it defaults to 2.
- Keyword ALL computes the mean of all valid values.
- MEAN will not replace missing values if there are not enough valid surrounding cases to satisfy the span specification.

Example

```
RMV B=MEAN(A,3).
```

- This example produces a new variable called *B*.
- *B* will have the same values as variable *A* but with missing values replaced by means of valid surrounding values.
- Each mean is based on six values—that is, the three nearest valid values on each side of the missing value.

MEDIAN Function

MEDIAN replaces missing values with the median of valid surrounding values. The number of surrounding values used to compute the median depends on the span.

- The specification on MEDIAN is a variable or variable list and a span, in parentheses.
- The span specification is optional and can be any positive integer or keyword ALL.
- A span of *n* uses *n* valid cases before and after the missing value.
- If span is not specified, it defaults to 2.
- Keyword ALL computes the median of all valid values.
- MEDIAN will not replace missing values if there are not enough valid surrounding cases to satisfy the span specification.

Example

```
RMV B=MEDIAN(A,3).
```

- This example produces a new variable called *B*.

- *B* will have the same values as *A* but with missing values replaced by medians of valid surrounding values.
- Each median is based on six values—that is, the three nearest valid values on each side of the missing value.

SMEAN Function

SMEAN replaces missing values in the new variable with the variable mean.

- The only specification on SMEAN is a variable or variable list in parentheses.
- The SMEAN function is equivalent to the MEAN function with a span specification of ALL.

Example

```
RMV VAR1 TO VAR4=SMEAN(VARA VARB VARC VARD).
```

- Four new variables (*VAR1*, *VAR2*, *VAR3*, and *VAR4*) are created.
- *VAR1* copies the values of *VARA*, *VAR2* copies *VARB*, *VAR3* copies *VARC*, and *VAR4* copies *VARD*. Any missing values in an existing variable are replaced with the mean of that variable.

TREND Function

TREND replaces missing values in the new variable with the linear trend for that point. The existing variable is regressed on an index variable scaled 1 to *n*. Missing values are replaced with their predicted values.

- The only specification on TREND is a variable or variable list in parentheses.

Example

```
RMV YHAT=TREND(VARY).
```

- This example creates a new variable called *YHAT*.
- *YHAT* has the same values as *VARY* but with missing values replaced by predicted values.

ROC

```
ROC varlist BY varname({varvalue  })
                       {'varvalue'}

[/MISSING = {EXCLUDE**}]
            {INCLUDE  }

[/CRITERIA = [CUTOFF({INCLUDE**})] [TESTPOS({LARGE**}) [CI({95** })]
                    {EXCLUDE  }            {SMALL  }      {value}

             [DISTRIBUTION({FREE** })]]
                           {NEGEXPO}

[/PLOT = [CURVE**[(REFERENCE)]] [NONE]]

[/PRINT = [SE] [COORDINATES]].
```

** Default if subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
ROC
  pred  BY default (1).
```

Overview

ROC produces a receiver operating characteristic (ROC) curve and an estimate of the area under the curve.

Options

Distributional Assumptions. In the CRITERIA subcommand, the user can choose the nonparametric or parametric method to estimate the standard error of the area under the curve. Currently, the bi-negative exponential distribution is the only parametric option.

Optional Output. In addition to an estimate of the area under the ROC curve, the user may request its standard error, a confidence interval, and a *p* value under the null hypothesis that the area under the curve equals 0.5. A table of cutoff values and coordinates used to plot the ROC curve may also be displayed.

Basic Specification

The basic specification is one variable as the test result variable and one variable as the actual state variable with one of its values. ROC uses the nonparametric (distribution-free) method to calculate the area under the ROC curve. The default and minimum output is a chart of the ROC curve and a table of the area under the curve.

Syntax Rules

- Minimum syntax: You always need a test result variable and one actual state variable with one of its values in the ROC command line.
- The test result variable must be numeric, but the state variable can be any type with any format.
- Subcommands can be specified in any order.
- When a subcommand is duplicated, only the last one is honored given that all duplicates have no syntax errors. A syntax warning is issued.
- Within a subcommand, if two or more exclusive or contradictory keywords are given, the latter keywords override the earlier ones. A syntax warning is issued.
- If a keyword is duplicated within a subcommand, it is silently ignored.

Limitations

- Only the nonparametric method and one parametric method are available as the computational options for the standard error of the area under the curve at this moment. In the future, binormal and bilogistic distributions may be added to the parametric option.

Examples

```
ROC
  pred  BY default (1)
  /PLOT = CURVE
  /CRITERIA = CUTOFF(INCLUDE) TESTPOS(LARGE)
              DISTRIBUTION(FREE) CI(95)
  /MISSING = EXCLUDE.
```

- *pred* is the test result variable, and *default* is the actual state variable. The "positive" group is identified by the value 1.
- The PLOT subcommand specifies that the ROC curve chart should be displayed without the diagonal reference line.
- CRITERIA specifies that classification of values of the test result variable as members of the "positive" group includes values greater than or equal to the cutoff values, the standard error of the area under the curve is to be estimated nonparametrically, and the confidence level for the asymptotic interval for the area under the curve is 95.
- MISSING specifies that both user-missing and system-missing values are excluded.
- No optional table output is printed.

varlist BY varname(varvalue)

The varlist specifies one or more test result variables. They must be of numeric type.

The varname separated from the varlist by the word BY specifies the actual state variable. It can be of any type and any format. The user must also specify a varvalue in brackets after the second varname to define the "positive" group of the actual state variable. All other valid state values are assumed to indicate the negative group.

MISSING Subcommand

Cases with system-missing values in the test result variable and the actual state variable are always excluded from the analysis. However, the MISSING subcommand allows the user to redefine the user-missing values to be valid.

EXCLUDE *Exclude both user-missing and system-missing values.* Cases with a system-missing value or a user-missing value in either the test result variable or the actual state variable are excluded from the analysis. This is the active default.

INCLUDE *User-missing values are treated as valid.* Cases with a system-missing value in either the test result variable or the actual state variable are excluded from the analysis.

CRITERIA Subcommand

The CRITERIA subcommand allows the user to decide whether or not the cutoff value is included as the positive test result value, whether or not the larger or smaller value direction of the test result variable indicates the positive test result, the confidence level of the asymptotic confidence interval produced by /PRINT = SE, and the estimation method for the standard error of the area under the curve.

CUTOFF(INCLUDE) *Positive classification of test result values includes the cutoff values.* Note that the positive test result direction is controlled by the TESTPOS keyword. This is the active default.

CUTOFF(EXCLUDE) *Positive classification of test result values excludes the cutoff values.* This distinction leads to the different sets of cutoff values, but none of the output (chart or table) is affected at this moment because the user cannot choose the cutoff values for the classification.

TESTPOS(LARGE) *The user can specify which direction of the test result variable indicates increasing strength of conviction that the subject is test positive.* The larger the test result value is, the more positive the test result is. LARGE is the active default.

TESTPOS(SMALL) *The smaller the test result value is, the more positive the test result is.*

CI(n) *Confidence level in the (two-sided) asymptotic confidence interval of the area.* The user can specify any confidence level in (0, 100) for the asymptotic confidence interval created by /PRINT = SE. The active default parameter value is 95.

DISTRIBUTION(FREE) *The method of calculating the standard error of the area under the curve.* When FREE, the standard error of the area under the curve is estimated nonparametrically—that is, without any distributional assumption.

DISTRIBUTION(NEGEXPO) *The standard error is estimated assuming the bi-negative exponential distribution.* This latter option is valid only when the number of positive actual state observations equals the number of negative actual state observations.

PRINT Subcommand

The PRINT subcommand controls the display of optional table output. Note that the area under the curve is always displayed.

SE *Standard error of the area estimate.* In addition to the standard error of the estimated area under the curve, the asymptotic 95% (or other user-specified confidence level) confidence interval as well as the asymptotic *p* value under the null hypothesis that the true area = 0.5 are calculated. Note that the area under the curve statistic is asymptotically normally distributed.

COORDINATES *Coordinate points of the ROC curve along with the cutoff values.* Pairs of sensitivity and 1 – specificity values are given with the cutoff values for each curve.

PLOT Subcommand

The PLOT subcommand controls the display of chart output.

CURVE(REFERENCE) *The ROC curve chart is displayed.* The keyword CURVE is the active default. In addition, the user has an option to draw the diagonal reference line (sensitivity = 1 – specificity) by the bracketed parameter REFERENCE.

NONE *The ROC curve chart is suppressed.*

SAMPLE

```
SAMPLE {decimal value}
       {n FROM m     }
```

This command does not read the active dataset. It is stored, pending execution with the next command that reads the dataset. For more information, see Command Order on p. 36.

Example

```
SAMPLE .25.
```

Overview

SAMPLE permanently draws a random sample of cases for processing in all subsequent procedures. For a temporary sample, use a TEMPORARY command before SAMPLE.

Basic Specification

The basic specification is either a decimal value between 0 and 1 or the sample size followed by keyword FROM and the size of the active dataset.

- To select an approximate percentage of cases, specify a decimal value between 0 and 1.
- To select an exact-size random sample, specify a positive integer that is less than the file size, and follow it with keyword FROM and the file size.

Operations

- SAMPLE is a permanent transformation.
- Sampling is based on a pseudo-random-number generator that depends on a seed value that is established by the program. On some implementations of the program, this number defaults to a fixed integer, and a SAMPLE command that specifies *n* FROM *m* will generate the identical sample whenever a session is rerun. To generate a different sample each time, use the SET command to reset SEED to a different value for each session. See the SET command for more information.
- If sampling is done by using the *n* FROM *m* method, and the TEMPORARY command is specified, successive samples will not be the same because the seed value changes each time that a random-number series is needed within a session.
- A proportional sample (a sample that is based on a decimal value) usually does not produce the exact proportion that is specified.
- If the number that is specified for *m* following FROM is less than the actual file size, the sample is drawn only from the first *m* cases.
- If the number following FROM is greater than the actual file size, the program samples an equivalent proportion of cases from the active dataset.
- If SAMPLE follows SELECT IF, SAMPLE samples only cases that are selected by SELECT IF.

- If SAMPLE precedes SELECT IF, cases are selected from the sample.
- If more than one SAMPLE command is specified in a session, each command acts on the sample that was selected by the preceding SAMPLE command.
- If N OF CASES is used with SAMPLE, the program reads as many records as required to build the specified *n* cases. It makes no difference whether N OF CASES precedes or follows SAMPLE.

Limitations

SAMPLE cannot be placed in a FILE TYPE-END FILE TYPE or INPUT PROGRAM-END INPUT PROGRAM structure. SAMPLE can be placed nearly anywhere following these commands in a transformation program. For more information, see Commands and Program States on p. 2025..

Examples

Sampling an Approximate Percentage of Cases

```
SAMPLE .25.
```

- This command samples approximately 25% of the cases in the active dataset.

Sampling a Specific Number of Cases

```
SAMPLE 500 FROM 3420.
```

- The active dataset must have 3420 or more cases to obtain a random sample of exactly 500 cases.
- If the file contains fewer than 3420 cases, proportionally fewer cases are sampled.
- If the file contains more than 3420 cases, a random sample of 500 cases is drawn from the first 3420 cases.

Sampling Subgroups

```
DO IF  SEX EQ 'M'.
SAMPLE 1846 FROM 8000.
END IF.
```

- SAMPLE is placed inside a DO IF-END IF structure to sample subgroups differently. Assume that this survey is for 10,000 people in which 80% of the sample is male, while the known universe is 48% male. To obtain a sample that corresponds to the known universe and that maximizes the size of the sample, 1846 (48/52*2000) males and all females must be sampled. The DO IF structure restricts the sampling process to the males.

SAVE

```
SAVE OUTFILE='filespec'

 [/VERSION={3**}]
           {2  }

 [/UNSELECTED=[{RETAIN}]
              {DELETE}

 [/KEEP={ALL**  }] [/DROP=varlist]
        {varlist}

 [/RENAME=(old varlist=new varlist)...]

 [/MAP]  [/{COMPRESSED  }]
           {UNCOMPRESSED}

 [/NAMES]

 [/PERMISSIONS={READONLY }
               {WRITEABLE}
```

**Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
SAVE OUTFILE='/data/empl.sav'.
```

Overview

SAVE produces an SPSS-format data file, which contains data plus a dictionary. The dictionary contains a name for each variable in the data file plus any assigned variable and value labels, missing-value flags, and variable print and write formats. The dictionary also contains document text that was created with the DOCUMENTS command.

XSAVE also creates SPSS-format data files. The difference is that SAVE causes data to be read, while XSAVE is not executed until data are read for the next procedure.

See SAVE TRANSLATE on p. 1675 for information about saving data files that can be used by other programs.

Options

Compatibility with Earlier Releases. You can save a data file that can be read by releases prior to 7.5.

Variable Subsets and Order. You can use the DROP and KEEP subcommands to save a subset of variables and reorder the variables that are saved.

Filtered Cases. If filtering is in effect, you use the UNSELECTED subcommand to specify inclusion or exclusion of filtered cases. By default, all cases are included.

Variable Names. You can use the RENAME subcommand to rename variables as they are copied into the SPSS-format data file.

Variable Map. To confirm the names and order of the variables that are saved in the SPSS-format data file, use the MAP subcommand. MAP displays the variables that are saved in the SPSS-format data file next to their corresponding names in the active dataset.

Data Compression. You can use the COMPRESSED or UNCOMPRESSED subcommand to write the data file in compressed or uncompressed form.

Basic Specification

The basic specification is the OUTFILE subcommand, which specifies a name for the SPSS-format data file to be saved.

Subcommand Order

- Subcommands can be specified in any order.

Syntax Rules

- OUTFILE is required and can be specified only once. If OUTFILE is specified more than once, only the last specified OUTFILE is in effect.
- KEEP, DROP, RENAME, and MAP can each be used as many times as needed.
- Only one of the subcommands COMPRESSED or UNCOMPRESSED can be specified per SAVE command.

Operations

- SAVE is executed immediately and causes the data to be read.
- The new SPSS-format data file dictionary is arranged in the same order as the active dataset dictionary, unless variables are reordered with the KEEP subcommand. Documentary text from the active dataset dictionary is always saved unless it is dropped with the DROP DOCUMENTS command before SAVE.
- New variables that were created by transformations and procedures that occurred prior to the SAVE command are included in the new SPSS-format data file, and variables that were altered by transformations are saved in their modified form. Results of any temporary transformations that immediately precede the SAVE command are included in the file; scratch variables are not included.
- SPSS-format data files are binary files that are designed to be read and written by SPSS only. SPSS-format data files can be edited only with the UPDATE command. Use the MATCH FILES and ADD FILES commands to merge SPSS-format data files.
- The active dataset is still available for transformations and procedures after SAVE is executed.
- SAVE processes the dictionary first and displays a message that indicates how many variables will be saved. After the data are written, SAVE indicates how many cases were saved. If the second message does not appear, the file was probably not completely written.

Examples

Renaming Variables for a Saved Version

```
GET FILE='/hubempl.sav'.
SAVE OUTFILE='/data/empl88.sav' /RENAME=(AGE=AGE88) (JOBCAT=JOBCAT88).
```

- The GET command retrieves the SPSS-format data file *hubempl.sav*.
- The RENAME subcommand renames variable *AGE* to *AGE88* and variable *JOBCAT* to *JOBCAT88*.
- SAVE causes the data to be read and saves a new SPSS-format data file with filename *empl88.sav*. The original SPSS-format data file *hubempl.sav* is not changed.

Performing Temporary Transformations Prior to Saving

```
GET FILE='/data/hubempl.sav'.
TEMPORARY.
RECODE DEPT85 TO DEPT88 (1,2=1) (3,4=2) (ELSE=9).
VALUE LABELS DEPT85 TO DEPT88 1 'MANAGEMENT' 2 'OPERATIONS' 9 'UNKNOWN'.
SAVE OUTFILE='/data/hubtemp.sav'.
CROSSTABS DEPT85 TO DEPT88 BY JOBCAT.
```

- The GET command retrieves the SPSS-format data file *hubempl.sav*.
- The TEMPORARY command indicates that RECODE and VALUE LABELS are in effect only for the next command that reads the data (SAVE).
- The RECODE command recodes values for all variables between and including *DEPT85* and *DEPT88* on the active dataset.
- The VALUE LABELS command specifies new labels for the recoded values.
- The OUTFILE subcommand on SAVE specifies *hubtemp.sav* as the new SPSS-format data file. The *hubtemp.sav* file will include the recoded values for *DEPT85* to *DEPT88* and the new value labels.
- The CROSSTABS command crosstabulates *DEPT85* to *DEPT88* with *JOBCAT*. Because the RECODE and VALUE LABELS commands were temporary, the CROSSTABS output does not reflect the recoding and new labels.
- If XSAVE were specified instead of SAVE, the data would be read only once. Both the saved SPSS-format data file and the CROSSTABS output would reflect the temporary recoding and labeling of the department variables.

OUTFILE Subcommand

OUTFILE specifies the SPSS-format data file to be saved. OUTFILE is required and can be specified only once. If OUTFILE is specified more than once, only the last OUTFILE is in effect.

VERSION Subcommand

VERSION allows you to save a data file that can be opened in releases prior to 7.5. If VERSION is not specified or is specified with no value, the default of 3 is used, which saves the file in a format that cannot be read by releases prior to 7.5. Specify 2 to save a file that is compatible with earlier releases.

Variable Names

For data files with variable names that are longer than eight bytes in version 10.*x* or 11.*x*, unique, eight-byte versions of variable names are used (but the original variable names are preserved for use in release 12.0 or later). In releases prior to version 10.0, the original long variable names are lost if you save the data file.

UNSELECTED Subcommand

UNSELECTED determines whether cases that were excluded on a previous FILTER or USE command are to be retained or deleted in the SPSS-format data file. The default is RETAIN. The UNSELECTED subcommand has no effect when the active dataset does not contain unselected cases.

RETAIN *Retain the unselected cases*. All cases in the active dataset are saved. This setting is the default when UNSELECTED is specified by itself.

DELETE *Delete the unselected cases*. Only cases that meet the FILTER or USE criteria are saved in the SPSS-format data file.

DROP and KEEP Subcommands

DROP and KEEP are used to save a subset of variables. DROP specifies the variables that are not to be saved in the new data file; KEEP specifies the variables that are to be saved in the new data file; variables that are not named on KEEP are dropped.

- Variables can be specified in any order. The order of variables on KEEP determines the order of variables in the SPSS-format data file. The order on DROP does not affect the order of variables in the SPSS-format data file.
- Keyword ALL on KEEP refers to all remaining variables that were not previously specified on KEEP or DROP. ALL must be the last specification on KEEP.
- If a variable is specified twice on the same subcommand, only the first mention is recognized.
- Multiple DROP and KEEP subcommands are allowed. If a variable is specified that is not in the active dataset, or that has been dropped because of a previous DROP or KEEP subcommand, an error results, and the SAVE command is not executed.
- Keyword TO can be used to specify a group of consecutive variables in the active file.

Example

```
GET FILE='/data/personnel.sav'.
COMPUTE TENURE=(12-CMONTH +(12*(88-CYEAR)))/12.
```

```
COMPUTE JTENURE=(12-JMONTH +(12*(88-JYEAR)))/12.
VARIABLE LABELS       TENURE 'Tenure in Company'
                    JTENURE 'Tenure in Grade'.
SAVE OUTFILE='/data/personnel88.sav' /DROP=GRADE STORE
  /KEEP=LNAME NAME TENURE JTENURE ALL.
```

- The variables *TENURE* and *JTENURE* are created by COMPUTE commands and are assigned variable labels by the VARIABLE LABELS command. *TENURE* and *JTENURE* are added to the end of the active dataset.
- DROP excludes variables *GRADE* and *STORE* from file *personnel88.sav*. KEEP specifies that *LNAME*, *NAME*, *TENURE*, and *JTENURE* are the first four variables in file *personnel88.sav*, followed by all remaining variables not specified on DROP. These remaining variables are saved in the same sequence as they appear in the original file.

RENAME Subcommand

RENAME changes the names of variables as they are copied into the new SPSS-format data file.

- The specification on RENAME is a list of old variable names followed by an equals sign and a list of new variable names. The same number of variables must be specified on both lists. Keyword TO can be used in the first list to refer to consecutive variables in the active dataset and can be used in the second list to generate new variable names. The entire specification must be enclosed in parentheses.
- Alternatively, you can specify each old variable name individually, followed by an equals sign and the new variable name. Multiple sets of variable specifications are allowed. The parentheses around each set of specifications are optional.
- RENAME does not affect the active dataset. However, if RENAME precedes DROP or KEEP, variables must be referred to by their new names on DROP or KEEP.
- Old variable names do not need to be specified according to their order in the active dataset.
- Name changes take place in one operation. Therefore, variable names can be exchanged between two variables.
- Multiple RENAME subcommands are allowed.

Examples

```
SAVE OUTFILE='/data/empl88.sav'
  /RENAME AGE=AGE88 JOBCAT=JOBCAT88.
```

- RENAME specifies two name changes for the file *empl88.sav*: The variable *AGE* is renamed to *AGE88*, and the variable *JOBCAT* is renamed to *JOBCAT88.*

```
SAVE OUTFILE='/data/empl88.sav'
  /RENAME (AGE JOBCAT=AGE88 JOBCAT88).
```

- The name changes are identical to the changes in the previous example: *AGE* is renamed to *AGE88*, and *JOBCAT* is renamed to *JOBCAT88*. The parentheses are required with this method.

MAP Subcommand

MAP displays a list of the variables in the SPSS-format data file and their corresponding names in the active dataset.

- The only specification is keyword MAP.
- Multiple MAP subcommands are allowed. Each MAP subcommand maps the results of subcommands that precede it (but not results of subcommands that follow it).

Example

```
GET FILE='/data/hubempl.sav'.
SAVE OUTFILE='/data/empl88.sav' /RENAME=(AGE=AGE88)(JOBCAT=JOBCAT88)
  /KEEP=LNAME NAME JOBCAT88 ALL /MAP.
```

- MAP confirms the new names for *AGE* and *JOBCAT* and the order of variables in the *empl88.sav* file (*LNAME*, *NAME*, and *JOBCAT88*, followed by all remaining variables from the active dataset).

COMPRESSED and UNCOMPRESSED Subcommands

COMPRESSED saves the file in compressed form. UNCOMPRESSED saves the file in uncompressed form. In a compressed file, small integers (from −99 to 155) are stored in one byte instead of the eight bytes that are used in an uncompressed file.

- The only specification is the keyword COMPRESSED or UNCOMPRESSED.
- Compressed data files occupy less disk space than uncompressed data files.
- Compressed data files take longer to read than uncompressed data files.
- The GET command, which reads SPSS-format data files, does not need to specify whether the files that it reads are compressed or uncompressed.
- Only one of the subcommands COMPRESSED or UNCOMPRESSED can be specified per SAVE command. COMPRESSED is usually the default, though UNCOMPRESSED may be the default on some systems.

NAMES Subcommand

For all variable names that are longer than eight bytes, NAMES displays the eight-byte equivalents that will be used if you read the data file into a version prior to release 12.0.

PERMISSIONS Subcommand

The PERMISSIONS subcommand sets the operating system read/write permissions for the file.

READONLY *File permissions are set to read-only for all users.* The file cannot be saved by using the same file name with subsequent changes unless the read/write permissions are changed in the operating system or the subsequent SAVE command specifies PERMISSIONS=WRITEABLE.

WRITEABLE *File permissions are set to allow writing for the file owner.* If file permissions were set to read-only for other users, the file remains read-only for them.

Your ability to change the read/write permissions may be restricted by the operating system.

Data File Compatibility with Previous Releases

A data file saved in Unicode mode (see SET command, Unicode subcommand) cannot be read by versions of SPSS prior to 16.0. To save a Unicode data file in a format that can be read by earlier releases, open the file in code page mode and re-save it. The file will be saved in the encoding based on the current locale setting (see SET command, LOCALE subcommand). Some data loss may occur if the file contains characters not recognized by the current locale.

SAVE DIMENSIONS

This command is available only on Windows operating systems.

```
SAVE DIMENSIONS

  /OUTFILE='filespec'

  /METADATA='filespec'

 [/UNSELECTED=[{RETAIN**}]
               {DELETE}

 [/KEEP={ALL**  }] [/DROP=varlist]
        {varlist}

 [/MAP]
```

**Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Release History

Release 15.0

- Command introduced.

Example

```
SAVE DIMENSIONS
  /OUTFILE='/data/survey.sav'
  /METADATA='/data/survey.mdd'.
```

Overview

SAVE DIMENSIONS produces an SPSS-format data file and a Dimensions metadata file that you can use to read the SPSS data file into Dimensions applications such as mrTables and mrInterview. This is particularly useful when "roundtripping" data between SPSS and Dimensions applications. For example, you can read an mrInterview data source into SPSS, calculate some new variables, and then save the data in a form that can be read by mrTables, without loss of any of the original metadata attributes.

Options

Variable Subsets and Order. You can use the DROP and KEEP subcommands to save a subset of variables and reorder the variables that are saved.

Filtered Cases. If filtering is in effect, you use the UNSELECTED subcommand to specify inclusion or exclusion of filtered cases. By default, all cases are included.

Variable Map. To confirm the names and order of the variables that are saved in the SPSS-format data file, use the MAP subcommand. MAP displays the variables that are saved in the SPSS-format data file next to their corresponding names in the active dataset.

Basic Specification

The basic specification is the OUTFILE subcommand that specifies a name for the SPSS-format data file to be saved and the METADATA subcommand that specifies the name for the Dimensions metadata file.

Subcommand Order

- Subcommands can be specified in any order.

Syntax Rules

- OUTFILE and METADATA are required and can be specified only once.
- KEEP, DROP, MAP, and UNSELECTED are optional.

Operations

For new variables and datasets not created from Dimensions data sources, SPSS variable attributes are mapped to Dimensions metadata attributes in the metadata file according to the methods described in the SPSS SAV DSC documentation in the Dimensions Development Library.

If the active dataset was created from a Dimensions data source:

- The new metadata file is created by merging the original metadata attributes with metadata attributes for any new variables, plus any changes to original variables that might affect their metadata attributes (for example, addition of, or changes to, value labels).
- For original variables read from the Dimensions data source, any metadata attributes not recognized by SPSS are preserved in their original state. For example, SPSS converts grid variables to regular SPSS variables, but the metadata that defines these grid variables is preserved when you save the new metadata file.
- If any Dimensions variables were automatically renamed to conform to SPSS variable naming rules, the metadata file maps the converted names back to the original Dimensions variable names.

The presence or absence of value labels can affect the metadata attributes of variables and consequently the way those variables are read by Dimensions applications. If value labels have been defined for any nonmissing values of a variable, they should be defined for all nonmissing values of that variable; otherwise, the unlabeled values will be dropped when the data file is read by Dimensions.

OUTFILE Subcommand

OUTFILE specifies the SPSS-format data file to be saved.

- OUTFILE is required and can be specified only once.

- File specifications should be enclosed in quotes.
- The standard extension for an SPSS data file is *.sav*. You should explicitly specify the extension; it will not be automatically appended to the file name.

METADATA Subcommand

METADATA specifies the Dimensions metadata file to be saved. See the Operations section of the Overview for more information.

- METADATA is required and can be specified only once.
- File specifications should be enclosed in quotes.
- The standard extension for a Dimensions metadata file is *.mdd*. You should explicitly specify the extension; it will not be automatically appended to the file name.

UNSELECTED Subcommand

UNSELECTED determines whether cases that were excluded on a previous FILTER or USE command are to be retained or deleted in the SPSS-format data file. The default is RETAIN. The UNSELECTED subcommand has no effect when the active dataset does not contain unselected cases. Since the metadata file does not contain case data, this subcommand has no effect on the contents of the metadata file.

RETAIN *Retain the unselected cases*. All cases in the active dataset are saved. This is the default.

DELETE *Delete the unselected cases*. Only cases that meet the FILTER or USE criteria are saved in the SPSS-format data file.

DROP and KEEP Subcommands

DROP and KEEP are used to save a subset of variables. DROP specifies the variables that are not to be saved in the new data file; KEEP specifies the variables that are to be saved in the new data file; variables that are not named on KEEP are dropped.

- Variables can be specified in any order. The order of variables on KEEP determines the order of variables in the SPSS-format data file. The order on DROP does not affect the order of variables in the SPSS-format data file.
- Keyword ALL on KEEP refers to all remaining variables that were not previously specified on KEEP or DROP. ALL must be the last specification on KEEP.
- If a variable is specified twice on the same subcommand, only the first mention is recognized.
- Multiple DROP and KEEP subcommands are allowed. If a variable is specified that is not in the active dataset or that has been dropped because of a previous DROP or KEEP subcommand, an error results, and the SAVE DIMENSIONS command is not executed.

- Keyword TO can be used to specify a group of consecutive variables in the active file.
- If the active dataset was created from a Dimensions data source, any original variables defined as grid or array elements in the Dimensions data source are retained in the metadata file, even if those variables are not included in the SPSS data file. Thus, the original grid or array structure is preserved, but there will be no case data for any variables not included in the SPSS data file.

Example

```
SAVE DIMENSIONS
  /OUTFILE='/data/survey.sav'
  /METADATA='/data/survey.mdd'
  /DROP gridVar7
  /KEEP gridVar1 to gridVar8.
```

Assuming that the order of the variables in the active dataset is *gridVar1*, *gridVar2*, *gridVar3*,...*gridVar8* and that all eight variables are grid variables in the original Dimensions data source, *gridVar7* will be dropped from *survey.sav*, but the original metadata for *gridVar7* will be preserved in *survey.mdd*.

MAP Subcommand

MAP displays a list of the variables in the SPSS-format data file and their corresponding names in the active dataset.

- The only specification is keyword MAP.
- Multiple MAP subcommands are allowed. Each MAP subcommand maps the results of the DROP and KEEP subcommands that precede it (but not results of subcommands that follow it).

Example

```
SAVE DIMENSIONS
  /OUTFILE='/data/survey.sav'
  /METADATA='/data/survey.mdd'
  /DROP var7 /MAP
  /KEEP var1 to var8 /MAP.
```

SAVE MODEL

```
SAVE MODEL OUTFILE='filename'

 [/KEEP={ALL**      }]
        {model names}
        {procedures }

 [/DROP={model names}]
        {procedures }

 [/TYPE={MODEL**}]
        {COMMAND}
```

**Default if the subcommand is omitted.

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Example

```
SAVE MODEL OUTFILE='ACFMOD.DAT'.
```

Overview

SAVE MODEL saves the models that are created by certain procedures in a model file. The saved model file can be read later in the session or in another session with the READ MODEL command.

Options

You can save a subset of models into the file using the DROP and KEEP subcommands. You can use the TYPE subcommand to control whether models are specified by model name or by the name of the procedure that generated them.

Basic Specification

The basic specification is the OUTFILE subcommand followed by a filename.

- By default, SAVE MODEL saves all currently active models in the specified file. Each model that is saved in the file includes information such as the procedure that created it, the model name, the specified variable names, subcommands and specifications used, and parameter estimates. The names of the models are either the default *MOD_n* names or the names that are assigned on the MODEL NAME command. In addition to the model specifications, the TSET settings that are currently in effect are saved.

Subcommand Order

- Subcommands can be specified in any order.

Syntax Rules

- If a subcommand is specified more than once, only the last subcommand is executed.

Operations

- SAVE MODEL is executed immediately.
- Model files are designed to be written and read by specific procedures and should not be edited.
- The active models are not affected by the SAVE MODEL command.
- DATE specifications are not saved in the model file.
- Models are not saved in SPSS data files.
- The following procedures can generate models that can be saved with the SAVE MODEL command: AREG, ARIMA, EXSMOOTH, SEASON, and SPECTRA in the Trends module; ACF, CASEPLOT, CCF, CURVEFIT, PACF, PPLOT, and TSPLOT in the Base system; and WLS and 2SLS in Regression Models.

Limitations

- A maximum of one filename can be specified.
- The READ MODEL command can only read models created by a SAVE MODEL command on the same operating system/platform.

OUTFILE Subcommand

OUTFILE names the file where models will be stored and is the only required subcommand.

- The only specification on OUTFILE is the name of the model file.
- The filename should be enclosed in quotes.
- Only one filename can be specified.
- You can store models in other directories by specifying a fully qualified filename.

KEEP and DROP Subcommands

KEEP and DROP allow you to save a subset of models. By default, all currently active models are saved.

- KEEP specifies models to be saved in the model file.
- DROP specifies models that are not saved in the model file.
- Models can be specified by using individual model names or the names of the procedures that created them. To use procedure names, you must specify COMMAND on the TYPE subcommand.
- Model names are either the default *MOD_n* names or the names that are assigned with MODEL NAME.
- If you specify a procedure name on KEEP, all models that are created by that procedure are saved; on DROP, any models created by that procedure are not included in the model file.
- Model names and procedure names cannot be mixed on a single SAVE MODEL command.

- If more than one KEEP or DROP subcommand is specified, only the last subcommand is executed.
- You can specify the keyword ALL on KEEP to save all models that are currently active. This setting is the default.

Example

```
SAVE MODEL OUTFILE='ACFCCF.DAT'
  /KEEP=ACF1 ACF2.
```

- In this example, only models *ACF1* and *ACF2* are saved in model file *ACFCCF.DAT*.

TYPE Subcommand

TYPE indicates whether models are specified by model name or procedure name on DROP and KEEP.

- One keyword, MODEL or COMMAND, can be specified after TYPE.
- MODEL is the default and indicates that models are specified as model names.
- COMMAND indicates that the models are specified by procedure name.
- TYPE has no effect if KEEP or DROP is not specified.
- The TYPE specification applies only to the current SAVE MODEL command.

Example

```
SAVE MODEL OUTFILE='CURVE1.DAT'
  /KEEP=CURVEFIT
  /TYPE=COMMAND.
```

- This command saves all models that were created by the CURVEFIT procedure into the model file *CURVE1.DAT*.

SAVE TRANSLATE

This command is not available on all operating systems.

```
SAVE TRANSLATE

[{/OUTFILE=file               }]
 {/CONNECT=ODBC connect string}

 [/ENCRYPTED]

 [/TYPE={CSV  }]
        {DB2  }
        {DB3  }
        {DB4  }
        {ODBC }
        {PC   }
        {SAS  }
        {STATA}
        {SYM  }
        {SLK  }
        {TAB  }
        {WKS  }
        {WK1  }
        {WK3  }
        {XLS  }

 [/VERSION={1}]
           {2}
           {3}
           {4}
           {5}
           {6}
           {7}
           {8}
           {12}
           {X}

 [/FIELDNAMES]

 [/CELLS={VALUES}]
         {LABELS}

 [/TEXTOPTIONS [DELIMITER='char'] [QUALIFIER='char']
               [DECIMAL={DOT  }]
                        {COMMA}
               [FORMAT={PLAIN   }]]
                       {VARIABLE}

 [/EDITION={INTERCOOLED}
           {SE         }

 [/PLATFORM={ALPHA}]
            {WINDOWS}
            {UNIX}

 [{/VALFILE=filename}]

 [/TABLE = 'database table name']

 [/SQL = 'SQL statement' [/SQL = 'SQL statement']]

 [{/APPEND }]
  {/REPLACE}

 [/RENAME=(old varlist=new varlist)[(...)]

 [/KEEP={ALL    }]
        {varlist}
```

```
[/DROP=varlist]

[/UNSELECTED=[{RETAIN}]
             {DELETE}

[/MISSING={IGNORE}]
          {RECODE}

[{/COMPRESSED  }]
 {/UNCOMPRESSED}

[/MAP]
```

- OUTFILE is not valid for TYPE=ODBC but is required for all other types.
- CONNECT is required for TYPE=ODBC but is invalid for all other types.
- APPEND, SQL, ENCRYPTED, and TABLE are available only for TYPE=ODBC.
- FIELDNAMES is available for spreadsheet formats and text data formats.
- PLATFORM and VALFILE are available only for TYPE=SAS, and PLATFORM is required.
- CELLS is available for TYPE=XLS /VERSION=8, TYPE=TAB, and TYPE=CSV.
- TEXTOPTIONS is available only for TYPE=TAB and TYPE=CSV.
- EDITION is available only for TYPE=STATA.
- COMPRESSED and UNCOMPRESSED are available only for TYPE=PC.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Release History

Release 14.0

- Value STATA added to list for TYPE subcommand.
- EDITION subcommand introduced for TYPE=STATA.
- SQL subcommand introduced.
- MISSING subcommand introduced.
- Field/column names specified on the RENAME subcommand can contain characters (for example, spaces, commas, slashes, plus signs) that are not allowed in SPSS variable names.
- Continuation lines for connection strings on the CONNECT subcommand do not need to begin with a plus sign.

Release 15.0

- ENCRYPTED subcommand introduced.
- Value CSV added to list for TYPE subcommand.
- TEXTOPTIONS subcommand introduced for TYPE=CSV and TYPE=TAB.

Release 16.0

- VERSION=12 introduced for writing data in Excel 2007 XLSX format with TYPE=XLS.

Example

```
SAVE TRANSLATE OUTFILE='/data/sales.xls'.
```

Overview

SAVE TRANSLATE translates the active dataset into a file that can be used by other software applications. Supported formats are 1-2-3, Symphony, Multiplan, Excel, dBASE II, dBASE III, dBASE IV, tab-delimited text files, comma-delimited text files, SAS, Stata, SPSS/PC+ data files, and ODBC database sources. For ODBC database sources, it can also manipulate database tables.

Options

Variable Subsets. You can use the DROP and KEEP subcommands to specify variables to omit or retain in the resulting file.

Variable Names. You can use the RENAME subcommand to rename variables as they are copied to the external file format. For spreadsheets and text data files, use FIELDNAMES to include the variable names in the file.

Variable Map. To confirm the names and order of the variables that are saved in the resulting file, use the MAP subcommand. MAP displays the variables that are saved in the file next to their corresponding names in the active dataset.

Value Labels. For Excel spreadsheets and tab-delimited and comma-delimited text files, you can use the CELLS subcommand to export value labels rather than values in spreadsheet files. For SAS files, you can use the VALFILE subcommand to create a SAS syntax file containing your data's value labels. For Stata files, value labels for numeric variables are automatically saved as Stata value labels.

Limitations

- A maximum of 2,048 cases can be saved to 1-2-3 Release 1A; a maximum of 8,192 cases can be saved to 1-2-3 Release 2.0 or Symphony files.
- A maximum of 16,384 cases can be saved to Excel 2.1. For Excel 95, Excel 97 and Excel 2007, if the number of cases exceeds the single sheet maximum, multiple sheets are created in the workbook.
- A maximum of 256 variables can be saved to Excel 2.1 Excel 95, and Excel 97; a maximum of 16,000 variables can be saved to Excel 2007.
- A maximum of 65,535 cases and 32 variables can be saved to dBASE II, a maximum of one billion cases (subject to disk space availability) and 128 variables can be saved to dBASE III, and a maximum of one billion cases (subject to disk space availability) and 255 variables can be saved to dBASE IV.
- A maximum of 2,047 variables can be saved to Stata 5–6 and Intercooled Stata 7–8. A maximum of 32,767 variables can be saved to Stata SE 7–8.

Operations

- The active dataset remains available after SAVE TRANSLATE is executed.
- If the active dataset contains more variables than the file can receive, SAVE TRANSLATE writes the maximum number of variables that the file can receive.

Spreadsheets

Variables in the active dataset become columns, and cases become rows in the spreadsheet file.

- If you specify FIELDNAMES, variable names become the first row.
- To save value labels instead of data values, use the CELLS subcommand. For more information, see CELLS Subcommand on p. 1684.
- The resulting spreadsheet file is given the range name of SPSS.
- System-missing values are translated to #NULL! in Excel files.

SPSS formats are translated as follows:

SPSS	1-2-3/Symphony	Excel
Number	Fixed	0.00;#,##0.00;...
COMMA	Comma	0.00;#,##0.00;...
DOLLAR	Currency	$#,##0_);...
DATE	Date	d-mmm-yy
TIME	Time	hh:mm:ss
String	Label	General

dBASE

Variables in the active dataset become fields, and cases become records in the database file.

- Characters that are allowed in variable names, but not in dBASE field names, are translated to colons in dBASE II and underscores in dBASE III and dBASE IV.
- Numeric variables containing the system-missing value are translated to **** in dBASE III and dBASE IV and 0 in dBASE II.
- The width and precision of translated numeric variables are taken from the print format—the total number of characters for the number is taken from the width of the print format, and the number of digits to the right of the decimal point is taken from the decimals in the print format. To adjust the width and precision, use the PRINT FORMATS command before using SAVE TRANSLATE. Values that cannot be converted to the given width and precision are converted to missing values.
- A maximum of 65,535 cases and 32 variables can be saved to dBASE II, a maximum of one billion cases (subject to disk space availability) and 128 variables can be saved to dBASE III, and a maximum of one billion cases (subject to disk space availability) and 255 variables can be saved to dBASE IV.

Variable formats are translated to dBASE formats as follows:

SPSS	dBASE
Number	Numeric
String	Character
Dollar	Numeric
Comma	Numeric

Comma-Delimited (CSV) Text Files

Variables in the active dataset become columns, and cases become rows in the text file.

- If you specify `FIELDNAMES`, variable names are written in the first row.
- To save value labels instead of data values, use the `CELLS` subcommand. For more information, see CELLS Subcommand on p. 1684.
- Use the `TEXTOPTIONS` subcommand to override the default delimiter, qualifier, decimal indicator, or data value formatting. For more information, see TEXTOPTIONS Subcommand on p. 1684.
- System-missing values are translated to a blank space in text files.

Note: Tab characters embedded in string values are preserved as tab characters in the tab-delimited file. No distinction is made between tab characters embedded in values and tab characters that separate values.

Tab-Delimited Text Files

Variables in the active dataset become columns, and cases become rows in the text file.

- If you specify `FIELDNAMES`, variable names are written to the first row.
- To save value labels instead of data values, use the `CELLS` subcommand. For more information, see CELLS Subcommand on p. 1684.
- Use the `TEXTOPTIONS` subcommand to override the default decimal indicator or data value formatting. For more information, see TEXTOPTIONS Subcommand on p. 1684.
- System-missing values are translated to a blank space in text files.

SAS Files

Data can be saved in one of six different SAS data file formats. A SAS transport file is a sequential file that is written in SAS transport format and can be read by SAS with the `XPORT` engine and `PROC COPY` or the `DATA` step.

- Certain characters that are allowed in SPSS variable names are not valid in SAS, such as @, #, and $. These illegal characters are replaced with an underscore when the data are exported.
- SPSS variable names that contain multibyte characters (e.g., Japanese or Chinese characters) are converted to variable names of the general form *Vnnn*, where *nnn* is an integer value.

- SPSS variable labels containing more than 40 characters are truncated when exported to a SAS v6 file.
- Where they exist, SPSS variable labels are mapped to the SAS variable labels. If no variable label exists in the SPSS data, the variable name is mapped to the SAS variable label.
- SAS allows only one value for missing, whereas SPSS allows the definition of numerous missing values. As a result, all missing values in SPSS are mapped to a single missing value in the SAS file.

The following table shows the variable type matching between the original data in SPSS and the exported data in SAS.

SPSS Variable Type	SAS Variable Type	SAS Data Format
Numeric	Numeric	12
Comma	Numeric	12
Dot	Numeric	12
Scientific Notation	Numeric	12
Date	Numeric	Date
Date (Time)	Numeric	Time
Date (Date-Time)	Numeric	DateTime
Dollar	Numeric	12
Custom Currency	Numeric	12
String	Character	$8

Stata Files

- Data can be written in Stata 5–8 format and in both Intercooled and SE format (versions 7 and 8 only).
- Data files that are saved in Stata 5 format can be read by Stata 4.
- The first 80 bytes of variable labels are saved as Stata variable labels.
- For numeric variables, the first 80 bytes of value labels are saved as Stata value labels. For string variables, value labels are dropped.
- For versions 7 and 8, the first 32 bytes of variable names in case-sensitive form are saved as Stata variable names. For earlier versions, the first eight bytes of variable names are saved as Stata variable names. Any characters other than letters, numbers, and underscores are converted to underscores.
- SPSS variable names that contain multibyte characters (for example, Japanese or Chinese characters) are converted to variable names of the general form *Vnnn*, where *nnn* is an integer value.

- For versions 5–6 and Intercooled versions 7–8, the first 80 bytes of string values are saved. For Stata SE 7–8, the first 244 bytes of string values are saved.
- For versions 5–6 and Intercooled versions 7–8, only the first 2,047 variables are saved. For Stata SE 7–8, only the first 32,767 variables are saved.

SPSS Variable Type	Stata Variable Type	Stata Data Format
Numeric	Numeric	g
Comma	Numeric	g
Dot	Numeric	g
Scientific Notation	Numeric	g
Date*, Datetime	Numeric	D_m_Y
Time, DTime	Numeric	g (number of seconds)
Wkday	Numeric	g (1–7)
Month	Numeric	g (1–12)
Dollar	Numeric	g
Custom Currency	Numeric	g
String	String	s

*Date, Adate, Edate, SDate, Jdate, Qyr, Moyr, Wkyr

SPSS/PC+ System Files

Variables are saved as they are defined. The resulting file is given the extension *.sys* if no extension is explicitly specified. The dictionary is saved so that labels, formats, missing value specifications, and other dictionary information are preserved.

ODBC Database Sources

The following rules apply when writing to a database with `TYPE=ODBC`:

- If you specify a table name that does not exist in the database, a new table with that name is created.
- If any case cannot be stored in the database for any reason, an error is returned. Therefore, either all cases are stored or no cases are stored.
- At insert time, a check is performed to see whether the value that is being stored in a column is likely to cause an overflow. If so, the user is warned about the overflow and is informed that a *SYSMIS* is stored instead.
- If any variable names in the active dataset contain characters that are not allowed by the database, they are replaced by an underscore. If this process causes a duplicate variable name, a new variable name is generated.

By default, SPSS variable formats are mapped to database field types based on the following general scheme. Actual database field types may vary, depending on the database.

SPSS Variable Format	Database Field Type
Numeric	Float or Double
Comma	Float or Double
Dot	Float or Double
Scientific Notation	Float or Double
Date	Date or Datetime or Timestamp
Datetime	Datetime or Timestamp
Time, DTime	Float or Double (number of seconds)
Wkday	Integer (1–7)
Month	Integer (1–12)
Dollar	Float or Double
Custom Currency	Float or Double
String	Char or Varchar

- For database Datetime/Timestamp formats that don't allow fractional seconds, fraction seconds in SPSS Datetime values are truncated.
- The default width of Char database data types for SPSS string variables is the defined width of the string variable. If the defined width of the string exceeds the maximum width allowed by the database, the values are truncated to the maximum width, and a warning is issued.
- You can override the default settings by using the SQL subcommand to create or update tables. For more information, see SQL Subcommand on p. 1687.

TYPE Subcommand

TYPE indicates the format of the resulting file.

- TYPE can be omitted for spreadsheet files if the file extension that is named on OUTFILE is the default for the type of file that you are saving.
- TYPE with the keyword DB2, DB3, or DB4 is required for translating to dBASE files.
- TYPE takes precedence over the file extension.

ODBC *Database accessed via ODBC.*

XLS *Excel.*

CSV *Comma-delimited text data files.*

TAB *Tab-delimited text data files.*

SAS *SAS data files and SAS transport files.*

STATA *Stata data files.*

DB2 *dBASE II.*

DB3 *dBASE III or dBASE III PLUS.*

DB4 *dBASE IV.*

WK1	*1-2-3 Release 2.0.*
WKS	*1-2-3 Release 1.4.*
SYM	*Symphony releases.*
SLK	*Multiplan (symbolic format).*
PC	*SPSS/PC+ system files.*

Example

```
SAVE TRANSLATE OUTFILE='PROJECT.XLS' /TYPE=XLS (/VERSION=8).
```

- `SAVE TRANSLATE` translates the active dataset into the Excel workbook file named *PROJECT.XLS*.

VERSION Subcommand

`VERSION` specifies the file version for multiversion applications. For example, this subcommand is necessary to differentiate between different versions of Excel. If `VERSION` is not specified, the lowest supported version number is assumed.

Version	Application
1	Symphony Release 1.0
2	Excel 2.1, Symphony Release 2.0, dBASE II
3	dBASE III or dBASE III PLUS
4	dBASE IV
5	Excel 95 Workbook, Stata 4–5
6	SAS v6, Stata 6
7	SAS v7–8, Stata 7
8	Excel 97–2003 Workbook, Stata 8
12	Excel 2007 Workbook
X	SAS transport file

Example

```
SAVE TRANSLATE OUTFILE='STAFF.XLS' /TYPE=XLS /VERSION=8.
```

- `SAVE TRANSLATE` creates an Excel workbook file in the version 97 format.

OUTFILE Subcommand

`OUTFILE` assigns a name to the file to be saved. The only specification is the name of the file. On some operating systems, file specifications should be enclosed in quotes.

Example

```
SAVE TRANSLATE OUTFILE='STAFF.DBF'/TYPE=DB3.
```

- SAVE TRANSLATE creates a dBASE III file called *STAFF.DBF*. The TYPE subcommand is required to specify the type of dBASE file to save.

FIELDNAMES Subcommand

FIELDNAMES writes variable names to the first row in spreadsheets and tab-delimited and comma-delimited text files.

Example

```
SAVE TRANSLATE OUTFILE='/data/csvfile.csv' /TYPE=CSV /FIELDNAMES.
```

CELLS Subcommand

For TYPE=XLS (/VERSION=8), TYPE=TAB, and TYPE=CSV, the CELLS subcommand specifies whether data values or value labels are saved.

CELLS=VALUES. *Saves data values.* This is the default.

CELLS=LABELS. *Saves value labels instead of values.* For values with no corresponding value label, the value is saved.

Example

```
SAVE TRANSLATE OUTFILE='/data/sales.xls'
  /TYPE=XLS /VERSION=8
  /CELLS=LABELS.
```

TEXTOPTIONS Subcommand

For TYPE=CSV, the TEXTOPTIONS subcommand controls the delimiter and qualifier. For TYPE=CSV and TYPE=TAB, it controls the decimal indicator and the data value formatting. For all other types, this subcommand is ignored.

DELIMITER="char". *Specifies the delimiter (separator) between values.* The value must be a single character (single byte), enclosed in quotes (single or double quotes). The default is either a comma or semicolon, based on the decimal indicator. If the decimal indicator is a period, then the default separator is a comma. If the decimal indicator is a comma, then the default separator is a semicolon. The value cannot be the same as the QUALIFIER or DECIMAL value. This setting only applies for TYPE=CSV. For other types, it is ignored.

QUALIFIER="char". *Specifies the qualifier to use to enclose values that contain the delimiter character.* The default is a double quote. The value must be a single character (single byte), enclosed in quotes (single or double quotes). Values that contain the qualifier character will also be enclosed by the qualifier and qualifiers within the value will be doubled. The value cannot

be the same as the DELIMITER or DECIMAL value. This setting only applies for TYPE=CSV. For other types, it is ignored.

DECIMAL=DOT|COMMA. *Specifies the value to use as the decimal indicator for numeric values.* The default is the current SPSS decimal indicator. This setting has no effect on the decimal indicator used with FORMAT=VARIABLE for comma, dollar, custom currency, and dot formats. (Comma, dollar, and custom currency always use the period as the decimal indicator; dot always uses the comma as the decimal indicator.) The value cannot be the same as the DELIMITER or QUALIFER value. (If DECIMAL=DOT, the default delimiter is a comma; if DECIMAL=COMMA, the default delimiter is a semicolon.)

- **DOT.** *Use a period (.) as the decimal indicator.*
- **COMMA.** *Use a comma (,) as the decimal indicator.*

The default decimal indicator is the current SPSS decimal indicator. The current SPSS decimal indicator can be set with SET LOCALE (which uses the OS locale decimal indicator) or SET DECIMAL and can be shown with SHOW DECIMAL. The TEXTOPTIONS DECIMAL setting overrides the default decimal indicator in the current SAVE TRANSLATE command but does not change the default/current SPSS decimal indicator, and it has no effect on the determination of the default delimiter for TYPE=CSV.

FORMAT=PLAIN|VARIABLE. *Specifies the data formats to use when writing out data values.*

- **PLAIN.** *Remove all "extraneous" formatting from numeric values.* This is the default. For example, a dollar format value of $12,345.67 is written simply as 12345.67 (or 12345,67, depending on the decimal indicator). The number of decimal positions for each value is the number of decimal positions necessary to preserve the entire value (and different values of the same variable may have a different number of decimal positions). Dates are written in the general format mm/dd/yyyy. Times are written in the general format hh:mm:ss.
- **VARIABLE.** *Use the print format for each variable to write data values.* For example, a value of 12345.67 with a print format of DOLLAR10.2 is written as $12,345.67 (and is qualified with double quotes or the user-specified qualifier if a comma is the value delimiter).

Print formats can be set with the PRINT FORMATS or FORMATS commands and displayed with DISPLAY DICTIONARY.

EDITION Subcommand

The EDITION subcommand specifies the edition for Stata files. EDITION only applies to Stata version 7 or later.

INTERCOOLED	Saves the data file in Stata Intercooled format. This setting is the default. Only the first 2,047 variables are saved, and only the first 80 bytes of string values are saved.
SE	Saves the data file in Stata SE format. The first 32,767 variables are saved, and the first 244 bytes of string values are saved.

Example

```
SAVE TRANSLATE OUTFILE='/data/newdata.dta' /TYPE=STATA
```

```
/VERSION=8 /EDITION=SE.
```

This subcommand is ignored for any file types other than Stata version 7 or later.

PLATFORM Subcommand

The PLATFORM subcommand is required for all SAS file types, with the exception of SAS transport files. Enter the keyword corresponding to the platform for which the target SAS file is intended. There is no default value for this command. Choose from the following keywords: WINDOWS, ALPHA, UNIX.

Example

```
SAVE TRANSLATE OUTFILE='STAFF.SD7' /TYPE=SAS /VERSION=7
/PLATFORM=WINDOWS /VALFILE='LABELS.SAS'.
```

VALFILE Subcommand

The VALFILE subcommand, which is available only for SAS file formats, excluding the SAS transport file format, saves value labels to a SAS syntax file. This syntax file is used in conjunction with the saved SAS data file to re-create value labels in SAS.

- The syntax file has an *.sas* file extension.

Example

```
SAVE TRANSLATE OUTFILE='STAFF.SD7' /TYPE=SAS /VERSION=7
/PLATFORM=WINDOWS /VALFILE='LABELS.SAS'.
```

- SAVE TRANSLATE saves the current data as a SAS v7 file and creates a SAS syntax file named *LABELS.SAS*, which contains the value labels for the data.

ODBC Database Subcommands

The CONNECT, ENCRYPTED, TABLE, SQL, and APPEND subcommands are used with TYPE=ODBC.

CONNECT Subcommand

CONNECT identifies the database name and other parameters for TYPE=ODBC.

- The database must already exist. You cannot create a new database with SAVE TRANSLATE (although you can create new tables in an existing database).
- If you are unsure what the connect string should be, you can use the Export to Database Wizard to generate SAVE TRANSLATE command syntax. If the connection string is specified on multiple lines, each line must be enclosed in quotes.

Example

```
SAVE TRANSLATE
```

```
/TYPE=ODBC
/CONNECT
'DSN=MS Access Database;DBQ=C:\examples\data\dm_demo.mdb;'
'DriverId=25;FIL=MS Access;MaxBufferSize=2048;PageTimeout=5;'
/TABLE='mytable'.
```

ENCRYPTED Subcommand

The ENCRYPTED subcommand indicates that the password in the CONNECT string is encrypted. By default, the password is assumed to be unencrypted. Both the Database Wizard and Export to Database Wizard generate encrypted passwords.

The ENCRYPTED subcommand has no additional specifications.

TABLE Subcommand

TABLE identifies the table name for TYPE=ODBC.

- Table names should be enclosed in quotes.
- You can replace an existing table or append new records to an existing table.
- You can create a new table in the database by specifying a table name that does not currently exist in the database.

Example

```
SAVE TRANSLATE
   /TYPE=ODBC
   /CONNECT
   'DSN=MS Access Database;DBQ=C:\examples\data\dm_demo.mdb;'
   'DriverId=25;FIL=MS Access;MaxBufferSize=2048;PageTimeout=5;'
   /TABLE='mytable'.
```

SQL Subcommand

The SQL subcommand provides the ability to issue any SQL directives that are needed in the target database. It can be used, for example, to define joins or alter table properties in the database to include new columns or modify column properties.

- Each SQL statement must be enclosed in quotes.
- You can use multiple lines for a single SQL statement by using multiple quoted strings connected with plus signs (the standard string concatenation symbol).
- Each quoted line cannot exceed 256 characters.
- Multiple SQL statements can be included by using multiple SQL subcommands.
- Table and field specifications in SQL statements refer to tables and fields available in the database, not datasets and variables available in the SPSS session (although in many cases the names may be the same).
- Regardless of the position of the SQL subcommand, the SQL statements are executed last, after all other actions executed by the SAVE TRANSLATE command.

Example: Adding New Columns to an Existing Table

```
SAVE TRANSLATE /TYPE=ODBC
 /CONNECT=
 'DSN=MS Access Database;DBQ=C:\examples\data\dm_demo.mdb;'
 'DriverId=25;FIL=MS Access;MaxBufferSize=2048;PageTimeout=5;'
  /TABLE = 'NewColumn'
  /KEEP ID income_score
  /REPLACE
  /SQL='ALTER TABLE CombinedTable ADD COLUMN income_score REAL'
  /SQL='UPDATE CombinedTable INNER JOIN NewColumn ON ' +
  'CombinedTable.ID=NewColumn.ID SET ' +
  'CombinedTable.income_score=NewColumn.income_score'.
```

- The TABLE, KEEP, and REPLACE subcommands create or replace a table named *NewColumn* that contains two variables: a key variable (*ID*) and a computed score (*income_score*).
- The first SQL subcommand, specified on a single line, adds a column to an existing table that will contain values of the computed variable *income_score*. At this point, all we have done is create an empty column in the existing database table, and the fact that both database tables and the active dataset use the same name for that column is merely a convenience for simplicity and clarity.
- The second SQL subcommand, specified on multiple lines with the quoted strings concatenated with plus signs, adds the *income_score* values from the new table to the existing table, matching rows (cases) based on the value of the key variable *ID*.

The end result is that an existing table is modified to include a new column containing the values of the computed variable.

Example: Specifying Data Types for a New Table

```
SAVE TRANSLATE /TYPE=ODBC
  /CONNECT='DSN=MS Access Database;DBQ=c:\temp\temp.mdb;DriverId=25;FIL=MS'+
  ' Access;MaxBufferSize=2048;PageTimeout=5;'
  /TABLE=tempTable    /REPLACE
  /SQL='CREATE TABLE NewTable(numVar double, intVar integer, dollarVar currency)'
  /SQL='INSERT INTO NewTable(numVar, intVar, dollarVar) SELECT * FROM tempTable'
  /SQL='DROP TABLE tempTable'.
```

- The TABLE subcommand creates a new table that contains variables in the active dataset with the default database data types. In this example, the original variables have SPSS variable formats of F8.2, F4.0, and Dollar10.2 respectively, but the default database type for all three is double.
- The first SQL subcommand creates another new table with data types explicitly defined for each field. At this point, this new table contains no data.
- The second SQL subcommand inserts the data from the *tempTable* into *NewTable*. This does not affect the data types previously defined for *NewTable*, so *intVar* will have a data type of integer and *dollarVar* will have a data type of currency.
- The last SQL subcommand deletes *tempTable*, since it is no longer needed.

APPEND Subcommand

APPEND appends rows (cases) to an existing database table after type and variable name validations. There must be a matching column in the table for each SPSS variable. If a column that can correctly store a variable is not found, a failure is returned. If the table contains more columns than the number of SPSS variables, the command still stores the data in the table. The variable names and column names must match exactly. A variable can be stored in a column as long as the column type is a type that can store values of the variable type. A column of any numeric type (short integer, integer, float, double, etc.) is valid for a numeric variable, and a column of any character type is valid for a string variable.

- APPEND is valid only for TYPE=ODBC.
- APPEND and REPLACE are mutually exclusive.

Note: APPEND can only add rows to a table, not columns. If you want to add columns (fields) to a database table, see the SQL subcommand.

REPLACE Subcommand

REPLACE gives permission to overwrite an existing file (or database table) of the same name. REPLACE takes no further specifications.

- SAVE TRANSLATE will not overwrite an existing file without an explicit REPLACE subcommand. The default behavior is to not overwrite.
- For database tables (TYPE=ODBC), APPEND and REPLACE are mutually exclusive.

Note: For database tables, REPLACE destroys an existing table and replaces it with the data written by the SAVE TRANSLATE command, which may lead to loss of database-specific information, such as the designation of key variables (fields) and data formats. If you want to update an existing table with new values in some existing rows or by adding additional fields to the table, see the SQL subcommand.

UNSELECTED Subcommand

UNSELECTED determines whether cases that were excluded on a previous FILTER or USE command are to be retained or deleted. The default is RETAIN. The UNSELECTED subcommand has no effect when the active dataset does not contain unselected cases.

RETAIN	*Retain the unselected cases*. All cases in the active dataset are saved. This setting is the default when UNSELECTED is specified by itself.
DELETE	*Delete the unselected cases*. Only cases that meet the FILTER or USE criteria are saved.

DROP and KEEP Subcommands

Use DROP or KEEP to include only a subset of variables in the resulting file. DROP specifies a set of variables to exclude. KEEP specifies a set of variables to retain. Variables that are not specified on KEEP are dropped.

- Specify a list of variable, column, or field names separated by commas or spaces.
- KEEP does not affect the order of variables in the resulting file. Variables are kept in their original order.
- Specifying a variable that is not in the active dataset or that has been dropped because of a previous DROP or KEEP subcommand results in an error, and the SAVE command is not executed.

Example

```
SAVE TRANSLATE OUTFILE='ADDRESS.DBF' /TYPE=DB4 /DROP=PHONENO, ENTRY.
```

- SAVE TRANSLATE creates a dBASE IV file named *ADDRESS.DBF*, dropping the variables *PHONENO* and *ENTRY*.

RENAME Subcommand

RENAME changes the names of variables as they are copied into the resulting file.

- The specification on RENAME is a list of old variable names followed by an equals sign and a list of new variable names. The same number of variables must be specified on both lists. The keyword TO can be used in the first list to refer to consecutive variables in the active dataset and can be in the second list to generate new variable names. The entire specification must be enclosed in parentheses.
- Alternatively, you can specify each old variable name individually, followed by an equals sign and the new variable name. Multiple sets of variable specifications are allowed. The parentheses around each set of specifications are optional.
- New names cannot exceed 64 bytes. Characters not allowed in SPSS variable names can be used in new names for the target file, but if the name contains special characters (e.g., spaces, commas, slashes, plus signs) the name must be enclosed in quotes.
- RENAME does not affect the active dataset. However, if RENAME precedes DROP or KEEP, variables must be referred to by their new names on DROP or KEEP.
- Old variable names do not need to be specified according to their order in the active dataset.
- Name changes take place in one operation. Therefore, variable names can be exchanged between two variables.
- Multiple RENAME subcommands are allowed.

Examples

```
SAVE TRANSLATE OUTFILE='STAFF.SYM' VERSION=2 /FIELDNAMES
  /RENAME AGE=AGE88 JOBCAT=JOBCAT88.
```

- RENAME renames the variable *AGE* to *AGE88* and renames *JOBCAT* to *JOBCAT88* before they are copied to the first row of the spreadsheet.

```
SAVE TRANSLATE OUTFILE='STAFF.SYM' VERSION=2 /FIELDNAMES
```

```
/RENAME (AGE JOBCAT=AGE88 JOBCAT88).
```

- The name changes are identical to the changes in the previous example: *AGE* is renamed to *AGE88*, and *JOBCAT* is renamed to *JOBCAT88*. The parentheses are required with this method.

MISSING Subcommand

The MISSING subcommand controls the treatment of user-missing values. By default, user-missing values are treated as regular valid values in the target file.

IGNORE *Treat user-missing values as regular valid values*. This setting is the default.

RECODE *Recode numeric user-missing values to system-missing, and recode string user-missing values to blank spaces*.

MAP Subcommand

MAP displays a list of the variables in the resulting file and their corresponding names in the active dataset.

- The only specification is the keyword MAP.
- Multiple MAP subcommands are allowed. Each MAP subcommand maps the results of subcommands that precede it but not the results of subcommands that follow it.

Example

```
GET FILE=HUBEMPL.
SAVE TRANSLATE OUTFILE='STAFF.SYM' /VERSION=2 /FIELDNAMES
  /RENAME=(AGE=AGE88)(JOBCAT=JOBCAT88).
```

- MAP is specified to confirm that the variable *AGE* is renamed to *AGE88* and *JOBCAT* is renamed to *JOBCAT88*.

SCRIPT

This command is available only on Windows operating systems and applies only to Sax Basic scripts.

```
SCRIPT 'filename' [(quoted string)]
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Overview

SCRIPT runs a script to customize the program or automate regularly performed tasks.

Basic Specification

The basic specification is keyword SCRIPT with a filename. The filename is required. The optional quoted string, enclosed in parentheses, can be passed to the script.

Operations

- SCRIPT runs the specified script. The effect is the same as opening the script file in the Script Editor and running it from there.
- The invoked script is not synchronized with the syntax stream, so any syntax following the SCRIPT command should not assume that the script has completed.

Limitations

This command is available only on Windows operating systems and applies only to Sax Basic scripts.

Running Scripts That Contain Syntax Commands

If a script that is run via the SCRIPT command contains syntax commands, those commands must be run asynchronously. To run commands asynchronously, set the bSync parameter of the ExecuteCommands method to False, as in:

```
Dim objSpssApp as ISpssApp
Dim strCommands as String
Set objSpssApp = CreateObject("SPSS.Application")

' Construct and execute syntax commands:

strCommands = "GET FILE = '/data/bank.sav' " & vbCr
strCommands = strCommands & "Display Dictionary."
objSpssApp.ExecuteCommands strCommands, False
```

SEASON

SEASON is available in the Trends option.

```
SEASON VARIABLES= series names

 [/MODEL={MULTIPLICATIVE**}]
         {ADDITIVE        }

 [/MA={EQUAL   }]
      {CENTERED}

 [/PERIOD=n]

 [/APPLY [='model name']]
```

**Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
SEASON VARIABLES = VARX
  /MODEL=ADDITIVE.
```

Overview

SEASON estimates multiplicative or additive seasonal factors for time series by using any specified periodicity. SEASON is an implementation of the Census Method I, otherwise known as the ratio-to-moving-average method. See (Makridakis, Wheelwright, and McGee, 1983) and (McLaughlin, 1984).

Options

Model Specification. You can specify either a multiplicative or additive model on the MODEL subcommand. You can specify the periodicity of the series on the PERIOD subcommand.

Computation Method. Two methods of computing moving averages are available on the MA subcommand for handling series with even periodicities.

Statistical Output. Specify TSET PRINT=BRIEF to display only the initial seasonal factor estimates. TSET PRINT=DETAILED produces the same output as the default.

New Variables. To evaluate the displayed averages, ratios, factors, adjusted series, trend-cycle, and error components without creating new variables, specify TSET NEWVAR=NONE prior to SEASON. This can result in faster processing time. To add new variables without erasing the values of previous Trends-generated variables, specify TSET NEWVAR=ALL. This saves all new variables that are generated during the current session to the active dataset and may require extra processing time. When the default (TSET NEWVAR=CURRENT) is in effect, only variables from the current procedure are saved to the active dataset, and the suffix #n is used to distinguish variables that are

generated by different series. TSET MXNEWVAR specifies the maximum number of new variables that can be generated by a procedure. The default is 60. The order in which new variables are added to the active dataset's dictionary is *ERR*, *SAS*, *SAF*, and *STC*.

Basic Specification

The basic specification is one or more series names.

- By default, SEASON uses a multiplicative model to compute and display moving averages, ratios, seasonal factors, the seasonally adjusted series, the smoothed trend-cycle components, and the irregular (error) component for each specified series (variable). The default periodicity is the periodicity that is established with TSET PERIOD or DATE.
- Unless the default on TSET NEWVAR is changed prior to the procedure, SEASON creates four new variables, with the following prefixes, for each specified series (these variables are automatically named, labeled, and added to the active dataset):

  SAF. *Seasonal adjustment factors.* These values indicate the effect of each period on the level of the series.

  SAS. *Seasonally adjusted series.* These values are the values that are obtained after removing the seasonal variation of a series.

  STC. *Smoothed trend-cycle components.* These values show the trend and cyclical behavior that are present in the series.

  ERR. *Residual or "error" values.* These values are the values that remain after the seasonal, trend, and cycle components have been removed from the series.

Subcommand Order

- Subcommands can be specified in any order.

Syntax Rules

- VARIABLES can be specified only once.
- Other subcommands can be specified more than once, but only the last specification of each one is executed.

Operations

- The endpoints of the moving averages and ratios are displayed as system-missing in the output.
- Missing values are not allowed anywhere in the series. (You can use the RMV command to replace missing values, use TSET MISSING=INCLUDE to include user-missing values, and use USE to ignore missing observations at the beginning or end of a series. See RMV and USE for more information.)

Limitations

- A maximum of one VARIABLES subcommand is allowed. There is no limit on the number of series that are named on the list.

VARIABLES Subcommand

VARIABLES specifies the series names and is the only required subcommand.

- Each specified series must contain at least four full seasons of data.

MODEL Subcommand

MODEL specifies whether the seasonal decomposition model is multiplicative or additive.

- The specification on MODEL is the keyword MULTIPLICATIVE or ADDITIVE.
- If more than one keyword is specified, only the first keyword is used.
- MULTIPLICATIVE is the default if the MODEL subcommand is not specified or if MODEL is specified without any keywords.

Example

```
SEASON VARIABLES = VARX
  /MODEL=ADDITIVE.
```

- This example uses an additive model for the seasonal decomposition of *VARX*.

MA Subcommand

MA specifies how to treat an even-periodicity series when computing moving averages.

- MA should be specified only when the periodicity is even. When periodicity is odd, the EQUAL method is always used.
- For even-periodicity series, the keyword EQUAL or CENTERED can be specified. CENTERED is the default.
- EQUAL calculates moving averages with a span (number of terms) equal to the periodicity and all points weighted equally.
- CENTERED calculates moving averages with a span (number of terms) equal to the periodicity plus 1 and endpoints weighted by 0.5.
- The periodicity is specified on the PERIOD subcommand.

Example

```
SEASON VARIABLES = VARY
  /MA=CENTERED
  /PERIOD=12.
```

- In this example, moving averages are computed with spans of 13 terms and endpoints weighted by 0.5.

PERIOD Subcommand

PERIOD indicates the size of the period.

- The specification on PERIOD indicates how many observations are in one period or season and can be any positive integer.
- If PERIOD is not specified, the periodicity that is established on TSET PERIOD is in effect. If TSET PERIOD is not specified, the periodicity that is established on the DATE command is used. If periodicity was not established anywhere, the SEASON command will not be executed.

Example

```
SEASON VARIABLES = SALES
  /PERIOD=12.
```

- In this example, a periodicity of 12 is specified for *SALES*.

APPLY Subcommand

APPLY allows you to use a previously defined SEASON model without having to repeat the specifications.

- The only specification on APPLY is the name of a previous model in quotation marks. If a model name is not specified, the model that was specified on the previous SEASON command is used. Model names are either the default *MOD_n* names that are assigned by Trends or the names that are assigned on the MODEL NAME command.
- To change one or more model specifications, specify the subcommands of only those portions that you want to change after the APPLY subcommand.
- If no series are specified on the command, the series that were originally specified with the model that is being reapplied are used.
- To change the series used with the model, enter new series names before or after the APPLY subcommand. If a series name is specified before APPLY, the slash before the subcommand is required.

Example

```
SEASON VARIABLES = X1
  /MODEL=ADDITIVE.
SEASON VARIABLES = Z1
  /APPLY.
```

- The first command specifies an additive model for the seasonal decomposition of *X1*.
- The second command applies the same type of model to series *Z1*.

Example

```
SEASON X1 Y1 Z1
  /MODEL=MULTIPLICATIVE.
SEASON APPLY
  /MODEL=ADDITIVE.
```

- The first command specifies a multiplicative model for the seasonal decomposition of *X1*, *Y1*, and *Z1*.
- The second command applies an additive model to the same three variables.

SELECT IF

```
SELECT IF [(]logical expression[)]
```

The following relational operators can be used in logical expressions:

Symbol	Definition
EQ or =	Equal to
NE or ~= or ¬ = or <>	Not equal to
LT or <	Less than
LE or <=	Less than or equal to
GT or >	Greater than
GE or >=	Greater than or equal to

The following logical operators can be used in logical expressions:

Symbol	Definition
AND or &	Both relations must be true
OR or |	Either relation can be true
NOT	Reverses the outcome of an expression

This command does not read the active dataset. It is stored, pending execution with the next command that reads the dataset. For more information, see Command Order on p. 36.

Example

```
SELECT IF (SEX EQ 'MALE').
```

Overview

`SELECT IF` permanently selects cases for analysis based on logical conditions that are found in the data. These conditions are specified in a *logical expression.* The logical expression can contain relational operators, logical operators, arithmetic operations, and any functions that are allowed in `COMPUTE` transformations. For temporary case selection, specify a `TEMPORARY` command before `SELECT IF`.

Basic Specification

The basic specification is simply a logical expression.

Syntax Rules

- Logical expressions can be simple logical variables or relations, or these expressions can be complex logical tests involving variables, constants, functions, relational operators, and logical operators. The logical expression can use any of the numeric or string functions that are allowed in COMPUTE transformations (see COMPUTE and see Transformation Expressions on p. 63).
- Parentheses can be used to enclose the logical expression. Parentheses can also be used within the logical expression to specify the order of operations. Extra blanks or parentheses can be used to make the expression easier to read.
- A relation can compare variables, constants, or more complicated arithmetic expressions. Relations cannot be abbreviated. For example, (A EQ 2 OR A EQ 5) is valid while (A EQ 2 OR 5) is not valid. Blanks (not commas) must be used to separate relational operators from the expressions that are being compared.
- A relation cannot compare a string variable to a numeric value or variable, or vice versa. A relation cannot compare the result of the logical functions SYSMIS, MISSING, ANY, or RANGE to a number.
- String values that are used in expressions must be specified in quotation marks and must include any leading or trailing blanks. Lowercase letters are considered distinct from uppercase letters.

Operations

- SELECT IF permanently selects cases. Cases that are not selected are dropped from the active dataset.
- The logical expression is evaluated as true, false, or missing. If a logical expression is true, the case is selected; if it is false or missing, the case is not selected.
- Multiple SELECT IF commands that are issued prior to a procedure command must all be true for a case to be selected.
- SELECT IF should be placed before other transformations for efficiency.
- Logical expressions are evaluated in the following order: numeric functions, exponentiation, arithmetic operators, relational operators, and logical operators. Use parentheses to change the order of evaluation.
- If N OF CASES is used with SELECT IF, the program reads as many records as required to build the specified *n* cases. It makes no difference whether N OF CASES precedes or follows SELECT IF.
- System variable $CASENUM is the sequence number of a case in the active dataset. Although it is syntactically correct to use $CASENUM on SELECT IF, it does not produce the expected results. To select a set of cases based on their sequence in a file, create your own sequence variable with the transformation language prior to making the selection (see the Examples on p. 1700).

Missing Values

- If the logical expression is indeterminate because of missing values, the case is not selected. In a simple relational expression, a logical expression is indeterminate if the expression on either side of the relational operator is missing.

- If a compound expression is used in which relations are joined by the logical operator OR, the case is selected if either relation is true, even if the other relation is missing.
- To select cases with missing values for the variables within the expression, use the missing-value functions. To include cases with values that have been declared user-missing, along with other cases, use the VALUE function.

Limitations

SELECT IF cannot be placed within a FILE TYPE-END FILE TYPE or INPUT PROGRAM-END INPUT PROGRAM structure. SELECT IF can be placed nearly anywhere following these commands in a transformation program. For more information, see Commands and Program States on p. 2025.

Examples

Working With Simple Logical Expressions

```
SELECT IF (SEX EQ 'MALE').
```

- All subsequent procedures will use only cases in which the value of *SEX* is MALE.
- Because uppercase and lowercase are treated differently in comparisons of string variables, cases for which the value of *SEX* is male are not selected.

```
SELECT IF (INCOME GT 75000 OR INCOME LE 10000).
```

- The logical expression tests whether a case has a value that is either greater than 75,000 or less than or equal to 10,000. If either relation is true, the case is used in subsequent analyses.

```
SELECT IF (V1 GE V2).
```

- This example selects cases where variable *V1* is greater than or equal to *V2*. If either *V1* or *V2* is missing, the logical expression is indeterminate, and the case is not selected.

```
SELECT IF (SEX = 'F' & INCOME <= 10000).
```

- The logical expression tests whether string variable *SEX* is equal to F and whether numeric variable *INCOME* is less than or equal to 10,000. Cases that meet both conditions are included in subsequent analyses. If either *SEX* or *INCOME* is missing for a case, the case is not selected.

```
SELECT IF (SYSMIS(V1)).
```

- The logical expression tests whether *V1* is system-missing. If it is system-missing, the case is selected for subsequent analyses.

```
SELECT IF (VALUE(V1) GT 0).
```

- Cases are selected if *V1* is greater than 0, even if the value of *V1* has been declared user-missing.

```
SELECT IF (V1 GT 0).
```

- Cases are not selected if *V1* is user-missing, even if the user-missing value is greater than 0.

```
SELECT IF ((V1-15) LE (V2*(-0.001))).
```

- The logical expression compares whether *V1* minus 15 is less than or equal to *V2* multiplied by −0.001. If it is true, the case is selected.

```
SELECT IF ((YRMODA(88,13,0) - YRMODA(YVAR,MVAR,DVAR)) LE 30).
```

- The logical expression subtracts the number of days representing the date *(YVAR*, *MVAR*, and *DVAR*) from the number of days representing the last day in 1988. If the difference is less than or equal to 30, the case is selected.

Understanding and Changing the Order of Evaluation

```
SELECT IF (RECEIV GT DUE AND (REVNUS GE EXPNS OR BALNCE GT 0)).
```

- By default, AND is executed before OR. This expression uses parentheses to change the order of evaluation.
- The program first tests whether variable *REVNUS* is greater than or equal to variable *EXPNS*, or variable *BALNCE* is greater than 0. Second, the program tests whether *RECEIV* is greater than *DUE*. If one of the expressions in parentheses is true and *RECEIV* is greater than *DUE*, the case is selected.
- Without the parentheses, the program would first test whether *RECEIV* is greater than *DUE* and *REVNUS* is greater than or equal to *EXPNS*. Second, the program would test whether *BALNCE* is greater than 0. If the first two expressions are true *or* if the third expression is true, the case is selected.

Selecting Cases Based on Their Sequence in a File

```
COMPUTE  #CASESEQ=#CASESEQ+1.
SELECT IF (MOD(#CASESEQ,2)=0).
```

- This example computes a scratch variable, *#CASESEQ*, containing the sequence numbers for each case. Every other case is selected, beginning with the second case.
- *#CASESEQ* must be a scratch variable so that it is not reinitialized for every case. An alternative is to use the LEAVE command.

Using SELECT IF within a DO IF Structure

```
DO IF  SEX EQ 'M'.
+   SELECT IF PRESTIGE GT 50.
ELSE IF  SEX EQ 'F'.
+   SELECT IF PRESTIGE GT 45.
END IF.
```

- The SELECT IF commands within the DO IF structure select males with prestige scores above 50 and females with prestige scores above 45.

SELECTPRED

SELECTPRED is available in SPSS Server.

```
SELECTPRED dependent variable [(MLEVEL={S})]
                                      {O}
                                      {N}
           [BY factor list] [WITH covariate list]

[/EXCEPT VARIABLES=varlist]

[/SCREENING [STATUS={ON**}]  [PCTMISSING={70**  }]
                    {OFF }               {number}
            [PCTEQUAL={95**  }]  [PCTUNEQUAL={90**  }]

                    {LRCHISQ       }          {number}
                    {CRAMERSV      }
                    {LAMBDA        }
           [SHOWUNSELECTED={0**    }]
                           {integer}

[/MISSING USERMISSING={EXCLUDE**}]
                      {INCLUDE  }

[/PRINT [CPS**]  [EXCLUDED**] [SELECTED**]  [NONE]]
        [SUMMARY**[([PEARSONCHISQ] [LRCHISQ] [CRAMERSV] [LAMBDA])]]

[/PLOT SUMMARY]
```

** Default if the subcommand or keyword is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Release History

Release 14.0

- Command introduced.

Example

```
SELECTPRED response_01.
```

Overview

The SELECTPRED procedure submits a large number of predictor variables and selects a smaller subset for use in predictive modeling procedures. This procedure uses a univariable method that considers each predictor in isolation, as opposed to the multivariable method of selecting procedures that is used by the NAIVEBAYES procedure. The SELECTPRED procedure

supports both categorical and scale dependent variables and accepts very large sets of predictors. SELECTPRED is useful when rapid computing is required.

Options

Methods. The SELECTPRED procedure includes a screening step as well as the univariable predictor selection method.

Missing Values. Cases with missing values for the dependent variable or for all predictors are excluded. The SELECTPRED procedure has an option for treating user-missing values of categorical variables as valid. User-missing values of scale variables are always treated as invalid.

Output. SELECTPRED displays pivot table output by default but offers an option for suppressing most such output. The procedure optionally displays lists of categorical and scale predictors—not a model—by way of global macro variables. These global macro variables can be used to represent the subset of selected predictors in subsequent procedures.

Basic Specification

The basic specification is the SELECTPRED command followed by a dependent variable.

By default, SELECTPRED determines the measurement level of the dependent variable based on its dictionary setting. All other variables in the dataset — except the weight variable if it is defined — are treated as predictors, with the dictionary setting of each predictor determining its measurement level. SELECTPRED performs the screening step and then selects a subset of predictors by using a univariable method. User-missing values are excluded, and default pivot table output is displayed.

Syntax Rules

- All subcommands are optional.
- Only a single instance of each subcommand is allowed.
- An error occurs if a keyword is specified more than once within a subcommand.
- Parentheses, equals signs, and slashes that are shown in the syntax chart are required.
- The command name, subcommand names, and keywords must be spelled in full.
- Empty subcommands are not honored.

Operations

The SELECTPRED procedure begins by excluding the following types of cases and predictors.

- Cases with a missing value for the dependent variable.
- Cases with missing values for all predictors.
- Predictors with missing values for all cases.
- Predictors with the same value for all cases.

A further screening step can be used to exclude the following types of predictors:

- Predictors with a large percentage of missing values.

- Categorical predictors with a large percentage of cases representing a single category.
- Categorical predictors with a large percentage of categories containing one case.
- Scale predictors with a small coefficient of variation (standard deviation divided by mean).

The univariable predictor selection method also ranks each predictor based on its association with the dependent variable and selects the top subset of predictors to use in subsequent modeling procedures. The ranking criterion that is used for any given predictor depends on the measurement level of the dependent variable as well as the measurement level of the predictor.

Categorical Dependent Variable.

- For categorical predictors, the ranking criterion can be the Pearson chi-square p-value, likelihood ratio chi-square p-value, Cramér's *V*, or Lambda.
- For scale predictors, the F p-value from a one-way ANOVA is always used as the criterion.
- For mixed predictors, the categorical predictors use the chi-square p-value or the likelihood ratio chi-square p-value, and the scale predictors use the F p-value from a one-way ANOVA.

Scale Dependent Variable.

- For categorical predictors, the F p-value from a one-way ANOVA is always used as the criterion.
- For scale predictors, the p-value for a Pearson correlation coefficient is always used.
- For mixed predictors, both types of p-values are used, depending on the predictor type.

Frequency Weight

If a `WEIGHT` variable is specified, its values are used as frequency weights by the `SELECTPRED` procedure.

- Cases with missing weights or weights that are less than 0.5 are not used in the analyses.
- The weight values are rounded to the nearest whole numbers before use. For example, 0.5 is rounded to 1, and 2.4 is rounded to 2.

Limitations

`SPLIT FILE` settings are ignored by the `SELECTPRED` procedure.

Examples

```
SELECTPRED response_01
  /EXCEPT VARIABLES=custid response_02 response_03
  /MISSING USERMISSING=INCLUDE.
```

- This analysis specifies *response_01* as the dependent variable.
- All other variables are to be considered as possible predictors, with the exception of *custid*, *response_02*, and *response_03*.

- User-missing values of categorical variables are treated as valid for the purpose of selecting predictors.
- All other settings fall back to their default values.

Variable Lists

The variable lists specify the dependent variable, any categorical predictors (also known as factors), and any scale predictors (also known as covariates).

- The dependent variable must be the first specification on SELECTPRED.
- The dependent variable may not be the weight variable.
- The dependent variable may be followed by the measurement-level specification, which contains, in parentheses, the MLEVEL keyword followed by an equals sign and then S for scale, O for ordinal, or N for nominal. SELECTPRED treats ordinal and nominal dependent variables equivalently as categorical.
- If a measurement level is specified, it temporarily overrides the dependent variable's setting in the data dictionary.
- If no measurement level is specified, SELECTPRED defaults to the dictionary setting.
- If a measurement level is not specified, and no setting is recorded in the data dictionary, a numeric variable is treated as scale and a string variable is treated as categorical.
- A string variable may be defined as ordinal or nominal only.
- The names of the factors, if any, must be preceded by the keyword BY. If BY is specified with no factors, a warning is issued, and the keyword is ignored.
- The names of the covariates, if any, must be preceded by the keyword WITH. If WITH is specified without covariates, a warning is issued, and the keyword is ignored.
- If the dependent variable or the weight variable is specified within a factor list or a covariate list, the variable is ignored in the list.
- All variables that are specified within a factor or covariate list must be unique. If duplicate variables are specified within a list, the duplicates are ignored.
- If duplicate variables are specified across the factor and covariate lists, an error is issued.
- The universal keywords TO and ALL may be specified in the factor and covariate lists.
- If neither BY nor WITH is specified, all variables in the active dataset except the dependent variable, the weight variable, and any variables that are specified on the EXCEPT subcommand, are treated as predictors. If the dictionary setting of a predictor is nominal or ordinal, the predictor is treated as a factor. If the dictionary setting is scale, the predictor is treated as a covariate.
- The dependent variable and factor variables can be numeric or string.
- The covariates must be numeric.

EXCEPT Subcommand

The EXCEPT subcommand lists any variables that the SELECTPRED procedure should exclude from the factor or covariate lists on the command line. This subcommand is useful if the factor or covariate lists contain a large number of variables—specified by using the TO or ALL keyword, for example—but there are a few variables (for example, Case ID) that should be excluded.

- The EXCEPT subcommand ignores duplicate variables, the dependent variable, and variables that are not specified on the command line's factor or covariate lists.
- There is no default variable list on the EXCEPT subcommand.

SCREENING Subcommand

The SCREENING subcommand specifies settings for the screening step, which excludes unsuitable predictors.

STATUS=option *Perform the screening step.* Valid options are ON or OFF. If OFF is specified, any other SCREENING specifications are ignored. The default value is ON.

PCTMISSING=number *Percentage of missing values in a predictor.* If the percentage of cases representing a single category in a predictor is greater than the specified value, the predictor is excluded. The specified value must be a positive number that is less than or equal to 100. The default value is 70.

PCTEQUAL=number *Percentage of cases representing a single category in a categorical predictor.* If the percentage of cases representing a single category in a predictor is greater than the specified value, the predictor is excluded. This setting applies only to categorical predictors. The specified value must be a positive number that is less than or equal to 100. The default value is 95.

PCTUNEQUAL=number *Percentage of categories containing one case in a categorical predictor.* If the percentage of a predictor's categories containing only one case is greater than the specified value, the predictor is excluded. This setting applies only to categorical predictors. The specified value must be a positive number that is less than or equal to 100. The default value is 90.

STDDEV=number *Minimum standard deviation for a scale predictor.* If the standard deviation is less than the specified value, the predictor is excluded. This setting applies only to scale predictors. The specified value must be a non-negative number. The default value is 0, which turns off the standard deviation check.

CV=number *Coefficient of variation for a scale predictor.* A predictor's coefficient of variation is defined as its standard deviation divided by its mean. If the absolute value of the coefficient of variation is less than the specified value, the predictor is excluded. This setting applies only to scale predictors and applies only if the mean is not equal to 0. The specified value must be a positive number. The default value is 0.001.

CRITERIA Subcommand

The CRITERIA subcommand specifies computational settings for the SELECTPRED procedure.

SIZE Keyword

The SIZE keyword specifies the number of predictors to select. Value AUTO indicates that the number should be computed automatically. Alternatively, a positive integer less than the number of unique predictors on the SELECTPRED command may be specified. AUTO is the default.

RANKING Keyword

The RANKING keyword specifies the ranking criterion that is used for categorical predictors if the target is categorical.

PEARSONCHISQ	*Rank predictors based on Pearson chi-square p-value.* Predictors are sorted in ascending order of Pearson chi-square p-values. This criterion is the default.
LRCHISQ	*Rank predictors based on likelihood ratio chi-square p-value.* Predictors are sorted in ascending order of likelihood ratio chi-square p-values.
CRAMERSV	*Rank predictors based on Cramer's* V. Predictors are sorted in descending order of Cramer's *V*. If this criterion is used when the target is categorical but predictors are mixed (that is, some categorical, some scale), the PEARSONCHISQ default is used instead.
LAMBDA	*Rank predictors based on Lambda (asymmetric).* Predictors are sorted in descending order of Lambda. If this criterion is used when the target is categorical but predictors are mixed; that is, some categorical, some scale, then the PEARSONCHISQ default is used instead.

PCUTOFF Keyword

The PCUTOFF keyword specifies the cutoff whenever a p-value is used as a ranking criterion. More particularly, if p-values are used to rank predictors, only those predictors for which the p-value is less than the PCUTOFF value may be selected. A positive number that is less than or equal to 1 may be specified. Specifying 1 turns off the limit on p-values. The default is 0.05.

SHOWUNSELECTED Keyword

The SHOWUNSELECTED keyword specifies a limit on the number of unselected predictors to display in tables and charts. If the specified number *n* is greater than 0, the top *n* unselected predictors are displayed. A non-negative integer may be specified. The default is 0.

TIMER Keyword

The TIMER keyword specifies the maximum number of minutes during which the SELECTPRED procedure can be run. If the time limit is exceeded, the procedure is terminated, and no results are given. Any number that is greater than or equal to 0 may be specified. Specifying 0 turns the timer off completely. The default is 5.

MISSING Subcommand

The MISSING subcommand controls whether user-missing values for categorical variables are treated as valid values. By default, user-missing values for categorical variables are treated as invalid.

- User-missing values for scale variables are always treated as invalid.
- System-missing values for any variables are always treated as invalid.

USERMISSING=EXCLUDE	*User-missing values for categorical variables are treated as invalid.* This setting is the default.
USERMISSING=INCLUDE	*User-missing values for categorical variables are treated as valid values.*

PRINT Subcommand

The PRINT subcommand indicates the tabular output to display. If PRINT is not specified, the default tables are displayed. If PRINT is specified, only the requested tables are displayed.

CPS Keyword

The CPS keyword displays the case processing summary table, which summarizes the number of cases that are included and excluded in the analysis.

EXCLUDED Keyword

The EXCLUDED keyword displays a table of screened predictors. The table lists screened predictors by type (categorical or scale) and reason for being screened. The table includes predictors that are screened due to missing or constant values for all cases, as well as any additional screening that is requested on the SCREENING subcommand.

SUMMARY Keyword

The SUMMARY keyword displays a statistical summary of selected and unselected predictors. Selected predictors are always displayed. The maximum number of unselected predictors that can be displayed is determined by the SHOWUNSELECTED option on the CRITERIA subcommand.

The SUMMARY keyword may be followed, optionally, by one or more ranking criterion keywords in parentheses. When the target is categorical, and predictors are categorical or of mixed type, the RANKING option on the CRITERIA subcommand specifies the ranking criterion actually used by the algorithm to select predictors. The parenthesized list that follows the SUMMARY keyword displays additional ranking criteria for comparative purposes. The criterion that is actually used is always displayed, irrespective of whether it is specified following SUMMARY.

If a parenthesized list follows SUMMARY, then keywords in the list may be given in any order. If a specified keyword is inapplicable, it is ignored, and a warning is issued.

PEARSON-CHISQ	*Display the Pearson chi-square statistics.*
LRCHISQ	*Display the likelihood ratio chi-square statistics.*
CRAMERSV	*Display the Cramer's* V *statistics*.
LAMBDA	*Display the Lambda statistics.*

SELECTED Keyword

The SELECTED keyword displays a table of selected predictors by type (categorical or scale).

NONE Keyword

The NONE keyword suppresses all tabular output except the Notes table and any warnings. This keyword may not be specified with any other keywords.

PLOT Subcommand

The PLOT subcommand and SUMMARY keyword display a chart that summarizes the selected and unselected predictors. Selected predictors are always displayed. The maximum number of unselected predictors that can be displayed is determined by the SHOWUNSELECTED option on the CRITERIA subcommand.

SET

```
SET  [WORKSPACE={6148**}]  [MXCELLS={AUTOMATIC**} ]

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Release History

Release 13.0

- RNG and MTINDEX subcommands introduced.
- Default for MXERRS subcommand increased to 100.
- SORT subcommand introduced.
- LOCALE subcommand introduced.

Release 14.0

- Default for WORKSPACE subcommand increased to 6148.

Release 15.0

- LABELS replaces VALUES as the default for the TNUMBERS subcommand.
- JOURNAL subcommand is obsolete and no longer supported.
- Value EXTERNAL added to list for SORT subcommand, replacing the value SPSS as the default. Value SS is deprecated.

Release 16.0

- MCACHE subcommand introduced.

- THREADS subcommand introduced.
- UNICODE subcommand introduced.

Example

```
SET BLANKS=0/UNDEFINED=NOWARN.
```

Overview

Many of the running options in the program can be tailored to your own preferences with the SET command. The default settings for these options vary from system to system. To display the current settings, use the SHOW command. A setting that is changed by SET remains in effect for the entire working session unless changed again by another SET command. The PRESERVE command saves the current settings so that you can return to them later in the session by using the RESTORE command. PRESERVE and RESTORE are especially useful with the macro facility.

Options

Memory Management. Use the WORKSPACE subcommand to dynamically allocate memory when some procedures indicate memory shortage. Use the MXCELLS subcommand to increase maximum cell numbers for a pivot table.

Output Format. Use the FORMAT subcommand to change the default (F8.2) print and write formats used for numeric variables. Use the TLOOK and CTEMPLATE subcommands to specify a TableLook file and/or a chart template file. (*Note*: TableLooks created in earlier versions of SPSS cannot be used in version 16.0 or later.) Use the ONUMBERS, OVARS, TNUMBERS, and TVARS subcommands to define default display of variables in the outline or pivot tables. Use the TFIT subcommand to specify default column widths.

Samples and Random Numbers. You can use the RNG, SEED, and MTINDEX subcommands to change the random number generator and initialization value.

Output Destination. You can use the ERRORS, MESSAGES, PRINTBACK, and RESULTS subcommands to send error messages, resource-utilization messages, command printback, and the output from your commands to your screen and/or to a file. You can also suppress each of these items by using the keyword NONE.

Journal Files. You can use the JOURNAL subcommand to determine whether the program keeps a journal file during a session. A journal file records the commands that you have entered along with any error or warning messages that are generated by the commands. A modified journal file can be used as a command file in subsequent sessions.

Macro Displays. You can use the MEXPAND, MITERATE, and MNEST subcommands to control macro expansion, the maximum number of loop iterations, and nesting levels within a macro. You can also use the MPRINT subcommands to control the display of the variables, commands, and parameters that a macro uses.

Blanks and Undefined Input Data. You can use the BLANKS subcommand to specify the value that the program should use when it encounters a completely blank field for a numeric variable. You can also use UNDEFINED to turn off the warning message that the program issues when it encounters an invalid value for a numeric variable.

Maximum Warnings. You can use MXWARNS to limit the warning messages for each set of commands that read the data, after which further warnings are suppressed.

Maximum Loops. You can use MXLOOPS to raise or lower the maximum number of iterations that are allowed for the LOOP-END LOOP structure.

Scratch File Compression. You can specify whether scratch files are kept in compressed or uncompressed form using the COMPRESSION subcommand.

Custom Currency Formats. You can customize currency formats for your own applications using the CCA, CCB, CCC, CCD, and CCE subcommands. For example, you can display currency as French francs rather than American dollars.

Cache File. The CACHE subcommand creates a complete copy of the active data file in temporary disk space after a specified number of changes in the active data file. Caching the active data file can improve performance.

Basic Specification

The basic specification is at least one subcommand.

Subcommand Order

Subcommands can be named in any order.

Syntax Rules

- You can specify as many subcommands as needed. Subcommands must be separated by at least one space or slash.
- Only one keyword or argument can be specified for each subcommand.
- SET can be used more than once in the command sequence.
- YES and ON are aliases for each other. NO and OFF are aliases for each other.

Operations

- Settings that are specified on SET remain in effect until they are changed by another SET command or until the current session is ended.
- Each time that SET is used, only the specified settings are changed. All other settings remain at their previous settings or the default.
- Where filenames are specified, they must include the full path. Relative file specifications, file handles, and filenames without a path are not allowed.

Example

```
SET BLANKS=0/UNDEFINED=NOWARN.
```

- BLANKS specifies 0 as the value that the program should use when it encounters a completely blank field for a numeric variable.
- UNDEFINED=NOWARN suppresses the message that is displayed whenever anything other than a number or a blank is encountered as the value for a numeric variable.

WORKSPACE and MXCELLS Subcommands

WORKSPACE allocates more memory for some procedures when you receive a message indicating that the available memory has been used up or indicating that only a given number of variables can be processed. MXCELLS increases the maximum number of cells you can create for a new pivot table when you receive a warning that a pivot table cannot be created because it exceeds the maximum number of cells that are allowed.

- WORKSPACE allocates workspace memory in kilobytes for some procedures that allocate only one block of memory. The default is 6148.
- Do not increase the workspace memory allocation unless the program issues a message that there is not enough memory to complete a procedure.
- Use MXCELLS with caution. Set MXCELLS at a number higher than the limit indicated in the warning message that you receive. After the table is created, restore the number to the default.
- The memory-allocation or cell maximum number increase takes effect as soon as you run the SET command.

Note: The MXMEMORY subcommand is no longer supported.

FORMAT Subcommand

FORMAT specifies the default print and write formats for numeric variables. This default format applies to numeric variables that are defined on DATA LIST in freefield format and to all numeric variables that are created by transformation commands (unless a format is explicitly specified).

- The specification must be a simple F format. The default is F8.2.
- You can use the PRINT FORMATS, WRITE FORMATS, and FORMATS commands to change print and write formats.
- Format specifications on FORMAT are output formats. When specifying the width, enough positions must be allowed so that any punctuation characters, such as decimal points, commas, and dollar signs, can be included.
- If a numeric data value exceeds its width specification, the program still attempts to display some value. The program rounds decimal values, removes punctuation characters, tries scientific notation, and finally, if there is still not enough space, produces asterisks indicating that a value is present but cannot be displayed in the assigned width.

TLOOK and CTEMPLATE Subcommands

TLOOK and CTEMPLATE specify a file that is used to define the table and chart appearance in the output. The default for either command is NONE, which produces tables and charts that use the system defaults.

- TLOOK determines the properties of output tables that are produced. The properties include the borders, placement of titles, column and row labels, text font, and column and cell formats. (*Note*: TableLooks created in earlier versions of SPSS cannot be used in version 16.0 or later.)
- CTEMPLATE determines the properties of output charts and plots. The properties include line style, color, fill pattern, and text font of relevant chart elements (such as frames, titles, labels, and legends).
- The specification on TLOOK or CTEMPLATE remains in effect until a new TLOOK or CTEMPLATE is specified.

NONE *Use the system defaults.* The tables and charts in the output do not use customized properties.

filename *Use the specified file as a template for tables/charts in the output.* You should specify a full path, enclosed in quotes (Directory settings on the CD and INSERT commands do not apply to the template file location).

ONUMBERS, OVARS, TNUMBERS, and TVARS Subcommands

ONUMBERS, OVARS, TNUMBERS, and TVARS control how variables are displayed in the outline for pivot table output and in the pivot tables.

- ONUMBERS controls the display of variable values in the outline for pivot tables. The default is LABELS.
- OVARS controls the display of variables in the outline for pivot tables. The default is LABELS.
- TNUMBERS controls the display of variable values and/or value labels in the pivot tables. The default is LABELS.
- TVARS controls the display of variable names and/or variable labels in the pivot tables. The default is LABELS.

NAMES *Display variable names.*

VALUES *Display variable values.*

LABELS *Display variable labels.*

BOTH *Display both labels and values for variables or both names and labels for variables.*

TFIT Subcommand

TFIT controls the default column widths of the pivot tables. The default at installation is BOTH.

BOTH *Adjust column widths to accommodate both labels and data.*

LABELS *Adjust column widths to accommodate labels only.* This setting produces compact tables, but data values that are wider than labels will be displayed as asterisks.

RNG, SEED, and MTINDEX Subcommands

Two random number generators are available. The generator that is currently in effect is set by the RNG subcommand:

RNG=MC *The random number generator that is used in version 12 and previous releases.* If you need to reproduce randomized results that were generated in previous releases based on a specified seed value, use this random number generator. This setting is the default.

RNG=MT *Mersenne Twister random number generator.* This generator is a newer random number generator that is more reliable for simulation purposes. If reproducing randomized results from version 12 or earlier is not an issue, use this random number generator.

If you need to reproduce the same randomized results in the future, you can set the initialization value for the random number generator:

SEED={integer | RANDOM} *Initialization value for MC random number generator*. The value must be a positive integer that is less than 2,000,000,000 or the keyword RANDOM, which randomly sets the initialization value. The default is 2,000,000.

MTINDEX={value | RANDOM} *Initialization value for the MT random number generator.* The value can be any positive or negative value, including fractional values (expressed as decimals), or the keyword RANDOM. The default is 2,000,000.

Example

```
SET RNC=MT MTINDEX=-12345.678.
```

EPOCH Subcommand

EPOCH defines the 100-year-span dates that are entered with two-digit years and date functions with a two-digit year specification.

AUTOMATIC *100-year span beginning 69 years prior to the current date and ending 30 years after the current date.*

begin year *First year of the 100-year span.*

Examples

```
SET EPOCH=1900.
```

- All dates that are entered with two-digit year values are read as years between 1900 and 1999. For example, a date that is entered as 10/29/87 is read as 10/29/1987.

```
SET EPOCH=1980.
```

- Dates that are entered with two-digit year values between 80 and 99 are read as years between 1980 and 1999.
- Dates that are entered with two-digit year values between 00 and 79 are read as years between 2000 and 2079.

ERRORS, MESSAGES, RESULTS, and PRINTBACK Subcommands

ERRORS, MESSAGES, RESULTS, and PRINTBACK are used with keywords LISTING and NONE to route program output. ERRORS, MESSAGES, and RESULTS apply only to text output. PRINTBACK applies to all commands that are entered in a syntax window or generated from a dialog box during a session.

- ERRORS refers to both error messages and warning messages for text output.
- MESSAGES refers to resource-utilization messages that are displayed with text output, including the heading and the summaries (such as the amount of memory that is used by a command).
- RESULTS refers to the text output that is generated by program commands.
- PRINTBACK refers to command printback in the journal file. Syntax is always displayed as part of the Notes in the syntax window.

LISTING *Display output in the designated output window.* This alias is ON or YES. For PRINTBACK, the alias is BOTH. The executed commands are printed back in the journal and displayed in the log in the output window. You can either display an icon only or list all commands.

NONE *Suppress the output.* The alias is NO or OFF.

The default routes vary from operating system to operating system and vary according to the way commands are executed. In windowed environments, the typical defaults are:

Subcommand	Windowed Environments
ERRORS	LISTING
MESSAGES	NONE
PRINTBACK	BOTH
RESULTS	LISTING

JOURNAL Subcommand

This subcommand is obsolete and no longer supported. To set the location of the journal file, which contains a log of submitted commands and error and warning messages that are generated during a session, and turn the journal on and off:

▶ From the menus in any SPSS window, choose:

Edit
Options

▶ On the File Locations tab, specify the journal location and select journal options.

MEXPAND and MPRINT Subcommands

MEXPAND and MPRINT control whether macros are expanded and whether the expanded macros are displayed. For more information about macros, see the DEFINE command and Using the Macro Facility on p. 2045.

The specifications for MEXPAND are:

ON *Expand macros.* This setting is the default.

OFF *Do not expand macros.* The command line that calls the macro is treated like any other command line. If the macro call is a command, it will be executed; otherwise, it will trigger an error message.

The specifications for MPRINT are:

ON *Include expanded macro commands in the output.*

OFF *Exclude expanded macro commands from the output.* This is the default.

- MPRINT is effective only when MEXPAND is ON and is independent of the PRINTBACK subcommand.

MITERATE and MNEST Subcommands

MITERATE and MNEST control the maximum loop traversals and the maximum nesting levels permitted in macro expansions, respectively.

- The specification on MITERATE or MNEST is a positive integer. The default for MITERATE is 1000. The default for MNEST is 50.

BLANKS Subcommand

BLANKS specifies the value that the program should use when it encounters a completely blank field for a numeric variable. By default, the program uses the system-missing value.

- BLANKS controls only the translation of numeric fields. If a blank field is read with a string format, the resulting value is a blank.
- The value that is specified on BLANKS is not automatically defined as a missing value.
- The BLANKS specification applies to all numeric variables. You cannot use different specifications for different variables.
- BLANKS must be specified before data are read. Otherwise, blanks in numeric fields are converted to the system-missing value (the default) as they are read.

UNDEFINED Subcommand

UNDEFINED controls whether the program displays a warning message when it encounters anything other than a number or a blank as the value for a numeric variable. The default is WARN.

WARN *Display a warning message when an invalid value is encountered for a numeric variable.* This setting is the default.

NOWARN *Suppress warning messages for invalid values.*

MXERRS Subcommand

MXERRS controls the maximum number of errors that are allowed in a session. The default is 100.

- MXERRS applies only to command files that are submitted for execution through SPSSB (a batch-processing facility that is available with SPSS Server).
- Eligible errors are errors that stop execution of a command but continue the session.
- When the MXERRS limit is exceeded, SPSS stops processing commands but continues to scan for additional errors.
- In interactive mode or in SPSS and other windowed environments, MXERRS does not apply.

MXWARNS Subcommand

MXWARNS controls the number of warnings that are issued. The default is 10. The behavior of this setting depends on mode of operation: interactive or SPSSB. In this context, "interactive" includes any mode of operation other than SPSSB.

Interactive. In interactive mode, MXWARNS limits the number of warnings that are issued for each set of commands that read the data (for example, a group of transformation commands followed by a statistical procedure).

- Exceeding the limit does not halt execution of commands; it simply suppresses further warnings.
- MXWARNS=0 suppresses all warnings except a warning that further warnings have been suppressed.
- MXWARNS does not affect the display of error messages, and errors do not count toward the warning limit.

SPSSB. In SPSSB (a batch-processing facility that is available with SPSS Server), MXWARNS limits the total number of warnings that are allowed in a job.

- When the MXWARNS limit is exceeded, SPSS stops processing commands but continues to scan for errors.
- When the combined total number of warnings and errors exceeds the MXWARNS limit, SPSS stops processing commands but continues to scan for errors.

MXLOOPS Subcommand

MXLOOPS specifies the maximum number of times that a loop that is defined by the LOOP–END LOOP structure is executed for a single case or input record. The default is 40.

- MXLOOPS prevents infinite loops, which may occur if no cutoff is specified for the loop structure (see LOOP–END LOOP).

- MXLOOPS will limit the number of loops for any loop structure that doesn't have an indexing clause, including loops with conditional IF clauses. If a loop has an indexing clause (e.g., LOOP #i=1 to 1000), the indexing clause overrides the MXLOOPS setting.
- When a loop is terminated, control passes to the command immediately following the END LOOP command, even if the END LOOP condition is not yet met.

EXTENSIONS Subcommand

This subcommand is no longer supported.

COMPRESSION Subcommand

COMPRESSION determines whether scratch files that are created during a session are in compressed or uncompressed form.

- A compressed scratch file occupies less space on disk than an uncompressed scratch file but requires more processing.
- The specification takes effect the next time that a scratch file is written and stays in effect until SET COMPRESSION is specified again or until the end of the session.
- The default setting varies. Use SHOW to display the default on your system.

YES *Compress scratch files.*

NO *Do not compress scratch files.*

BLOCK Subcommand

BLOCK specifies the character that is used for drawing icicle plots.

- You can specify any single character either as a quoted string or as a quoted hexadecimal pair preceded by the character *X*.
- The default is X'2A'.

Example

```
SET BLOCK='#'.
```

- This command specifies a pound sign (#) as the character to be used for drawing bar charts. The character is specified as a quoted string.

BOX Subcommand

BOX specifies the characters that are used to draw table borders in text output. The specification is either a 3-character or 11-character quoted string, in which the characters have the following representations:

1	horizontal line	7	upper right corner
2	vertical line	8	left T
3	middle (cross)	9	right T
4	lower left corner	10	top T
5	upper left corner	11	bottom T
6	lower right corner		

- The characters can be specified either as a quoted string or hexadecimal pairs. Specify an *X* before the quoted hexadecimal pairs.
- The defaults vary from system to system. To display the current settings, use the SHOW command.

LENGTH and WIDTH Subcommands

LENGTH and WIDTH specify the maximum page length and width for the output, respectively. The default for LENGTH is 59 lines; the default for WIDTH is 80. These two subcommands apply only to text output.

- The page length includes the first printed line on the page through the last line that can be printed. The printer that you use most likely includes a margin at the top; that margin is not included in the length that is used by this program. The default, 59 lines, allows for a 1/2-inch margin at the top and bottom of an 11-inch page printed with 6 lines per inch or an 8 1/2-inch page that is printed with 8 lines per inch.
- You can specify any length from 40 through 999,999 lines. If a long page length is specified, the program continues to provide page ejects and titles at the start of each procedure and at logical points in the display, such as between crosstabulations.
- To suppress page ejects, use keyword NONE on LENGTH. The program will insert titles at logical points in the display but will not supply page ejects.
- You can specify any number of characters from 80 through 255 for WIDTH. The specified width does not include the carriage control character. All procedures can fit the output to an 80-column page by using a 10-pt. fixed-pitch font.

HEADER Subcommand

HEADER controls whether the output includes headings. The HEADER subcommand applies to both default headings and headings that are specified on the TITLE and SUBTITLE commands. This command applies only to text output from this program. The default is NO.

NO *Suppress headings in text output.* All general headings, including pagination, are replaced by a single blank line.

YES *Display headings in text output.*

BLANK *Suppress headings but start a new page.*

CCA, CCB, CCC, CCD, and CCE Subcommands

You can use the subcommands CCA, CCB, CCC, CCD, and CCE to specify up to five custom currency formats.

- Each custom currency subcommand defines one custom format and can include four specifications in the following order: a negative prefix, a prefix, a suffix, and a negative suffix.
- The specifications are delimited by either periods or commas, whichever you do not want to use as a decimal point in the format.
- If your custom currency format includes periods or commas that you need to distinguish from delimiters, use a single quotation mark as an escape character before the period or comma that is part of the custom currency format. For example, if the format includes a period but the decimal indicator is a comma, the period must also be used as the delimiter.
- Each currency specification must always contain three commas or three periods. All other specifications are optional.
- Use blanks in the specification only where you want blanks in the format.
- The entire specification must be enclosed in single or double quotation marks. If the format includes a single quotation mark as an escape character, the entire specification must be enclosed in double quotation marks.
- A specification cannot exceed 16 characters (excluding the apostrophes).
- Custom currency formats cannot be specified as input formats on DATA LIST. Use them only as output formats in the FORMATS, WRITE FORMATS, PRINT FORMATS, WRITE, and PRINT commands.

Specifying a Custom Currency Format

```
SET CCA='-,$,,'.
```

- A minus sign (-) preceding the first command is used as the negative prefix.
- A dollar sign is specified for the prefix.
- No suffixes are specified (there are two consecutive commas before the closing apostrophe).
- Because commas are used as separators in the specification, the decimal point is represented by a period.

Specifying Multiple Custom Currency Formats

```
SET CCA='(,,,-)'  CCB=',,%,' CCC='(,$,,)' CCD='-/-.Dfl ..-'.
FORMATS VARA(CCA9.0)/ VARB(CCB6.1)/ VARC(CCC8.0)/ VARD(CCD14.2).
```

- SET defines four custom currency formats.
- FORMATS assigns these formats to specific variables.

Table 210-1
Custom currency examples

	CCA	CCB	CCC	CCD
negative prefix	(	none	(	–/–
prefix	none	none	$	Dfl
suffix	none	%	none	none
negative suffix	–)	none	)	–
separator	,	,	,	.
sample positive number	23,456	13.7%	$352	Dfl 37.419,00
sample negative number	(19,423–)	13.7%	($189)	–/–Dfl 135,19–

DECIMAL Subcommand

DECIMAL can be used to override the default decimal indicator. The default decimal indicator is the OS locale decimal indicator or the decimal indicator for the locale specified on the LOCALE subcommand.

DOT. The decimal indicator is a period.

COMMA. The decimal indicator is a comma.

A subsequent LOCALE subcommand—either on the same or separate SET command—will override the DECIMAL setting. For more information, see LOCALE Subcommand on p. 1725.

CACHE Subcommand

The CACHE subcommand creates a complete copy of the active data file in temporary disk space after a specified number of changes in the active data file. If you have the available disk space, this feature can improve performance. The default number of changes that can occur before the active file is cached is 20.

Example

```
SET CACHE 10.
```

SMALL Subcommand

The SMALL subcommand controls the display of numbers in scientific notation in output for small decimal values.

Example

```
SET SMALL = 0.

SET SMALL = .001.
```

- The first SET SMALL command suppresses the display of scientific notation in all output.
- The second SET SMALL command will only display scientific notation for values that are less than 0.001.

OLANG Subcommand

The OLANG subcommand controls the language that is used in output. OLANG does not apply to simple text output. Available languages may vary. (The General tab in the Options dialog box displays a list of available output languages.) Valid language keywords include ENGLISH, FRENCH, GERMAN, SPANISH, ITALIAN, JAPANESE, KOREAN, and CHINESE. Additional valid language keywords may include POLISH and RUSSIAN.

Output that is produced after the command is executed will be in the specified language (if that language is available). Additional language materials may be available for downloading from the SPSS Web site.

Example

```
SET OLANG = GERMAN.
```

- The language keyword is not case-sensitive.
- Do *not* enclose the language keyword in quotation marks or other string delimiters.

DEFOLANG Subcommand

The DEFOLANG subcommand specifies the default output language (if the language that is specified on the OLANG subcommand is not available). The initial default setting is the language of the installed software version. For example, if you install the English version of the software on a Japanese operating system, the default output language is English.

Example

```
SET DEFOLANG = JAPANESE.
```

- The language keyword is not case-sensitive.
- Do *not* enclose the language keyword in quotation marks or other string delimiters.

SCALEMIN Subcommand

For SPSS data files that were created prior to release 8.0 and data read from text data files or database tables, you can specify the minimum number of data values for a numeric variable that is used to classify the variable as scale or nominal. Variables with fewer than the specified number of unique values are classified as nominal. All string variables and any variables with defined

value labels are classified as nominal, regardless of the number of unique values. This setting has no effect on default measurement level for data read from SAS, Stata, or Excel files.

SORT Subcommand

By default, SPSS tries to use an external, third-party sorting mechanism, which may reduce processing time with large data sources. The third-party sorting option is available only if you have SPSS Server. The specific sorting engine is defined by your server administrator. If you are not connected to an SPSS Server or the SPSS Server cannot find the third-party sort engine, the built-in sorting mechanism is used.

EXTERNAL	*Use the external, third-party sort engine if available.* This setting is the default. If the third-party sort engine is not available, this setting is ignored, and the built-in sorting mechanism is used. `COXREG` and `CURVEFIT` use built-in sorting regardless of the `SORT` setting.
SPSS	*Use the built-in sorting mechanism.*
SS	This setting is deprecated. It has the same effect as `EXTERNAL`.

LOCALE Subcommand

The `LOCALE` subcommand allows you to change the locale used for data analysis. `LOCALE` also allows you to change the locale that is used by the SPSS Analytic Server. By default, when you connect to the server, the server locale is set to your computer's system locale if possible. With the `LOCALE` subcommand, you can override the default behavior and process data files in other locales without changing your computer's system or user locale.

- The default locale is the current operating system locale.
- The `LOCALE` subcommand persists. The next time that SPSS is started on your computer, SPSS will run in that locale.
- If the locale ID does not match the system locale, not all output will be rendered correctly.
- You can use `SHOW LOCALE` to view the current SPSS locale.

Example

```
SET LOCALE='Japanese'.
```

- When you are connecting to a server, the relevant locale ID is defined in the *loclmap.xml* file, which is located on the server computer. Check with your server administrator for available locale IDs.
- Locale ID values of the general form *Language_Country.codepage#*, which were valid in previous releases, are not valid in release 16.0 or later. In most instances, the "Language" portion of the old locale specification should be a valid locale ID in release 16.0 or later. For example, instead of 'Japanese_Japan.932', you could specify simply 'Japanese'. For a complete list of names and aliases that can be used to specify locale, go to *http://www.iana.org/assignments/character-sets*

Two-letter language abbreviations adhere to the ISO 639-1 standard: *http://www.loc.gov/standards/iso639-2/php/code_list.php*

Two-letter country codes adhere to the ISO 3166 standard: *http://en.wikipedia.org/wiki/ISO_3166-1*

Example

```
SET LOCALE='ja_JP.Shift_JIS'
```

- "ja" is the two-letter language code for Japanese.
- "JP" is the two-letter country code for Japan.
- "Shift_JIS" is the name of the character set.

THREADS Subcommand

The `THREADS` subcommand specifies the number of threads that multithreaded procedures use when calculating results. By default, SPSS uses an internal algorithm to determine the number of threads for a particular computer. You can change this setting, but the default will often provide the best performance. The default also appears as the recommended setting when you run the `SHOW` command.

Using more than one thread is relevant only if your computer has multiple processors or each processor has multiple cores. Also, this setting affects only selected procedures that take advantage of it. These are `CORRELATIONS`, `CSSELECT`, `FACTOR`, `PARTIAL CORR`, and `REGRESSION`.

Note: `PRESERVE` and `RESTORE` do not operate on this subcommand.

MCACHE Subcommand

The `MCACHE` subcommand specifies the memory cache (in kilobytes) that multithreaded procedures use when calculating results. By default, SPSS uses an internal algorithm to determine the memory cache for a particular computer. You can change this setting, but the default will often provide the best performance. The default also appears as the recommended setting when you run the `SHOW` command.

Using the memory cache is relevant only if your computer has multiple processors or each processor has multiple cores. Also, this setting affects only selected procedures that take advantage of it. These are `CORRELATIONS`, `FACTOR`, `PARTIAL CORR`, and `REGRESSION`.

Note: `PRESERVE` and `RESTORE` do not operate on this subcommand.

UNICODE Subcommand

The `UNICODE` subcommand controls the default behavior for determining the encoding for reading and writing data files and syntax files.

NO. *Use the current locale setting to determine the encoding for reading and writing data and command syntax files.* This is referred to as **code page mode**. This is the default. The alias is `OFF`. For information on the current locale setting, see LOCALE Subcommand.

YES. *Use Unicode encoding (UTF-8) for reading and writing data and command syntax files.* This is referred to as **Unicode mode**. The alias is ON.

- You can only change the UNICODE setting when there are no open data sources.
- The UNICODE setting persists across sessions and remains in effect until it is explicitly changed.

There are a number of important implications regarding Unicode mode and Unicode files:

- Data and syntax files saved in Unicode encoding should not be used in releases of SPSS prior to 16.0.
- When code page data files are read in Unicode mode, the defined width of all string variables is tripled. You can use ALTER TYPE to automatically adjust the width of all string variables.
- The GET command determines the file encoding for an SPSS-format data file from the file itself, regardless of the current mode setting (and defined string variable widths in code page files are tripled in Unicode mode).
- For text data files read with DATA LIST and related commands (for example, REPEATING DATA and FILE TYPE) or written with PRINT or WRITE, you can override the default encoding with the ENCODING subcommand.
- GET DATA uses the default encoding for reading text data files (TYPE=TXT), which is UTF-8 in Unicode mode or the code page determined by the current locale in code page mode.
- OMS uses default encoding for writing text files (FORMAT=TEXT and FORMAT=TABTEXT) and for writing SPSS-format data files (FORMAT=SAV).
- GET SAS, GET STATA, GET TRANSLATE, and SAVE TRANSLATE read and write data in the current locale code page, regardless of mode.
- For syntax files run via INCLUDE or INSERT, you can override the default encoding with the ENCODING subcommand.

SHOW

```
SHOW [ALL] [BLANKS] [BOX] [BLOCK] [CC] [CCA] [CCB]
 [CCC] [CCD] [CCE] [CACHE] [COMPRESSION] [CTEMPLATE] [DECIMAL] [DEFOLANG]
 [DIRECTORY] [ENVIRONMENT] [EPOCH] [ERRORS] [FILTER] [FORMAT] [HEADER]
 [LENGTH] [LICENSE] [LOCALE] [MESSAGES] [MEXPAND] [MITERATE]
 [MNEST] [MPRINT] [MXCELLS] [MXERRS] [MXLOOPS] [MXWARNS]
 [N] [OLANG] [ONUMBERS] [OVARS] [PRINTBACK] [RESULTS] [SCALEMIN]
 [SCOMPRESSION] [SEED] [SMALL] [SORT] [SYSMIS] [TFIT] [TLOOK]
 [TMSRECORDING] [TNUMBERS] [TVARS] [UNDEFINED] [UNICODE] [VERSION]
 [WEIGHT] [WIDTH] [WORKSPACE] [$VARS]
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Release History

Release 13.0

- BLKSIZE and BUFNO subcommands are obsolete and no longer supported.
- SORT subcommand introduced.

Release 15.0

- TMSRECORDING subcommand introduced.

Release 16.0

- UNICODE subcommand introduced.
- MCACHE subcommand introduced.
- THREADS subcommand introduced.

Example

```
SHOW.
```

Overview

SHOW displays current settings for running options. Most of these settings can be changed by using the SET command.

Basic Specification

The basic specification is simply the command keyword, which displays important current settings (keyword ALL). Some displayed option settings are applicable only when you have options such as Tables and Categories.

Subcommand Order

Subcommands can be named in any order.

Syntax

- If any subcommands are specified, only the requested settings are displayed.
- SHOW can be specified more than once.

Example

```
SHOW BLANKS /UNDEFINED /MXWARNS.
```

- BLANKS shows the value to which a completely blank field for a numeric variable is translated.
- UNDEFINED indicates whether a message is displayed whenever the program encounters anything other than a number or a blank as the value for a numeric variable.
- MXWARNS displays the maximum number of warnings that are allowed before a session is terminated.

Subcommands

The following alphabetical list shows the available subcommands.

ALL	*Display important settings that are applicable to your system.* This setting is the default.
BLANKS	*Value to which a completely blank field for a numeric variable is translated.* The default is the system-missing value.
BOX	*Characters used to draw boxes.* Both character and hexadecimal representations are displayed. The default is X'2D7C2B2B2B2B2B2B2B2B'. This setting applies only to text output from the program.
BLOCK	*Character used to draw bar charts.* Both character and hexadecimal representations are displayed. The default is X'2A'. This setting applies only to the text output from the program.
CC	*Custom currency formats.* CC shows the current custom currency formats that have been defined for CCA, CCB, CCC, CCD, and CCE on SET. In Windows environments, the formats reflect the Regional Settings Properties. You can also request any of these keywords individually.
CACHE	*Cache active data file*. This setting shows the number of changes in the active data file before a cache file is created. The default is 20.
COMPRESSION	*Compression of scratch files.* The setting is either ON or OFF (alias YES or NO). The default varies by system.
CTEMPLATE	*Chart template file.* The setting is either NONE or a filename.

DECIMAL *Decimal indicator.* This setting indicates the current character used as the decimal indicator. DOT indicates that a period is the decimal indicator; COMMA indicates that a comma is the decimal indicator.

DEFOLANG *Default output language.* This setting indicates the default output language to use if the language that is specified on the OLANG subcommand is not available. The initial default setting is the language version of the installed software.

DIRECTORY *Default directory*. This setting indicates the root directory that is used to determine the locations of files that are specified with no paths or relative paths. A wide variety of actions can change the current default directory during a session.

ENVIRONMENT *Operating system and computer information.* This setting includes information about environment variables, defined paths, domain, etc.

EPOCH *Range of years for date-format variables and date functions entered with a two-digit year value.* AUTOMATIC indicates a 100-year range beginning 69 years before the current year and 30 years after the current year.

ERRORS *Error messages for text output.* The setting can be LISTING (alias YES or ON) or NONE (alias NO or OFF).

EXTENSIONS No longer supported.

FILTER *Filter status*. This setting indicates whether filtering is currently in effect (FILTER command) and indicates the filter variable that is in use (if any).

FORMAT *Default print and write formats for numeric variables that are defined on DATA LIST in freefield format and all numeric variables created by transformation commands.* The default is F8.2.

HEADER *Headings for text output.* The setting is YES, NO, or BLANK. The default is NO.

JOURNAL No longer supported.

LENGTH *Maximum page length for output.* The default is 59. This setting applies only to the text output from the program.

LICENSE *Licensed components, expiration date, release number, and maximum number of users permitted by the license*.

LOCALE *Operating system locale setting and codepage*. In Windows operating systems, locale is set in the Regional Options of the Control Panel.

MCACHE *Memory cache size in kilobytes.* The default and recommended setting are based on your specific hardware.

MESSAGES *Resource-utilization messages for text output.* The setting can be LISTING (alias YES or ON) or NONE (alias NO or OFF).

MEXPAND *Macro expansion.* The setting is either ON (alias YES) or OFF (alias NO). The default is ON.

MITERATE *Maximum loop iterations permitted in macro expansions.* The default is 1000.

MNEST *Maximum nesting level for macros.* The default is 50.

MPRINT *Inclusion of expanded macros in the output.* The setting is either ON (alias YES) or OFF (alias NO). The default is OFF.

MXCELLS *Maximum number of cells that are allowed for a new pivot table.* The default is AUTOMATIC, which allows the number to be determined by the available memory.

MXERRS *Maximum number of errors allowed and number of errors so far in current session*. In most implementations of SPSS, the maximum number of errors defined on SET MXERRS is ignored. However, the information that SHOW MXERRS provides about number of errors in the current session can be useful.

MXLOOPS *Maximum executions of a loop on a single case.* The default is 40.

MXMEMORY No longer supported.

MXWARNS *Maximum number of warnings and errors that are shown for text output.* The default is 10.

N *Unweighted number of cases in the active dataset.* `N` displays *UNKNOWN* if a active dataset has not yet been created. `N` cannot be changed with `SET`.

OLANG *Output language for pivot tables.*

ONUMBERS *Display of variable values in the outline for pivot tables.* The settings can be `LABELS`, `VALUES`, and `BOTH`.

OVARS *Display of variables as headings.* The settings can be `LABELS`, `NAMES`, and `BOTH`.

PRINTBACK *Command printback.* The setting can be `BOTH` (alias `LISTING`, `YES`, or `ON`) or `NONE` (alias `NO` or `OFF`). The default is `BOTH` at system installation.

RESULTS *Output from commands.* This setting is not applicable to output that is displayed in pivot tables. The setting can be `LISTING` (alias `YES` or `ON`) or `NONE` (alias `NO` or `OFF`).

SCALEMIN *For data files that were created in versions prior to version 8.0, the minimum number of unique values for a numeric variable that is used to classify the variable as scale.* This setting affects only pre-8.0 data files that are opened in later versions.

SCOMPRESSION *Compression of SPSS-format data files.* This setting can be overridden by the `COMPRESSED` or `UNCOMPRESSED` subcommands on the `SAVE` or `XSAVE` commands. The default setting varies by system. `SCOMPRESSION` cannot be changed with `SET`.

SEED *Seed for the random-number generator.* The default is generally 2,000,000 but may vary by system.

SMALL *Decimal value to control display of scientific notation in output.*

SORT *Sorting mechanism that is currently in effect: SPSS or external, third-party (if available).*

SYSMIS *The system-missing value.* `SYSMIS` cannot be changed with `SET`.

TFIT *Adjust column widths in pivot tables.* The settings can be `BOTH` (label and data) and `LABELS`.

THREADS *Number of threads.* The default and recommended setting are based on your specific hardware.

TLOOK *Pivot table template file.* The setting can be either `NONE` or a filename.

TMSRECORDING *TMS recording status*. `Yes` indicates that a TMS block for writing transformations to PMML is currently in effect. `No` indicates that TMS is not currently in effect. For more information, see TMS BEGIN on p. 1800.

TNUMBERS *Display of variable values in pivot tables.* The settings can be `VALUES`, `LABELS`, and `BOTH`.

TVARS *Display of variables as headings.* The settings can be `NAMES`, `LABELS`, and `BOTH`.

UNDEFINED *Warning message for undefined data.* `WARN` is the default. `NOWARN` suppresses messages but does not alter the count of warnings toward the `MXWARNS` total.

UNICODE *Unicode mode status.* The setting is either `YES` (alias `ON`) or `NO` (alias `OFF`).

VERSION *Version number and creation date.*

WEIGHT *Variable that is used to weight cases.* `WEIGHT` can be specified for `SHOW` only and cannot be changed with `SET`.

WIDTH *Maximum page width for the output.* The default is 132 columns for batch mode and 80 for interactive mode. This setting applies only to text output from the program.

WORKSPACE	*Special workspace memory limit in kilobytes.* The default is 6148.
$VARS	*Values of system variables.* `$VARS` cannot be changed with `SET`.

SORT CASES

```
SORT CASES [BY] varlist[({A})] [varlist...]
                        {D}
```

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
SORT CASES BY DIVISION (A) STORE (D).
```

Overview

SORT CASES reorders the sequence of cases in the active dataset based on the values of one or more variables. You can optionally sort cases in ascending or descending order, or you can use combinations of ascending and descending order for different variables.

Basic Specification

The basic specification is a variable or list of variables that are used as sort keys. By default, cases are sorted in ascending order of each variable, starting with the first variable that is named. For each subsequent variable, cases are sorted in ascending order within categories of the previously named variables.

Syntax Rules

- Keyword BY is optional.
- BY variables can be numeric or string but not scratch, system, or temporary variables.
- You can explicitly request the default sort order (ascending) by specifying A or UP in parentheses after the variable name. To sort cases in descending order, specify D or DOWN.
- An order specification (A or D) applies to all variables in the list, up to the previous order specification. If you combine ascending and descending order on the same SORT CASES command, you may need to specify the default A explicitly.

Operations

- SORT CASES first sorts the file according to the first variable that is named. For subsequent variables, cases are sorted within categories of the previously named variables.
- The sort sequence is based on the locale-defined order (and is not necessarily the same as the numerical order of the character codes). The default locale is the operating system locale. You can change the locale with SET LOCALE. Use SHOW LOCALE to display the current locale.

Examples

```
SORT CASES BY DIVISION (A) STORE (D).
```

- Cases are sorted in ascending order of variable *DIVISION*. Cases are further sorted in descending order of *STORE* within categories of *DIVISION*. A must be specified so that D applies to *STORE* only.

```
SORT CASES DIVISION STORE (A) AGE (D).
```

- Cases are sorted in ascending order of *DIVISION*. Keyword BY is not used in this example.
- Cases are further sorted in ascending order of *STORE* within values of *DIVISION*. Specification A applies to both *DIVISION* and *STORE*.
- Cases are further sorted in descending order of *AGE* within values of *STORE* and *DIVISION*.

SORT CASES with Other Procedures

- In AGGREGATE, cases are sorted in order of the break variable or variables. You do not have to use SORT CASES prior to running AGGREGATE, because the procedure does its own sorting.
- You can use SORT CASES in conjunction with the BY keyword in ADD FILES to interleave cases with the same variables but from different files.
- With MATCH FILES, cases must be sorted in the same order for all files that you combine.
- With UPDATE, cases must be sorted in ascending order of the key variable or variables in both the master file and all transaction files.
- You can use the PRINT command to check the results of a SORT CASES command. To be executed, PRINT must be followed by a procedure or EXECUTE.

SORT VARIABLES

```
SORT VARIABLES [BY] {NAME          } [({A})]
                    {TYPE          }   {D}
                    {FORMAT        }
                    {LABEL         }
                    {VALUES        }
                    {MISSING       }
                    {MEASURE       }
                    {COLUMNS       }
                    {ALIGNMENT     }
                    {ATTRIBUTE name}
```

If there are any pending transformations, this command reads the active dataset and causes execution of any pending commands. Otherwise, it takes effect immediately without reading the active dataset.

Release History

Release 16.0.

- Command introduced.

Example

```
SORT VARIABLES BY NAME (A).
```

Overview

SORT VARIABLES sorts the variables in the active dataset based on the values of the selected dictionary attribute.

Basic Specification

The basic specification is the command name SORT VARIABLES followed by the name of a single dictionary attribute.

Syntax Rules

- Only one dictionary attribute can be specified.
- The BY keyword is optional.
- You can explicitly request the default sort order (ascending) by specifying A or UP in parentheses after the attribute name. To sort variables in descending order, specify D or DOWN.

Sorting Options

Variables can be sorted based on the values of any one of the following dictionary attributes:

NAME. *Sort variables by variable names.* The primary sort is alphabetical, but trailing digits are sorted numerically within ties on the preceding part. For example, *V2* comes before *V10* in ascending order.

TYPE. *Group variables by type (numeric or string) and sort string variables by defined width.* In default ascending order, numeric variables come before string variables, and shorter string variables come before longer string variables.

FORMAT. *Group variables by format (for example, Date, Dollar, String).*

LABEL. *Sort variables in alphabetical order by variable labels.* In default ascending order, all variables without defined variable labels come before variables with defined variable labels. For more information, see VARIABLE LABELS on p. 1960.

VALUES. *Sort variables by value labels.* In default ascending order, all variables without defined value labels come before variables with defined value labels. For more information, see VALUE LABELS on p. 1946.

MISSING. *Group variables by defined missing values.* In default ascending order, all variables without defined missing values come before variables with defined missing values. For more information, see MISSING VALUES on p. 1113.

MEASURE. *Sort variables by measurement level.* The default ascending order is: nominal, ordinal, scale. For more information, see VARIABLE LEVEL on p. 1962.

COLUMNS. *Sort variables by column width.* Column width is the width of the column that displays the variable in Data View of the Data Editor. For more information, see VARIABLE WIDTH on p. 1963.

ALIGNMENT. *Group variables by alignment.* The default ascending order is: left, right, center. For more information, see VARIABLE ALIGNMENT on p. 1956.

ATTRIBUTE name. *Sort variables by values of the specified custom variable attribute name.* In default ascending order, all variables without values for the named attribute come before variables with values for the named attribute. For more information, see VARIABLE ATTRIBUTE on p. 1957.

SPCHART

```

**Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Release History

Release 15.0

- (XBARONLY) keyword introduced on XR and XS subcommands.
- RULES subcommand introduced.
- ID subcommand introduced.

Example

```
SPCHART  /TEMPLATE='CNTR.CHT'
  /IR=SUBSIZE.
```

Overview

SPCHART generates several types of high-resolution control charts. A control chart plots a quality characteristic that is measured or computed from a sample versus the sample number or time. This technique is a widely used process-control technique for testing the hypothesis that the process is in a state of statistical control. All control charts display four series:

- The process line representing the quality characteristic for each sample.
- The center line indicating the average value of the quality characteristic that corresponds to the in-control state.
- Two horizontal lines showing the upper control limit and lower control limit.

Control charts are used for improving productivity, preventing defects and unnecessary process adjustments, and gathering information about process capability.

SPCHART produces X-bar, R, s, individuals, and moving range charts as well as np, p, c, and u charts. You may need to transform your data to conform to the required data organization that is described under each chart type subcommand.

Control charts are available only on systems where high-resolution display is available.

Options

Titles and Footnotes. You can use the TITLE, SUBTITLE, and FOOTNOTE subcommands to specify a title, subtitle, and footnote for the control chart.

Chart Type. You can request a specific type of control chart by using the XR, XS, IR, I, NP, P, C, or U subcommand.

Templates. You can specify a template, using the TEMPLATE subcommand, to override the default chart attribute settings on your system.

Control Limits. You can specify a sigma value on the SIGMA subcommand to modify the calculated upper and lower control limits. You can also use the USL and LSL subcommands to specify fixed limits. The upper and lower limits that you specify will be displayed simultaneously with the calculated control limits.

Control Rules. You can specify control rules that help you quickly identify out-of-control points.

Basic Specification

The basic specification is a chart type subcommand. By default, the title of the generated chart is Control Chart followed by the label of the process variable. The subtitle provides split-file information if split-file processing is in effect, and the one-line footnote provides the sigma value.

Subcommand Order

Subcommands can be specified in any order.

Syntax Rules

- Only one chart type subcommand can be specified.
- Keyword `SPAN` is used only with `IR` and `I` subcommands.
- Keyword `CONFORM` or `NONCONFORM` is used only with `NP` and `P` subcommands.

Operations

- `SPCHART` plots four basic series: the process, the center line, the upper control line, and the lower control line.
- The chart title, subtitle, and footnote are assigned as they are specified on `TITLE`, `SUBTITLE`, and `FOOTNOTE` subcommands. If you do not use these subcommands, the chart title is Control Chart, followed by the label of the process variable, and a one-line footnote displays the sigma level.
- The category variable label is used as the title for the *category axis*. If no variable label is defined, the variable name is used. If no category variable is defined, the title is null.
- The category variable value labels are used as the *category axis* labels. If no value labels are defined, values are used. If no category variable is defined, integer values from 1 to *n* are used, where *n* is the number of subgroups or units plotted.
- All series are plotted as lines. When a series has a constant value across all samples, the value is reported in the legend entry for the series.
- Case weights are not honored for control charts when each case is a subgroup. Case weights are honored when each case is a unit and when the weights are integers. When weighted data are used in an individuals chart, replicated cases are plotted on the control chart.
- The calculated control limits are always displayed and can be suppressed only by editing the chart in a chart window.
- You can specify preset control limits for an X-bar or I chart, as some industries often do. The specified control limits are displayed simultaneously with the calculated limits.

Limitations

- Control charts cannot have fewer than 2 points or more than 3000 points.
- The subgroup size in X-bar and range charts cannot exceed 100.
- The span for individual charts is limited to 100.

Example

```
SPCHART  /TEMPLATE='CNTR.CHT'
  /IR=SUBSIZE.
```

- This command generates an individuals chart and a moving range chart. The process variable *SUBSIZE* is a numeric variable that measures the size variation of the product.
- Both charts use the attributes that are defined for the template that is saved in *CNTR.CHT*.
- The default span (2) and sigma value (3) are used.
- Because no BY variable is specified, the *x* axis is labeled by sequence numbers.

TITLE, SUBTITLE, and FOOTNOTE Subcommands

TITLE, SUBTITLE, and FOOTNOTE specify lines of text that are placed at the top or bottom of the control chart.

- One or two lines of text can be specified for TITLE or FOOTNOTE, and one line of text can be specified for SUBTITLE.
- Each line of text must be enclosed in quotes. The maximum length of any line is 72 characters.
- The default font sizes and types are used for the title, subtitle, and footnote.
- By default, the title, subtitle, and footnote are left-aligned with the *y* axis.
- If you do not specify TITLE, the default title is Control Chart followed by the label of the process variable.
- If you do not specify SUBTITLE, the subtitle provides the split-file information if split-file processing is in effect; otherwise, it is null, which leaves more space for the chart.
- If you do not specify FOOTNOTE, the sigma level is identified as the first line of the footnote.

Example

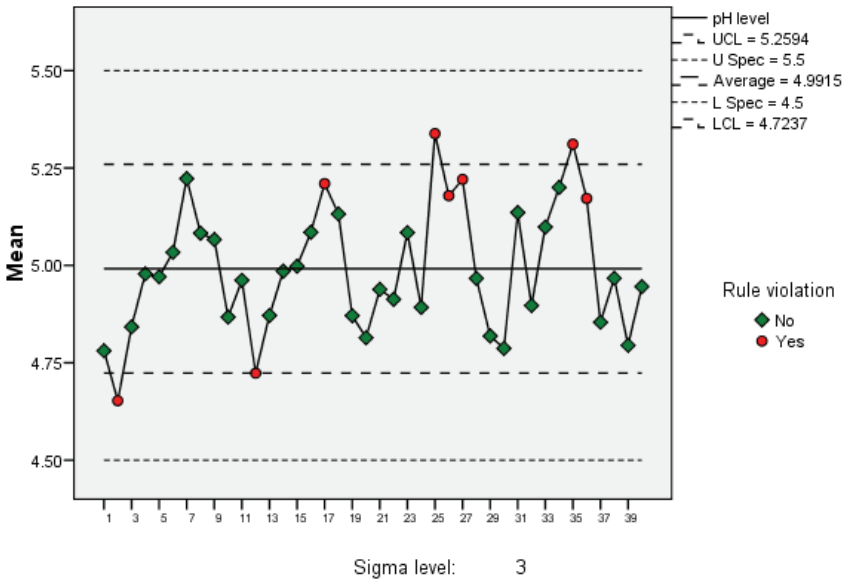
```
SPCHART TITLE = 'Wheel Production'
  /SUBTITLE = 'Process Control'
  /IR=SUBSIZE.
```

XR and XS Subcommands

XR produces an X-bar chart and an R chart. XS produces an X-bar chart and an s chart. X-bar, R, and s charts are control charts for continuous variables, such as size, weight, length, and temperature.

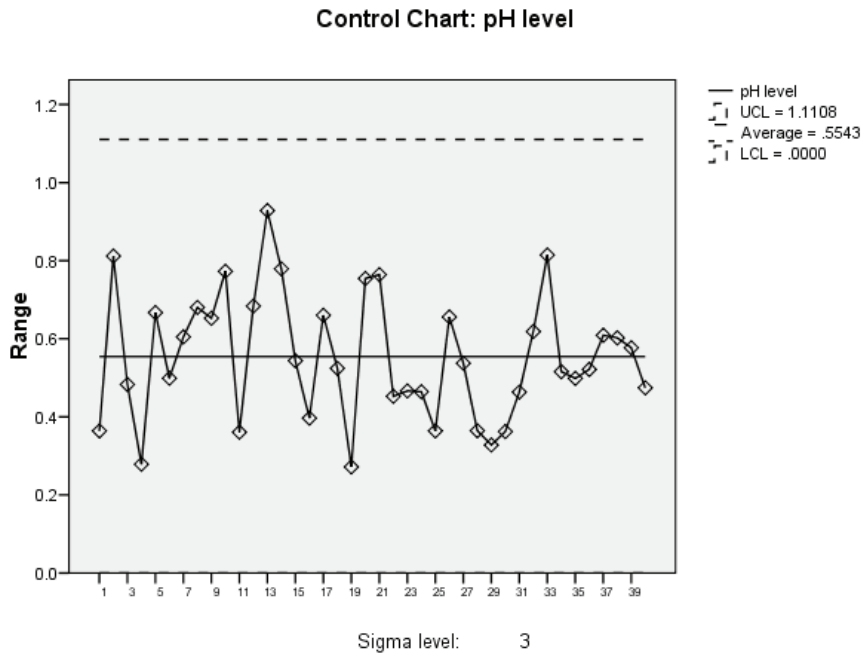
An X-bar chart plots the mean of each subgroup. The center line indicates the mean of subgroup means. The control limits are calculated from subgroup means, numbers, standard deviations, and the user-specified SIGMA value. The following figure shows an X-bar chart.

Figure 214-1
X-bar chart



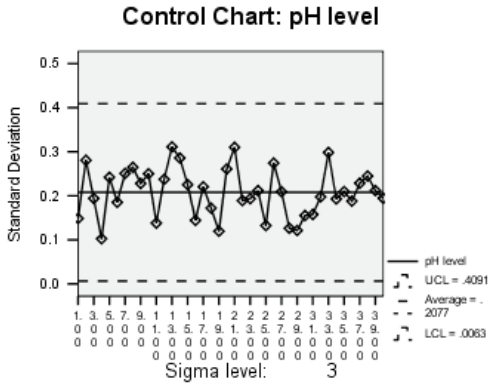
An R chart plots range values (maximum-minimum) of successive subgroups. The center line indicates the mean of subgroup ranges. The control limits are calculated from subgroup ranges, numbers, and the user-specified `SIGMA` value. The R chart tests whether the process variability is in control. When the subgroup size is relatively small (4, 5, or 6), the range method yields almost as good an estimator of the variance as does the subgroup variance. The following figure shows an R chart.

Figure 214-2
R chart



An s chart plots subgroup standard deviations. The center line indicates the mean of subgroup standard deviations. The control limits are calculated from subgroup standard deviations, numbers, and the user-specified `SIGMA` value. The s chart tests whether the process variability is in control, especially when the subgroup size is moderate to large. The following figure shows an s chart.

Figure 214-3
An s chart



Data Organization

For X-bar, R, or s charts, data can be organized where each case is a unit or where each case is a subgroup.

- If each case is a unit with a subgroup identifier, cases are assigned to a category according to the value of the identifier. Table 214-1 is an example of this type of data organization. The data do not have to be sorted by subgroup. A BY variable (the subgroup identifier) is required to sort and aggregate data and label the process variable.
- If each case is a subgroup, there are as many variables as individuals within one sample. A sample identifier is not required. When there is a sample identifier, it is used for labeling. Table 214-2 shows this type of organization.

Table 214-1
Each case is a unit for X-bar, R, and s charts

Subgroup	Length

11:30	6.46
8:50	6.32
11:30	6.37
8:50	6.39
11:30	6.36
...	...

Table 214-2
Each case is a subgroup for X-bar, R, and s charts

Subgroup	N1	N2	N3	N4
8:50	6.35	6.40	6.32	6.39
11:30	6.39	6.46	6.37	6.36
...	...	...	...	...

Variable Specification

If data are organized as shown in Table 214-1, the variable specifications on XR and XS subcommands are

```
VAR BY VAR
```

The variable that is specified before BY is the process variable, which is the variable that contains values for all instances to be plotted (for example, *LENGTH* in Table 214-1). The variable that is specified after BY is the category variable or the BY variable, which is the subgroup identifier (for example, *SUBGROUP* in Table 214-1). The process variable must be numeric, while the category variable can be of any type. The chart is sorted by the category variable.

If data are organized as shown in Table 214-2, the variable specifications on XR and XS subcommands are

```
VAR VAR [VAR...] [BY VAR]
```

Each of the variables that is specified before BY represents an instance to be plotted (for example, *N1* to *N3* in Table 214-2). At least two variables are required, and each variable must be numeric. Keyword BY and the category variable (for example, *SUBGROUP* in Table 214-2) are optional; if specified, the category variable provides labels for the *category axis* and can be any type of variable. If omitted, the *category axis* is labeled from 1 to the number of variables that are specified before keyword BY.

Example

```
SPCHART /TEMPLATE='CTRL.CHT'
 /XR SUBSIZE BY SHIFT.
```

- The data are organized as shown in Table 214-1. *SUBSIZE* is a numeric variable that measures the part size. *SHIFT* contains the subgroup identifier (work shift number).
- The chart template is stored in the chart file *CTRL.CHT*.

(XBARONLY) Keyword

(XBARONLY) suppresses the R or s secondary charts. If this keyword is omitted, the R or s chart will be generated with the X-bar chart.

Example

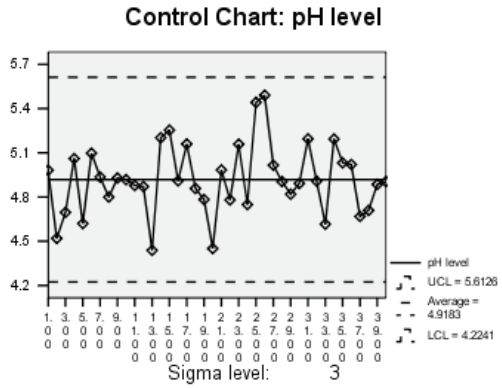
```
SPCHART
  /XR=ph BY time (XBARONLY)
  /CAPSIGMA=RBAR
  /SIGMAS=3
  /MINSAMPLE=2.
```

I and IR Subcommands

I produces an individuals chart, and IR produces an individuals chart and a moving range chart. Both types are control charts for continuous variables, such as size, weight, length, and temperature.

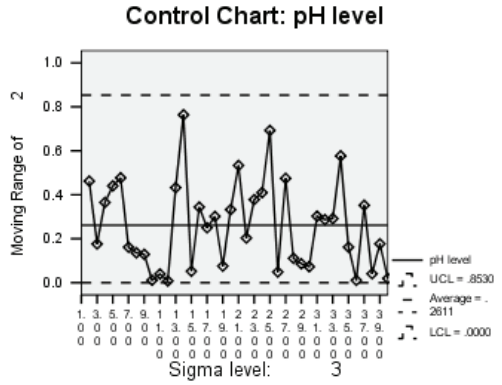
An individuals chart plots each individual observation on a control chart. The center line indicates the mean of all individual values, and the control limits are calculated from the mean of the moving ranges, the span, and the user-specified SIGMA value. Individuals charts are often used with moving range charts to test process variability when the subgroup size is 1. This situation occurs frequently when automated inspection and measurement technology is used and every manufactured unit is analyzed. The situation also occurs when the process is so slow that a larger subgroup size becomes impractical. The following figure shows an individuals chart.

Figure 214-4
Individuals chart



A moving range chart plots moving ranges of *n* successive observations on a control chart, where *n* is the specified span (see SPAN Subcommand on p. 1754). The center line is the mean of moving ranges, and the control limits are calculated from the ranges, the span, and the user-specified `SIGMA` value (see SIGMA Subcommand on p. 1755). The following figure shows a moving range chart.

Figure 214-5
Moving range chart



Data Organization

For individuals charts and moving range charts, data must be organized so that each case is a unit. Cases are not sorted or aggregated before plotting.

Variable Specification

The variable specification for `I` or `IR` subcommand is

```
VAR [BY VAR]
```

You must specify the process variable that contains the value for each individual observation. Each observation is plotted for the individuals chart. The range of *n* consecutive observations (where *n* is the value that is specified on the SPAN subcommand) is calculated and plotted for the moving range chart. The range data for the first *n*-1 cases are missing, but the mean and the limit series are not missing.

Keyword BY and the category variable are optional. When specified, the category variable is used for labeling the *category axis* and can be any type of variable. If omitted, the *category axis* is labeled 1 to the number of individual observations in the process variable.

Example

```
SPCHART /TEMPLATE='CTRL.CHT'
  /IR=SUBSIZE.
```

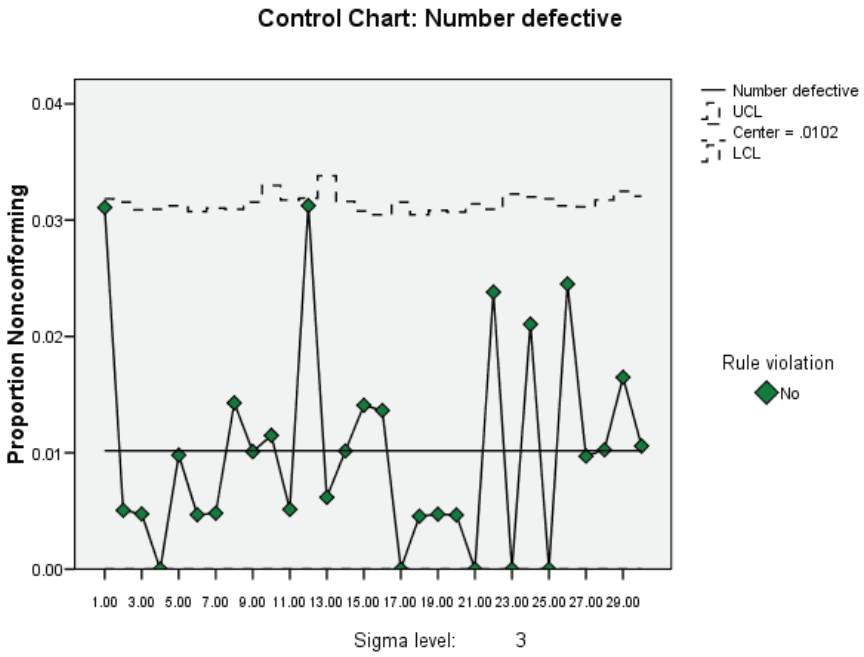
- This command requests an individuals chart and a moving range chart.
- The default span (2) and sigma value (3) are used.

P and NP Subcommands

P produces a p chart and NP produces an np chart. Both charts are control charts for attributes. That is, these charts use data that can be counted, such as the number of nonconformities and the percentage of defects.

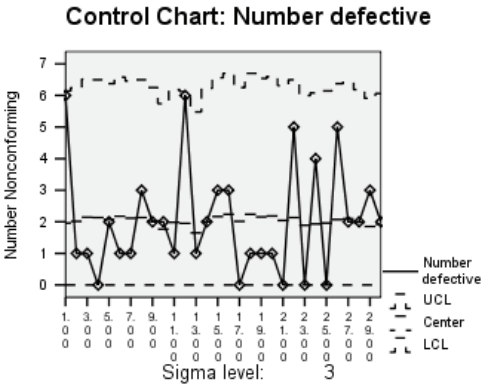
A p chart plots the **fraction nonconforming** on a control chart. Fraction nonconforming is the proportion of nonconforming or defective items in a subgroup to the total number of items in that subgroup. This measurement is expressed as a decimal or, occasionally, as a percentage. The center line of the control chart is the mean of the subgroup fractions, and the control limits are based on a binomial distribution and can be controlled by the user-specified SIGMA value.

Figure 214-6
A p chart



An np chart plots the number nonconforming rather than the fraction nonconforming. The center line is the mean of the numbers of nonconforming or defective items. The control limits are based on the binomial distribution and can be controlled by the user-specified `SIGMA` value. When the subgroup sizes are unequal, np charts are not recommended.

Figure 214-7
A np chart



Data Organization

Data for p and np charts can be organized where each case is a unit or where each case is a subgroup.

- If each case is a unit with a conformity status variable and a subgroup identifier, cases are assigned to a category by the value of the subgroup identifier. Table 214-3 is an example of this type of data organization. The data do not have to be sorted. A BY variable (the subgroup identifier) is required to sort and aggregate data and label the *category axis*.
- If each case is a subgroup, one variable contains the total number of items within a subgroup, and one variable contains the total number of nonconforming or defective items in the subgroup. The subgroup identifier is optional. If specified, the subgroup identifier is used for labeling purposes. Table 214-4 is an example of this type of data organization. The data are the same as the data that are used in Table 214-3.

Table 214-3
Each case is a unit for p and np charts

Subgroup	Outcome
January	Cured
January	Cured
January	Cured
January	Relapse
February	Relapse
February	Cured
February	Relapse
February	Relapse
...	...

Table 214-4
Each case is a subgroup for p and np charts

Subgroup	Relapse	N
January	1	4
February	3	4
...	...	...

Variable Specification

If data are organized as illustrated in Table 214-3, the variable specification on P or NP subcommands is

```
VAR BY VAR
```

The variable that is specified before BY is the status variable (for example, *OUTCOME* in Table 214-3). The value of this variable determines whether an item is considered conforming or nonconforming. The status variable can be any type, but if it is a string, the value that is specified on CONFORM (or NONCONFORM) must be enclosed in quotes (see CONFORM and NONCONFORM Subcommands on p. 1755). The variable that is specified after BY is the category variable and can be any type of variable. The chart is sorted by values of the category variable.

If data are organized as shown in Table 214-4, the variable specification on P or NP is

```
COUNT(VAR) N({VAR}) [BY VAR]
```

```
{VAL}
```

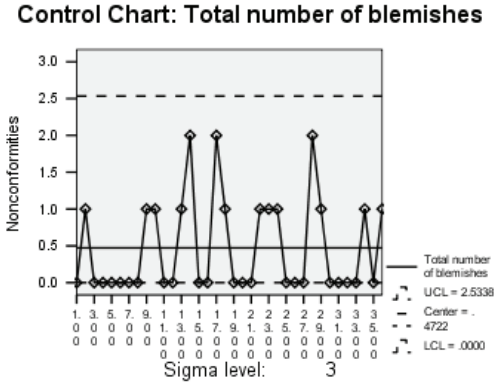
The variable that is specified on keyword COUNT is the variable that contains the number of nonconforming or defective items (for example, *RELAPSE* in Table 214-4). The specification on keyword N is either the variable that contains the sample size or a positive integer for a constant size across samples (for example, *N* in Table 214-4). The COUNT variable cannot be larger than the N variable for any given subgroup; if it is larger, the subgroup is dropped from calculation and plotting. Keyword BY and the category variable are optional. When specified, the category variable is used for *category axis* labels; otherwise, the *category axis* is labeled 1 to the number of subgroups. Cases are unsorted for the control chart.

C and U Subcommands

C produces a c chart and U produces a u chart. Both charts are control charts for attributes. That is, the charts use data that can be counted.

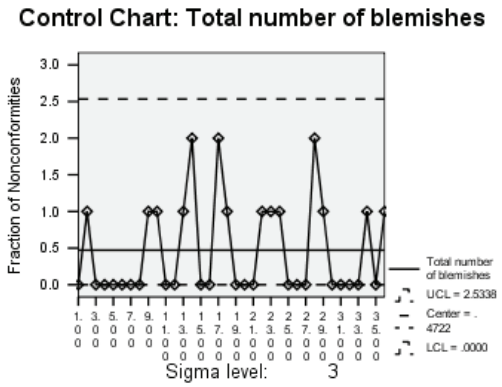
A c chart plots the total number of defects or nonconformities in each subgroup. A defect or nonconformity is one specification that an item fails to satisfy. Each nonconforming item has at least one defect, but any nonconforming item may have more than one defect. The center line of the c chart indicates the mean of the defect numbers of all subgroups. The control limits are based on the Poisson distribution and can be controlled by the user-specified SIGMA value. When the sample sizes are not equal, c charts are not recommended.

Figure 214-8
A c chart



A u chart plots the average number of defects or nonconformities per inspection unit within a subgroup. Each subgroup contains more than one inspection unit. The center line of the u chart indicates the average number of defects per unit of all subgroups. The control limits are based on Poisson distribution and can be controlled by the user-specified SIGMA value.

Figure 214-9
A u chart



Data Organization

Data for c and u charts can be organized where each case is a unit or where each case is a subgroup.

- If each case is a unit with a variable containing the number of defects for that unit and a subgroup identifier, cases are assigned to each subgroup by the value of the identifier. Table 214-5 is an example of this type of data organization. Data do not have to be sorted by subgroup. A BY variable (the subgroup identifier) is required to sort and aggregate data and to label the *category axis*.
- If each case is a subgroup, one variable contains the total number of units within the subgroup, and one variable contains the total number of defects for all units within the subgroup. The subgroup identifier is optional. When specified, the subgroup identifier is used as *category axis* labels; otherwise, the number 1 to the number of subgroups are used to label the *category axis*. Table 214-6 is an example of this method of data organization. The data are the same as the data in Table 214-5.

Table 214-5
Each case is a unit for c and u charts

ID	Subgroup	Count
1	January	0
2	January	2
3	January	0
4	January	0
5	February	5
6	February	1
7	February	0
8	February	0
...	...	...

Table 214-6
Each case is a subgroup for c and u charts

Subgroup	Relapses	N
JANUARY	1	4
FEBRUARY	3	4
...	...	...

Variable Specification

If data are organized as shown in Table 214-5, the variable specification on C and U subcommands is

```
VAR BY VAR
```

The variable that is specified before keyword BY contains the number of defects in each unit (for example, *COUNT* in Table 214-5). The variable must be numeric. The variable that is specified after keyword BY is the subgroup identifier (for example, *SUBGROUP* in Table 214-5). This variable can be any type of variable. The chart is sorted by values of the subgroup identifier.

If data are organized as shown in Table 214-6, the variable specification on C and U subcommands is

```
COUNT(VAR) N({VAR}) [BY VAR]
             {VAL}
```

The specification is the same as the specification for p and np charts.

STATISTICS Subcommand

Any keyword may be specified in any place in the subcommand, but for conceptual clarity, the keywords are organized as follows: the Process Capability Indices, the Process Performance Indices, and the Measure(s) for Assessing Normality.

- This subcommand is silently ignored if the chart is not an XR, XS, IR, and I chart.
- A duplicated subcommand name causes a syntax error.
- A duplicated keyword is silently ignored.
- There is no default keyword or parameter value.

The Process Capability Indices

CP *Capability of the process.*

CPU *The distance between the process mean and the upper specification limit scaled by capability sigma.*

CPL *The distance between the process mean and the lower specification limit scaled by capability sigma.*

K *The deviation of the process mean from the midpoint of the specification limits.* This measurement is computed independently of the estimated capability sigma.

CPK *Capability of the process related to both dispersion and centeredness.* It is the minimum of CpU and CpL. If only one specification limit is provided, we compute and report a unilateral CpK instead of taking the minimum.

CR *The reciprocal of CP.*

CPM *An index relating capability sigma and the difference between the process mean and the target value.* A target value must be specified on the TARGET subcommand by the user.

CZU *The number of capability sigmas between the process mean and the upper specification limit.*

CZL *The number of capability sigmas between the process mean and the lower specification limit.*

CZMIN *The minimum number of capability sigmas between the process mean and the specification limits.*

CZMAX *The maximum number of capability sigmas between the process mean and the specification limits.*

CZOUT *The estimated percentage outside the specification limits.* The standard normal approximation is based on the CZ_U and CZ_L.

- For each of the keywords (other than CPK), both the LSL subcommand and the USL subcommand must be specified. Otherwise, the keyword(s) are ignored, and a syntax warning is issued. For CPK, at least one of the LSL and USL subcommands must be specified.
- If the TARGET subcommand is not specified, the keyword CPM is ignored, and a syntax warning is issued.

The Process Performance Indices

PP *Performance of the process.*

PPU *The distance between the process mean and the upper specification limit scaled by process standard deviation.*

PPL *The distance between the process mean and the lower specification limit scaled by process standard deviation.*

PPK *Performance of the process related to both dispersion and centeredness.* It is the minimum of PpU and PpL. If only one specification limit is provided, we compute and report a unilateral PpK instead of taking the minimum.

PR *The reciprocal of PP.*

PPM *An index relating process variance and the difference between the process mean and the target value.* A target value must be specified on the TARGET subcommand by the user.

PZU *The number of standard deviations between the process mean and the upper specification limit.*

PZL *The number of standard deviations between the process mean and the lower specification limit.*

PZMIN *The minimum number of standard deviations between the process mean and the specification limits.*

PZMAX *The maximum number of standard deviations between the process mean and the specification limits.*

PZOUT *The estimated percentage outside the specification limits.* The standard normal approximation is based on the PZ_U and PZ_L.

- For each of the keywords (other than PPK), both the LSL subcommand and the USL subcommand must be specified. Otherwise, we ignore the keyword(s) and issue a syntax warning. For PPK, at least one of the LSL and USL subcommands must be specified.

- If the TARGET subcommand is not specified, the keyword PPM is ignored, and a syntax warning is issued.

Measure(s) for Assessing Normality

AZOUT *The observed percentage outside the specification limits.* A point is defined outside the specification limits when its value is greater than or equal to the upper specification limit or is less than or equal to the lower specification limit.

- For AZOUT, both the LSL subcommand and the USL subcommand must be specified. Otherwise, we ignore the keyword and issue a syntax warning.

RULES Subcommand

RULES specifies the rules for identifying out-of-control points. If a point violates any rule, it appears in the primary chart with a different shape and color compared to in-control points. Note that only the last point in a discovered pattern shall be marked for a rule violation, and any and all overlapping patterns are treated as separate patterns. A table of rule violations is also included in the output that displays the points marked in the control chart. If desired, use the ID keyword to specify the variable that identifies points in this table.

- Any keyword may be specified in any place in the subcommand.
- A duplicated subcommand name causes a syntax error.
- A duplicated keyword is silently ignored.
- The default keyword is ALL.
- If the subcommand is omitted, no control rules are used.

ALL	*All rules.*
UCL	*Greater than +3 sigma.*
R2UPPER	*2 points out of the last 3 greater than +2 sigma.*
R4UPPER	*4 points out of the last 5 greater than +1 sigma.*
R8UPPER	*8 consecutive points above the center line.*
R8LOWER	*8 consecutive points below the center line.*
R4LOWER	*4 points out of the last 5 less than -1 sigma.*
R2LOWER	*2 points out of the last 3 less than -2 sigma.*
LCL	*Less than -3 sigma.*
TRUP	*6 consecutive points trending up.*
TRDOWN	*6 consecutive points trending down.*
ALTERNATING	*14 consecutive points alternating.*

ID Subcommand

ID specifies a variable that identifies points in the table of rule violations. If this subcommand is omitted, the BY variable is used. Without the RULES subcommand, ID has no effect.

CAPSIGMA Subcommand

This subcommand defines the capability sigma estimator, which is required in computing all the Process Capability Indices (except K that is requested by the STATISTICS subcommand, which applies to /XR, /XS, /I, or /IR only). There are four options:

RBAR	*Mean sample range.* The estimated capability sigma is based on the mean of the sample group ranges.
SBAR	*Mean sample standard deviation.* The estimated capability sigma is based on the mean of the sample group standard deviations.
MRBAR	*Mean sample moving range.* The estimated capability sigma is based on the mean of the sample moving ranges. The span that is defined by the SPAN subcommand is used. (Recall that its passive default value is 2.)
WITHIN	*Sample within-group variance.* The estimated capability sigma is the square root of the sample within-group variance.

The validity of specification depends on the chart specification (i.e., /XR, /XS, /I, or /IR).

Table 214-7
Valid CAPSIGMA options by chart specification

Chart Specification	Valid CAPSIGMA Options
XR	RBAR (default) SBAR WITHIN
XS	RBAR SBAR (default) WITHIN
I	MRBAR (default)
IR	MRBAR (default)

- When this subcommand is omitted or specified without a keyword by the user, the default conditional on the chart specification is implicitly assumed (see the table above).
- The user specification of an invalid combination (e.g., /I and /CAPSIGMA = RBAR) causes a syntax error, if this subcommand is relevant (i.e., an applicable STATISTICS keyword is specified). Otherwise, we issue a syntax warning. When the chart specification is not /XR, /XS, /I, or /IR, the CAPSIGMA subcommand is silently ignored.
- The user specification of this subcommand, when valid with respect to the chart specification, is silently ignored, unless an applicable STATISTICS keyword is specified.
- A duplicated subcommand name causes a syntax error.
- A duplicated keyword is silently ignored, but if two or more keywords are specified and they do not have identical meanings, a syntax error message is issued.

SPAN Subcommand

SPAN specifies the span from which the moving range for an individuals chart is calculated. The specification must be an integer value that is greater than 1. The default is 2. SPAN applies only to I and IR chart specifications.

Example

```
SPCHART /IR=SUBSIZE /SPAN=5.
```

- The SPAN subcommand specifies that the moving ranges are computed from every five individual samples.

CONFORM and NONCONFORM Subcommands

Either CONFORM or NONCONFORM is required when you specify a status variable on the P or NP subcommand. You make that specification when data are organized so that each case is an inspection unit (see P and NP Subcommands on p. 1746).

- Either subcommand requires a value specification. The value can be numeric or string. String values must be enclosed within quotes.
- If CONFORM is specified, all values for the status variable (other than the specified value) are tabulated as nonconformities. If NONCONFORM is specified, only the specified value is tabulated as a nonconformity.
- CONFORM and NONCONFORM apply only to P and NP chart specifications.

SIGMA Subcommand

SIGMA allows you to define the sigma level for a control chart. The value specified on SIGMA is used in calculating the upper and lower control limits on the chart. You can specify a number larger than 1 but less than or equal to 10. A larger SIGMA value means a greater range between the upper and the lower control limits. The default is 3.

MINSAMPLE Subcommand

MINSAMPLE specifies the minimum sample size for X-bar, R, or s charts. When you specify XR or XS on SPCHART, any subgroup with a size that is smaller than the size that is specified on MINSAMPLE is excluded from the chart and from all computations. If each case is a subgroup, there must be at least as many variables named as the number that is specified on MINSAMPLE. The default is 2.

LSL and USL Subcommand

LSL and USL allow you to specify fixed lower and upper control limits. Fixed control limits are often used in manufacturing processes as designer-specified limits. These limits are displayed on the chart, along with the calculated limits. If you do not specify LSL and USL, no fixed control limits are displayed. However, if you want only the specified control limits, you must edit the chart in a chart window to suppress the calculated series.

Example

```
SPCHART /TEMPLATE='CTRL.CHT'
  /XS=SUBSIZE
```

```
/USL=74.50
/LSL=73.50.
```

- The USL and LSL subcommands specify the control limits according to the designing engineer. The center line is probably at 74.00.
- The specified upper and lower limits are displayed together with the control limits that are calculated from the observed standard deviation and the sigma value.

TARGET Subcommand

This subcommand defines the target value that is used in computing CpM and PpM requested by the STATISTICS subcommand. The value may be any real number that is less than or equal to the USL value and greater than or equal to the LSL value.

- If no applicable STATISTICS keyword is specified, this subcommand is silently ignored.
- If the value is numeric but out of the valid range, we issue a warning and ignore the CPM and/or PPM keyword(s), if any, in the STATISTICS subcommand.

MISSING Subcommand

MISSING controls the treatment of missing values in the control chart.

- The default is NOREPORT and EXCLUDE.
- REPORT and NOREPORT are alternatives and apply only to category variables. REPORT and NOREPORT control whether categories (subgroups) with missing values are created.
- INCLUDE and EXCLUDE are alternatives and apply to process variables.

NOREPORT	*Suppress missing-value categories.* This setting is the default.
REPORT	*Report and plot missing-value categories.*
EXCLUDE	*Exclude user-missing values.* Both user-missing and system-missing values for the process variable are excluded from computation and plotting. This setting is the default.
INCLUDE	*Include user-missing values.* Only system-missing values for the process variable are excluded from computation and plotting.

SPECTRA

SPECTRA is available in the Trends option.

```
SPECTRA VARIABLES= series names

 [/{CENTER NO**}]
   {CENTER     }

 [/{CROSS NO**}]
   {CROSS     }

 [/WINDOW={HAMMING** [({5   })]    }]
          {              {span}     }
          {BARTLETT [(span)]        }
          {PARZEN [(span)]          }
          {TUKEY [(span)]           }
          {UNIT or DANIELL [(span)]}
          {NONE                     }
          {w-p, ..., w0, ..., wp    }

 [/PLOT= [P] [S] [CS] [QS] [PH] [A]
         [G] [K] [ALL] [NONE]
         [BY {FREQ  }]]
             {PERIOD}

 [/SAVE = [FREQ (name)] [PER (name)] [SIN (name)]
          [COS (name)]  [P (name)]   [S (name)]
          [RC (name)]   [IC (name)]  [CS (name)]
          [QS (name)]   [PH (name)]  [A (name)]
          [G (name)]    [K (name)]]

 [/APPLY [='model name']]
```

**Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
SPECTRA VARIABLES = HSTARTS.
```

Overview

SPECTRA plots the periodogram and spectral density function estimates for one or more series. You can also request bivariate spectral analysis. Moving averages, termed *windows,* can be used for smoothing the periodogram values to produce spectral densities.

Options

Output. In addition to the periodogram, you can use the PLOT subcommand to produce a plot of the estimated spectral density. You can use the keyword BY on PLOT to suppress the display of the plot by frequency or the plot by period. To display intermediate values and the plot legend, specify TSET PRINT=DETAILED before SPECTRA. To reduce the range of values that are displayed in the plots, you can center the data by using the CENTER subcommand.

Cross-Spectral Analysis. You can specify cross-spectral (bivariate) analysis with the CROSS subcommand and select which bivariate plots are produced by using PLOT.

New Variables. Variables that are computed by SPECTRA can be saved to the active dataset for use in subsequent analyses with the SAVE subcommand. TSET MXNEWVAR specifies the maximum number of new variables that can be generated by a procedure. The default is 60.

Spectral Windows. You can specify a spectral window and its span for calculation of the spectral density estimates.

Basic Specification

The basic specification is one or more series names.

- By default, SPECTRA plots the periodogram for each specified series. The periodogram is shown first by frequency and then by period. No new variables are saved by default.

Subcommand Order

- Subcommands can be specified in any order.

Syntax Rules

- VARIABLES can be specified only once.
- Other subcommands can be specified more than once, but only the last specification of each subcommand is executed.

Operations

- SPECTRA cannot process series with missing observations. (You can use the RMV command to replace missing values, use TSET MISSING=INCLUDE to include user-missing values, and use USE to ignore missing observations at the beginning or end of a series. See RMV and USE for more information.)
- If the number of observations in the series is odd, the first case is ignored.
- If the SAVE subcommand is specified, new variables are created for each specified series. For bivariate analyses, new variables are created for each series pair.
- SPECTRA requires memory both to compute variables and to build plots. Requesting fewer plots may enable you to analyze larger series.

Limitations

- A maximum of one VARIABLES subcommand is allowed. There is no limit on the number of series named on the list.

Example

```
SPECTRA VARIABLES = HSTARTS
  /CENTER
  /PLOT P S BY FREQ.
```

- This example produces a plot of the periodogram and spectral density estimate for series *HSTARTS*.
- CENTER adjusts the series to have a mean of 0.
- PLOT specifies that the periodogram (P) and the spectral density estimate (S) should be plotted against frequency (BY FREQ).

VARIABLES Subcommand

VARIABLES specifies the series names and is the only required subcommand.

- VARIABLES must be specified before the other subcommands.
- Each specified series is analyzed separately unless the CROSS subcommand is specified.
- The series must contain at least six cases.

Example

```
SPECTRA VARIABLES = VARX VARY.
```

- This command produces the default display for two series, *VARX* and *VARY*.

CENTER Subcommand

CENTER adjusts the series to have a mean of 0. This process reduces the range of values that are displayed in the plots.

- If CENTER is not specified, the ordinate of the first periodogram value is $2n$ times the square of the mean of the series, where n is the number of cases.
- You can specify CENTER NO to suppress centering when applying a previous model with APPLY.

Example

```
SPECTRA VARIABLES = VARX VARY
  /CENTER.
```

- This example produces the default display for *VARX* and *VARY*. The plots are based on the series after their means have been adjusted to 0.

WINDOW Subcommand

WINDOW specifies a spectral window to use when the periodogram is smoothed to obtain the spectral density estimate. If WINDOW is not specified, the Tukey-Hamming window with a span of 5 is used.

- The specification on WINDOW is a window name and a span in parentheses, or a sequence of user-specified weights.
- The window name can be any one of the keywords listed below.

- Only one window keyword is accepted. If more than one keyword is specified, the first keyword is used.
- The span is the number of periodogram values in the moving average and can be any integer. If an even number is specified, it is decreased by 1.
- Smoothing near the end of series is accomplished via reflection. For example, if the span is 5, the second periodogram value is smoothed by averaging the first, third, and fourth values and twice the second value.

The following data windows can be specified. Each formula defines the upper half of the window. The lower half is symmetric with the upper half. In all formulas, p is the integer part of the number of spans divided by 2, D_p is the Dirichlet kernel of order p, and F_p is the Fejer kernel of order p(Priestley, 1981).

HAMMING *Tukey-Hamming window.* The weights are

$$W_k = 0.54D_p(2\pi f_k) + 0.23D_p\left(2\pi f_k + \tfrac{\pi}{p}\right) + 0.23D_p\left(2\pi f_k - \tfrac{\pi}{p}\right)$$

where k=0, ... p. This is the default.

TUKEY *Tukey-Hanning window.* The weights are

$$W_k = 0.5D_p(2\pi f_k) + 0.25D_p\left(2\pi f_k + \tfrac{\pi}{p}\right) + 0.25D_p\left(2\pi f_k - \tfrac{\pi}{p}\right)$$

where k=0, ... p.

PARZEN *Parzen window.* The weights are

$$W_k = \tfrac{1}{p}(2 + \cos(2\pi f_k))\left(F_{p/2}(2\pi f_k)\right)^2$$

where k=0, ... p.

BARTLETT *Bartlett window.* The weights are

$$W_k = F_p(2\pi f_k)$$

where k=0, ... p.

UNIT *Equal-weight window.* The weights are $w_k = 1$ where k=0, ... p. `DANIELL` is an alias for `UNIT`.

NONE *No smoothing.* If `NONE` is specified, the spectral density estimate is the same as the periodogram.

w *User-specified weights.* W_0 is applied to the periodogram value that is being smoothed, and the weights on either side are applied to preceding and following values. If the number of weights is even, it is assumed that w_p is not supplied. The weight after the middle one is applied to the periodogram value being smoothed. W_0 must be positive.

Example

```
SPECTRA VARIABLES = VAR01
  /WINDOW=TUKEY(3)
  /PLOT=P S.
```

- In this example, the Tukey window weights with a span of 3 are used.
- The PLOT subcommand plots both the periodogram and the spectral density estimate, both by frequency and period.

PLOT Subcommand

PLOT specifies which plots are displayed.

- If PLOT is not specified, only the periodogram is plotted for each specified series. Each periodogram is shown both by frequency and by period.
- You can specify more than one plot keyword.
- Keywords can be specified in any order.
- The plot keywords K, CS, QS, PH, A, and G apply only to bivariate analyses. If the subcommand CROSS is not specified, these keywords are ignored.
- The period (horizontal) axis on a plot by period (BY PERIOD) is scaled in natural logarithms from 0.69 to ln(*n*), where *n* is the number of cases.
- The frequency (horizontal) axis on a plot by frequency (BY FREQ) is scaled from 0 to 0.5, expressing the frequency as a fraction of the length of the series.
- The periodogram and estimated spectrum (vertical axis) are scaled in natural logs.

The following plot keywords are available:

P	*Periodogram.* This setting is the default.
S	*Spectral density estimate.*
K	*Squared coherency.* Applies only to bivariate analyses.
CS	*Cospectral density estimate.* Applies only to bivariate analyses.
QS	*Quadrature spectrum estimate.* Applies only to bivariate analyses.
PH	*Phase spectrum.* Applies only to bivariate analyses.
A	*Cross amplitude.* Applies only to bivariate analyses.
G	*Gain.* Applies only to bivariate analyses.
ALL	*All plots.* For bivariate analyses, this setting includes all plots listed above. For univariate analyses, this setting includes the periodogram and the spectral density estimate.

BY Keyword

By default, SPECTRA displays both frequency and period plots. You can use BY to produce only frequency plots or only period plots.

- BY FREQ indicates that all plots are plotted by frequency only. Plots by period are not produced.

- BY PERIOD indicates that all plots are plotted by period only. Plots by frequency are not produced.

Example

```
SPECTRA VARIABLES = SER01
  /PLOT=P S BY FREQ.
```

- This command plots both the periodogram and the spectral density estimate for *SER01*. The plots are shown by frequency only.

CROSS Subcommand

CROSS is used to specify bivariate spectral analysis.

- When CROSS is specified, the first series named on the VARIABLES subcommand is the independent variable. All remaining variables are dependent.
- Each series after the first series is analyzed with the first series independently of other series that is named.
- Univariate analysis of each specified series is still performed.
- You can specify CROSS NO to turn off bivariate analysis when applying a previous model with APPLY.

Example

```
SPECTRA VARIABLES = VARX VARY VARZ
  /CROSS.
```

- In this example, bivariate spectral analyses of series *VARX* with *VARY* and *VARX* with *VARZ* are requested in addition to the usual univariate analyses of *VARX*, *VARY*, and *VARZ*.

SAVE Subcommand

SAVE saves computed SPECTRA variables to the active dataset for later use. SPECTRA displays a list of the new variables and their labels, showing the type and source of those variables.

- You can specify any or all of the output keywords listed below.
- A name to be used for generating variable names must follow each output keyword. The name must be enclosed in parentheses.
- For each output keyword, one variable is created for each series named on SPECTRA and for each bivariate pair.
- The keywords RC, IC, CS, QS, PH, A, G, and K apply only to bivariate analyses. If CROSS is not specified, these keywords are ignored.
- SAVE specifications are not used when models are reapplied by using APPLY. They must be specified each time variables are to be saved.
- The output variables correspond to the Fourier frequencies. They do not correspond to the original series.

- Because each output variable has only (n/2 + 1) cases (where n is the number of cases), the values for the second half of the series are set to system-missing.
- Variable names are generated by adding *_n* to the specified name, where *n* ranges from 1 to the number of series specified.
- For bivariate variables, the suffix is *_n_n*, where the *n*s indicate the two variables that are used in the analysis.
- The frequency (FREQ) and period (PER) variable names are constant across all series and do not have a numeric suffix.
- If the generated variable name is longer than the maximum variable name length, or if the specified name already exists, the variable is not saved.

The following output keywords are available:

FREQ	*Fourier frequencies.*
PER	*Fourier periods.*
SIN	*Value of a sine function at the Fourier frequencies.*
COS	*Value of a cosine function at the Fourier frequencies.*
P	*Periodogram values.*
S	*Spectral density estimate values.*
RC	*Real part values of the cross-periodogram.* Applies only to bivariate analyses.
IC	*Imaginary part values of the cross-periodogram.* Applies only to bivariate analyses.
CS	*Cospectral density estimate values.* Applies only to bivariate analyses.
QS	*Quadrature spectrum estimate values.* Applies only to bivariate analyses.
PH	*Phase spectrum estimate values.* Applies only to bivariate analyses.
A	*Cross-amplitude values.* Applies only to bivariate analyses.
G	*Gain values.* Applies only to bivariate analyses.
K	*Squared coherency values.* Applies only to bivariate analyses.

Example

```
SPECTRA VARIABLES=STRIKES RUNS
   /SAVE= FREQ (FREQ) P (PGRAM) S (SPEC).
```

- This example creates five variables: *FREQ*, *PGRAM_1*, *PGRAM_2*, *SPEC_1*, and *SPEC_2*.

APPLY Subcommand

APPLY allows you to use a previously defined SPECTRA model without having to repeat the specifications.

- The only specification on APPLY is the name of a previous model in quotation marks. If a model name is not specified, the model that was specified on the previous SPECTRA command is used. Model names are either the default *MOD_n* names that are assigned by Trends or the names that are assigned on the MODEL NAME command.

- To change one or more model specifications, specify the subcommands of only those portions you want to change after the APPLY subcommand.
- If no series are specified on the command, the series that were originally specified with the model that is being reapplied are used.
- To change the series that are used with the model, enter new series names before or after the APPLY subcommand. If a variable name is specified before APPLY, the slash before the subcommand is required.
- The SAVE specifications from the previous model are *not* reused by APPLY. They must be specified each time that variables are to be saved.

Examples

```
SPECTRA VARIABLES = VAR01
  /WINDOW=DANIELL (3)
  /CENTER
  /PLOT P S BY FREQ.
SPECTRA APPLY
  /PLOT P S.
```

- The first command plots both the periodogram and the spectral density estimate for *VAR01*. The plots are shown by frequency only.
- Because the PLOT subcommand is respecified, the second command produces plots by both frequency and period. All other specifications remain the same as in the first command.

SPLIT FILE

```
SPLIT FILE              {OFF       }
          [{LAYERED }] {BY varlist}
           {SEPARATE}
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Example

```
SPLIT FILE BY SEX.
```

Overview

SPLIT FILE splits the active dataset into subgroups that can be analyzed separately. These subgroups are sets of adjacent cases in the file that have the same values for the specified split variables. Each value of each split variable is considered a break group, and cases within a break group must be grouped together in the active dataset. If they are not grouped together, the SORT CASES command must be used before SPLIT FILE to sort cases in the proper order.

Basic Specification

The basic specification is keyword BY followed by the variable or variables that define the split-file groups.

- By default, the split-file groups are compared within the same table(s).
- You can turn off split-file processing by using keyword OFF.

Syntax Rules

- SPLIT FILE can specify both numeric and string split variables, including variables that are created by temporary transformations. SPLIT FILE cannot specify scratch or system variables.
- SPLIT FILE is in effect for all procedures in a session unless you limit it with a TEMPORARY command, turn it off, or override it with a new SPLIT FILE or SORT CASES command.

Operations

- SPLIT FILE takes effect as soon as it is encountered in the command sequence. Therefore, pay special attention to the position of SPLIT FILE among commands. For more information, see Command Order on p. 36.
- The file is processed sequentially. A change or break in values on any one of the split variables signals the end of one break group and the beginning of the next break group.

- AGGREGATE ignores the SPLIT FILE command. To split files by using AGGREGATE, name the variables that are used to split the file as break variables ahead of any other break variables on AGGREGATE. AGGREGATE still produces one file, but the aggregated cases are in the same order as the split-file groups.
- If SPLIT FILE is in effect when a procedure writes matrix materials, the program writes one set of matrix materials for every split group. If a procedure reads a file that contains multiple sets of matrix materials, the procedure automatically detects the presence of multiple sets.
- If SPLIT FILE names any variable that was defined by the NUMERIC command, the program prints page headings that indicate the split-file grouping.

Limitations

- SPLIT FILE can specify or imply up to eight variables.
- Each eight bytes of a string variable counts as a variable toward the limit of eight variables. So a string variable with a defined width of greater than 64 bytes cannot be used as a split file variable.

LAYERED and SEPARATE Subcommands

LAYERED and SEPARATE specify how split-file groups are displayed in the output.

- Only one of these subcommands can be specified. If neither subcommand is specified with the BY variable list, LAYERED is the default.
- LAYERED and SEPARATE do not apply to the text output.

LAYERED *Display split-file groups in the same table in the outermost column.*

SEPARATE *Display split-file groups as separate tables.*

Examples

Sorting and Splitting a File

```
SORT CASES BY SEX.
SPLIT FILE BY SEX.
FREQUENCIES VARS=INCOME /STATISTICS=MEDIAN.
```

- SORT CASES arranges cases in the file according to the values of variable *SEX*.
- SPLIT FILE splits the file according to the values of variable *SEX*, and FREQUENCIES generates separate median income tables for men and women.
- By default, the two groups (men and women) are compared in the same Frequency and Statistics tables.

Applying a Temporary Split File

```
SORT CASES BY SEX.
TEMPORARY.
SPLIT FILE SEPARATE BY SEX.
FREQUENCIES VARS=INCOME /STATISTICS=MEDIAN.
FREQUENCIES VARS=INCOME /STATISTICS=MEDIAN.
```

- Because of the TEMPORARY command, SPLIT FILE applies to the first procedure only. Thus, the first FREQUENCIES procedure generates separate tables for men and women. The second FREQUENCIES procedure generates tables that include both sexes.

Turning Off a Split File

```
SORT CASES BY SEX.
SPLIT FILE SEPARATE BY SEX.
FREQUENCIES VARS=INCOME /STATISTICS=MEDIAN.
SPLIT FILE OFF.
FREQUENCIES VARS=INCOME /STATISTICS=MEDIAN.
```

- SPLIT FILE does not apply to the second FREQUENCIES procedure because it is turned off after the first FREQUENCIES procedure. This example produces the same results as the example above.

Overriding a Previous Split File

```
SORT CASES BY SEX RACE.
SPLIT FILE BY SEX.
FREQUENCIES VARS=INCOME /STATISTICS=MEDIAN.
SPLIT FILE BY SEX RACE.
FREQUENCIES VARS=INCOME /STATISTICS=MEDIAN.
```

- The first SPLIT FILE command applies to the first FREQUENCIES procedure. The second SPLIT FILE command overrides the first command and splits the file by sex and race. This split is in effect for the second FREQUENCIES procedure.

STRING

```
STRING varlist (An) [/varlist...]
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Example

```
STRING STATE1 (A2).
```

Overview

STRING declares new string variables that can be used as target variables in data transformations.

Basic Specification

The basic specification is the name of the new variables and, in parentheses, the variable format.

Syntax Rules

- If keyword TO is used to create multiple string variables, the specified format applies to each variable that is named and implied by TO.
- To declare variables with different formats, separate each format group with a slash.
- STRING can be used within an input program to determine the order of string variables in the dictionary of the active dataset. When used for this purpose, STRING must precede DATA LIST in the input program. See the Examples for the NUMERIC command on p. 1278.
- STRING cannot be used to redefine an existing variable.
- String variables cannot have zero length; A0 is an illegal format.
- All implementations of the program allow the A format. Other string formats may be available on some systems. In addition, the definition of a long string depends on your operating system. Use keyword LOCAL on the INFO command to obtain documentation for your operating system.

Operations

- STRING takes effect as soon as it is encountered in the command sequence. Therefore, pay special attention to the position of STRING among commands. For more information, see Command Order on p. 36.
- New string variables are initialized as blanks.
- Variables that are declared on STRING are added to the active dataset in the order in which they are specified. This order is not changed by the order in which the variables are used in the transformation language.

- The length of a string variable is fixed by the format that is specified when the variable is declared. This length cannot be changed by FORMATS. To change the length of a string variable, declare a new variable with the desired length, and then use COMPUTE to assign the values of the original variable to it.

Examples

```
STRING STATE1 (A2).
RECODE STATE ('IO'='IA') (ELSE=COPY) INTO STATE1.
```

- STRING declares variable *STATE1* with an A2 format.
- RECODE specifies *STATE* as the source variable and specifies *STATE1* as the target variable. The original value IO is recoded to IA. Keywords ELSE and COPY copy all other state codes unchanged. Thus, *STATE* and *STATE1* are identical except for cases with the original value IO.

```
STRING V1 TO V6 (A8) / V7 V10 (A16).
```

- STRING declares variables *V1*, *V2*, *V3*, *V4*, *V5*, and *V6*, each with an A8 format, and variables *V7* and *V10*, each with an A16 format.

SUBTITLE

```
SUBTITLE  ']text[']
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Example

```
SUBTITLE "Children's Training Shoes Only".
```

Overview

SUBTITLE inserts a left-justified subtitle on the second line from the top of each page of the output. The default subtitle contains the installation name and information about the hardware and operating system.

Basic Specification

The only specification is the subtitle itself.

Syntax Rules

- The subtitle can include any characters. To specify a blank subtitle, enclose a blank within quotes.
- The subtitle can be up to 60 characters. Subtitles that are longer than 60 characters are truncated.
- The quotes enclosing the subtitle are optional; using them allows you to include single or double quotes in the subtitle.
- More than one SUBTITLE command is allowed in a single session.
- A subtitle cannot be placed between a procedure command and BEGIN DATA–END DATA or within data records when the data are inline.

Operations

- Each SUBTITLE command overrides the previous command and takes effect on the next output page.
- SUBTITLE is independent of TITLE and each command can be changed separately.
- The subtitle will not be displayed if HEADER=NO is specified on SET.

Examples

Using Single and Double Quotes

```
TITLE 'Running Shoe Study from Runner''s World Data'.
SUBTITLE "Children's Training Shoes Only".
```

- The title is enclosed in single quotes, so the single quote (apostrophe) in *Runner's* must be specified as a two single quotes.
- The subtitle is enclosed in double quotes, so the apostrophe in *Children's* is simply specified as a single quote.

Suppressing the Default Subtitle

```
TITLE 'Running Shoe Study from Runner''s World Data'.
SUBTITLE ' '.
```

- This subtitle is specified as a blank, which suppresses the default subtitle.

SUMMARIZE

```
SUMMARIZE [TABLES=]{varlist} [BY varlist] [BY...] [/varlist...]
                   {ALL    }

 [/TITLE ='string']     [/FOOTNOTE= 'string']

 [/CELLS= [COUNT**] [MEAN ] [STDDEV]
                  [MEDIAN] [GMEDIAN] [SEMEAN]  [SUM ]
                  [MIN] [MAX] [RANGE] [VARIANCE]
                  [KURT] [SEKURT] [SKEW] [SESKEW]
                  [FIRST] [LAST]
                  [NPCT] [SPCT] [NPCT(var)] [SPCT(var)]
                  [HARMONIC] [GEOMETRIC]
                  [DEFAULT]
                  [ALL] [NONE]  ]

 [/MISSING=[{EXCLUDE**}][{VARIABLE**  }]
            {INCLUDE  }  {TABLE       }
            {DEPENDENT}

 [FORMAT=[{NOLIST**      }] [{CASENUM   }] [{TOTAL**}]  [MISSING='string']
          {LIST [LIMIT=n]}   {NOCASENUM }   {NOTOTAL}
          {VALIDLIST     }

 [/STATISTICS=[ANOVA] [{LINEARITY}] [NONE**] ]
                       {ALL      }
```

**Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
SUMMARIZE SALES.
```

Overview

SUMMARIZE produces univariate statistics for specified variables. You can break the variables into groups defined by one or more control (independent) variables. Another procedure that displays univariate statistics is FREQUENCIES.

Options

Cell Contents. By default, SUMMARIZE displays means, standard deviations, and cell counts. You can also use the CELLS subcommand to display aggregated statistics, including sums, variances, median, range, kurtosis, skewness, and their standard error.

Statistics. In addition to the statistics that are displayed for each cell of the table, you can use the STATISTICS subcommand to obtain a one-way analysis of variance and test of linearity.

Format. By default, SUMMARIZE produces a Summary Report with a total category for each group that is defined by the control variables. You can use the FORMAT subcommand to request a Listing Report with or without case numbers. You can also remove the total category from each

group. You can use the TITLE and FOOTNOTE subcommands to specify a title and a caption for the Summary or Listing Report.

Basic Specification

The basic specification is TABLES with a variable list. Each variable creates a category. The actual keyword TABLES can be omitted.

- The minimum specification is a dependent variable.
- By default, SUMMARIZE displays a Case Processing Summary table, showing the number and percentage of cases included, excluded, and their total. SUMMARIZE also displays a Summary Report, showing means, standard deviations, and number of cases for each category.

Syntax Rules

- Both numeric and string variables can be specified. String variables can be short or long.
- If there is more than one TABLES subcommand, FORMAT=LIST or VALIDLIST results in an error.
- String specifications for TITLE and FOOTNOTE must be enclosed in quotes and cannot exceed 255 bytes. When the specification breaks on multiple lines, enclose each line in quotes, and separate the specifications for each line by at least one blank.
- Each subcommand (except TABLES) can be specified only once. If a subcommand is specified multiple times, a warning results, and the last specification is used.
- Multiple TABLES subcommands are allowed, but multiple specifications use a lot of computer resources and time.
- There is no limit on the number of variables that you can specify on each TABLES subcommand.
- When a variable is specified more than once, only the first occurrence is honored. If the same variables are specified after different BY keywords, an error results.

Limitations

- Only 10 BY keywords can be specified.

Operations

- The data are processed sequentially. It is not necessary to sort the cases before processing. If a BY keyword is used, the output is always sorted.
- A Case Processing Summary table is always generated, showing the number and percentage of the cases included, excluded, and the total.
- For each combination of control variables specified after different BY keywords, SUMMARIZE produces a group in the Summary Report (depending on the specification on the FORMAT subcommand). By default, mean, standard deviation, and number of cases are displayed for each group and for the total.
- An ANOVA table and a Measure of Association table are produced if additional statistics are requested.

Example

```
SUMMARIZE TABLES=V1 BY SEX BY GROUP
  /STATISTICS=ANOVA.
```

- A Case Processing Summary table lists the number and percentage of cases included, excluded, and the total.
- A Summary Report displays means, standard deviations, and numbers of cases for each group defined by each combination of *SEX* and *GROUP*.
- An ANOVA table displays analysis of variance with only *SEX* as the grouping variable.

TABLES Subcommand

TABLES specifies the dependent and control variables.

- You can specify multiple TABLES subcommands on a single SUMMARIZE command.
- For FORMAT=LIST or VALIDLIST, only one TABLES subcommand is allowed. Multiple dependent and control variables add more breaks to the Listing Report. Total statistics are displayed at the end for each combination that is defined by different values of the control variables.
- For FORMAT=NOLIST, which is the default, each use of keyword BY adds a dimension to the requested table. Total statistics are displayed with each group.
- The order in which control variables are displayed is the same as the order in which they are specified on TABLES. The values of the first control variable that is defined for the table appear in the leftmost column of the table and change the most slowly in the definition of groups.
- Statistics are displayed for each dependent variable in the same report.
- More than one dependent variable can be specified in a table list, and more than one control variable can be specified in each dimension of a table list.

TITLE and FOOTNOTE Subcommands

TITLE and FOOTNOTE provide a title and a caption for the Summary or Listing Report.

- TITLE and FOOTNOTE are optional and can be placed anywhere.
- The specification on TITLE or FOOTNOTE is a string enclosed in quotes. To specify a multiple-line title or footnote, enclose each line in quotes and separate the specifications for each line by at least one blank.
- The string that you specify cannot exceed 255 characters.

CELLS Subcommand

By default, SUMMARIZE displays the means, standard deviations, and cell counts in each cell. Use CELLS to modify cell information.

- If CELLS is specified without keywords, SUMMARIZE displays the default statistics.

- If any keywords are specified on CELLS, only the requested information is displayed.
- MEDIAN and GMEDIAN use a lot of computer resources and time. Requesting these statistics (via these keywords or ALL) may slow down performance.

DEFAULT	*Means, standard deviations, and cell counts.* This setting is the default if CELLS is omitted.
MEAN	*Cell means.*
STDDEV	*Cell standard deviations.*
COUNT	*Cell counts.*
MEDIAN	*Cell median.*
GMEDIAN	*Grouped median.*
SEMEAN	*Standard error of cell mean.*
SUM	*Cell sums.*
MIN	*Cell minimum.*
MAX	*Cell maximum.*
RANGE	*Cell range.*
VARIANCE	*Variances.*
KURT	*Cell kurtosis.*
SEKURT	*Standard error of cell kurtosis.*
SKEW	*Cell skewness.*
SESKEW	*Standard error of cell skewness.*
FIRST	*First value.*
LAST	*Last value.*
SPCT	*Percentage of total sum.*
NPCT	*Percentage of total number of cases.*
SPCT(var)	*Percentage of total sum within specified variable.* The specified variable must be one of the control variables.
NPCT(var)	*Percentage of total number of cases within specified variable.* The specified variable must be one of the control variables.
HARMONIC	*Harmonic mean.*
GEOMETRIC	*Geometric mean.*
ALL	*All cell information.*

MISSING Subcommand

MISSING controls the treatment of cases with missing values. There are two groups of keywords.

- EXCLUDE, INCLUDE, and DEPENDENT specify the treatment of user-missing values. The default is EXCLUDE.

EXCLUDE	*All user-missing values are excluded.* This setting is the default.
INCLUDE	*User-missing values are treated as valid values.*
DEPENDENT	*User-missing values are considered missing in a dependent variable and valid in a grouping variable (variables that are specified after a BY keyword).*

- VARIABLE and TABLE specify how cases with missing values for dependent variables are excluded. The default is VARIABLE.
- Cases with missing values for any control variables are always excluded.

VARIABLE *A case is excluded when all values for variables in that table are missing.* This setting is the default.

TABLE *A case is excluded when any value is missing within a table.*

FORMAT Subcommand

FORMAT specifies whether you want a case listing for your report and whether you want case numbers displayed for the listing. FORMAT also determines whether your reports will display a total category for each group and how the reports will indicate missing values.

NOLIST *Display a Summary Report without a case listing.* This setting is the default.

LIST *Display a Listing Report.* By default, LIST shows all cases. It can be followed by the optional keyword LIMIT, an equals sign, and a positive integer to limit the number of cases in the report. For example, /FORMAT LIST LIMIT=10 will limit the report to the first 10 cases.

VALIDLIST *Display a Listing Report showing only valid cases.*

CASENUM *Display case numbers as a category in the Listing Reports.* This setting is the default when FORMAT=LIST or VALIDLIST.

NOCASENUM *Do not display case numbers.*

TOTAL *Display the summary statistics for the total of each group with the label* Total. This is the default.

NOTOTAL *Display the total category without a label.*

MISSING='string' *Display system-missing values as a specified string.*

STATISTICS Subcommand

Use STATISTICS to request a one-way analysis of variance and a test of linearity for each table list.

- Statistics that are requested on STATISTICS are computed in addition to the statistics that are displayed in the Group Statistics table.
- If STATISTICS is specified without keywords, SUMMARIZE computes ANOVA.
- If two or more dimensions are specified, the second and subsequent dimensions are ignored in the analysis-of-variance table.

ANOVA *Analysis of variance.* ANOVA displays a standard analysis-of-variance table and calculates eta and eta squared (displayed in the Measures of Association table). This setting is the default if STATISTICS is specified without keywords.

LINEARITY *Test of linearity.* LINEARITY (alias ALL) displays additional statistics to the tables that are created by the ANOVA keyword—the sums of squares, degrees of freedom, and mean square associated with linear and nonlinear components, the *F* ratio, and the significance level for the ANOVA table and Pearson's *r* and r^2 for the Measures of Association table. LINEARITY is ignored if the control variable is a string.

NONE *No additional statistics.* This setting is the default if STATISTICS is omitted.

Example

```
SUMMARIZE TABLES=INCOME BY SEX BY RACE
  /STATISTICS=ANOVA.
```

- SUMMARIZE produces a Group Statistics table of *INCOME* by *RACE* within *SEX* and computes an analysis of variance only for *INCOME* by *SEX*.

SURVIVAL

SURVIVAL is available in the Advanced Models option.

```
SURVIVAL TABLES=survival varlist
                [BY varlist (min, max)...][BY varlist (min, max)...]

  /INTERVALS=THRU n BY a [THRU m BY b ...]

  /STATUS=status variable({min, max}) FOR {ALL             }
                          {value   }      {survival varlist}
 [/STATUS=...]

 [/PLOT  ({ALL     })={ALL            } BY {ALL    }     BY {ALL    }]
          {LOGSURV }  {survival varlis}    {varlist}        {varlist}
          {SURVIVAL}
          {HAZARD  }
          {DENSITY }
          {OMS     }

 [/PRINT={TABLE**}]
         {NOTABLE}

 [/COMPARE={ALL**           } BY {ALL**  }   BY {ALL**  }]
           {survival varlist}    {varlist}      {varlist}

 [/CALCULATE=[{EXACT**    }] [PAIRWISE] [COMPARE] ]
              {CONDITIONAL}
              {APPROXIMATE}

 [/MISSING={GROUPWISE**}  [INCLUDE] ]
           {LISTWISE   }

 [/WRITE=[{NONE**}] ]
          {TABLES}
          {BOTH  }
```

**Default if the subcommand or keyword is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
SURVIVAL TABLES=MOSFREE BY TREATMNT(1,3)
  /STATUS = PRISON (1) FOR MOSFREE
  /INTERVAL=THRU 24 BY 3.
```

Overview

SURVIVAL produces actuarial life tables, plots, and related statistics for examining the length of time to the occurrence of an event, often known as **survival time**. Cases can be classified into groups for separate analyses and comparisons. Time intervals can be calculated with the SPSS date- and time-conversion functions—for example, CTIME.DAYS or YRMODA. For a closely related alternative nonparametric analysis of survival times using the product-limit Kaplan-Meier estimator, see the KM command. For an analysis of survival times with covariates, including time-dependent covariates, see the COXREG command.

Options

Life Tables. You can list the variables to be used in the analysis, including any control variables on the TABLES subcommand. You can also suppress the life tables in the output with the PRINT subcommand.

Intervals. SURVIVAL reports the percentage alive at various times after the initial event. You can select the time points for reporting with the INTERVALS subcommand.

Plots. You can plot the survival functions for all cases or separately for various subgroups with the PLOT subcommand.

Comparisons. When control variables are listed on the TABLES subcommand, you can compare groups based on the Wilcoxon (Gehan) statistic using the COMPARE subcommand. You can request pairwise or approximate comparisons with the CALCULATE subcommand.

Writing a File. You can write the life tables, including the labeling information, to a file with the WRITE subcommand.

Basic Specification

- The basic specification requires three subcommands: TABLES, INTERVALS, and STATUS. TABLES identifies at least one survival variable from the active dataset, INTERVALS divides the time period into intervals, and STATUS names a variable that indicates whether the event occurred.
- The basic specification prints one or more life tables, depending on the number of survival and control variables specified.

Subcommand Order

- TABLES must be first.
- Remaining subcommands can be named in any order.

Syntax Rules

- Only one TABLES subcommand can be specified, but multiple survival variables can be named. A survival variable cannot be specified as a control variable on any subcommands.
- Only one INTERVALS subcommand can be in effect on a SURVIVAL command. The interval specifications apply to all of the survival variables listed on TABLES. If multiple INTERVALS subcommands are used, the last specification supersedes all previous ones.
- Only one status variable can be listed on each STATUS subcommand. To specify multiple status variables, use multiple STATUS subcommands.
- You can specify multiple control variables on one BY keyword. Use a second BY keyword to specify second-order control variables to interact with the first-order control variables.
- All variables, including survival variables, control variables, and status variables, must be numeric. SURVIVAL does not process string variables.

Operations

- SURVIVAL computes time intervals according to specified interval widths, calculates the survival functions for each interval, and builds one life table for each group of survival variables. The life table is displayed unless explicitly suppressed.
- When the PLOT subcommand is specified, SURVIVAL plots the survival functions for all cases or separately for various groups.
- When the COMPARE subcommand is specified, SURVIVAL compares survival-time distributions of different groups based on the Wilcoxon (Gehan) statistic.

Limitations

- Maximum 20 survival variables.
- Maximum 100 control variables total on the first- and second-order control-variable lists combined.
- Maximum 20 THRU and BY specifications on INTERVALS.
- Maximum 35 values can appear on a plot.

Example

```
SURVIVAL TABLES=MOSFREE BY TREATMNT(1,3)
  /STATUS = PRISON (1) FOR MOSFREE
  /INTERVALS = THRU 24 BY 3.
```

- The survival analysis is used to examine the length of time between release from prison and return to prison for prisoners in three treatment programs. The variable *MOSFREE* is the length of time in months a prisoner stayed out of prison. The variable *TREATMNT* indicates the treatment group for each case.
- A value of 1 on the variable *PRISON* indicates a terminal outcome—that is, cases coded as 1 have returned to prison. Cases with other non-negative values for *PRISON* have not returned. Because we don't know their final outcome, such cases are called censored.
- Life tables are produced for each of the three subgroups. INTERVALS specifies that the survival experience be described every three months for the first two years.

TABLES Subcommand

TABLES identifies the survival and control variables to be included in the analysis.

- The minimum specification is one or more survival variables.
- To specify one or more first-order control (or factor) variables, use the keyword BY followed by the control variable(s). First-order control variables are processed in sequence. For example, BY A(1,3) B(1,2) results in five groups (A=1, A=2, A=3, B=1, and B=2).
- You can specify one or more second-order control variables following a second BY keyword. Separate life tables are generated for each combination of values of the first-order and second-order controls. For example, BY A(1,3) BY B(1,2) results in six groups (A=1 B=1, A=1 B=2, A=2 B=1, A=2 B=2, A=3 B=1, and A=3, B=2).

- Each control variable must be followed by a value range in parentheses. These values must be integers separated by a comma or a blank. Non-integer values in the data are truncated, and the case is assigned to a subgroup based on the integer portion of its value on the variable. To specify only one value for a control variable, use the same value for the minimum and maximum.
- To generate life tables for all cases combined, as well as for control variables, use COMPUTE to create a variable that has the same value for all cases. With this variable as a control, tables for the entire set of cases, as well as for the control variables, will be produced.

Example

```
SURVIVAL TABLES = MOSFREE BY TREATMNT(1,3) BY RACE(1,2)
  /STATUS = PRISON(1)
  /INTERVAL = THRU 24 BY 3.
```

- *MOSFREE* is the survival variable, and *TREATMNT* is the first-order control variable. The second BY defines *RACE* as a second-order control group having a value of 1 or 2.
- Six life tables with the median survival time are produced, one for each pair of values for the two control variables.

INTERVALS Subcommand

INTERVALS determines the period of time to be examined and how the time will be grouped for the analysis. The interval specifications apply to all of the survival variables listed on TABLES.

- SURVIVAL always uses 0 as the starting point for the first interval. Do not specify the 0. The INTERVALS specification *must* begin with the keyword THRU.
- Specify the terminal value of the time period after the keyword THRU. The final interval includes any observations that exceed the specified terminal value.
- The grouping increment, which follows the keyword BY, must be in the same units as the survival variable.
- The period to be examined can be divided into intervals of varying lengths by repeating the THRU and BY keywords. The period must be divided in ascending order. If the time period is not a multiple of the increment, the endpoint of the period is adjusted upward to the next even multiple of the grouping increment.
- When the period is divided into intervals of varying lengths by repeating the THRU and BY specifications, the adjustment of one period to produce even intervals changes the starting point of subsequent periods. If the upward adjustment of one period completely overlaps the next period, no adjustment is made and the procedure terminates with an error.

Example

```
SURVIVAL TABLES = MOSFREE BY TREATMNT(1,3)
  /STATUS = PRISON(1) FOR MOSFREE
  /INTERVALS = THRU 12 BY 1 THRU 24 BY 3.
```

- INTERVALS produces life tables computed from 0 to 12 months at one-month intervals and from 13 to 24 months at three-month intervals.

Example

```
SURVIVAL  ONSSURV BY TREATMNT (1,3)
  /STATUS = OUTCOME (3,4) FOR ONSSURV
  /INTERVALS = THRU 50 BY 6.
```

- On the INTERVALS subcommand, the value following BY (6) does not divide evenly into the period to which it applies (50). Thus, the endpoint of the period is adjusted upward to the next even multiple of the BY value, resulting in a period of 54 with 9 intervals of 6 units each.

Example

```
SURVIVAL  ONSSURV BY TREATMNT (1,3)
  /STATUS = OUTCOME (3,4) FOR ONSSURV
  /INTERVALS = THRU 50 BY 6 THRU 100 BY 10 THRU 200 BY 20.
```

- Multiple THRU and BY specifications are used on the INTERVAL subcommand to divide the period of time under examination into intervals of different lengths.
- The first THRU and BY specifications are adjusted to produce even intervals as in the previous example. As a result, the following THRU and BY specifications are automatically readjusted to generate 5 intervals of 10 units (through 104), followed by 5 intervals of 20 units (through 204).

STATUS Subcommand

To determine whether the terminal event has occurred for a particular observation, SURVIVAL checks the value of a status variable. STATUS lists the status variable associated with each survival variable and the codes that indicate that a terminal event occurred.

- Specify a status variable followed by a value range enclosed in parentheses. The value range identifies the codes that indicate that the terminal event has taken place. All cases with non-negative times that do not have a code in the value range are classified as **censored cases**, which are cases for which the terminal event has not yet occurred.
- If the status variable does not apply to all the survival variables, specify FOR and the name of the survival variable(s) to which the status variable applies.
- Each survival variable on TABLES must have an associated status variable identified by a STATUS subcommand.
- Only one status variable can be listed on each STATUS subcommand. To specify multiple status variables, use multiple STATUS subcommands.
- If FOR is omitted on the STATUS specification, the status-variable specification applies to all of the survival variables not named on another STATUS subcommand.
- If more than one STATUS subcommand omits the keyword FOR, the final STATUS subcommand without FOR applies to all survival variables not specified by FOR on other STATUS subcommands. No warning is printed.

Example

```
SURVIVAL  ONSSURV BY TREATMNT (1,3)
  /INTERVALS = THRU 50 BY 5, THRU 100 BY 10
  /STATUS = OUTCOME (3,4) FOR ONSSURV.
```

- STATUS specifies that a code of 3 or 4 on *OUTCOME* means that the terminal event for the survival variable *ONSSURV* occurred.

Example

```
SURVIVAL TABLES = NOARREST MOSFREE BY TREATMNT(1,3)
  /STATUS = ARREST (1) FOR NOARREST
  /STATUS = PRISON (1)
  /INTERVAL=THRU 24 BY 3.
```

- STATUS defines the terminal event for *NOARREST* as a value of 1 for *ARREST*. Any other value for *ARREST* is considered censored.
- The second STATUS subcommand defines the value of 1 for *PRISON* as the terminal event. The keyword FOR is omitted. Thus, the status-variable specification applies to *MOSFREE*, which is the only survival variable not named on another STATUS subcommand.

PLOT Subcommand

PLOT produces plots of the cumulative survival distribution, the hazard function, and the probability density function. The PLOT subcommand can plot only the survival functions generated by the TABLES subcommand; PLOT cannot eliminate control variables.

- When specified by itself, the PLOT subcommand produces all available plots for each survival variable. Points on each plot are identified by values of the first-order control variables. If second-order controls are used, a separate plot is generated for every value of the second-order control variables.
- To request specific plots, specify, in parentheses following PLOT, any combination of the keywords defined below.
- Optionally, generate plots for only a subset of the requested life tables. Use the same syntax as used on the TABLES subcommand for specifying survival and control variables, omitting the value ranges. Each survival variable named on PLOT must have as many control levels as were specified for that variable on TABLES. However, only one control variable needs to be present for each level. If a required control level is missing on the PLOT specification, the default BY ALL is used for that level. The keyword ALL can be used to refer to an entire set of survival or control variables.
- To determine the number of plots that will be produced, multiply the number of functions plotted by the number of survival variables times the number of first-order controls times the number of distinct values represented in all of the second-order controls.

ALL	*Plot all available functions.* ALL is the default if PLOT is used without specifications.
LOGSURV	*Plot the cumulative survival distribution on a logarithmic scale.*
SURVIVAL	*Plot the cumulative survival distribution on a linear scale.*
HAZARD	*Plot the hazard function.*
DENSITY	*Plot the density function.*
OMS	*Plot the one-minus-survival function.*

Example

```
SURVIVAL TABLES = NOARREST MOSFREE BY TREATMNT(1,3)
  /STATUS = ARREST (1) FOR NOARREST
  /STATUS = PRISON (1) FOR MOSFREE
  /INTERVALS = THRU 24 BY 3
  /PLOT (SURVIVAL,HAZARD) = MOSFREE.
```

- Separate life tables are produced for each of the survival variables (*NOARREST* and *MOSFREE*) for each of the three values of the control variable *TREATMNT*.
- PLOT produces plots of the cumulative survival distribution and the hazard rate for *MOSFREE* for the three values of *TREATMNT* (even though *TREATMNT* is not included on the PLOT specification).
- Because plots are requested only for the survival variable *MOSFREE*, no plots are generated for the variable *NOARREST*.

PRINT Subcommand

By default, SURVIVAL prints life tables. PRINT can be used to suppress the life tables.

TABLE *Print the life tables.* This is the default.

NOTABLE *Suppress the life tables.* Only plots and comparisons are printed. The WRITE subcommand, which is used to write the life tables to a file, can be used when NOTABLE is in effect.

Example

```
SURVIVAL TABLES = MOSFREE BY TREATMNT(1,3)
  /STATUS = PRISON (1) FOR MOSFREE
  /INTERVALS = THRU 24 BY 3
  /PLOT (ALL)
  /PRINT = NOTABLE.
```

- PRINT NOTABLE suppresses the printing of life tables.

COMPARE Subcommand

COMPARE compares the survival experience of subgroups defined by the control variables. At least one first-order control variable is required for calculating comparisons.

- When specified by itself, the COMPARE subcommand produces comparisons using the TABLES variable list.
- Alternatively, specify the survival and control variables for the comparisons. Use the same syntax as used on the TABLES subcommand for specifying survival and control variables, omitting the value ranges. Only variables that appear on the TABLES subcommand can be listed on COMPARE, and their role as survival, first-order, and second-order control variables cannot be altered. The keyword TO can be used to refer to a group of variables, and the keyword ALL can be used to refer to an entire set of survival or control variables.
- By default, COMPARE calculates exact comparisons between subgroups. Use the CALCULATE subcommand to obtain pairwise comparisons or approximate comparisons.

Example

```
SURVIVAL TABLES = MOSFREE BY TREATMNT(1,3)
  /STATUS = PRISON (1) FOR MOSFREE
  /INTERVAL = THRU 24 BY 3
  /COMPARE.
```

- COMPARE computes the Wilcoxon (Gehan) statistic, degrees of freedom, and observed significance level for the hypothesis that the three survival curves based on the values of *TREATMNT* are identical.

Example

```
SURVIVAL TABLES=ONSSURV,RECSURV BY TREATMNT(1,3)
  /STATUS = RECURSIT(1,9) FOR RECSURV
  /STATUS = STATUS(3,4) FOR ONSSURV
  /INTERVAL = THRU 50 BY 5 THRU 100 BY 10
  /COMPARE = ONSSURV BY TREATMNT.
```

- COMPARE requests a comparison of *ONSSURV* by *TREATMNT*. No comparison is made of *RECSURV* by *TREATMNT*.

CALCULATE Subcommand

CALCULATE controls the comparisons of survival for subgroups specified on the COMPARE subcommand.

- The minimum specification is the subcommand keyword by itself. EXACT is the default.
- Only one of the keywords EXACT, APPROXIMATE, and CONDITIONAL can be specified. If more than one keyword is used, only one is in effect. The order of precedence is APPROXIMATE, CONDITIONAL, and EXACT.
- The keywords PAIRWISE and COMPARE can be used with any of the EXACT, APPROXIMATE, or CONDITIONAL keywords.
- If CALCULATE is used without the COMPARE subcommand, CALCULATE is ignored. However, if the keyword COMPARE is specified on CALCULATE and the COMPARE subcommand is omitted, an error message is generated.

- Data can be entered into SURVIVAL for each individual case or aggregated for all cases in an interval. The way in which data are entered determines whether an exact or an approximate comparison is most appropriate. For more information, see Using Aggregated Data on p. 1787..

EXACT	*Calculate exact comparisons.* This is the default. You can obtain exact comparisons based on the survival experience of each observation with individual data. While this method is the most accurate, it requires that all of the data be in memory simultaneously. Thus, exact comparisons may be impractical for large samples. It is also inappropriate when individual data are not available and data aggregated by interval must be used.
APPROXIMATE	*Calculate approximate comparisons only.* Approximate comparisons are appropriate for aggregated data. The approximate-comparison approach assumes that all events occur at the midpoint of the interval. With exact comparisons, some of these midpoint ties can be resolved. However, if interval widths are not too great, the difference between exact and approximate comparisons should be small.
CONDITIONAL	*Calculate approximate comparisons if memory is insufficient.* Approximate comparisons are produced only if there is insufficient memory available for exact comparisons.
PAIRWISE	*Perform pairwise comparisons.* Comparisons of all pairs of values of the first-order control variable are produced along with the overall comparison.
COMPARE	*Produce comparisons only.* Survival tables specified on the TABLES subcommand are not computed, and requests for plots are ignored. This allows all available workspace to be used for comparisons. The WRITE subcommand cannot be used when this specification is in effect.

Example

```
SURVIVAL TABLES = MOSFREE BY TREATMNT(1,3)
  /STATUS = PRISON (1) FOR MOSFREE
  /INTERVAL = THRU 24 BY 3
  /COMPARE /CALCULATE = PAIRWISE.
```

- PAIRWISE on CALCULATE computes the Wilcoxon (Gehan) statistic, degrees of freedom, and observed significance levels for each pair of values of *TREATMNT*, as well as for an overall comparison of survival across all three *TREATMNT* subgroups: group 1 with group 2, group 1 with group 3, and group 2 with group 3.
- All comparisons are exact comparisons.

Example

```
SURVIVAL TABLES = MOSFREE BY TREATMNT(1,3)
  /STATUS = PRISON (1) FOR MOSFREE
  /INTERVAL = THRU 24 BY 3
  /COMPARE /CALCULATE = APPROXIMATE COMPARE.
```

- APPROXIMATE on CALCULATE computes the Wilcoxon (Gehan) statistic, degrees of freedom, and probability for the overall comparison of survival across all three *TREATMNT* subgroups using the approximate method.
- Because the keyword COMPARE is specified on CALCULATE, survival tables are not computed.

Using Aggregated Data

When aggregated survival information is available, the number of censored and uncensored cases at each time point must be entered. Up to two records can be entered for each interval, one for censored cases and one for uncensored cases. The number of cases included on each record is used as the weight factor. If control variables are used, there will be up to two records (one for censored and one for uncensored cases) for each value of the control variable in each interval. These records must contain the value of the control variable and the number of cases that belong in the particular category as well as values for survival time and status.

Example

```
DATA LIST  / SURVEVAR 1-2 STATVAR 4 SEX 6 COUNT 8.
VALUE LABELS  STATVAR 1 'DECEASED' 2 'ALIVE'
              /SEX 1 'FEMALE' 2 'MALE'.
BEGIN DATA
 1 1 1 6
 1 1 1 1
 1 2 2 2
 1 1 2 1
 2 2 1 1
 2 1 1 2
 2 2 2 1
 2 1 2 3
   ...
END DATA.
WEIGHT COUNT.
SURVIVAL TABLES = SURVEVAR BY SEX (1,2)
  /INTERVALS = THRU 10 BY 1
  /STATUS = STATVAR (1) FOR SURVEVAR.
```

- This example reads aggregated data and performs a SURVIVAL analysis when a control variable with two values is used.
- The first data record has a code of 1 on the status variable *STATVAR*, indicating that it is an uncensored case, and a code of 1 on *SEX*, the control variable. The number of cases for this interval is 6, the value of the variable *COUNT*. Intervals with weights of 0 do not have to be included.
- *COUNT* is not used in SURVIVAL but is the weight variable. In this example, each interval requires four records to provide all of the data for each *SURVEVAR* interval.

MISSING Subcommand

MISSING controls missing-value treatments. The default is GROUPWISE.

- Negative values on the survival variables are automatically treated as missing data. In addition, cases outside of the value range on a control variable are excluded.
- GROUPWISE and LISTWISE are mutually exclusive. However, each can be used with INCLUDE.

GROUPWISE	*Exclude missing values groupwise.* Cases with missing values on a variable are excluded from any calculation involving that variable. This is the default.
LISTWISE	*Exclude missing values listwise.* Cases missing on any variables named on TABLES are excluded from the analysis.
INCLUDE	*Include user-missing values.* User-missing values are included in the analysis.

WRITE Subcommand

WRITE writes data in the survival tables to a file. This file can be used for further analyses or to produce graphics displays.

- When WRITE is omitted, the default is NONE. No output file is created.
- When WRITE is used, a PROCEDURE OUTPUT command must precede the SURVIVAL command. The OUTFILE subcommand on PROCEDURE OUTPUT specifies the output file.
- When WRITE is specified without a keyword, the default is TABLES.

NONE	*Do not write procedure output to a file.* This is the default when WRITE is omitted.
TABLES	*Write survival-table data records.* All survival-table statistics are written to a file.
BOTH	*Write out survival-table data and label records.* Variable names, variable labels, and value labels are written out along with the survival table statistics.

Format

WRITE writes five types of records. The keyword TABLES writes record types 30, 31, and 40. The keyword BOTH writes record types 10, 20, 30, 31, and 40. The format of each record type is described in the following tables.

Table 220-1
Record type 10, produced only by keyword BOTH

Columns	Content	Format
1–2	Record type (10)	F2.0
3–7	Table number	F5.0
8–15	Name of survival variable	A8
16–55	Variable label of survival variable	A40
56	Number of BY's (0, 1, or 2)	F1.0
57–60	Number of rows in current survival table	F4.0

- One type-10 record is produced for each life table.

- Column 56 specifies the number of orders of control variables (0, 1, or 2) that have been applied to the life table.
- Columns 57–60 specify the number of rows in the life table. This number is the number of intervals in the analysis that show subjects entering; intervals in which no subjects enter are not noted in the life tables.

Table 220-2
Record type 20, produced by keyword BOTH

Columns	Content	Format
1–2	Record type (20)	F2.0
3–7	Table number	F5.0
8–15	Name of control variable	A8
16–55	Variable label of control variable	A40
56–60	Value of control variable	F5.0
61–80	Value label for this value	A20

- One type-20 record is produced for each control variable in each life table.
- If only first-order controls have been placed in the survival analysis, one type-20 record will be produced for each table. If second-order controls have also been applied, two type-20 records will be produced per table.

Table 220-3
Record type 30, produced by both keywords TABLES and BOTH

Columns	Content	Format
1–2	Record type (30)	F2.0
3–7	Table number	F5.0
8–13	Beginning of interval	F6.2
14–21	Number entering interval	F8.2
22–29	Number withdrawn in interval	F8.2
30–37	Number exposed to risk	F8.2
38–45	Number of terminal events	F8.2

- Information on record type 30 continues on record type 31. Each pair of type-30 and type-31 records contains the information from one line of the life table.

Table 220-4
Record type 31, continuation of record type 30

Columns	Content	Format
1–2	Record type (31)	F2.0
3–7	Table number	F5.0
8–15	Proportion terminating	F8.6
16–23	Proportion surviving	F8.6
24–31	Cumulative proportion surviving	F8.6
32–39	Probability density	F8.6
40–47	Hazard rate	F8.6

Columns	Content	Format
48–54	S.E. of cumulative proportion surviving	F7.4
55–61	S.E. of probability density	F7.4
62–68	S.E. of hazard rate	F7.4

- Record type 31 is a continuation of record type 30.
- As many type-30 and type-31 record pairs are output for a table as it has lines (this number is noted in columns 57–60 of the type-10 record for the table).

Table 220-5
Record type 40, produced by both keywords TABLES and BOTH

Columns	Content	Format
1–2	Record type (40)	F2.0

- Type-40 records indicate the completion of the series of records for one life table.

Record Order

The SURVIVAL output file contains records for each of the life tables specified on the TABLES subcommand. All records for a given table are produced together in sequence. The records for the life tables are produced in the same order as the tables themselves. All life tables for the first survival variable are written first. The values of the first- and second-order control variables rotate, with the values of the first-order controls changing more rapidly.

Example

```
PROCEDURE OUTPUT OUTFILE = SURVTBL.
SURVIVAL TABLES = MOSFREE BY TREATMNT(1,3)
  /STATUS = PRISON (1) FOR MOSFREE
  /INTERVAL = THRU 24 BY 3
  /WRITE = BOTH.
```

- WRITE generates a procedure output file called *SURVTBL*, containing life tables, variable names and labels, and value labels stored as record types 10, 20, 30, 31, and 40.

SYSFILE INFO

```
SYSFILE INFO [FILE=] 'file specification'
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Example

```
SYSFILE INFO FILE='PERSNL.SAV'.
```

Overview

SYSFILE INFO displays complete dictionary information for all variables in an SPSS-format data file. You do not have to retrieve the file withGET to use SYSFILE INFO. If the file has already been retrieved, use DISPLAY DICTIONARY to display dictionary information.

Basic Specification

The basic specification is the command keyword and a complete file specification that is enclosed in quotes.

Syntax Rules

- Only one file specification is allowed per command. To display dictionary information for more than one SPSS-format data file, use multiple SYSFILE INFO commands.
- The file extension, if there is one, must be specified, even if it is the default.
- The subcommand keyword FILE is optional. When FILE is specified, the equals sign is required.

Operations

- No procedure is needed to execute SYSFILE INFO, because SYSFILE INFO obtains information from the dictionary alone.
- SYSFILE INFO displays file and variable information. File information includes number of variables and cases in the file; file label; file documents; defined multiple response sets; variable sets; and information that is used by other applications (such as Clementine, Data Entry for Windows, and TextSmart). Variable information includes the variable name; label; sequential position in the file; print and write format; missing values; and value labels for each variable in the specified file.

TDISPLAY

```
TDISPLAY  [{ALL          }]
           {model names  }
           {command names}

[/TYPE={MODEL**}]
       {COMMAND}
```

**Default if the subcommand is omitted.

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Example

```
TDISPLAY.
```

Overview

TDISPLAY displays information about currently active models. These models are automatically generated by a number of procedures for use with the APPLY subcommand.

Options

If models are specified on TDISPLAY, information about only those models is displayed. You can use the TYPE subcommand to control whether models are specified by model name or by the name of the procedure that generated them.

Basic Specification

The basic specification is simply the command keyword TDISPLAY.

- By default, TDISPLAY produces a list of all currently active models. The list includes the model names, the commands that created each model, model labels (if specified), and creation dates and times.

Syntax Rules

- To display information about a subset of active models, specify those models after TDISPLAY.
- Models can be specified by using individual model names or the names of the procedures that created them. To use procedure names, you must specify the TYPE subcommand with the keyword COMMAND.
- Model names are either the default *MOD_n* names or the names that are assigned with MODEL NAME.
- If procedure names are specified, all models that are created by those procedures are displayed.
- Model names and procedure names cannot be mixed on the same TDISPLAY command.

- You can specify the keyword ALL after TDISPLAY to display all models that are currently active. This setting is the default.

Operations

- Only currently active models are displayed.
- The following procedures can generate models that can be displayed with the TDISPLAY command: AREG, ARIMA, EXSMOOTH, SEASON, and SPECTRA in the Trends module; ACF, CASEPLOT, CCF, CURVEFIT, PACF, PPLOT, and TSPLOT in the Base system; and WLS and 2SLS in Regression Models.

TYPE Subcommand

TYPE indicates whether models are specified by model name or procedure name.

- One keyword, MODEL or COMMAND, can be specified after TYPE.
- MODEL is the default and indicates that models are specified as model names.
- COMMAND specifies that models are specified by procedure name.
- TYPE has no effect if model names or command names are not listed after TDISPLAY.
- If more than one TYPE subcommand is specified, only the last subcommand is used.
- The TYPE specification applies only to the current TDISPLAY command.

Example

```
TDISPLAY ACF CURVEFIT
  /TYPE=COMMAND.
```

- This command displays all currently active models that were created by procedures ACF and CURVEFIT.

TEMPORARY

```
TEMPORARY
```

This command does not read the active dataset. It is stored, pending execution with the next command that reads the dataset. For more information, see Command Order on p. 36.

Overview

TEMPORARY signals the beginning of temporary transformations that are in effect only for the next procedure. With the exception of variables created or modified by the next procedure (for example, residual values saved as variables by REGRESSION), numeric or string variables created while the TEMPORARY command is in effect are temporary variables, and any modifications made to existing variables while the TEMPORARY command is in effect are also temporary. Any variables created or modified by the next procedure are permanent.

With TEMPORARY, you can perform separate analyses for subgroups in the data and then repeat the analysis for the file as a whole. You can also use TEMPORARY to transform data for one analysis but not for other subsequent analyses.

TEMPORARY can be applied to the following commands:

- Transformation commands COMPUTE, RECODE, IF, and COUNT, and the DO REPEAT utility.
- The LOOP and DO IF structures.
- Format commands PRINT FORMATS, WRITE FORMATS, and FORMATS.
- Data selection commands SELECT IF, SAMPLE, FILTER, and WEIGHT.
- Variable declarations NUMERIC, STRING, and VECTOR.
- Labeling commands VARIABLE LABELS and VALUE LABELS, and the MISSING VALUES command.
- SPLIT FILE.
- XSAVE.

Basic Specification

The only specification is the keyword TEMPORARY. There are no additional specifications.

Operations

- Once TEMPORARY is specified, you cannot refer to previously existing scratch variables.
- Temporary transformations apply to the next command that reads the data. Once the data are read, the temporary transformations are no longer in effect.
- The XSAVE command leaves temporary transformations in effect. SAVE, however, reads the data and turns temporary transformations off after the file is written. (See “Examples.”)

- TEMPORARY cannot be used with SORT CASES, MATCH FILES, ADD FILES, or COMPUTE with a LAG function. If any of these commands follows TEMPORARY in the command sequence, there must be an intervening procedure or command that reads the data to first execute the TEMPORARY command.
- TEMPORARY cannot be used within the DO IF–END IF or LOOP–END LOOP structures.

Examples

Basic Example

```
SORT CASES BY SEX.
TEMPORARY.
SPLIT FILE BY SEX.
FREQUENCIES VARS=INCOME /STATISTICS=MEDIAN.
FREQUENCIES VARS=INCOME /STATISTICS=MEDIAN.
```

- SPLIT FILE applies to the first FREQUENCIES procedure, which generates separate median income tables for men and women.
- SPLIT FILE is not in effect for the second FREQUENCIES procedure, which generates a single median income table that includes both men and women.

Temporary Transformations for a New Variable

```
DATA LIST FILE=HUBDATA RECORDS=3
  /1 #MOBIRTH #DABIRTH #YRBIRTH 6-11 DEPT88 19.
COMPUTE    AGE=($JDATE - YRMODA(#YRBIRTH,#MOBIRTH,#DABIRTH))/365.25.
VARIABLE LABELS AGE 'EMPLOYEE''S AGE'
           DEPT88 'DEPARTMENT CODE IN 1988'.

TEMPORARY.
RECODE AGE (LO THRU 20=1)(20 THRU 25=2)(25 THRU 30=3)(30 THRU 35=4)
       (35 THRU 40=5)(40 THRU 45=6)(45 THRU 50=7)(50 THRU 55=8)
       (55 THRU 60=9)(60 THRU 65=10)(65 THRU HI=11).
VARIABLE LABELS AGE 'EMPLOYEE AGE CATEGORIES'.
VALUE LABELS AGE 1 'Up to 20' 2 '20 to 25' 3 '25 to 30' 4 '30 to 35'
       5 '35 to 40' 6 '40 to 45' 7 '45 to 50' 8 '50 to 55'
       9 '55 to 60' 10 '60 to 65' 11 '65 and older'.

FREQUENCIES VARIABLES=AGE.
MEANS AGE BY DEPT88.
```

- COMPUTE creates variable *AGE* from the dates in the data.
- FREQUENCIES uses the temporary version of variable *AGE* with temporary variable and value labels.
- MEANS uses the unrecoded values of *AGE* and the permanent variable label.

Using XSAVE With Temporary

```
GET FILE=HUBEMPL.
TEMPORARY.
RECODE DEPT85 TO DEPT88 (1,2=1) (3,4=2) (ELSE=9).
VALUE LABELS DEPT85 TO DEPT88 1 'MANAGEMENT'
                              2 'OPERATIONS'
                              3 'UNKNOWN'.
XSAVE OUTFILE=HUBTEMP.
```

```
CROSSTABS DEPT85 TO DEPT88 BY JOBCAT.
```

- Both the saved SPSS-format data file and the CROSSTABS output will reflect the temporary recoding and labeling of the department variables.
- If XSAVE is replaced with SAVE, the SPSS-format data file will reflect the temporary recoding and labeling but the CROSSTABS output will not.

TIME PROGRAM

```
TIME PROGRAM.
[commands to compute time dependent covariates]
```

This command does not read the active dataset. It is stored, pending execution with the next command that reads the dataset. For more information, see Command Order on p. 36.

Overview

TIME PROGRAM is required to define time-dependent covariates. These are covariates whose values change during the course of the study.

Basic Specification

The basic specification is the TIME PROGRAM command followed by one or more commands that define time-dependent covariates.

Syntax Rules

- TIME PROGRAM and the transformations that define the time-dependent covariate(s) must precede the command that analyzes the time-dependent covariate(s).
- A time-dependent covariate is a function of the current time, which is represented by the special variable *T_*.
- The active dataset must not have a variable named *T_*. If it does, rename the variable. Otherwise, you will trigger an error.
- *T_* cannot be specified as a covariate. Any other variable in the TIME PROGRAM can be specified on the covariate list.
- For every time-dependent covariate, values are generated for each valid case for all uncensored times in the same stratum that occur before the observed time. If no STRATA subcommand is specified, all cases are considered to belong to one stratum.
- If any function defined by the time program results in a missing value for a case that has no missing values for any other variable used in the procedure, this causes an error.

Example

```
TIME PROGRAM.
COMPUTE Z=AGE + T_.

COXREG VARIABLES = SURVIVAL WITH Z
  /STATUS SURVSTA EVENT (1).
```

- TIME PROGRAM defines the time-dependent covariate *Z* as the current age. *Z* is then specified as a covariate in COXREG.

TITLE

```
TITLE ['']text['']
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Example

```
TITLE "Running Shoe Study from Runner's World Data".
```

Overview

TITLE inserts a left-justified title on the top line of each page of output. The default title indicates the version of the system being used.

Basic Specification

The only specification is the title.

Syntax Rules

- The title can include any characters. To specify a blank title, enclose a blank in quotes (" ").
- The title can be up to 60 bytes long. Titles longer than 60 bytes are truncated.
- The quotes enclosing the title are optional; using them allows you to include apostrophes or quotation marks in the title. For more information, see String Values in Command Specifications on p. 35.
- More than one TITLE command is allowed in a single session.
- A title cannot be placed between a procedure command and BEGIN DATA–END DATA or within data records when the data are inline.

Operations

- The title is displayed as part of the output heading, which also includes the date and page number. If HEADER=NO is specified on SET, the heading, including the title and subtitle, will not be displayed.
- Each TITLE command overrides the previous one and takes effect on the next output page.
- Only the title portion of the heading changes. The date and page number are still displayed.
- TITLE is independent of SUBTITLE, and each can be changed separately.

Examples

```
TITLE My Title.
TITLE "Fred's Title".
TITLE 'Fred''s "Quoted" Title'.
```

- The first title doesn't need to be enclosed in quotes because it doesn't contain any quotes or apostrophes.
- The second title is enclosed in double quotes because it contains an apostrophe (single quote).
- The last title is enclosed in single quotes since it contains double quotes, and two single quotes are used to specify the apostrophe.

TMS BEGIN

```
TMS BEGIN
   /DESTINATION OUTFILE='file specification'
```

Release History

Release 15.0

- Command introduced.

Release 16.0

- Added support for new string functions CHAR.CONCAT, CHAR.LENGTH, and CHAR.SUBSTR within TMS blocks.

Example

```
TMS BEGIN
 /DESTINATION OUTFILE='/mydir/mytransformations.xml'.
COMPUTE modelvar=ln(var).
TMS END.
```

Overview

The TMS BEGIN command indicates the beginning of a block of transformations to be exported to a file in PMML format—specifically, PMML 3.1 with SPSS extensions. The exported transformations can be merged (using TMS MERGE) with a PMML model file in order to include any transformations of the raw data required to create the variables used in the model. The merged PMML file can be used to score data with SmartScore, SPSS Server (a separate product), or Clementine. When you score data with a model file containing transformations, the transformations will be applied to the data before scoring. The transformations are carried out as part of the internal scoring process and have no effect on the active dataset. The TMS END command is used to end the block.

From the point of view of the active dataset, transformations in a TMS BEGIN-TMS END block are no different than transformations outside a TMS block—they are pending and will be executed with the next command that reads the active dataset. Source variables used in transformation expressions in TMS blocks must exist in the active dataset. In a typical scenario, you would run TMS BEGIN-TMS END command syntax on the raw dataset used to build the associated model, assuming it contains the source variables used in any transformation expressions.

Commands within a TMS block are categorized as belonging to one of four types: exported, tolerated, invalid, and those causing an implicit TMS END.

Exported. These are commands that produce export to PMML. Commands in this category include the supported transformations—for example, RECODE. Many transformations are expressed with functions included on a COMPUTE command. Export to PMML is supported for a limited set

of such functions. The set of commands that produce export to PMML, as well as the set of supported functions, are provided at the end of this topic.

Tolerated. These are commands that can be included in a TMS BEGIN-TMS END block, are executed in normal fashion, but do not produce export to PMML. Examples include NUMERIC, STRING, USE, INCLUDE, and INSERT. In the case of INCLUDE or INSERT, supported transformations from the inserted file will be exported to PMML.

Invalid. These are commands that cannot be processed within a TMS block and will give rise to an error. The list of invalid commands is provided at the end of this topic.

Implicit TMS END. These commands are executed in normal fashion but cause an implicit end to the current block, which then causes the output PMML file to be written. Transformations (in the current block) occurring after one of these commands are not exported to the output PMML file. Commands in this category include all of the statistical procedures—for example, ANOVA and REGRESSION—as well as the EXECUTE command. ADD FILES and MATCH FILES belong to this category as well as any command that causes a different dataset to become active—for example, DATASET ACTIVATE, GET, and GET DATA.

Basic Specification

The basic specification for TMS BEGIN is the command name followed by a DESTINATION subcommand that contains an OUTFILE specification.

Syntax Rules

- The DESTINATION subcommand is required.
- An error occurs if the DESTINATION subcommand is specified more than once.
- An error occurs if the OUTFILE keyword is specified more than once.
- Equal signs (=) shown in the syntax chart are required.
- Subcommand names and keywords must be spelled in full.

Operations

- Once a TMS BEGIN command is executed, it remains in effect until the end of the session, until explicitly ended by a TMS END command, or until a command that implicitly ends a TMS block—for example, any statistical procedure—is encountered.
- TMS commands (for example, TMS MERGE) are not allowed within a TMS block.
- TMS BEGIN verifies that the path specified for the destination file is valid. If the path is invalid, the commands in the block will be processed in the normal manner but no PMML will be exported.
- The following conditions will cause the destination file to be written: a command that causes an implicit end of the block is executed; the TMS block ends explicitly with TMS END; the current session ends before the block ends (either explicitly or implicitly). The destination file is unavailable to other commands until after it is written. TMS END has no effect if the block is ended implicitly.

- An error occurs if a transformation in the block is not supported. The command containing the invalid transformation is not executed. This type of error does not cause an implicit end to the TMS block and has no effect on when the destination file is written.
- The order of the transformations in the destination file may not be the order in which they were specified in the TMS block.
- Transformations specified in a TMS block are processed in the normal manner—that is, pending and to be executed with the next command that reads the active dataset.

Exported Commands

The following commands produce export to PMML.

ADD VALUE LABELS
COMPUTE
DO REPEAT - END REPEAT
MISSING VALUES
RECODE
VALUE LABELS
VARIABLE LABELS
VARIABLE LEVEL

- For COMPUTE, the target variable must be a variable that has not already been assigned a value or otherwise used in the associated TMS block. For example, the following is invalid:

```
COMPUTE var = var + 1.
```

- For RECODE, all input and output keywords are supported except CONVERT. In addition, you must always recode INTO a variable that has not already been assigned a value or otherwise used in the associated TMS block. When a recoding transformation is carried out on a dataset to be scored, the results depend on whether the target variable exists in the dataset. If the target variable already exists, cases with values (of the source variable) not mentioned in the value specifications for the recode are not changed. If the target variable does not already exist, cases with values not mentioned are assigned the system-missing value.

Invalid Commands

The following commands are invalid inside a TMS block.

AGGREGATE
BREAK
COUNT
DO IF - END IF
ELSE
ELSE IF
END CASE
END FILE

FILE TYPE - END FILE TYPE
FILTER
IF
INPUT PROGRAM - END INPUT PROGRAM
KEYED DATA LIST
LEAVE
LOOP - END LOOP
N OF CASES
POINT
RECORD TYPE
REPEATING DATA
REREAD
SAMPLE
SELECT IF
VECTOR
WEIGHT
WRITE

Supported Functions, Operations, and System Variables

The following functions, operations, and system variables are supported for use with the `COMPUTE` command in `TMS` blocks. In a few cases—for example, `CHAR.SUBSTR`—multiple forms (differing in the number of parameters) exist, but only a single form is supported. The parameters available in the supported form are shown.

+ Addition
- Subtraction
* Multiplication
/ Division
** Exponentiation
ABS
CDF.NORMAL
CDFNORM
CHAR.CONCAT
CHAR.LENGTH
CHAR.SUBSTR(strexpr,pos)
CONCAT
EXP
IDF.NORMAL
LG10
LENGTH

LN
LOWER
LTRIM(strexpr)
MAX
MEAN
MIN
MOD
PDF.NORMAL
RND
RTRIM(strexpr)
SD
SQRT
SUBSTR(strexpr,pos)
SUM
SYSMIS
TRUNC
UPCASE
VALUE
VARIANCE

Notes

- The relational operators EQ, NE, LT, LE, GT, and GE are not supported.
- Within a TMS block it is recommended to use CHAR.CONCAT, CHAR.LENGTH, and CHAR.SUBSTR in place of CONCAT, LENGTH, and SUBSTR.
- SmartScore does not support string arguments for the MAX and MIN functions.

EXAMPLES

```
TMS BEGIN
 /DESTINATION OUTFILE='/mydir/mytransformations.xml'.
COMPUTE modelvar=ln(var).
TMS END.
```

- TMS BEGIN marks the beginning of a block of transformation commands that will be evaluated for export to PMML.
- The variable *var* is transformed with a log function to create the variable *modelvar*, which is to be used in a model. The details of this transformation will be included as PMML in the file */mydir/mytransformations.xml*.
- TMS END marks the end of the block and causes the output file to be written, but has no effect on the state of the transformations contained in the block. In the present example, the transformation to create *modelvar* is still pending after the completion of the block.

Tolerated Commands in a TMS Block

```
TMS BEGIN
 /DESTINATION OUTFILE='/mydir/mytransformations.xml'.
STRING new_strvar (A1).
RECODE strvar ('A','B','C'='A') ('D','E','F'='B') (ELSE=' ')
   INTO new_strvar.
TMS END.
```

- The STRING command is used to create a new string variable that is to be the target of a recode transformation of an existing string variable. STRING is a tolerated command so it is executed in the normal manner, without generating an error or implicitly ending the TMS block.

Commands that Cause an Implicit TMS END

```
TMS BEGIN
 /DESTINATION OUTFILE='/mydir/mytransformations.xml'.
RECODE numvar1 (0=1) (1=0) (ELSE=SYSMIS) INTO new_numvar1.
FREQUENCIES new_numvar1.
RECODE numvar2 (1 THRU 5=1)(6 THRU 10=2)(11 THRU HI=3)(ELSE=0)
   INTO new_numvar2.
TMS END.
```

- The FREQUENCIES command causes an implicit end to the TMS block, causing the output PMML file to be written. The output file only contains the recode transformation for *numvar1*—that is, the transformations prior to the command causing the implicit TMS END.
- Although the FREQUENCIES command implicitly ends the block, the recode transformation for *numvar2* is processed in the normal manner and remains pending until the next command that reads the active dataset.
- Although we have included it in this example, the TMS END command is not needed when there is a command that implicitly ends the TMS block. In this example, execution of the TMS END command generates a warning indicating that there is no current TMS command in effect.

Using EXECUTE in a TMS Block

```
TMS BEGIN
 /DESTINATION OUTFILE='/mydir/mytransformations.xml'.
RECODE numvar1 (0=1) (1=0) (ELSE=SYSMIS) INTO new_numvar1.
RECODE numvar2 (1 THRU 5=1)(6 THRU 10=2)(11 THRU HI=3)(ELSE=0)
   INTO new_numvar2.
EXECUTE.
```

- You can include EXECUTE in a TMS block. In its usual manner, it will cause all pending transformations to be executed. In addition, it causes an implicit end to the block which then causes the output PMML file to be written.
- In the current example, we have omitted the TMS END command since the block is implicitly ended by the EXECUTE command.

DESTINATION Subcommand

The `DESTINATION` subcommand is required. It must include the `OUTFILE` keyword followed by an equals sign (=) and a file specification in quotes or a previously defined file handle defined with the `FILE HANDLE` command. It is recommended to include the extension *.xml* in the file specification.

TMS END

```
TMS END
   [/PRINT RESULTS={SUMMARY**}]
                   {NONE}
```

** Default if the subcommand or keyword is omitted.

Release History

Release 15.0

- Command introduced.

Example

```
TMS BEGIN
 /DESTINATION OUTFILE='/mydir/mytransformation.xml'.
COMPUTE mymodelvar=ln(var).
TMS END
 /PRINT RESULTS=NONE.
```

Overview

The TMS END command is used to indicate the end of a block of transformations to be exported to a file in PMML format—specifically, PMML 3.1 with SPSS extensions. The exported transformations can be merged (using TMS MERGE) with a PMML model file in order to include any transformations of the raw data required to create the variables used in the model. The merged PMML file can be used to score data with SmartScore, SPSS Server (a separate product), or Clementine. When you score data with a model file containing transformations, the transformations will be applied to the data before scoring. The transformations are carried out as part of the internal scoring process and have no effect on the active dataset. The TMS BEGIN command is used to indicate the beginning of the block.

Basic Specification

The basic specification for TMS END is the command name. For examples of TMS BEGIN-TMS END blocks, see the TMS BEGIN command.

Syntax Rules

- An error occurs if the PRINT subcommand is specified more than once.
- An error occurs if the RESULTS keyword is specified more than once.
- Equal signs (=) shown in the syntax chart are required.
- Subcommand names and keywords must be spelled in full.

Operations

- TMS END will generate a warning if there is no TMS BEGIN command in effect. This condition occurs in the obvious case that there is no prior TMS BEGIN command, but will also occur if there is a TMS BEGIN command followed by a command that implicitly ends a TMS block—for instance, any statistical procedure or the EXECUTE command—followed by TMS END.
- TMS END causes the destination file to be written, unless the associated TMS block ended implicitly (see previous bullet), thus causing the file to be written before execution of TMS END. For more information, see the Examples for the TMS BEGIN command.
- TMS END does not cause transformations in the associated TMS block to be executed. In normal fashion, they are pending and will be executed with the next command that reads the active dataset.

PRINT Subcommand

The PRINT subcommand is optional and specifies whether or not to print a table summarizing the derived variables defined by the transformations in the block.

SUMMARY *Print a summary of the derived variables.* This is the default.

NONE *Do not print a summary.*

TMS MERGE

```
TMS MERGE
   /DESTINATION OUTFILE='file specification'
   /TRANSFORMATIONS INFILE='file specification'
   /MODEL INFILE='file specification'
   [/PRINT RESULTS={SUMMARY**}]
                   {NONE}
```

** Default if the subcommand or keyword is omitted.

Release History

Release 15.0

- Command introduced.

Example

```
TMS MERGE
   /DESTINATION OUTFILE='/mydir/mymergedmodel.xml'
   /TRANSFORMATIONS INFILE='/mydir/mytransformations.xml'
   /MODEL INFILE='/mydir/mymodel.xml'.
```

Overview

The TMS MERGE command is used to merge a PMML file containing transformations with a PMML model file containing variables whose derivations are expressed by those transformations. The merged file can be used to score data with SmartScore, SPSS Server (a separate product), or Clementine. When you score data with a model file containing transformations, the transformations will be applied to the data before scoring. The transformations are carried out as part of the internal scoring process and have no effect on the active dataset. Transformations are exported as PMML using the TMS BEGIN and TMS END commands. For more information, see TMS BEGIN on p. 1800.

Basic Specification

The basic specification is the command name followed by DESTINATION, TRANSFORMATIONS, and MODEL subcommands that contain file specifications.

Syntax Rules

- Each subcommand can be specified only once.
- Subcommands may be used in any order.
- An error occurs if a keyword is specified more than once within a subcommand.
- Equal signs (=) shown in the syntax chart are required.
- Subcommand names and keywords must be spelled in full.

Operations

- TMS MERGE has no effect on the active dataset. It relies completely on the information contained in the transformations and model files.
- TMS MERGE verifies that the paths specified for the input files and destination file are valid. The destination file is unavailable to other commands until the TMS MERGE command is ended.
- An error occurs if properties of derived variables in the transformations file do not match the properties for those same variables in the model file—for example, conflicting definitions of missing values.

TRANSFORMATIONS, MODEL, and DESTINATION Subcommands

The TRANSFORMATIONS, MODEL, and DESTINATION subcommands specify the file containing the transformations (created from a TMS BEGIN-TMS END block), the file containing the model specifications, and the destination for the merged file. All three of these subcommands are required.

- File specifications should be enclosed in quotation marks.
- The filename must be specified in full. No extension is supplied.
- It is recommended to include the extension *.xml* in the specification for the destination file.

PRINT Subcommand

The PRINT subcommand is optional and specifies whether or not to print tables summarizing the variables in the merged XML file.

SUMMARY *Print summary tables.* This is the default.

NONE *Do not print summary tables.*

TREE

TREE is available in the Classification Trees option.

Note: Square brackets used in the TREE syntax chart are required parts of the syntax and are not used to indicate optional elements. Equals signs (=) used in the syntax chart are required elements. All subcommands are optional.

```
TREE dependent_variable [level]

/INFLUENCE varname

/OUTFILE TRAININGMODEL = 'filespec' TESTMODEL = 'filespec'

/MISSING  NOMINALMISSING = {MISSING**}
                           {VALID    }
```

** Default if subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Release History

Release 13.0

- Command introduced.

Example

```
TREE risk BY income age creditscore employment.
```

Overview

The TREE procedure creates a tree-based classification model. It classifies cases into groups or predicts values of a dependent variable based on values of predictor variables. The procedure provides validation tools for exploratory and confirmatory classification analysis.

Options

Model. You can specify the dependent (target) variable and one or more independent (predictor) variables. Optionally you can force one independent variable into the model as the first variable.

Growing Method. Four growing algorithms are available: CHAID (the default), Exhaustive CHAID, CRT, and QUEST. Each performs a type of recursive splitting. First, all predictors are examined to find the one that gives the best classification or prediction by splitting the sample into subgroups (nodes). The process is applied recursively, dividing the subgroups into smaller and smaller groups. It stops when one or more stopping criteria are met.

The four growing methods have different performance characteristics and features:

- CHAID chooses predictors that have the strongest interaction with the dependent variable. Predictor categories are merged if they are not significantly different with respect to the dependent variable (Kass, 1980).
- Exhaustive CHAID is a modification of CHAID that examines all possible splits for each predictor (Biggs et al., 1991).
- CRT is a family of methods that maximizes within-node homogeneity (Breiman et al., 1984).
- QUEST trees are computed rapidly, but the method is available only if the dependent variable is nominal. (Loh and Shih, 1997).

Stopping Criteria. You can set parameters that limit the size of the tree and control the minimum number of cases in each node.

Validation. You can assess how well your tree structure generalizes to a larger sample. Split-sample partitioning and cross-validation are supported. Partitioning divides your data into a training sample, from which the tree is grown, and a testing sample, on which the tree is tested. Cross-validation involves dividing the sample into a number of smaller samples. Trees are generated excluding the data from each subsample in turn. For each tree, misclassification risk is estimated using data for the subsample that was excluded in generating it. A cross-validated risk estimate is calculated as the average risk across trees.

Output. Default output includes a tree diagram and risk statistics. Classification accuracy is reported if the dependent variable is categorical. Optionally, you can obtain charts of gain- and profit-related measures as well as classification rules that can be used to select or score new cases. You can also save the model's predictions to the active dataset, including assigned segment (node), predicted class/value, and predicted probability.

Basic Specification

- The basic specification is a dependent variable and one or more independent variables.

Operations

- The tree is grown until one or more stopping criteria are met. The default growing method is CHAID.
- The type of model depends on the measurement level of the dependent variable. If the dependent variable is scale (continuous), a prediction model is computed. If it is categorical (nominal or ordinal), a classification model is generated.

- Measurement level determines allowable combinations of predictor values within a node. For ordinal and scale predictors, only adjacent categories/values may occur in a node. There are no restrictions on grouping of nominal categories.
- TREE honors the SET SEED value if split-sample model validation is requested.
- SPLIT FILE is ignored by the TREE procedure.
- If a WEIGHT variable is defined the weights are treated as replication weights. Fractional weights are rounded.

Syntax Rules

- The minimum specification is a dependent variable, the keyword BY and one or more independent variables.
- All subcommands are optional.
- Only a single instance of each subcommand is allowed.
- A keyword may be specified only once within a subcommand.
- Equals signs (=) shown in the syntax chart are required.
- Subcommand names and keywords must be spelled in full.
- Subcommands may be used in any order.

Limitations

- SPLIT FILE is ignored by the TREE procedure.
- CHAID and Exhaustive CHAID: A categorical dependent variable may not have more than 126 categories. If the dependent variable categorical, then the limit for a categorical predictor is also 126 categories.
- CRT: A nominal predictor may not have more than 25 categories.
- QUEST: If a predictor is nominal, then the limit for the dependent variable (which must be nominal) is 127 categories. A nominal predictor may not have more than 25 categories.

Examples

```
TREE risk BY income age creditscore employment.
```

- A tree model is computed that estimates credit risk using an individual's income, age, credit score, and employment category as predictor variables.
- The default method, CHAID, is used to grow the tree.
- Since measurement level is not specified, it is obtained from the data dictionary for each model variable. If no measurement levels have been defined, numeric variables are treated as scale and string variables are treated as nominal.

```
TREE risk [o] BY income [o] age [s] creditscore [s] employment [n]
  /METHOD TYPE=CRT
  /VALIDATION TYPE=SPLITSAMPLE
  /SAVE NODEID PREDVAL.
```

- A tree model is computed that estimates credit risk using an individual's income, age, credit score, and employment category as predictor variables.

- Age and credit score will be treated as scale variables, risk and income as ordinal, and employment category as nominal.
- The CRT method, which performs binary splits, is used to grow the tree.
- Split-sample validation is requested. By default, 50% of cases are assigned to the training sample. Remaining cases are used to validate the tree.
- Two variables are saved to the active dataset: node (segment) identifier and predicted value.

Model Variables

The command name `TREE` is followed by the dependent variable, the keyword `BY`, and one or more independent variables.

Dependent Variable

The dependent (target) variable must be the first specification on the `TREE` command.

- Only one dependent variable can be specified.
- The dependent variable cannot be the `WEIGHT` variable.

Independent Variables

You can specify one or more independent (predictor) variables.

- `ALL` and `TO` can be used in the independent variable list. `ALL` represents all variables in the active dataset. `TO` refers to a range of variables in the active dataset.
- In general, if the independent variable list refers to the `WEIGHT` variable or a variable that is used elsewhere in the tree specification (e.g., dependent variable or cell weight variable), the variable is not used as an independent variable. The exception is that scale variables used both in the independent variable list and the `INTERVAL` subcommand are not dropped from the independent variable list.
- Repeated instances of the same independent variable are filtered out of the list. For example, `a b a c a` is equivalent to `a b c`. Assuming that the active dataset contains variables *a*, *b*, and *c*, `a ALL` is also equivalent to `a b c`.

Measurement Level

Optionally, a measurement level can be specified in square brackets following any model variable. The measurement level can be defined as scale (`[S]`), ordinal (`[O]`), or nominal (`[N]`). Categorical (`[C]`) is accepted as a synonym for nominal.

- If a measurement level is specified, it temporarily overrides the setting recorded in the data dictionary. If a measurement level is not specified for a variable, the dictionary setting is used.
- If a measurement level is not specified and no setting is recorded in the data dictionary, a numeric variable is treated as scale and a string variable is treated as nominal.
- If a string variable is defined as scale, a warning is issued and the variable is treated as nominal.

- A measurement level applies only to the variable that immediately precedes it in the variable list. For example, `age income [S]` and `age TO income [S]` assign the scale level of measurement to *income* only.
- The keyword `ALL` followed by a measurement level specification will apply that measurement level to all independent variables.
- If a variable appears more than once in the independent variable list and the measurement level varies across instances, the measurement level specified for the last instance of the variable is used. For example, if `ALL [S] z [N] is specified`, *z* is treated as a nominal predictor.

FORCE Keyword

- By default, the procedure evaluates each predictor variable for inclusion in the model. The optional `FORCE` keyword forces an independent variable into the model as the first split variable (the first variable used to split the root node into child nodes).
- The `FORCE` keyword must be followed by an equals sign (=) and a single variable.
- A measurement level may be specified in square brackets following the variable name. If the variable is also included in the independent variable list, the measurement level specified for the `FORCE` variable is used. If the variable has a specified measurement level in the independent list but no explicit measurement level on the `FORCE` specification, the defined measurement level for the variable is used.
- The variable cannot be the dependent variable or the `WEIGHT` variable.

Example

```
TREE risk [o] BY income [o] age [s] creditscore [s] FORCE = gender [n].
```

- The independent variables *income*, *age*, and *creditscore* may or may not be included in the model, depending on how strongly they interact with the dependent variable *risk*.
- The independent variable *gender* will be included in the model regardless of the level of interaction with the dependent variable, and the root node will first be split into nodes for male and female before any other independent variables are considered.

DEPCATEGORIES Subcommand

For categorical dependent variables, the `DEPCATEGORIES` subcommand controls the categories of the dependent variable included in the model and/or specifies target categories.

- By default, all valid categories are used in the analysis and user-missing values are excluded.
- There is no default target category.
- `DEPCATEGORIES` applies only to categorical dependent variables. If the dependent variable is scale, the subcommand is ignored and a warning is issued.

Example

```
TREE risk [n] BY income [o] age [s] creditscore [s] employment [n]
  /DEPCATEGORIES USEVALUES=[VALID 99] TARGET=[1].
```

USEVALUES keyword

USEVALUES controls the categories of the dependent variable included in the model.

- The keyword is followed by an equals sign (=) and a list of values enclosed in square brackets, as in: USEVALUES=[1 2 3].
- At least two values must be specified.
- Any cases with dependent variable values not included in the list are excluded from the analysis.
- Values can be string or numeric but must be consistent with the data type of the dependent variable. String and date values must be quoted. Date values must be consistent with the variable's print format.
- If the dependent variable is nominal, the list can include user-missing values. If the dependent variable is ordinal, any user-missing values in the list are excluded and a warning is issued.
- The keywords VALID and MISSING can be used to specify all valid values and all user-missing values respectively. For example, USEVALUES=[VALID MISSING] will include all cases with valid or user-missing values for the dependent variable.
- A warning is issued if a specified category does not exist in the data or in the training sample if split-sample validation is in effect. For more information, see VALIDATION Subcommand on p. 1827.

TARGET Keyword

The TARGET keyword specifies categories of the dependent variable that are of primary interest in the analysis. For example, if you are trying to predict mortality, "death" would be defined as the target category. If you are trying to identify individuals with high or medium credit risk, you would define both "high credit risk" and "medium credit risk" as target categories.

- The keyword is followed by an equals sign (=) and a list of values enclosed in square brackets, as in: TARGET=[1].
- There is no default target category. If not specified, some classification rule options and gains-related output are not available.
- Values can be string or numeric but must be consistent with the data type of the dependent variable. String and date values must be quoted. Date values must be consistent with the variable's print format.
- If USEVALUES is also specified, the target categories must also be included (either implicitly or explicitly) in the USEVALUES list.
- If a target category is user-missing and the dependent variable is not nominal, the target category is ignored and a warning is issued.

TREE Subcommand

The TREE subcommand allows you to specify the appearance of the tree or suppress it altogether. You can control its orientation, node contents, and the labeling of splits and nodes. Each keyword is followed by an equals sign (=) and the value for that keyword.

Example

```
TREE risk BY income age creditscore
  /TREE DISPLAY=LEFTTORIGHT NODES=BOTH BRANCHSTATISTICS=NO.
```

DISPLAY Keyword

The DISPLAY keyword controls the orientation the tree and can also be used to suppress the display of the tree. The following alternatives are available:

TOPDOWN	*Tree grows top down*. The root node appears at the top of the diagram. The tree grows downward. This is the default.
LEFTTORIGHT	*Tree grows from left to right*.
RIGHTTOLEFT	*Tree grows from right to left*.
NONE	*Tree diagram is not generated*.

NODES Keyword

The NODES keyword controls the contents of tree nodes.

STATISTICS	*Nodes display summary statistics*. This is the default. For a categorical dependent variable, percentages and counts are shown for each category as well as the total count and percentage. (Total percentage is the percentage of cases in the sample assigned to the node. If you specify prior probabilities, the total percentage is adjusted to account for those priors.) For a scale dependent variable, nodes display mean, standard deviation, number of cases, and predicted value.
CHART	*Nodes display a summary chart*. For a categorical dependent variable, nodes display a bar chart of percentages for each category. For a scale dependent variable a histogram is shown that summarizes the distribution of the dependent variable.
BOTH	*Statistics and chart are shown*.

BRANCHSTATISTICS Keyword

The BRANCHSTATISTICS keyword controls whether branch (split) statistics are shown in the tree.

- For CHAID and Exhaustive CHAID, branch statistics include *F* value (for scale dependent variables) or chi-square value (for categorical dependent variables), as well as the significance value and degrees of freedom.
- For CRT, the improvement value is shown.
- For QUEST, *F*, the significance value, and degrees of freedom are shown for scale and ordinal independent variables. For nominal independent variables, chi-square, the significance value, and degrees of freedom are shown.

YES	*Branch statistics are displayed.* This is the default.
NO	*Branch statistics are not displayed.*

NODEDEFS Keyword

The NODEDEFS keyword controls whether descriptive labels are shown for each node. Node labels show the independent variable (predictor) values assigned to each node.

YES	*Node labels are displayed.* This is the default.
NO	*Node labels are not displayed.*

SCALE Keyword

The SCALE keyword controls the initial scale of the tree diagram.

AUTO	*Adjust the scale according to the number of nodes and levels of tree growth.* The scale is reduced automatically for large trees. This is the default.
value	*User-specified percentage value.* The value can be between 5 and 200, inclusive.

PRINT Subcommand

The PRINT subcommand controls the display of optional tabular output. If the PRINT subcommand is specified, only the output explicitly requested will be produced. The subcommand name is followed by an equals sign (=) and one or more of the following options:

MODELSUMMARY	*Model summary.* The summary includes the method used, variables included in the model, and variables specified but not included in the model. Shown by default if subcommand omitted.
IMPORTANCE	*Predictor importance.* Ranks each independent (predictor) variable according to its importance to the model. IMPORTANCE can be specified only for the CRT method; otherwise it is ignored, and a warning is issued.
SURROGATES	*Surrogate predictors.* Lists surrogate predictors for each split in the tree. Each node is split based on an independent (predictor) variable; for cases in which the value for that predictor is missing, other predictors having high associations with the original predictor are used for classification. These alternative predictors are called surrogates. SURROGATES can be specified only for the CRT and QUEST methods. If surrogates are not computed, this keyword is ignored, and a warning is issued.
CLASSIFICATION	*Classification table.* Shows the number of cases classified correctly and incorrectly for each category of the dependent variable. A warning is issued if CLASSIFICATION is specified for a scale dependent variable. Shown by default for categorical dependent variables if subcommand omitted.
RISK	*Risk estimate and its standard error.* A measure of the tree's predictive accuracy. For categorical dependent variables, the risk estimate is the proportion of cases correctly classified after adjustment for prior probabilities and misclassification costs. For scale dependent variables, the risk estimate is within-node variance. Shown by default if subcommand omitted.
CATEGORYSPECS	*Cost, prior probability, score, and profit values used in the analysis.* This keyword is ignored if the dependent variable is a scale variable.
TREETABLE	*Tree model in tabular format.* Summary information for each node in the tree, including parent node number, branch statistics, independent variable value(s) for the node, mean and standard deviation for scale dependent variables or counts and percents for categorical dependent variables.

CPS *Case processing summary.* Shown by default if subcommand omitted.

NONE *None of the output controlled by the PRINT subcommand is generated.* An error occurs if any other PRINT keyword is specified with NONE.

GAIN Subcommand

The GAIN subcommand controls the display of tables that summarize gain and index values and other measures that indicate the relative performance of nodes in the tree. You can obtain tables that summarize results by node, percentile group, or both. Each keyword is followed by an equals sign (=) and the value for that keyword.

Example

```
TREE risk BY income age creditscore
  /GAIN SUMMARYTABLE=YES TYPE=[NODE, PTILE].
```

SUMMARYTABLE Keyword

The SUMMARYTABLE keyword controls whether a summary table of index values is shown.

- For scale dependent variables, the table includes node number, number of cases, and mean value of the dependent variable.
- For categorical dependent variables, the table includes node number, number of cases, average profit, and ROI (return on investment) values.
- For categorical dependent variables, the summary table is not displayed unless profits have been specified on the PROFITS subcommand.

YES *Display summary table*. This is the default for scale dependent variables if the subcommand is omitted or SUMMARYTABLE=NO is not included on the subcommand.

NO *The summary table is not displayed.*

CATEGORYTABLE Keyword

The CATEGORYTABLE keyword displays gain and index values for target categories of the dependent variable.

- The dependent variable must be categorical.
- Target categories must be specified on the DEPCATEGORIES subcommand.
- A separate table is generated for each target category.
- If the dependent variable is scale or no target categories are specified, the keyword is ignored and a warning is issued.

YES *Display a table of gain statistics for each target category of the dependent variable.* The table includes percentage gain, response percent, and index percent (lift) by node or percentile group. This is the default.

NO No category table is shown.

TYPE Keyword

The TYPE keyword specifies the type of gain table(s) that are produced. The keyword is followed by an equals sign (=) and one or both of the following types enclosed in square brackets:

NODE *Terminal nodes.* Rows of the table represent terminal nodes. This is the default.

PTILE *Percentile.* Each row of the table summarizes a percentile group.

SORT Keyword

The SORT keyword specifies how rows are sorted in all gain tables.

DESCENDING *Rows are sorted in descending order of index value.* This is the default.

ASCENDING *Rows are sorted in ascending order of index value.*

INCREMENT Keyword

The INCREMENT keyword controls the width of percentile groupings for a percentile gain table (TYPE=[PTILE]).

- The default increment is 10, which gives decile intervals.
- You can specify one of the following percentage increments: 1, 2, 5, 10, 20, or 25. If a different value is specified, a warning is issued and the default increment is used.
- INCREMENT is ignored for node-by-node gain tables.

CUMULATIVE Keyword

The CUMULATIVE keyword specifies whether node-by-node tables (TYPE=[NODE]) include cumulative statistics. It is ignored for percentile gain tables, which are always cumulative.

YES *Cumulative statistics are displayed.* This is the default.

NO *Cumulative statistics are not displayed.*

PLOT Subcommand

The PLOT subcommand generates charts that may help you evaluate your tree model. The subcommand name is followed by an equals sign (=) and any or all of the following chart types:

GAIN *Line chart of percentage gain.* The chart shows percentage gain for each target category of the dependent variable. GAIN is available only for categorical dependent variables with target categories defined on the DEPCATEGORIES subcommand.

RESPONSE *Line chart of response.* The chart shows percentage of responses for each target category of the dependent variable. RESPONSE is available only for categorical dependent variables with target categories defined on the DEPCATEGORIES subcommand.

INDEX *Line chart of index percent.* The chart shows index percent (lift). INDEX is available only for categorical dependent variables with target categories defined on the DEPCATEGORIES subcommand.

MEAN	*Line chart of mean value for scale dependent variables.* If the dependent variable is categorical, this keyword is ignored and a warning is issued.
PROFIT	*Line chart of average profit for categorical dependent variables.* If profits are not defined or the dependent variable is scale, this keyword is ignored and a warning is issued. For more information, see PROFITS Subcommand on p. 1835.
ROI	*Line chart of ROI (return on investment).* ROI is computed as the ratio of profits to expenses. If profits are not defined or the dependent variable is scale, this keyword is ignored and a warning is issued.
IMPORTANCE	*Bar chart of model importance by predictor.* IMPORTANCE is available for CRT models only; otherwise the keyword is ignored and a warning is issued.

Example

```
TREE risk [o] BY income age creditscore
 /METHOD TYPE=CRT
 /DEPCATEGORIES TARGET=[1]
 /PLOT=IMPORTANCE GAIN INDEX INCREMENT=5.
```

INCREMENT Keyword

The INCREMENT keyword controls the width of percentile group charts.

- The keyword is followed by an equals sign (=) and one of the following values: 1, 2, 5, 10, 20, or 25. If a different value is specified a warning is issued and the default increment is used.
- INCREMENT is ignored for the predictor importance chart.

RULES Subcommand

The RULES subcommand generates syntax that can be used to select or classify cases based on values of independent (predictor) variables.

- You can generate rules for all nodes, all terminal nodes, the top *n* terminal nodes, terminal nodes that correspond to the top *n* percent of cases, or nodes with index values that meet or exceed a cutoff value.
- Rules are available in three different forms: SPSS, SQL, and generic (plain English pseudocode).
- You can specify an external destination file for the rules.
- Each keyword is followed by an equals sign (=) and the value for that keyword.

Example

```
TREE risk [o] BY income age creditscore
 /RULES NODES=TERMINAL SYNTAX=SPSS TYPE=SCORING
  OUTFILE='/jobfiles/treescores.sps'.
```

NODES Keyword

The NODES keyword specifies the scope of generated rules. Specify one of the following alternatives:

TERMINAL	*Generates rules for each terminal node.* This is the default.
ALL	*Generates rules for all nodes.* Rules are shown for all parent and terminal nodes.

For categorical dependent variables with defined target categories, the following additional alternatives are available:

TOPN(value)	*Generates rules for the top* n *terminal nodes based on index values.* The number must be a positive integer, enclosed in parentheses. If the number exceeds the number of nodes in the tree, a warning is issued and rules are generated for all terminal nodes.
TOPPCT(value)	*Generates rules for terminal nodes for the top* n *percent of cases based on index values.* The percent value must be a positive number greater than zero and less than 100, enclosed in parentheses.
MININDEX(value)	*Generates rules for all terminal nodes with an index value greater than or equal to the specified value.* The value be a positive number, enclosed in parentheses.

SYNTAX Keyword

The SYNTAX keyword specifies the syntax of generated rules. It determines the form of the selection rules in both output displayed in the Viewer and selection rules saved to an external file.

SPSS	*Command syntax language.* Rules are expressed as a set of commands that define a filter condition that can be used to select subsets of cases (this is the default) or as COMPUTE statements that can be used to score cases (with TYPE=SCORING).
SQL	*SQL.* Standard SQL rules are generated to select/extract records from a database or assign values to those records. The generated SQL rules do not include any table names or other data source information.
GENERIC	*Plain English pseudocode.* Rules are expressed as a set of logical "if...then" statements that describe the model's classifications or predictions for each node.

TYPE Keyword

The TYPE keyword specifies the type of SQL or SPSS rules to generate. It is ignored if generic rules are requested.

SCORING	*Scoring of cases.* The rules can be used to assign the model's predictions to cases that meet node membership criteria. A separate rule is generated for each node within the scope specified on the NODES keyword. This is the default.
SELECTION	*Selection of cases.* The rules can be used to select cases that meet node membership criteria. For SPSS and SQL rules, a single rule is generated to select all cases within the scope specified on the NODES keyword. *Note*: For SPSS or SQL rules with NODES=TERMINAL and NODES=ALL, TYPE=SELECTION will produce a rule that effectively selects every case included in the analysis.

SURROGATES Keyword

For CRT and QUEST, the SURROGATES keyword controls whether rules use surrogate predictors to classify cases that have missing predictor values. The keyword is ignored if the method is not CRT or QUEST or if generic rules are requested.

Rules that include surrogates can be quite complex. In general, if you just want to derive conceptual information about your tree, exclude surrogates. If some cases have incomplete predictor data and you want rules that mimic your tree, include surrogates.

INCLUDE *Include surrogates.* Surrogate predictors are used in generated rules. This is the default.

EXCLUDE *Exclude surrogates.* Rules exclude surrogate predictors.

LABELS Keyword

The LABELS keyword specifies whether value and variable labels are used in generic decision rules.

- By default, any defined value and variable labels are used. When labels aren't available, values and variable names are used.
- LABELS is ignored for SQL and SPSS rules.

YES *Any defined value and variable labels are used in generic rules.* This is the default.

NO *Values and variable names are used instead of labels.*

OUTFILE Keyword

OUTFILE writes the rules to an external text file.

- The keyword is followed by an equals sign (=) and a file specification enclosed in quotes.
- If the file specification includes a path, an error will result if the specified directory/folder location doesn't exist.
- For command syntax, the file can be used as a command syntax file in both interactive and batch modes.
- For SQL syntax, the generated SQL does not include any table names or other data source information.
- OUTFILE is ignored if NODES=NONE, and a warning is issued.

SAVE Subcommand

The SAVE subcommand writes optional model variables to the active dataset.

- Specify one or more model variables.

- Optionally, you can specify new variable names in parentheses after each model variable name. The names must be unique, valid variable names.
- If new names are not specified, or if specified names are not valid variable names, unique variable names are automatically generated using the model variable name with a suffix.

NODEID	*Node identifier.* The terminal node to which a case is assigned. The value is the tree node number.
PREDVAL	*Predicted value.* The class or value predicted by the model.
PREDPROB	*Predicted probability.* The probability associated with the model's prediction. One variable is saved for each category of the dependent variable. If you specify an optional variable name, it is used as a root for generated variable names. `PREDPROB` is ignored if the dependent variable is a scale variable. Probabilities are saved only for the first 126 categories of the dependent variable when the CRT or QUEST algorithms are used.
ASSIGNMENT	*Sample assignment.* The variable indicates whether a case was used in the training or testing sample. Cases in the training sample have a value of 1, and cases in the testing sample have a value of 0. `ASSIGNMENT` is ignored if split-sample validation is not specified.

Example

```
TREE risk [o] BY income age creditscore
 /SAVE NODEID(node_number) PREDVAL(predicted_value).
```

METHOD Subcommand

The `METHOD` subcommand specifies the growing method and optional parameters. Each keyword is followed by an equals sign (=) and the value for that keyword.

Example

```
TREE risk [o] BY income age creditscore
 /METHOD TYPE=CRT MAXSURROGATES=2 PRUNE=SE(0).
```

TYPE Keyword

`TYPE` specifies the growing method. For CRT and QUEST, splits are always binary. CHAID and Exhaustive CHAID allow multiway splits.

CHAID	*Chi-squared Automatic Interaction Detection.* At each step, CHAID chooses the independent (predictor) variable that has the strongest interaction with the dependent variable. Categories of each predictor are merged if they are not significantly different with respect to the dependent variable. This is the default method.
EXHAUS-TIVECHAID	*Exhaustive CHAID.* A modification of CHAID that examines all possible ways of merging predictor categories.
CRT	*Classification and Regression Trees.* CRT splits the data into segments that are as homogeneous as possible with respect to the dependent variable.
QUEST	*Quick, Unbiased, Efficient Statistical Tree.* A method that is fast and avoids other methods' bias in favor of predictors with many categories. QUEST can be specified only if the dependent variable is nominal. An error occurs if the dependent variable is ordinal or scale.

MAXSURROGATES Keyword

CRT and QUEST can use surrogates for independent (predictor) variables. For cases in which the value for that predictor is missing, other predictors having high associations with the original predictor are used for classification. These alternative predictors are called surrogates. The MAXSURROGATES keyword specifies the maximum number of surrogate predictors to compute.

If the growing method is CHAID or EXHAUSTIVECHAID, this keyword is ignored and a warning is issued.

AUTO *The maximum is the number of independent variables minus one.* This is the default.

value *User-specified value.* The value must be a non-negative integer that is less than the number of independent variables in the model. If you don't want to use surrogates in the model, specify MAXSURROGATES=0. If the value equals or exceeds the number of independent variables, the setting is ignored and a warning is issued.

PRUNE Keyword

For CRT and QUEST, the tree can be automatically pruned. Pruning can help avoid creating a tree that overfits the data. If you request pruning, the tree is grown until stopping criteria are met. Then it is trimmed automatically according to the specified criterion.

If the growing method is CHAID or EXHAUSTIVECHAID, PRUNE is ignored and a warning is issued.

NONE The tree is not pruned. This is the default.

SE(value) *Prune tree using standard error criterion.* The procedure prunes down to the smallest subtree with a risk value within a specified number of standard errors of that of the subtree with the minimum risk. You can specify the number of standard errors in parentheses. The default is 1. The value must be nonnegative. To obtain the subtree with the minimum risk, specify 0.

GROWTHLIMIT Subcommand

The GROWTHLIMIT subcommand specifies stopping criteria that limit the size of the tree. Each keyword is followed by an equals sign (=) and the value for that keyword.

Example

```
TREE risk [o] BY income age creditscore
 /METHOD TYPE=CRT
 /GROWTHLIMIT MAXDEPTH=4 MINCHILDSIZE=10.
```

MAXDEPTH Keyword

MAXDEPTH specifies the maximum number of levels of growth beneath the root node. You can change the maximum depth to adjust the size of the tree.

AUTO *Three levels for CHAID and Exhaustive CHAID, five levels for CRT and QUEST.* This is the default.

value *User-specified value.* The value must be a positive integer.

MINPARENTSIZE Keyword

MINPARENTSIZE specifies the minimum number of cases required to split a node. Nodes with fewer cases are not split. You can use this setting to avoid splitting nodes that have few cases.

- The size value must be a positive integer. The default is 100.
- MINPARENTSIZE must be greater than MINCHILDSIZE.

MINCHILDSIZE Keyword

MINCHILDSIZE specifies the minimum number of cases in any child node. A node will not be split if any of the resulting child nodes would have fewer cases than the specified value.

- The size value must be a positive integer. The default is 50.
- MINCHILDSIZE must be less than MINPARENTSIZE.

MINIMPROVEMENT Keyword

For CRT, you can use MINIMPROVEMENT to specify the minimum decrease in impurity. The CRT growing method attempts to maximize within-node homogeneity. In other words, a terminal node in which all cases have the same value for the dependent variable is a homogeneous, "pure" node. A node is not split if impurity would decrease less than the specified value.

The improvement value must be positive value. The default is 0.0001. As the value increases, the number of nodes in the tree tends to decrease.

VALIDATION Subcommand

The VALIDATION subcommand allows you to assess how well your tree structure generalizes to a larger population.

- Split-sample validation and cross-validation are available.
- By default, validation is not performed.
- If you want to be able to reproduce validated results later, use SET SEED before the TREE procedure to initial the random number seed.

Each keyword in the subcommand is followed by an equals sign (=) and the value for that keyword.

Example

```
TREE risk [o] BY income age creditscore
 /VALIDATION TYPE=SPLITSAMPLE(25) OUTPUT=TESTSAMPLE.
```

TYPE Keyword

NONE	*The tree model is not validated.* This is the default.
SPLITSAMPLE(percent)	*Split-sample validation.* The model is generated using a training sample and tested on a hold-out sample. The value or variable specified in parentheses determines the training sample size. Enter a percent value greater than 0 and less than 100, or a numeric variable, the values of which determine how cases are assigned to the training or testing samples: cases with a value of 1 for the variable are assigned to the training sample, and all other cases are assigned to the testing sample. The variable cannot be the dependent variable, weight variable, influence variable or a forced independent variable. For more information, see INFLUENCE Subcommand on p. 1835.*Note*: Split-sample validation should be used with caution on small data files (data files with a small number of cases). Small training sample sizes may yield poor models since there may not be enough cases in some categories to adequately grow the tree.
CROSSVALIDATION (value)	*Crossvalidate the tree model.* The sample is divided into a number of subsamples, or **folds**. Tree models are then generated excluding the data from each subsample in turn. The first tree is based on all of the cases *except* those in the first sample fold, the second tree is based on all of the cases except those in the second sample fold, and so on. For each tree, misclassification risk is estimated by applying the tree to the subsample excluded in generating it. Specify a positive integer between 2 and 25 in parentheses. The higher the value, the fewer the number of cases excluded for each tree model. Crossvalidation produces a single, final tree model. The cross-validated risk estimate for the final tree is calculated as the average of the risks for all of the trees. `CROSSVALIDATION` is ignored with a warning if `FORCE` is also specified.

OUTPUT Keyword

With split-sample validation, the `OUTPUT` keyword controls the output generated. This setting is ignored if `SPLITSAMPLE` is not specified.

BOTHSAMPLES	*Output is produced for training and test samples.* This is the default. Choose this option if you want to compare results for each partition.
TESTSAMPLE	*Output is produced for the test sample only.* Choose this option if you want validated results only.

CHAID Subcommand

The `CHAID` subcommand sets parameters for a CHAID tree. Except where noted, all parameters also apply to Exhaustive CHAID. It is ignored for CRT and QUEST trees, and an warning is issued.

Each keyword in the subcommand is followed by an equals sign (=) and the value for that keyword.

Example

```
TREE risk [o] BY income age creditscore
 /METHOD TYPE=CHAID
 /CHAID ALPHASPLIT=.01 INTERVALS=age income (10) creditscore (5).
```

ALPHASPLIT Keyword

The ALPHASPLIT keyword specifies the significance level for splitting of nodes. An independent variable will not be used in the tree if significance level for the split statistic (chi-square or *F*) is less than or equal to specified value.

- Specify a value greater than zero and less than 1.
- The default value is 0.05.

ALPHAMERGE Keyword

The ALPHAMERGE keyword specifies the significance level for merging of predictor categories. Small values tend to result in a greater degree of merging.

- Specify a value greater than zero and less than or equal to 1.
- The default value is 0.05.
- If you specify a value of 1, predictor categories are not merged.
- ALPHAMERGE is available only for the CHAID method. For Exhaustive CHAID, the keyword is ignored, and a warning is issued.

SPLITMERGED Keyword

The SPLITMERGED keyword specifies whether predictor categories that are merged in a CHAID analysis are allowed to be resplit.

NO	*Merged predictor categories cannot be resplit.* This is the default.
YES	*Merged predictor categories can be resplit.*

CHISQUARE Keyword

For nominal dependent variables, the CHISQUARE keyword specifies the chi-square measure used in CHAID analysis. For ordinal and scale dependent variables, the keyword is ignored and a warning is issued.

PEARSON	*Pearson chi-square.* This is the default.
LR	*Likelihood-ratio chi-square.*

CONVERGE Keyword

For nominal and ordinal dependent variables, the CONVERGE keyword specifies the convergence value for estimation of the CHAID model.

- Specify a value greater than zero and less than 1.
- The default value is 0.05.
- If the dependent variable is nominal or scale, this keyword is ignored, and a warning is issued.

MAXITERATIONS Keyword

For nominal and ordinal dependent variables, the MAXITERATIONS keyword specifies the maximum number of iterations for estimation of the CHAID model.

- Specify a positive integer value.
- The default value is 100.
- If the dependent variable is nominal or scale, this keyword is ignored, and a warning is issued.

ADJUST Keyword

The ADJUST keyword specifies how to adjust significance values for multiple comparisons.

BONFERRONI	*Significance values are adjusted using the Bonferroni method.* This is the default.
NONE	*Significance values are not adjusted.*

INTERVALS Keyword

In CHAID analysis, scale independent (predictor) variables are always banded into discrete groups (for example, 0-10, 11-20, 21-30, and so on) prior to analysis. You can use the INTERVALS keyword to control the number of discrete intervals for scale predictors.

- By default, each scale predictor is divided into 10 intervals that have approximately equal numbers of cases.
- The INTERVALS keyword is ignored if the model contains no scale independent variables.

value	*The specified value applies to all scale predictors.* For example: INTERVALS=5. The value must be a positive integer less than or equal to 64.
varlist (value)	*The specified value applies to the preceding variable list only.* Specify a list of variables followed by the number of intervals in parentheses. Multiple lists can be specified. For example: INTERVALS=age income (10) creditscore (5). The value must be a positive integer less than or equal to 64.

For the varlist (value) form:

- If a variable in the list is not a scale variable and/or the variable is not specified as an independent variable, the interval specification is ignored for that variable, and a warning is issued.
- If a variable appears in more than one list, the last specification is used.
- For any scale variables not include in the list(s), the default number of intervals (10) is used.

CRT Subcommand

The CRT subcommand sets parameters for the CRT method. For other tree growing methods, the subcommand is ignored, and a warning is issued.

Each keyword in the subcommand is followed by an equals sign (=) and the value for that keyword.

Example

```
TREE risk [o] BY income age creditscore
 /METHOD TYPE=CRT
 /CRT IMPURITY=TWOING MINIMPROVEMENT=.001.
```

IMPURITY Keyword

For categorical dependent variables, the IMPURITY keyword specifies the impurity measure used.

GINI	Gini is based on squared probabilities of membership for each category of the dependent variable. It reaches its minimum (zero) when all cases in a node fall into a single category. This is the default.
TWOING	Twoing groups categories of the dependent variable into the two best subclasses and computes the variance of the binary variable indicating the subclass to which each case belongs.
ORDEREDTWOING	A variant of twoing for ordinal dependent variables in which only adjacent classes can be combined. This method is available only for ordinal dependent variables only.

For scale dependent variables the least squared deviation (LSD) measure of impurity is used. It is computed as the within-node variance, adjusted for any frequency weights or influence values.

MINIMPROVEMENT Keyword

MINIMPROVEMENT specifies the minimum decrease in impurity for CRT trees. A node is not split if impurity would decrease less than the specified value.

- The default value is 0.0001.
- Specify a positive value. Large improvement values tend to result in smaller trees.

QUEST Subcommand

The ALPHASPLIT keyword on the QUEST subcommand sets the alpha criterion for selection of independent (predictor) variables. Specify a value greater than 0 and less than 1. The default is 0.05.

Example

```
TREE risk [n] BY income age creditscore
 /METHOD TYPE=QUEST
 /QUEST ALPHASPLIT=.01.
```

COSTS Subcommand

For categorical dependent variables, the COSTS subcommand allows you to specify penalties for misclassifying cases.

- Costs are used in node assignment and risk estimation for all trees.

- They also affect the tree-growing process for all trees except QUEST trees and CRT trees that use a twoing measure. To include cost information in the tree-growing process for such trees, use adjusted priors. For more information, see PRIORS Subcommand on p. 1833.
- The COST subcommand is ignored if the dependent variable is scale, and a warning is issued.

The subcommand name is followed by an equals sign (=) and one of the following alternatives:

EQUAL *Misclassification costs are equal across categories of the dependent variable.* Cost is set to 1 for all possible misclassifications. This is the default.

CUSTOM *User-specified costs.* Use this to specify costs for one or more combinations of actual and predicted categories. Any combination for which a cost is not specified defaults to 1.

Custom Costs

For each combination of dependent variable categories:

- Specify the actual category, predicted category, and misclassification cost, in that order.
- The cost value must be enclosed in square brackets.
- At least one cost specification must be provided, but you don't have to specify all possible combinations. Any combination for which a cost is not specified defaults to 1.
- If multiple cost specifications are provided for a particular combination of predicted and actual categories, the last one is used.
- Costs specified for categories that do not exist in the data are ignored, and a warning is issued.
- Cost values must be non-negative.
- Category values must be consistent with the data type of the dependent variable. String and date values must be quoted. Date values must be consistent with the variable's print format.
- Correct classifications, where the predicted category and the actual category match, are always assigned a cost of zero. A warning is issued if a nonzero cost is specified for a correct classification. For example, COSTS CUSTOM=1 1 [3] would be ignored and the cost would be set to 0.

Example

```
TREE risk [o] BY age income employment
 /COSTS CUSTOM=3 2 [2]
                3 1 [8].
```

- Assuming that the dependent variable is coded 1=*low*, 2=*medium*, and 3=*high*, the cost of misclassifying a high-risk individual as medium risk is 2.
- The cost of misclassifying a high-risk individual as low risk is 8.
- All other misclassifications, such as classifying a medium-risk individual as high risk, are assigned the default cost, 1.
- Correct classifications such as classifying a high-risk individual as high risk are always assigned a cost of 0.

PRIORS Subcommand

For CRT and QUEST trees with categorical dependent variables, the PRIORS subcommand allows you to specify prior probabilities of group membership. **Prior probabilities** are estimates of the overall relative frequency for each target category of the dependent variable prior to knowing anything about the values of the independent (predictor) variables. Using prior probabilities helps correct any tree growth caused by data in the sample that is not representative of the entire population.

- If the growing method is CHAID or Exhaustive CHAID, this subcommand is ignored and a warning is issued.
- If the dependent variable is scale, this subcommand is ignored and a warning is issued.

FROMDATA	*Obtain priors from the training sample.* Use this setting if the distribution of groups in the training sample is representative of the population distribution. This is the default. If you have not specified a training sample using the VALIDATION subcommand, then the distribution of values in the entire data file is used.
EQUAL	*Equal priors across categories.* Use this if categories of the dependent variable are represented equally in the population. For example, if there are four categories, approximately 25% of the cases are in each category.
CUSTOM	*User-specified prior probabilities.* For each category of the dependent variable, specify the category followed by a non-negative prior probability value enclosed in square brackets.

Custom Prior Probabilities

- Prior probabilities must be specified for all values of the dependent variable included in the analysis (either all non-missing values found in the data or all values defined on the DEPCATEGORIES subcommand).
- The values must be non-negative.
- The specified category values must be consistent with the data type of the dependent variable. String and date values must be quoted. Date values must be consistent with the variable's print format.
- If you specify the same category more than once, the last one is used.
- A warning is issued if you specify a prior probability for a category that does not exist in the data or in the training sample if split-sample validation is in effect. For more information, see VALIDATION Subcommand on p. 1827.
- Prior probability values are "normalized" to relative proportions before the tree is grown.

Example

```
TREE risk [o] BY age income employment
 /METHOD TYPE=CRT
 /PRIORS CUSTOM= 1 [30] 2 [75] 3 [45].
```

The prior probabilities of 30, 75, and 45 are normalized to proportions of 0.2, 0.5, and 0.3, respectively.

ADJUST Keyword

The ADJUST keyword specifies whether prior probabilities are adjusted to take into account misclassification costs.

NO	*Priors are unadjusted.* This is the default.
YES	*Priors are adjusted to take into account misclassification costs.*

SCORES Subcommand

For CHAID or Exhaustive CHAID trees with ordinal dependent variables, the SCORES subcommand allows you to specify scores that are used to scale the dependent variable. By default, scores are assigned in sorted value order: the first category is assigned a score of 1, the second category is assigned a score of 2, and so forth.

- If the growing method is CRT or QUEST, this subcommand is ignored, and a warning is issued.
- If the dependent variable is nominal or scale, this subcommand is ignored, and a warning is issued.

The subcommand name is followed by an equals sign (=) and one of the two following alternatives:

EQUALINCREMENTS	*Scores are ordinal ranks.* The lowest category of the dependent variable is assigned a score of 1, the next highest category is assigned a score of 2, and so on. This is the default.
CUSTOM	*User-specified scores.* For each category of the dependent variable, specify the category value followed by a score in square brackets.

Custom Scores

- Scores must be numeric and unique. You cannot assign the same score to more than one category.
- Scores must be specified for all values of the dependent variable included in the analysis (either all non-missing values found in the data or all values defined on the DEPCATEGORIES subcommand).
- Category values must be consistent with the data type of the dependent variable. String and date values must be quoted. Date values must be consistent with the variable's print format.
- If you specify multiple score values for the same category value, the last one is used.
- A warning is issued if you specify a score for a category that does not exist in the data or in the training sample if split-sample validation is in effect. For more information, see VALIDATION Subcommand on p. 1827.

Example

```
TREE income [o] BY age employment gender region
 /SCORES CUSTOM=1 [1] 2 [2.5] 3 [8].
```

- By default, the CHAID method is used to grow the tree.

- CUSTOM contains one score specification for each category of the ordinal dependent variable.
- Category 1 is assigned a score of 1; category 2 is assigned a score of 2.5; and category 3 is assigned a score of 8. In other words, scores are used to rescale income so there is a smaller gap between categories 1 and 2 than between 2 and 3.

PROFITS Subcommand

For categorical dependent variables, the PROFITS subcommand allows you to assign revenue and expense values to levels of the dependent variable. Revenues and expenses are used in tables and charts that summarize expected profits and return on investment (ROI). Profit is computed as revenue minus expense.

If the dependent variable is scale, this subcommand is ignored and warning is issued.

- The subcommand name is followed by an equals sign (=), the keyword CUSTOM, and a list of dependent variable values, each followed by a pair of values, representing revenues and expenses respectively, enclosed in square brackets.
- Revenue and expense values must be numeric and must be specified for all values of the dependent variable included in the analysis (either all non-missing values found in the data or all values defined on the DEPCATEGORIES subcommand).
- Category values must be consistent with the data type of the dependent variable. String and date values must be quoted. Date values must be consistent with the variable's print format.
- If you specify the same category value more than once, the expense and revenue values for the last one are used.
- A warning is issued if you specify a category of the dependent variable that does not exist in the data or in the training sample if split-sample validation is in effect. For more information, see VALIDATION Subcommand on p. 1827.

Example

```
TREE income [o] BY age employment gender region
 /PROFITS CUSTOM=1 [.1 .25]
                  2 [.5 .25]
                   3 [15 .25].
```

- Expected revenue and expense values are defined for each income category.
- Revenues vary across groups. For group 1, the lowest income group, expected revenue is 0.10 per individual. For group 2, the middle income group, expected revenue is 0.50 per individual. For group 3, the high income group, expected revenue is 15 per individual.
- The matrix specifies a fixed expense for each group. For each group, expected expense is 0.25 per person.

INFLUENCE Subcommand

The INFLUENCE subcommand defines an optional influence variable that defines how much influence a case has on the tree-growing process. Cases with lower influence values have less influence, cases with higher values have more.

- The variable must be numeric.
- The dependent variable cannot be used as the influence variable.
- The weight variable (see the WEIGHT command) cannot be used as the influence variable.
- For QUEST, this subcommand is ignored and a warning is issued.

OUTFILE Subcommand

The OUTFILE subcommand writes the tree model to an XML file.

TRAININGMODEL='filespec' *Writes the model to the specified file.* For split-sample validated trees, this is the model for the training sample.

TESTMODEL='filespec' *Writes the model for the test sample to the specified file.* Available only with /VALIDATION TYPE=SPLITSAMPLE. Ignored for unvalidated and cross-validated models.

Example

```
TREE income [o] BY age employment gender region
 /OUTFILE TRAININGMODEL='/myfolder/model.xml'.
```

MISSING Subcommand

The MISSING subcommand controls the handling of nominal, user-missing, independent (predictor) variable values.

- Handling of ordinal and scale user-missing independent variable values varies between growing methods.
- By default, if the values of all independent variables are system- or user-missing, the case is excluded.
- Handling of nominal dependent variables is controlled by the DEPCATEGORIES subcommand.
- For the dependent variable, cases with system-missing or user-missing ordinal or scale values are always excluded.

NOMINALMISSING Keyword

The NOMINALMISSING keyword controls the treatment of user-missing values of nominal independent (predictor) variables.

MISSING *Handling of user-missing values of nominal predictor variables depends on the growing method.* This is the default.

VALID *Treat user-missing values of nominal independent variables as valid values.* User-missing values of nominal independent variables are treated as ordinary values in tree growing and classification.

Method-Dependent Rules

If some, but not all independent variable values are system-or user-missing:

- For CHAID and Exhaustive CHAID, system- and user-missing scale and ordinal independent variable values are included in the tree-growing process as a "floating" category that is allowed to merge with other categories in tree nodes. By default, nominal user-missing values are also handled in this fashion.
- For CRT and QUEST, cases with missing independent variable values are excluded from the tree-growing process but are classified using surrogate predictors, if surrogates are included in the method. By default, nominal user-missing values are also handled in this fashion.

Weight Variables

If the analysis uses frequency weights or an influence variable, all cases with zero, negative, system-missing, or user-missing values of either variable are excluded from the analysis.

TSAPPLY

TSAPPLY is available in the Trends option.

Note: Square brackets that are shown in the TSAPPLY syntax chart are not used to indicate optional elements. Where indicated, they are required parts of syntax when a list of values is specified, but they may be omitted when a single value is specified. Equals signs (=) that are used in the syntax chart are required elements. The MODEL subcommand is required. All other subcommands are optional.

```
TSAPPLY
```

Global subcommands:

```
/MODELSUMMARY  PRINT=[MODELFIT** RESIDACF RESIDPACF NONE]
               PLOT=[SRSQUARE RSQUARE RMSE MAPE MAE MAXAPE
                     MAXAE NORMBIC RESIDACF RESIDPACF]

/MODELSTATISTICS DISPLAY={YES**}
                         {NO   }
                 MODELFIT=[SRSQUARE** RSQUARE RMSE MAPE MAE
                           MAXAPE MAXAE NORMBIC]

/MODELDETAILS    PRINT=[PARAMETERS RESIDACF RESIDPACF FORECASTS]
                 PLOT=[RESIDACF RESIDPACF]

/SERIESPLOT      OBSERVED FORECAST FIT FORECASTCI FITCI

/OUTPUTFILTER DISPLAY={ALLMODELS**                                        }
                      {[BESTFIT({N=integer  }) WORSTFIT({N=integer  })]}
                                {PCT=percent}           {PCT=percent}
              MODELFIT={SRSQUARE**}
                       {RSQUARE   }
                       {RMSE      }
                       {MAPE      }
                       {MAE       }
                       {MAXAPE    }
                       {MAXAE     }
                       {NORMBIC   }

/SAVE  PREDICTED(rootname)
       LCL(rootname)
       UCL(rootname)
       NRESIDUAL(rootname)

/AUXILIARY REESTIMATE={NO**}  CILEVEL={95**  }  MAXACFLAGS={24**   }
                      {YES }          {number}             {integer}
           SEASONLENGTH=integer

/MISSING USERMISSING={EXCLUDE**}
                     {INCLUDE  }
```

MODEL (local subcommand):

```
/MODEL  FILE=file   {DROP=['ModelID' 'ModelID' ...]}
                    {KEEP=['ModelID' 'ModelID' ...]}
        OUTFILE=file
```

**Default if the subcommand or keyword is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Release History

Release 14.0

- Command introduced.

Example

```
PREDICT THRU YEAR 2006 MONTH 6.
TSAPPLY
  /MODELDETAILS PRINT=FORECASTS
  /MODEL FILE='/models/models.xml'.
```

Overview

The TSAPPLY procedure loads existing time series models from an external file and applies them to data. Models are generated by using the TSMODEL procedure. You can use TSAPPLY to obtain forecasts for series for which new or revised data are available.

Options

Models. By default, parameter estimates saved in the model file are used to produce forecasts. Optionally, model parameters can be reestimated. Reestimation of model parameters has no effect on the model structure. For example, an ARIMA(1,0,1) model will remain so, but the autoregressive and moving-average parameters will be reestimated by using the data in the active dataset. Outliers, if any, are always taken from the model file.

Output. TSAPPLY offers the same output as the TSMODEL procedure. However, autocorrelations and partial autocorrelations are available only if model parameters are reestimated.

Saved Variables. You can save forecasts and their confidence intervals to the active dataset. Fit values and noise residuals are available if model parameters are reestimated.

Missing Values. You can control whether user-missing values are treated as valid or invalid values.

Basic Specification

- The basic specification is a MODEL subcommand that specifies a model file. By default, all models in the file are loaded.
- Default output includes a summary of the distribution of goodness of fit across loaded models and a table of stationary *R*-square, Ljung-Box Q, and number of outliers by model.

Syntax Rules

- The following subcommands are global: MODELSUMMARY, MODELSTATISTICS, MODELDETAILS, SERIESPLOT, OUTPUTFILTER, SAVE, AUXILIARY, and MISSING.
- Each global subcommand is optional, may be used only once, and must appear before any MODEL subcommand.

- The MODEL subcommand must be used at least once.
- An error occurs if a keyword or attribute is specified more than once within a subcommand.
- All subcommands other than MODEL are optional.
- Subcommand names and keywords must be spelled in full.
- Equals signs (=) that are shown in the syntax chart are required.
- An error is issued if any subcommand is empty.

Operations

- Models are applied to variables in the active dataset with the same names as the variables that are specified in the model.
- TSAPPLY honors time intervals and periodicity specified with the DATE command.
- The procedure verifies that date variables that are implied by the current date specification exist and that their values coincide with the date specification within the estimation period. If the data are filtered, values of date variables are verified within the filtered subset of data.
- If you choose to reestimate model parameters, reestimation happens within the currently active USE period. If the model has outliers, the outlier periods must be inside the effective USE period. The USE period is ignored if model parameters are not reestimated.
- The PREDICT command defines the end of the forecast period for tables, charts, and model variables that are produced by TSAPPLY.
- TSAPPLY does not honor the following commands: MODEL NAME, SAVE MODEL, and READ MODEL.
- TSAPPLY does not honor TSET. It does, however, provide options for missing-value handling, setting the width of confidence intervals, and setting the maximum number of lags displayed for autocorrelations.
- The TDISPLAY command does not display models that are saved by using TSAPPLY.

Limitations

- An error occurs if SPLIT FILE is in effect.
- WEIGHT is ignored with a warning.

Examples

This section provides simple examples that are designed to get you started with the TSAPPLY procedure. Further examples that are specific to each subcommand are provided in the subcommand topics.

Forecasting

```
PREDICT THRU YEAR 2006 MONTH 6.
TSAPPLY
  /MODELDETAILS PRINT=FORECASTS
  /MODEL FILE='/models/models.xml'.
```

- The PREDICT command is used to specify the forecast period for the TSAPPLY procedure.

- The MODELDETAILS subcommand specifies that the output includes a table containing the forecasts.
- The MODEL subcommand specifies that all models in the file */models/models.xml* will be applied to the active dataset. Models are applied to variables in the active dataset with the same names as the variables that are specified in the model.
- Forecasts are created by using the model parameters from *models.xml*, without reestimating any of those parameters. This behavior is the default behavior.

Forecasting with Reestimated Model Parameters

```
PREDICT THRU YEAR 2006 MONTH 6.
TSAPPLY
  /MODELDETAILS PRINT=FORECASTS
  /AUXILIARY REESTIMATE=YES
  /MODEL FILE='/models/models.xml'
         OUTFILE='/models/models_updated.xml'.
```

- The AUXILIARY subcommand specifies that model parameters for all models in */models/models.xml* will be reestimated prior to forecasting. Model parameters are reestimated by using the data in the active dataset.
- Reestimation of model parameters has no effect on the model structure. For example, an ARIMA(1,0,1) model will remain so, but the autoregressive and moving-average parameters will be reestimated.
- The OUTFILE keyword specifies that the reestimated models will be saved to the file */models/models_updated.xml*.

Applying a Selected Subset of Models

```
PREDICT THRU YEAR 2006 MONTH 6.
TSAPPLY
  /MODELDETAILS PRINT=FORECASTS
  /MODEL FILE='/models/models.xml' KEEP=['CustomArima_1'].
```

- The KEEP keyword specifies that only the model named *CustomArima_1* will be applied to the active dataset. All other models in */models/models.xml* will be excluded.

```
PREDICT THRU YEAR 2006 MONTH 6.
TSAPPLY
  /MODELDETAILS PRINT=FORECASTS
  /MODEL FILE='/models/models.xml' DROP=['Expert_1' 'Expert_2'].
```

- The DROP keyword specifies that the models named *Expert_1* and *Expert_2* will be excluded. All other models in */models/models.xml* will be applied to the active dataset.

Goodness-of-Fit Measures

The following model goodness-of-fit measures are available in TSAPPLY:

SRSQUARE **Stationary R-squared.** A measure that compares the stationary part of the model to a simple mean model. This measure is preferable to ordinary R-squared when there is a trend or seasonal pattern. Stationary R-squared can be negative with a range of negative infinity to 1. Negative values mean that the model under consideration is worse than the baseline model. Positive values mean that the model under consideration is better than the baseline model.

RSQUARE **R-squared.** An estimate of the proportion of the total variation in the series that is explained by the model. This measure is most useful when the series is stationary. R-squared can be negative with a range of negative infinity to 1. Negative values mean that the model under consideration is worse than the baseline model. Positive values mean that the model under consideration is better than the baseline model.

RMSE **RMSE.** Root Mean Square Error. The square root of mean square error. A measure of how much a dependent series varies from its model-predicted level, expressed in the same units as the dependent series.

MAPE **MAPE.** Mean Absolute Percentage Error. A measure of how much a dependent series varies from its model-predicted level. It is independent of the units used and can therefore be used to compare series with different units.

MAE **MAE.** Mean absolute error. Measures how much the series varies from its model-predicted level. MAE is reported in the original series units.

MAXAPE **MaxAPE.** Maximum Absolute Percentage Error. The largest forecasted error, expressed as a percentage. This measure is useful for imagining a worst-case scenario for your forecasts.

MAXAE **MaxAE.** Maximum Absolute Error. The largest forecasted error, expressed in the same units as the dependent series. Like MaxAPE, it is useful for imagining the worst-case scenario for your forecasts. Maximum absolute error and maximum absolute percentage error may occur at different series points–for example, when the absolute error for a large series value is slightly larger than the absolute error for a small series value. In that case, the maximum absolute error will occur at the larger series value and the maximum absolute percentage error will occur at the smaller series value.

NORMBIC **Normalized BIC.** Normalized Bayesian Information Criterion. A general measure of the overall fit of a model that attempts to account for model complexity. It is a score based upon the mean square error and includes a penalty for the number of parameters in the model and the length of the series. The penalty removes the advantage of models with more parameters, making the statistic easy to compare across different models for the same series.

MODELSUMMARY Subcommand

The MODELSUMMARY subcommand controls the display of tables and charts that summarize goodness of fit, residual autocorrelations, and residual partial autocorrelations across estimated models. Each keyword is followed by an equals sign (=) and one or more of the available options enclosed in square brackets.

Example

```
PREDICT THRU YEAR 2006 MONTH 6.
TSAPPLY
  /MODELDETAILS PRINT=FORECASTS
  /AUXILIARY REESTIMATE=YES
```

```
/MODELSUMMARY PLOT=[SRSQUARE MAXAPE]
/MODEL FILE='/models/models.xml'.
```

- The output includes two histograms: one histogram for stationary *R*-squared and one histogram for the maximum absolute percentage error. Each histogram consists of results across all models.

PRINT Keyword

The PRINT keyword controls the display of model summary tables.

MODELFIT	*Goodness of fit.* Table of summary statistics and percentiles for stationary *R*-square, *R*-square, root mean square error, mean absolute percentage error, mean absolute error, maximum absolute percentage error, maximum absolute error, and normalized Bayesian Information Criterion. Note that if models are not reestimated, model fit statistics are loaded from the model file. This table is displayed by default.
RESIDACF	*Residual autocorrelation function.* Table of summary statistics and percentiles for autocorrelations of the residuals. RESIDACF is ignored with a warning if REESTIMATE=NO.
RESIDPACF	*Residual partial autocorrelation function.* Table of summary statistics and percentiles for partial autocorrelations of the residuals. RESIDPACF is ignored with a warning if REESTIMATE=NO.
NONE	*No tables are shown.* An error occurs if NONE is used in combination with any other PRINT option.

PLOT Keyword

The PLOT keyword controls the display of model summary charts. By default no charts are shown. (For detailed definitions of the following terms, see Goodness-of-Fit Measures on p. 1842.)

SRSQUARE	*Histogram of Stationary* R-Square.
RSQUARE	*Histogram of* R-Square.
RMSE	*Histogram of Root Mean Square Error.*
MAPE	*Histogram of Mean Absolute Percentage Error.*
MAE	*Histogram of Mean Absolute Error.*
MAXAPE	*Histogram of Maximum Absolute Percentage Error.*
MAXAE	*Histogram of Maximum Absolute Error.*
NORMBIC	*Histogram of Normalized Bayesian Information Criterion (BIC).*
RESIDACF	*Boxplot of Residual Autocorrelation Function by Lag.* RESIDACF is ignored with a warning if REESTIMATE=NO.
RESIDPACF	*Boxplot of Residual Partial Autocorrelation Function by Lag.* RESIDPACF is ignored with a warning if REESTIMATE=NO.

MODELSTATISTICS Subcommand

The MODELSTATISTICS subcommand controls display of a table listing all models along with chosen goodness-of-fit statistics. Note that if models are not reestimated, model fit statistics are loaded from the model file.

Example

```
PREDICT THRU YEAR 2006 MONTH 6.
TSAPPLY
  /MODELDETAILS PRINT=FORECASTS
  /AUXILIARY REESTIMATE=YES
  /MODELSTATISTICS DISPLAY=YES MODELFIT=RSQUARE
  /MODEL FILE='/models/models.xml'.
```

- The output includes a table displaying the value of *R*-squared for each model.

DISPLAY Keyword

The DISPLAY keyword controls whether the model statistics table is shown.

YES	*Model statistics table is shown.* Table of model goodness of fit, Ljung-Box Q statistic, and number of outliers by model. This setting is the default. The Q statistic measures the degree of pattern in the residuals. Large values of Q in relation to its degrees of freedom indicate that model residuals are not randomly distributed.
NO	*Model statistics table is not shown.*

MODELFIT Keyword

The MODELFIT keyword controls which fit statistics are shown in the model statistics table, and this keyword is ignored if DISPLAY=NO. The keyword is followed by an equals sign (=) and one or more of the following options enclosed in square brackets. (For detailed definitions of the following terms, see Goodness-of-Fit Measures on p. 1842.)

SRSQUARE	*Stationary* R-*square*. This setting is the default.
RSQUARE	R-*Square.*
RMSE	*Root Mean Square Error.*
MAPE	*Mean Absolute Percentage Error.*
MAE	*Mean Absolute Error.*
MAXAPE	*Maximum Absolute Percentage Error.*
MAXAE	*Maximum Absolute Error.*
NORMBIC	*Normalized Bayesian Information Criterion (BIC).*

MODELDETAILS Subcommand

The MODELDETAILS subcommand controls the display of model parameters, model forecasts, and autocorrelations of noise residuals for individual models. Each keyword is followed by an equals sign (=) and one or more of the available options enclosed in square brackets.

Example

```
PREDICT THRU YEAR 2006 MONTH 6.
TSAPPLY
  /AUXILIARY REESTIMATE=YES
  /MODELDETAILS PRINT=[PARAMETERS FORECASTS]
```

```
/MODEL FILE='/models/models.xml'.
```

- The output includes tables displaying the model parameters and forecasts for each model.

PRINT Keyword

The PRINT keyword controls display of tables for individual models. By default, no tables are shown.

PARAMETERS	*Model parameter estimates.* Shows separate tables for ARIMA and exponential smoothing models. If outliers exist, parameter estimates for outliers are also displayed. Note that if models are not reestimated, parameter estimates are loaded from the model file.
RESIDACF	*Residual autocorrelation function.* Shows residual autocorrelations by lag. RESIDACF is ignored with a warning if REESTIMATE=NO.
RESIDPACF	*Residual partial autocorrelation function.* Shows residual partial autocorrelations by lag. RESIDPACF is ignored with a warning if REESTIMATE=NO.
FORECASTS	*Forecasts and confidence intervals.* Shows model forecasts and confidence intervals.

PLOT Keyword

The PLOT keyword controls display of charts for individual models. By default no charts are shown. PLOT is ignored with a warning if REESTIMATE=NO.

RESIDACF	*Residual autocorrelation function.* Shows residual autocorrelations by lag.
RESIDPACF	*Residual partial autocorrelation function.* Shows residual partial autocorrelations by lag.

SERIESPLOT Subcommand

The SERIESPLOT subcommand allows you to obtain plots of predicted values, observed values, and confidence intervals for each model. By default, no plots are shown. The subcommand is followed by one or more of the following keywords:

OBSERVED	*Displays all observed values of the dependent series.* OBSERVED is ignored with a warning if REESTIMATE=NO.
FORECAST	*Displays model-predicted values within the forecast period.*
FIT	*Displays model-predicted values within the estimation period.* FIT is ignored with a warning if REESTIMATE=NO.
FORECASTCI	*Displays upper and lower confidence limits within the forecast period.*
FITCI	*Displays upper and lower confidence limits within the estimation period.* FITCI is ignored with a warning if REESTIMATE=NO.

Example

```
PREDICT THRU YEAR 2006 MONTH 6.
TSAPPLY
  /MODELDETAILS PRINT=FORECASTS
  /AUXILIARY REESTIMATE=YES
```

```
/SERIESPLOT OBSERVED FORECAST
/MODEL FILE='/models/models.xml'.
```

- The output includes plots of the model-predicted values in the forecast period, as well as all observed values, for each model.

OUTPUTFILTER Subcommand

The OUTPUTFILTER subcommand controls which models are included in the model statistics table (MODELSTATISTICS subcommand), detailed model output (MODELDETAILS subcommand), and time series plots (SERIESPLOT subcommand).

- By default, all models are included in the output. OUTPUTFILTER can be used to display only the best-fitting or worst-fitting models (or both). If you request both, two sets of output are displayed.
- If model parameters are not reestimated, models are selected based on goodness-of-fit statistics that are loaded from the model file.
- OUTPUTFILTER is ignored if no output is requested on the MODELSTATISTICS, MODELDETAILS, or SERIESPLOT subcommands.
- OUTPUTFILTER has no effect on output from the MODELSUMMARY subcommand.

Example

```
PREDICT THRU YEAR 2006 MONTH 6.
TSAPPLY
  /MODELDETAILS PRINT=FORECASTS
  /OUTPUTFILTER DISPLAY=[BESTFIT(N=5) WORSTFIT(PCT=10)]
  /MODEL FILE='/models/models.xml'.
```

- The output consists of two sets of results: those results for the 5 best-fitting models and those results for models with fit values in the bottom 10%. The stationary *R*-squared value is used as the goodness-of-fit measure.

DISPLAY Keyword

The DISPLAY keyword controls which models are included in MODELSTATISTICS, MODELDETAILS, and SERIESPLOT output.

- By default, all models are displayed (DISPLAY=ALLMODELS).
- To display only those models with extreme goodness-of-fit values, specify BESTFIT, WORSTFIT, or both, in square brackets. One or both keywords must be specified.

ALLMODELS *All models are displayed.* All models that could be loaded (REESTIMATE=NO) or computed (REESTIMATE=YES) are shown. This setting is the default.

BESTFIT *Models having the highest fit values are shown.* To display the models with the N highest fit values, specify BESTFIT followed by N=count in parentheses—for example, BESTFIT(N=5). The count must be a positive integer. If the count exceeds the number of estimated models, all models are shown. To display the models with fit values in the top N%, specify PCT=percent in parentheses. For example, BESTFIT(PCT=5) displays models with fit values in the top 5% among estimated models. The percentage value must be greater than zero and less than 100.

WORSTFIT *Models having the lowest fit values are shown.* To display the models with the N lowest fit values, specify WORSTFIT followed by N=count in parentheses—for example, WORSTFIT(N=5). The count must be a positive integer. If the count exceeds the number of models estimated, all models are shown. To display the models with fit values in the lowest N%, specify PCT=percent in parentheses. For example, WORSTFIT(PCT=5) displays models with fit values in the bottom 5% among estimated models. The percentage value must be greater than zero and less than 100.

MODELFIT Keyword

The MODELFIT keyword specifies the fit measure that is used to filter models. MODELFIT is ignored if DISPLAY=ALLMODELS.

Specify one of the following options. (For detailed definitions of the following terms, see Goodness-of-Fit Measures on p. 1842.)

SRSQUARE *Stationary* R-*Square*. This setting is the default.

RSQUARE R-*Square.*

RMSE *Root Mean Square Error.*

MAPE *Mean Absolute Percentage Error.*

MAE *Mean Absolute Error.*

MAXAPE *Maximum Absolute Percentage Error.*

MAXAE *Maximum Absolute Error.*

NORMBIC *Normalized Bayesian Information Criterion (BIC).*

SAVE Subcommand

The SAVE subcommand is used to save new variables representing predicted values, residuals, and confidence intervals to the active dataset. By default, no new variables are saved to the active dataset.

- Specify one or more keywords, each keyword followed by an optional rootname to be used as the prefix for new variable names. Enclose the root name in parentheses. Each keyword gives rise to one new variable for each dependent variable.
- The root name, if specified, must conform to the rules for valid variable names.

- If no root name is specified, TSAPPLY uses a default name.
- The full variable name is the concatenation of the root name, the name of the associated dependent variable, and a model identifier. The variable name is extended if necessary to avoid variable naming conflicts.
- The PREDICT command controls whether new cases are added to the file when new variables are saved. New cases are added if PREDICT specifies a forecast period that extends beyond the length of the dependent-variable series.
- SAVE is ignored with a warning if temporary transformations are in effect.

Example

```
PREDICT THRU YEAR 2006 MONTH 6.
TSAPPLY
  /AUXILIARY REESTIMATE=YES
  /SAVE PREDICTED(ApplyPred) NRESIDUAL
  /MODEL FILE='/models/models.xml'.
```

- Two new variables are created for each of the models: one variable contains the model predictions, and the other variable contains the noise residuals.
- The root name (prefix) for the variables containing model predictions is *ApplyPred*.
- The root name for the variables containing noise residuals is *NResidual* (the default).

PREDICTED(rootname)	*Model fit and forecast values.* The default root name is *Predicted*. If REESTIMATE=NO, only forecasts are produced.
LCL(rootname)	*Lower confidence limits.* The default root name is *LCL*. If REESTIMATE=NO, lower confidence limits are only produced for forecasts.
UCL(rootname)	*Upper confidence limits.* The default root name is *UCL*. If REESTIMATE=NO, upper confidence limits are only produced for forecasts.
NRESIDUAL(rootname)	*Noise residuals.* The default rootname is *NResidual*. When transformations of the dependent variable are performed (for example, natural log), these residuals are the residuals for the transformed series. NRESIDUAL is ignored with a warning if REESTIMATE=NO.

AUXILIARY Subcommand

The AUXILIARY subcommand is used to specify whether model parameters are reestimated, set the confidence interval level for forecasts, set the maximum number of lags for autocorrelation and partial autocorrelation plots and tables, and specify the season length.

Example

```
PREDICT THRU YEAR 2006 MONTH 6.
TSAPPLY
  /MODELDETAILS PRINT=[PARAMETERS FORECASTS]
                PLOT=[RESIDACF RESIDPACF]
  /AUXILIARY REESTIMATE=YES MAXACFLAGS=36
  /MODEL FILE='/models/models.xml'.
```

REESTIMATE Keyword

REESTIMATE controls whether model parameters are reestimated. If REESTIMATE=NO (the default), parameter estimates that are recorded in the model file are used to produce forecasts. If REESTIMATE=YES, forecasts reflect reestimated model parameters. Outliers, if any, are always taken from the model file.

Note that if REESTIMATE=NO, any parameter estimates or goodness-of-fit statistics that are displayed in output are loaded from the model file and reflect the data that were used when each model was developed (or last updated). And if you use the OUTPUTFILTER subcommand, models will be selected on the basis of goodness-of-fit statistics that are recorded in the model file. In addition, forecasts will not take into account historical data—for either dependent or independent variables—in the active dataset. You must set REESTIMATE=YES if you want historical data to impact the forecasts. Finally, forecasts do not take into account values of the dependent series in the forecast period—but the forecasts do take into account values of independent variables in the forecast period. If you have more current values of the dependent series and want them to be included in the forecasts, you need to reestimate, adjusting the estimation period to include these values.

CILEVEL Keyword

The CILEVEL keyword sets the confidence level.

- Specify a positive number that is less than 100.
- The default is 95.

MAXACFLAGS Keyword

The MAXACFLAGS keyword sets the maximum number of lags displayed in residual autocorrelation and partial autocorrelation tables and plots. MAXACFLAGS is ignored if REESTIMATE=NO.

- Specify a positive integer.
- The default is 24.

SEASONLENGTH Keyword

The SEASONLENGTH keyword specifies the length of the seasonal period (the number of observations in one period or season) for the data.

- To adjust the season length, specify a positive integer.
- If SEASONLENGTH is not specified, the periodicity that is specified by using the DATE command defines the season length.
- Note that SEASONLENGTH is used to override the date specification for the active dataset to make it consistent with the date specification from the model file. An error occurs if these two specifications are not consistent.

MISSING Subcommand

The MISSING subcommand controls the handling of user-missing values.

- By default, user-missing values are treated as missing (invalid) data.
- System-missing values are always treated as invalid.
- Cases with missing values of a dependent variable that occur within the estimation period are included in the model. The specific handling of the missing value depends on the estimation method.
- For ARIMA models, a warning is issued if a predictor has any missing values within the estimation period. Any models involving the predictor are not reestimated.
- If any predictor has missing values within the forecast period, the procedure issues a warning and forecasts as far as it can.

Example

```
PREDICT THRU YEAR 2006 MONTH 6.
TSAPPLY
  /MODELDETAILS PRINT=FORECASTS
  /AUXILIARY REESTIMATE=YES
  /MISSING USERMISSING=INCLUDE
  /MODEL FILE='/models/models.xml'.
```

USERMISSING Keyword

The USERMISSING keyword controls the treatment of user-missing values and is required.

EXCLUDE	*Exclude user-missing values.* User-missing values are treated as missing. This setting is the default.
INCLUDE	*Include user-missing values.* User-missing values are treated as valid data.

MODEL Subcommand

The MODEL subcommand is required and specifies an external file, referred to as a **model file**, containing models that are developed by using TSMODEL. A model file specifies lag structure, parameters, outliers, and variables for each model.

- TSAPPLY assumes that the variables that are specified in the model file exist in the active dataset.
- You can use multiple MODEL subcommands to apply two or more sets of models to your data. Each MODEL subcommand is used to load models from a different model file. For example, one model file might contain models for series that represent unit sales, and another model file might contain models for series that represent revenue.

FILE Keyword

The FILE keyword is used to specify an external file containing models, and the keyword is required.

- A warning is issued if a model variable that is specified in the file does not exist in the active dataset or is not numeric. Models that refer to the variable are ignored.

- A warning is issued if a model specifies a variable transformation (square root or natural log) and one or more model variables to be transformed contain values that are invalid for the specified transformation—for example, negative values. Any such models will not be applied.
- An error occurs if the date interval or cycle length that is specified in the file is inconsistent with the date specification for the active dataset. The SEASONLENGTH keyword on the AUXILIARY subcommand can be used to override the date specification for the active dataset.
- An error occurs if the file cannot be read or is invalid.
- An error occurs if two or more MODEL subcommands specify the same file.
- When multiple MODEL subcommands are used, a warning occurs if the same model ID occurs in more than one model file. The first model with that ID is loaded. The check for duplicate model IDs takes place after DROP and KEEP are applied to each model file.
- A warning is issued, and forecasts are not available for a model, if REESTIMATE=NO and the model's forecast period is inconsistent with the current USE or PREDICT interval. Specifically, forecasts are not available if model forecasts would start before the beginning of the USE period or after the end of the PREDICT interval.

DROP Keyword

The DROP keyword is used to exclude models.

- Specify one or more quoted model identifiers, enclosed in square brackets—for example, ['Model_1' 'Model_2']. All other models in the file are loaded and applied to the data.
- Redundant items in the DROP list are ignored.
- An error occurs if all models are dropped.
- Model identifiers that do not exist in the file are ignored.

KEEP Keyword

The KEEP keyword specifies models to be applied.

- Specify one or more quoted model identifiers, enclosed in square brackets—for example, ['Model_1' 'Model_2']. All other models in the file are excluded.
- Redundant items in the KEEP list are ignored.
- Model identifiers that do not exist in the file are ignored.
- DROP and KEEP are mutually exclusive. An error occurs if both are specified.

OUTFILE Keyword

The OUTFILE keyword specifies an external file to which updated models are written.

- You can use OUTFILE to save models whose parameters are reestimated. OUTFILE is ignored with a warning if REESTIMATE=NO.
- The filename must be specified in full. No extension is supplied.
- Models that are excluded by using DROP or KEEP are not saved.
- You can specify the same external file on multiple MODEL subcommands. Models from the different subcommands are then saved to that single file.

TSET

```
TSET
 [PRINT={DEFAULT**}]  [/NEWVAR={CURRENT**}] [/MXAUTO={16**}]
        {BRIEF    }            {NONE     }           {lags}
        {DETAILED }            {ALL      }

 [/MXCROSS={7** }]  [/MXNEWVARS={60**}] [/MXPREDICT={60**}]
           {lags}               {n   }              {n   }

 [/MISSING={EXCLUDE**}]  [/CIN={95** }] [/TOLER={0.0001**}]
           {INCLUDE  }          {value}          {value   }

 [/CNVERGE={0.001**}]  [/ACFSE={IND**}]
           {value  }           {MA   }

 [/PERIOD=n]    [/ID=varname]

 [/{CONSTANT**}]
   {NOCONSTANT}

 [/DEFAULT]
```

**Default if the subcommand is omitted.

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Example

```
TSET PERIOD 6 NEWVAR NONE MXAUTO 25.
```

Overview

TSET sets global parameters to be used by procedures that analyze time series and sequence variables. To display the current settings of these parameters, use the TSHOW command.

Basic Specification

The basic specification is at least one subcommand.

Subcommand Order

- Subcommands can be specified in any order.

Syntax Rules

- The slash between subcommands is optional.
- You can specify DEFAULT on any subcommand to restore the default setting for that subcommand.
- Subcommand DEFAULT restores all TSET subcommands to their defaults.

Operations

- TSET takes effect immediately.
- Only the settings specified are affected. All others remain at their previous settings or the default.
- Subcommands on other procedures that perform the same function as subcommands on TSET override the TSET specifications for those procedures.
- Procedures that are affected by TSET specifications are CURVEFIT, CASEPLOT, NPPLOT, and TSPLOT.

DEFAULT Subcommand

DEFAULT resets all TSET settings back to their defaults. There are no additional specifications on DEFAULT.

ID Subcommand

ID specifies a variable whose values are used to label observations in plots.

- The only specification on ID is the name of a variable in the active dataset.
- If ID is not specified, the *DATE_* variable is used to label observations.
- If ID is specified within the procedure, it overrides the TSET specification for that procedure.

MISSING Subcommand

MISSING controls the treatment of user-missing values.

- The specification on MISSING is keyword INCLUDE or EXCLUDE. The default is EXCLUDE.
- INCLUDE indicates that observations with user-missing values should be treated as valid values and included in analyses.
- EXCLUDE indicates that observations with user-missing values should be excluded from analyses.

MXNEWVARS Subcommand

MXNEWVARS indicates the maximum number of new variables that can be generated by a procedure.

- The specification on MXNEWVARS indicates the maximum and can be any positive integer.
- The default maximum number is 60 new variables per procedure.

MXPREDICT Subcommand

MXPREDICT indicates the maximum number of new cases that can be added to the active dataset per procedure when the PREDICT command is used.

- The specification on MXPREDICT can be any positive integer.
- The default maximum number of new cases is 60 per procedure.

NEWVAR Subcommand

NEWVAR controls the creation of new variables in the active dataset.

- The specification on NEWVAR can be CURRENT, NONE, or ALL. The default is CURRENT.
- CURRENT specifies to save new variables and replace any existing variables of the same name.
- ALL specifies to save new variables without replacing existing ones.
- NONE specifies that no new variables are saved.

PERIOD Subcommand

PERIOD indicates the size of the period to be used for seasonal differencing.

- The specification on PERIOD indicates how many observations are in one season or period and can be any positive integer.
- There is no default for the PERIOD subcommand.
- The specification on TSET PERIOD overrides the periodicity of DATE variables.
- If a period is specified within an individual procedure, it overrides the TSET PERIOD specification for that procedure.

PRINT Subcommand

PRINT controls how much output is produced.

- The specification on PRINT can be BRIEF, DETAILED, or DEFAULT. The amount of output produced by DEFAULT is generally between the amount produced by BRIEF and DETAILED.
- For procedures with multiple iterations, BRIEF generally means that final statistics are displayed with no iteration history. DEFAULT provides a one-line summary at each iteration in addition to the final statistics. DETAILED provides a complete summary of each iteration (where necessary) plus the final statistics.
- For some procedures, the DEFAULT and DETAILED output is the same. For many of the simpler procedures, BRIEF, DEFAULT, and DETAILED are all the same.

TSHOW

```
TSHOW
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Overview

TSHOW displays a list of all the current specifications on the TSET, USE, PREDICT, and DATE commands.

Basic Specification

The command keyword TSHOW is the only specification.

Operations

- TSHOW is executed immediately.
- TSHOW lists every current specification for the TSET, USE, PREDICT, and DATE commands, as well as the default settings.

Example

```
TSHOW.
```

- The TSHOW command produces a list of the current settings on the TSET, USE, PREDICT, and DATE commands.

TSMODEL

TSMODEL is available in the Trends option.

Note: Square brackets that are shown in the TSMODEL syntax chart are not used to indicate optional elements. Where indicated, they are required parts of syntax when a list of values is specified, but they may be omitted when a single value is specified. Equals signs (=) that are used in the syntax chart are required elements. The MODEL subcommand is required. All other subcommands are optional.

```
TSMODEL
```

Global subcommands:

```

                                            {INNOVATIONAL    }
                                            {TRANSIENT       }
                                            {SEASONALADDITIVE}
                                            {LOCALTREND      }
```

**Default if the subcommand or keyword is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Release History

Release 14.0

- Command introduced.

Example

```
TSMODEL
  /MODEL DEPENDENT=sku1 TO sku10.
```

Overview

The TSMODEL procedure estimates exponential smoothing, univariate Autoregressive Integrated Moving Average (ARIMA), and multivariate ARIMA (or transfer function models) models for time series, and the procedure produces forecasts. The procedure includes an Expert Modeler that identifies and estimates an appropriate ARIMA or exponential smoothing model for each dependent-variable series. Alternatively, you can specify a custom ARIMA or exponential smoothing model.

Options

Automatic Model Identification. The Expert Modeler can identify an appropriate seasonal or nonseasonal ARIMA or exponential smoothing model for each dependent-variable series. If predictor variables are specified, the Expert Modeler selects, for inclusion in ARIMA models, those variables that have a statistically significant relationship with the dependent series. Model variables are transformed where appropriate by using differencing and/or a square root or natural log transformation. You can limit the set of candidate models to ARIMA models only or exponential smoothing models only.

Custom Models. You can specify a custom exponential smoothing or ARIMA model for one or more series. Seven exponential smoothing methods are available: simple, simple seasonal, Holt's linear trend, Brown's linear trend, damped trend, Winters' additive, and Winters' multiplicative. For ARIMA models, you can specify seasonal and nonseasonal autoregressive and moving average orders, differencing, as well as transfer functions for predictor variables. For exponential smoothing and ARIMA models, you can request that model variables be transformed prior to model estimation.

Outliers. If you use the Expert Modeler or specify a custom ARIMA model, TSMODEL can detect and model outlier time points automatically. The following outlier types can be identified: additive, additive patch, innovational, level shift, transient, seasonal additive, and local trend. Alternatively, if you request a custom ARIMA model, you can specify that one or more time points be modeled as outliers.

Output. Available output includes plots and tables that summarize the distribution of model goodness of fit, residual autocorrelations, and residual partial autocorrelations across models. In addition, you can obtain a table of model goodness of fit, Ljung-Box Q, and number of outliers by model. You can also obtain details for each model, including parameter estimates, forecasts, as well as autocorrelation and partial autocorrelation functions. Output can be restricted to the best-fitting or worst-fitting models based on goodness-of fit-values.

Saved Variables. You can save fit and forecast values to the active dataset as well as confidence intervals and noise residuals.

Missing Values. You can control whether user-missing values are treated as valid or invalid values.

Basic Specification

- The basic specification is a MODEL subcommand that specifies one or more dependent-variable series.
- By default, TSMODEL uses the Expert Modeler to identify and estimate the best ARIMA or exponential smoothing model for each series.
- Default output includes a summary of the distribution of goodness of fit across estimated models and a table of stationary *R*-square, Ljung-Box Q, and number of outliers by model.

Syntax Rules

- The following subcommands are global and apply to all models specified in a single instance of the TSMODEL command: MODELSUMMARY, MODELSTATISTICS, MODELDETAILS, SERIESPLOT, OUTPUTFILTER, SAVE, AUXILIARY, and MISSING.
- Each global subcommand is optional, may be used only once, and must appear before any MODEL subcommand.
- Models are specified in blocks. The MODEL subcommand indicates the start of a block. The MODEL subcommand must be used at least once.
- The following subcommands apply to the preceding MODEL subcommand and constitute—along with a MODEL subcommand—a MODEL block: EXPERTMODELER, EXSMOOTH, ARIMA, TRANSFERFUNCTION, AUTOOUTLIER, and OUTLIER. An error occurs if any of these subcommands precedes the first MODEL subcommand.
- The EXPERTMODELER, EXSMOOTH, and ARIMA subcommands are used within a MODEL block to specify the estimation method. If none of these subcommands is specified, the implicit default is EXPERTMODELER. An error occurs if more than one of these subcommands is specified within a MODEL block.
- AUTOOUTLIER may be used only once within a MODEL block.
- TRANSFERFUNCTION and OUTLIER may be used more than once within a MODEL block.
- Each keyword may be specified only once within a subcommand.
- Empty subcommands are not allowed; all subcommands must be specified with options.
- All subcommands other than MODEL are optional.
- Subcommand names and keywords must be spelled in full.
- Subcommands can be specified in any order, with the exception that global subcommands must precede the first MODEL subcommand.
- Equals signs (=) that are shown in the syntax chart are required.

Operations

- TSMODEL honors time intervals and periodicity specified with the DATE command.
- The procedure verifies that date variables that are implied by the current date specification exist and that their values coincide with the date specification within the estimation period. If SPLIT FILE is in effect, the check is done for each split. A split is skipped and a warning is issued if verification fails for that split. If the verification fails when SPLIT FILE is not in effect, an error occurs and processing terminates. If the data are filtered, values of date variables are verified within the filtered subset of data.

- The procedure honors the estimation (historical) period that is defined with the USE command. However, depending on available data, the actual use period may vary by dependent variable. For a given dependent variable, the estimation period is the period left after eliminating contiguous missing values of the dependent variable at the beginning and end of the USE period.
- If SPLIT FILE is in effect, and a split has fewer cases than implied by the USE period, a warning is issued and all available cases are used. If there are no cases in the USE period, the split is skipped altogether with a warning.
- The PREDICT command defines the end of the forecast period for tables, charts, and model variables that are produced by TSMODEL. The forecast period always starts after the end of the estimation (USE) period. Like the estimation period, the forecast period can vary by model, depending on available data. If a PREDICT specification ends on or before the effective end of the USE period, the forecast period is empty.
- The procedure does not honor the following commands: MODEL NAME or SAVE MODEL. Options for naming and saving models are provided with the TSMODEL procedure.
- The procedure does not honor TSET. The TSMODEL procedure provides options for handling missing values, setting the width of confidence intervals, setting the maximum number of lags displayed for autocorrelations, and setting season length.
- The TDISPLAY command does not display models that are saved by using TSMODEL.

Limitations

- WEIGHT is ignored with a warning.

Examples

This section provides simple examples that are designed to get you started with using the Expert Modeler, producing forecasts, saving results to the active dataset, and saving your model for later use. Further examples that are specific to each subcommand are provided in the subcommand topics.

Using the Expert Modeler

```
TSMODEL
  /MODEL DEPENDENT=sku1 TO sku10.
```

- The Expert Modeler is used to find the best-fitting exponential smoothing or ARIMA model for each of the dependent series *sku1* thru *sku10*.
- The procedure invokes the Expert Modeler because the MODEL subcommand is not followed by one of the model type subcommands (i.e., EXSMOOTH or ARIMA). The absence of a model type subcommand is equivalent to specifying /EXPERTMODELER TYPE=[ARIMA EXSMOOTH] TRYSEASONAL=YES.

Obtaining Model Forecasts

```
PREDICT THRU YEAR 2006 MONTH 6.
TSMODEL
  /SERIESPLOT FORECAST
```

```
  /MODELDETAILS PRINT=FORECASTS
  /MODEL DEPENDENT=revenue.
```

- The PREDICT command is used to specify the forecast period for the TSMODEL procedure.
- The SERIESPLOT subcommand specifies that the output contains a plot of the predicted values within the forecast period.
- The MODELDETAILS subcommand specifies that the output includes a table containing the predicted values within the forecast period.

Saving Models to an External File

```
TSMODEL
  /MODEL DEPENDENT=sku1 TO sku50 OUTFILE='/models/models_sku1TOsku50.xml'.
```

- The OUTFILE keyword specifies that each of the resulting models is to be saved to the file */models/models_sku1TOsku50.xml*.
- The saved models can be used to produce new forecasts with the TSAPPLY command when new data are available. For more information, see TSAPPLY on p. 1838.

Saving Model Predictions, Residuals, and Confidence Intervals as New Variables

```
TSMODEL
  /SAVE PREDICTED LCL UCL NRESIDUAL
  /MODEL DEPENDENT=revenue.
```

- The SAVE subcommand specifies that new variables containing the model predictions, noise residuals, and confidence intervals are saved to the active dataset.

Specifying Multiple Model Types

```
TSMODEL
  /MODEL DEPENDENT=sku1 TO sku10 INDEPENDENT=adspending
  /EXPERTMODELER TYPE=[ARIMA]
  /MODEL DEPENDENT=sku11 TO sku15
  /EXSMOOTH TYPE=WINTERSMULTIPLICATIVE.
```

- The first MODEL block specifies that the Expert Modeler is used to find the best-fitting ARIMA model for each of the dependent series *sku1* thru *sku10*, using the predictor variable *adspending*.
- The second MODEL block specifies that the Winters' multiplicative method is used to model each of the dependent series *sku11* thru *sku15*.
- In this example, different model types were used for different dependent variables. You can also specify multiple model types for the same dependent variable, thereby obtaining multiple models for the variable.

Goodness-of-Fit Measures

The following model goodness-of-fit measures are available in TSMODEL:

SRSQUARE **Stationary R-squared.** A measure that compares the stationary part of the model to a simple mean model. This measure is preferable to ordinary R-squared when there is a trend or seasonal pattern. Stationary R-squared can be negative with a range of negative infinity to 1. Negative values mean that the model under consideration is worse than the baseline model. Positive values mean that the model under consideration is better than the baseline model.

RSQUARE **R-squared.** An estimate of the proportion of the total variation in the series that is explained by the model. This measure is most useful when the series is stationary. R-squared can be negative with a range of negative infinity to 1. Negative values mean that the model under consideration is worse than the baseline model. Positive values mean that the model under consideration is better than the baseline model.

RMSE **RMSE.** Root Mean Square Error. The square root of mean square error. A measure of how much a dependent series varies from its model-predicted level, expressed in the same units as the dependent series.

MAPE **MAPE.** Mean Absolute Percentage Error. A measure of how much a dependent series varies from its model-predicted level. It is independent of the units used and can therefore be used to compare series with different units.

MAE **MAE.** Mean absolute error. Measures how much the series varies from its model-predicted level. MAE is reported in the original series units.

MAXAPE **MaxAPE.** Maximum Absolute Percentage Error. The largest forecasted error, expressed as a percentage. This measure is useful for imagining a worst-case scenario for your forecasts.

MAXAE **MaxAE.** Maximum Absolute Error. The largest forecasted error, expressed in the same units as the dependent series. Like MaxAPE, it is useful for imagining the worst-case scenario for your forecasts. Maximum absolute error and maximum absolute percentage error may occur at different series points–for example, when the absolute error for a large series value is slightly larger than the absolute error for a small series value. In that case, the maximum absolute error will occur at the larger series value and the maximum absolute percentage error will occur at the smaller series value.

NORMBIC **Normalized BIC.** Normalized Bayesian Information Criterion. A general measure of the overall fit of a model that attempts to account for model complexity. It is a score based upon the mean square error and includes a penalty for the number of parameters in the model and the length of the series. The penalty removes the advantage of models with more parameters, making the statistic easy to compare across different models for the same series.

MODELSUMMARY Subcommand

The MODELSUMMARY subcommand controls the display of tables and charts that summarize goodness of fit, residual autocorrelations, and residual partial autocorrelations across estimated models. Each keyword is followed by an equals sign (=) and one or more of the available options enclosed in square brackets.

Example

```
TSMODEL
  /MODELSUMMARY PLOT=[SRSQUARE MAXAPE]
```

```
/MODEL DEPENDENT=sku1 TO sku100.
```

- The output includes two histograms: one histogram for stationary R-squared and one histogram for the maximum absolute percentage error. Each histogram consists of results across all models (one model for each dependent variable).

PRINT Keyword

The PRINT keyword controls the display of model summary tables.

MODELFIT	*Goodness of fit.* Table of summary statistics and percentiles for stationary *R*-square, *R*-square, root mean square error, mean absolute percentage error, mean absolute error, maximum absolute percentage error, maximum absolute error, and normalized Bayesian Information Criterion.
RESIDACF	*Residual autocorrelation function.* Table of summary statistics and percentiles for autocorrelations of the residuals.
RESIDPACF	*Residual partial autocorrelation function.* Table of summary statistics and percentiles for partial autocorrelations of the residuals.
NONE	*No tables are shown.* An error occurs if NONE is used in combination with any other PRINT option.

PLOT Keyword

The PLOT keyword controls the display of model summary charts. By default, no charts are shown. (For detailed definitions of the following terms, see Goodness-of-Fit Measures on p. 1862.)

SRSQUARE	*Histogram of Stationary* R-*Square*.
RSQUARE	*Histogram of* R-*Square*.
RMSE	*Histogram of Root Mean Square Error.*
MAPE	*Histogram of Mean Absolute Percentage Error.*
MAE	*Histogram of Mean Absolute Error.*
MAXAPE	*Histogram of Maximum Absolute Percentage Error.*
MAXAE	*Histogram of Maximum Absolute Error.*
NORMBIC	*Histogram of Normalized Bayesian Information Criterion (BIC).*
RESIDACF	*Boxplot of Residual Autocorrelation Function by Lag.*
RESIDPACF	*Boxplot of Residual Partial Autocorrelation Function by Lag.*

MODELSTATISTICS Subcommand

The MODELSTATISTICS subcommand controls display of a table that lists all models, along with chosen goodness-of-fit statistics.

Example

```
TSMODEL
  /MODELSTATISTICS DISPLAY=YES MODELFIT=[RSQUARE]
```

```
/MODEL DEPENDENT=sku1 TO sku25.
```

- The output includes a table displaying the value of R-squared for each model.

DISPLAY Keyword

The DISPLAY keyword controls whether the model statistics table is shown.

YES	*Model statistics table is shown.* Table of model goodness of fit, Ljung-Box Q statistic, and number of outliers detected by model. This setting is the default. The Q statistic measures the degree of pattern in the residuals. Large values of Q in relation to its degrees of freedom indicate that model residuals are not randomly distributed.
NO	*Model statistics table is not shown.*

MODELFIT Keyword

The MODELFIT keyword controls which fit statistics are shown in the model statistics table, and the keyword is ignored if DISPLAY=NO. The keyword is followed by an equals sign (=) and one or more of the following options enclosed in square brackets. (For detailed definitions of the following terms, see Goodness-of-Fit Measures on p. 1862.)

SRSQUARE	*Stationary* R *-Square*. This setting is the default.
RSQUARE	R-*Square*.
RMSE	*Root Mean Square Error*.
MAPE	*Mean Absolute Percentage Error*.
MAE	*Mean Absolute Error*.
MAXAPE	*Maximum Absolute Percentage Error*.
MAXAE	*Maximum Absolute Error*.
NORMBIC	*Normalized Bayesian Information Criterion (BIC)*.

MODELDETAILS Subcommand

The MODELDETAILS subcommand controls the display of model parameters, model forecasts, and autocorrelations of noise residuals for individual models. Each keyword is followed by an equals sign (=) and one or more of the available options enclosed in square brackets.

Example

```
TSMODEL
  /MODELDETAILS PRINT=[PARAMETERS FORECASTS]
  /MODEL DEPENDENT=sku1 TO sku50.
```

- The output includes tables displaying the model parameters and forecasts for each model (one model for each dependent variable).

PRINT Keyword

The PRINT keyword controls display of tables for individual models. By default, no tables are shown.

PARAMETERS	*Model parameter estimates.* Shows separate tables for ARIMA and exponential smoothing models. If outliers exist, parameter estimates for outliers are also displayed.
RESIDACF	*Residual autocorrelation function.* Shows residual autocorrelations by lag.
RESIDPACF	*Residual partial autocorrelation function.* Shows residual partial autocorrelations by lag.
FORECASTS	*Forecasts and confidence intervals.* Shows model forecasts and confidence intervals.

PLOT Keyword

The PLOT keyword controls display of charts for individual models. By default, no charts are shown.

RESIDACF	*Residual autocorrelation function.* Shows residual autocorrelations by lag.
RESIDPACF	*Residual partial autocorrelation function.* Shows residual partial autocorrelations by lag.

SERIESPLOT Subcommand

The SERIESPLOT subcommand allows you to obtain plots of predicted values, observed values, and confidence intervals for each estimated model. By default, no plots are shown. The subcommand is followed by one or more of the following keywords:

OBSERVED	*Displays all observed values of the dependent series.*
FORECAST	*Displays model-predicted values within the forecast period.*
FIT	*Displays model-predicted values within the estimation period.*
FORECASTCI	*Displays upper and lower confidence limits within the forecast period.*
FITCI	*Displays upper and lower confidence limits within the estimation period.*

Example

```
TSMODEL
  /SERIESPLOT OBSERVED FORECAST
  /MODEL DEPENDENT=sku1 TO sku5
  /MODEL DEPENDENT=revenue INDEPENDENT=adspending.
```

- The plot includes the model-predicted values in the forecast period as well as all observed values for each of the dependent series.

OUTPUTFILTER Subcommand

The OUTPUTFILTER subcommand controls which models are included in the model statistics table (MODELSTATISTICS subcommand), detailed model output (MODELDETAILS subcommand), and time series plots (SERIESPLOT subcommand).

- By default, all models are included in the output. OUTPUTFILTER can be used to display only the best-fitting or worst-fitting models (or both). If you request both, two sets of output are displayed.
- OUTPUTFILTER is ignored if no output is requested on the MODELSTATISTICS, MODELDETAILS, or SERIESPLOT subcommands.
- OUTPUTFILTER has no effect on output from the MODELSUMMARY subcommand.

Example

```
TSMODEL
  /MODELSTATISTICS DISPLAY=YES MODELFIT=[SRSQUARE MAXAPE NORMBIC]
  /OUTPUTFILTER DISPLAY=[BESTFIT(N=5) WORSTFIT(PCT=10)]
  /MODEL DEPENDENT=sku1 TO sku200.
```

- The output consists of two sets of results: those results for the 5 best-fitting models and those results for models with fit values in the bottom 10%. The stationary R-squared value is used as the goodness-of-fit measure.

DISPLAY Keyword

The DISPLAY keyword controls which models are included in MODELSTATISTICS, MODELDETAILS, and SERIESPLOT output.

- By default, all models are displayed (DISPLAY=ALLMODELS).
- To display only those models with extreme goodness-of-fit values, specify BESTFIT, WORSTFIT, or both, in square brackets. One or both keywords must be specified.

ALLMODELS *All models are displayed.* All models that could be computed are shown. This setting is the default.

BESTFIT *Models having the highest fit values are shown.* To display the models with the N highest fit values, specify BESTFIT followed by N=count in parentheses—for example, BESTFIT(N=5). The count must be a positive integer. If the count exceeds the number of estimated models, all models are shown. To display the models with fit values in the top N%, specify PCT=percent in parentheses. For example, BESTFIT(PCT=5) displays models with fit values in the top 5% among estimated models. The percentage value must be greater than zero and less than 100.

WORSTFIT *Models having the lowest fit values are shown.* To display the models with the N lowest fit values, specify WORSTFIT followed by N=count in parentheses—for example, WORSTFIT(N=5). The count must be a positive integer. If the count exceeds the number of estimated models, all models are shown. To display the models with fit values in the lowest N%, specify PCT=percent in parentheses. For example, WORSTFIT(PCT=5) displays models with fit values in the bottom 5% among estimated models. The percentage value must be greater than zero and less than 100.

MODELFIT Keyword

The MODELFIT keyword specifies the fit measure that is used to filter models. MODELFIT is ignored if DISPLAY=ALLMODELS.

Specify one of the following options. (For detailed definitions of the following terms, see Goodness-of-Fit Measures on p. 1862.)

SRSQUARE	*Stationary* R-*Square*. This setting is the default.
RSQUARE	R-*Square*.
RMSE	*Root Mean Square Error*.
MAPE	*Mean Absolute Percentage Error*.
MAE	*Mean Absolute Error*.
MAXAPE	*Maximum Absolute Percentage Error*.
MAXAE	*Maximum Absolute Error*.
NORMBIC	*Normalized Bayesian Information Criterion (BIC)*.

SAVE Subcommand

The SAVE subcommand is used to save new variables representing predicted values, residuals, and confidence intervals to the active dataset. By default, no new variables are saved to the active dataset.

- Specify one or more keywords, each keyword followed by an optional rootname to be used as the prefix for new variable names. Enclose the rootname in parentheses. Each keyword gives rise to one new variable for each dependent variable.
- The rootname, if specified, must conform to the rules for valid variable names.
- If no rootname is specified, TSMODEL uses a default name.
- The full variable name is the concatenation of the rootname, the name of the associated dependent variable, and a model identifier. The variable name is extended if necessary to avoid variable naming conflicts.
- The PREDICT command controls whether new cases are added to the file when new variables are saved. New cases are added if PREDICT specifies a forecast period that extends beyond the length of the dependent-variable series.
- SAVE is ignored with a warning if temporary transformations are in effect.

Example

```
TSMODEL
  /SAVE PREDICTED(Pred) NRESIDUAL
  /MODEL DEPENDENT=sku1 TO sku10.
```

- Two new variables are created for each of the dependent variables *sku1* thru *sku10*: one variable contains the model predictions, and the other variable contains the noise residuals.

- The rootname (prefix) for the variables containing model predictions is *Pred*.
- The rootname for the variables containing noise residuals is *NResidual* (the default).

PREDICTED(rootname)	*Model fit and forecast values.* The default rootname is *Predicted*.
LCL(rootname)	*Lower confidence limits.* The default rootname is *LCL*.
UCL(rootname)	*Upper confidence limits.* The default rootname is *UCL*.
NRESIDUAL(rootname)	*Noise residuals.* The default rootname is *NResidual*. When transformations of the dependent variable are performed (for example, natural log), these residuals are the residuals for the transformed series.

AUXILIARY Subcommand

The AUXILIARY subcommand is used to set the confidence interval level for forecasts, set the maximum number of lags for autocorrelation and partial autocorrelation plots and tables, and set the season length.

Example

```
TSMODEL
  /MODELDETAILS PLOT=[RESIDACF RESIDPACF]
  /AUXILIARY MAXACFLAGS=36 SEASONLENGTH=6
  /MODEL DEPENDENT=sku1 TO sku20.
```

CILEVEL Keyword

The CILEVEL keyword sets the confidence level.

- Specify a positive number that is less than 100.
- The default is 95.

MAXACFLAGS Keyword

The MAXACFLAGS keyword sets the maximum number of lags displayed in residual autocorrelation and partial autocorrelation tables and plots.

- Specify a positive integer.
- The default is 24.

SEASONLENGTH Keyword

The SEASONLENGTH keyword is used to specify the length of the seasonal period (the number of observations in one period or season).

- The season length must be a positive integer.
- If SEASONLENGTH is not specified, the periodicity that is specified by using the DATE command defines the season length.

- If the Expert Modeler is used, a warning occurs and the season length is treated as 1 for any splits for which there are gaps in the data. If a custom model is specified, a warning is issued and the model is not estimated for any such splits.
- For custom ARIMA or exponential smoothing models, SEASONLENGTH is ignored if the specified model has no seasonal component.

MISSING Subcommand

The MISSING subcommand controls the handling of user-missing values.

- By default, user-missing values are treated as missing (invalid) data.
- System-missing values are always treated as invalid.
- Cases with missing values of a dependent variable that occur within the estimation period are included in the model. The specific handling of the missing value depends on the estimation method.
- A warning is issued if a predictor has missing values within the estimation period. For the Expert Modeler, models involving the predictor are estimated without the predictor. For custom ARIMA, models involving the predictor are not estimated.
- If any predictor has missing values within the forecast period, the procedure issues a warning and forecasts as far as it can.

Example

```
TSMODEL
  /MISSING USERMISSING=INCLUDE
  /MODEL DEPENDENT=revenue INDEPENDENT=adspending.
```

USERMISSING Keyword

The USERMISSING keyword controls the treatment of user-missing values and is required.

EXCLUDE	*Exclude user-missing values.* User-missing values are treated as missing. This setting is the default.
INCLUDE	*Include user-missing values.* User-missing values are treated as valid data.

MODEL Subcommand

The MODEL subcommand is required and is used to signal the start of a model specification, as well as to specify model variable(s).

- All variables must be numeric. Any string variables are filtered out, with a warning.
- Variables that define split-file groups are filtered out of all variable lists, with a warning.
- ALL and TO can be used in dependent and independent variable lists. ALL represents all variables in the active dataset. TO refers to a range of variables in the active dataset.

Note: Specification of the model type is optional and is accomplished by including an EXPERTMODELER, EXSMOOTH, or ARIMA subcommand following the MODEL subcommand. If the model type is not specified, the best-fitting ARIMA or exponential smoothing model

will automatically be selected by the Expert Modeler, which is equivalent to specifying /EXPERTMODELER TYPE=[ARIMA EXSMOOTH]. If you are unsure of which type of model to choose, or you want Expert Modeler to choose for you, use the MODEL subcommand without a model type subcommand.

Example

```
TSMODEL
  /MODEL DEPENDENT=store1 TO store100
         INDEPENDENT=adspending
         OUTFILE='/models/stores.xml'
         PREFIX='Expert'.
```

- DEPENDENT specifies that variables *store1* thru *store100* are to be modeled. The keyword TO refers to the order of the variables in the active dataset.
- The INDEPENDENT keyword specifies that the variable *adspending* is to be considered as a predictor variable.
- OUTFILE specifies that the resulting models are to be stored in the file */models/stores.xml*.
- PREFIX specifies that the models will be named *Expert_1* (the model for *store1*), *Expert_2* (the model for *store2*), etc.
- The absence of a model type subcommand (EXPERTMODELER, ARIMA, or EXSMOOTH) means that the Expert Modeler will be used to find the best-fitting exponential smoothing or ARIMA model.

DEPENDENT Keyword

The DEPENDENT keyword is used to specify one or more dependent variables and is required.

- At least one dependent variable must be specified.
- Repeated instances of the same variable are filtered out of the list.
- A separate model is generated for each dependent variable in each MODEL block. Identical dependent variables in separate MODEL blocks generate separate models.

INDEPENDENT Keyword

The INDEPENDENT keyword is used to specify one or more optional independent variables.

- Order of variables within the independent variable list matters when the Expert Modeler is used. The Expert Modeler drops nonsignificant independent variables one at a time, starting with the last variable in the list.
- In the case of custom ARIMA models, all independent variables are included in the model.
- Repeated instances of an independent variable are filtered out of the list. For example, a b a c a is equivalent to a b c. Assuming that the active dataset contains variables *a*, *b*, and *c*, ALL is also equivalent to a b c.
- An independent variable that also appears in the dependent variable list is treated solely as a dependent variable and is excluded from consideration as an independent variable for the model involving that particular dependent variable. For example, if you specify

DEPENDENT=a b and INDEPENDENT=a c, then *c* is the only independent variable when modeling *a*, but *a* and *c* are both used as independent variables when modeling *b*.

Events

- Event variables are special independent variables that are used to model effects of occurrences such as a flood, strike, or introduction of a new product line. Any abrupt shift in the level of the dependent series can be modeled by using event variables.
- To designate an independent variable as an event variable, specify [E] following the name of the variable. For example, INDEPENDENT=strike [E] indicates that the variable *strike* is an event variable.
- When the Expert Modeler is used, event variables enter the model with linear terms only (as opposed to transfer functions). Thus, event designation can save processing time and guard against overfitting when using the Expert Modeler.
- Custom ARIMA models ignore event designation.
- For event variables, the presence of an effect is indicated by cases with a value of 1. Cases with values other than 1 are treated as indicating no effect.
- The effect of an event can last a single time period or several periods. If the effect lasts several periods, the corresponding event variable should contain a series of consecutive 1s.
- Event designation applies only to the variable that immediately precedes the designation in the independent variable list. For example, x1 x2 x3 [E] and x1 TO x3 [E] designate *x3* (only) as an event variable. If event designation follows ALL, it applies to all independent variables.
- If a variable appears more than once in the independent variable list, the event specification for the last instance of the variable is honored. For example, if ALL x1 [E] is specified, *x1* is treated as an event variable; if ALL [E] X1 is specified, *x1* is treated as an ordinary predictor.

OUTFILE Keyword

The OUTFILE keyword is used to save models to an external file. Saved models can be used to obtain updated forecasts, based on more current data, using the TSAPPLY command. For more information, see TSAPPLY on p. 1838.

- Models are written to an XML file. Each model is assigned a unique name and a description that includes the name of the dependent variable and the model type.
- The filename must be specified in full. No extension is supplied.
- If two or more MODEL subcommands (within a single invocation of TSMODEL) specify the same external file, all models that are created by those MODEL subcommands are saved to that file.
- OUTFILE is ignored with a warning if SPLIT FILE is in effect.

PREFIX Keyword

Models are assigned unique names consisting of a customizable prefix, along with an integer suffix. The PREFIX keyword is used to specify a custom prefix.

- Custom prefixes must be specified in quotes—for example, `PREFIX='ExpertArima'`. The default prefix is 'Model'.
- Integer suffixes are unique across the set of models that have the same prefix; for example, *Model_1*, *Model_2*. Models with different prefixes, however, can have the same integer suffix—for example, *CustomArima_1*, *ExpertArima_1*.

EXPERTMODELER Subcommand

The `EXPERTMODELER` subcommand controls options for automatic model identification that is performed by the Expert Modeler.

Example

```
TSMODEL
  /MODEL DEPENDENT=store1 TO store100
         INDEPENDENT=adspending
  /EXPERTMODELER TYPE=[ARIMA].
```

- The keyword `ARIMA` specifies that the Expert Modeler is to limit the model search to the best-fitting ARIMA model.

TYPE Keyword

The `TYPE` keyword is required and is used to specify the model types that are evaluated: ARIMA, exponential smoothing, or both.

- By default, both ARIMA and exponential smoothing models are considered.
- Either `ARIMA`, `EXSMOOTH`, or both must be specified in square brackets.
- An error occurs if you specify the `EXSMOOTH` keyword by itself and the model contains independent variables.

The keyword is followed by an equals sign (=) and one or both of the following options enclosed in square brackets:

ARIMA	*ARIMA models are considered.*
EXSMOOTH	*Exponential smoothing models are considered.*

TRYSEASONAL Keyword

The `TRYSEASONAL` keyword specifies whether seasonal models are considered by the Expert Modeler.

- `TRYSEASONAL` is ignored if the data are nonperiodic (that is, season length is 1).

YES	*The Expert Modeler considers seasonal models.* This setting is the default.
NO	*The Expert Modeler does not consider seasonal models.* Only nonseasonal models are considered.

EXSMOOTH Subcommand

The EXSMOOTH subcommand controls options for custom exponential smoothing models.

- Using EXSMOOTH generates an error if independent variables are defined.
- For seasonal models (SIMPLESEASONAL, WINTERSADDITIVE, and WINTERSMULTIPLICATIVE), an error is generated if the season length has not been defined via the DATE command or the SEASONLENGTH keyword.

Example

```
TSMODEL
  /AUXILIARY SEASONLENGTH=12
  /MODEL DEPENDENT=store1 TO store100
  /EXSMOOTH TYPE=WINTERSMULTIPLICATIVE.
```

TYPE Keyword

The TYPE keyword is required and is used to specify the type of exponential smoothing model. There is no default method.

SIMPLE — **Simple exponential smoothing model.** This model is appropriate for series in which there is no trend or seasonality. Its only smoothing parameter is level. Simple exponential smoothing is most similar to an ARIMA model with zero orders of autoregression, one order of differencing, one order of moving average, and no constant.

SIMPLESEASONAL — **Simple seasonal exponential smoothing model.** This model is appropriate for series with no trend and a seasonal effect that is constant over time. Its smoothing parameters are level and season. Simple seasonal exponential smoothing is most similar to an ARIMA model with zero orders of autoregression, one order of differencing, one order of seasonal differencing, and orders 1, p, and p + 1 of moving average, where p is the number of periods in a seasonal interval (for monthly data, p = 12).

HOLT — **Holt's method.** This model is appropriate for series in which there is a linear trend and no seasonality. Its smoothing parameters are level and trend, which are not constrained by each other's values. Holt's model is more general than Brown's model but may take longer to compute for large series. Holt's exponential smoothing is most similar to an ARIMA model with zero orders of autoregression, two orders of differencing, and two orders of moving average.

BROWN — **Brown's method.** This model is appropriate for series in which there is a linear trend and no seasonality. Its smoothing parameters are level and trend, which are assumed to be equal. Brown's model is therefore a special case of Holt's model. Brown's exponential smoothing is most similar to an ARIMA model with zero orders of autoregression, two orders of differencing, and two orders of moving average, with the coefficient for the second order of moving average equal to the square of one-half of the coefficient for the first order.

DAMPEDTREND — **Damped trend method.** This model is appropriate for series with a linear trend that is dying out and with no seasonality. Its smoothing parameters are level, trend, and damping trend. Damped exponential smoothing is most similar to an ARIMA model with 1 order of autoregression, 1 order of differencing, and 2 orders of moving average.

WINTERSADDITIVE **Winters' additive method.** This model is appropriate for series with a linear trend and a seasonal effect that does not depend on the level of the series. Its smoothing parameters are level, trend, and season. Winters' additive exponential smoothing is most similar to an ARIMA model with zero orders of autoregression, one order of differencing, one order of seasonal differencing, and p + 1 orders of moving average, where p is the number of periods in a seasonal interval (for monthly data, p = 12).

WINTERSMULTIPLICATIVE **Winters' multiplicative method.** This model is appropriate for series with a linear trend and a seasonal effect that depends on the level of the series. Its smoothing parameters are level, trend, and season. Winters' multiplicative exponential smoothing is not similar to any ARIMA model.

TRANSFORM Keyword

The TRANSFORM keyword specifies a transformation that is performed on each dependent variable before it is modeled. By default, dependent variables are not transformed.

NONE *Dependent variable series are not transformed.* This setting is the default.

SQRT *A square root transformation is performed.*

LN *A natural log transformation is performed.*

ARIMA Subcommand

The ARIMA subcommand controls options for custom ARIMA models. The model must contain at least one parameter. An error occurs if the model has no autoregressive component, moving average component, outlier, or constant term, unless independent variables are selected.

Example: Basic Custom Seasonal ARIMA Model

```
TSMODEL
  /AUXILIARY SEASONLENGTH=12
  /MODEL DEPENDENT=passengers
  /ARIMA AR=[0] ARSEASONAL=[0] MA=[1] MASEASONAL=[1]
         DIFF=1 DIFFSEASONAL=1 TRANSFORM=LN.
```

- A custom ARIMA(0,1,1)(0,1,1) model is specified, including a natural log transformation of the dependent variable. The seasonal length is 12.

Example: Including Specific Lags in a Custom ARIMA Model

```
TSMODEL
  /MODEL DEPENDENT=revenue
  /ARIMA AR=0 MA=[1 3].
```

- A moving average model is specified. Moving average lags of orders 1 and 3 are included.

AR Keyword

The AR keyword specifies the nonseasonal autoregressive order of the model and is required.

- You can specify a single value or a list of values in square brackets. All values must be nonnegative integers.
- If you specify a single value, square brackets are optional. The specified lag will be included in the model.
- If you specify a list of positive integer values—for example, `[1 3]`—the specified lags are included in the model. Duplicate lags are ignored.

ARSEASONAL Keyword

The `ARSEASONAL` keyword specifies the seasonal autoregressive order of the model.

- You can specify a single value or a list of values in square brackets. All values must be nonnegative integers. The default order is zero.
- If you specify a single value, square brackets are optional. The specified lag will be included in the model.
- If you specify a list of positive integer values—for example, `[1 3]`—the specified lags are included in the model. Duplicate lags are ignored.
- An error occurs if `ARSEASONAL` specifies a nonzero value and the season length has not been defined via the `DATE` command or the `SEASONLENGTH` keyword.

MA Keyword

The `MA` keyword specifies the nonseasonal moving average order of the model and is required.

- You can specify a single value or a list of values in square brackets. All values must be nonnegative integers.
- If you specify a single value, square brackets are optional. The specified lag will be included in the model.
- If you specify a list of positive integer values—for example, `[1 3]`—the specified lags are included in the model. Duplicate lags are ignored.

MASEASONAL Keyword

The `MASEASONAL` keyword specifies the seasonal moving average order of the model.

- You can specify a single value or a list of values in square brackets. All values must be nonnegative integers. The default order is zero.
- If you specify a single value, square brackets are optional. The specified lag will be included in the model.
- If you specify a list of positive integer values—for example, `[1 3]`—the specified lags are included in the model. Duplicate lags are ignored.
- An error occurs if `MASEASONAL` specifies a nonzero value and the season length has not been defined via the `DATE` command or the `SEASONLENGTH` keyword.

CONSTANT Keyword

The CONSTANT keyword controls whether the model for each dependent variable includes a constant term.

YES	*The model includes a constant term.* This setting is the default.
NO	*No constant term is included in the model.*

TRANSFORM Keyword

The TRANSFORM keyword specifies a transformation that is performed on each dependent variable before it is modeled. By default, the variables are not transformed.

NONE	*Dependent-variable series are not transformed.* This setting is the default.
SQRT	*A square root transformation is performed.*
LN	*A natural log transformation is performed.*

DIFF Keyword

The DIFF keyword specifies the order of nonseasonal differencing.

- The order of nonseasonal differencing must be a nonnegative integer. The default order is zero.

DIFFSEASONAL Keyword

The DIFFSEASONAL keyword specifies the order of seasonal differencing.

- The order of seasonal differencing must be a nonnegative integer. The default order is zero.
- An error occurs if DIFFSEASONAL specifies a nonzero value and the season length has not been defined via the DATE command or the SEASONLENGTH keyword.

TRANSFERFUNCTION Subcommand

The TRANSFERFUNCTION subcommand specifies a transfer function and transformations for predictor variables in an ARIMA model.

- By default, for each predictor in an ARIMA model, the numerator and denominator orders of the transfer function (both seasonal and nonseasonal) are set to zero. The predictors are neither transformed nor differenced by default.
- The TRANSFERFUNCTION subcommand may be used more than once in a MODEL block to specify different transfer functions and/or transformations for different independent variables.
- If there are multiple TRANSFERFUNCTION subcommands that refer to the same predictor variable within a MODEL block, the last set of specifications is honored for that variable.
- The TRANSFERFUNCTION subcommand is ignored if the EXPERTMODELER or EXSMOOTH subcommand is used.

Example

```
TSMODEL
  /MODEL DEPENDENT=revenue INDEPENDENT=adspending
  /ARIMA AR=[1] MA=[0]
  /TRANSFERFUNCTION VARIABLES=adspending NUM=[1] DENOM=[1].
```

- A custom ARIMA(1,0,0) model is specified and includes the independent variable *adspending*.
- The TRANSFERFUNCTION subcommand specifies that *adspending* is to be modeled with numerator and denominator lags of order 1.

VARIABLES Keyword

The VARIABLES keyword is used to specify a list of predictors.

- Repeated instances of the same variable are filtered out of the list.
- Variables that have not been specified as independent (with the INDEPENDENT keyword) in the preceding MODEL subcommand are ignored.
- Use ALL to specify all independent variables. This setting is the default.

NUM Keyword

The NUM keyword specifies the numerator order of the transfer function for nonseasonal models.

- You can specify a single value or a list of values in square brackets. All values must be nonnegative integers. The default order is zero.
- The model always includes an implicit zero, even if not specified via the NUM keyword.
- If you specify a single value, square brackets are optional. The specified lag will be included in the model.
- If you specify a list of positive integer values—for example, [1 3]—the specified lags are included in the model. Duplicate lags are ignored.

NUMSEASONAL Keyword

The NUMSEASONAL keyword specifies the numerator order of the transfer function for seasonal models.

- You can specify a single value or a list of values in square brackets. All values must be nonnegative integers. The default order is zero.
- If you specify a single value, square brackets are optional. The specified lag will be included in the model.
- If you specify a list of positive integer values—for example, [1 3]—the specified lags are included in the model. Duplicate lags are ignored.
- An error occurs if NUMSEASONAL specifies a nonzero value and the season length has not been defined via the DATE command or the SEASONLENGTH keyword.

DENOM Keyword

The DENOM keyword specifies the denominator order of the transfer function for nonseasonal models.

- You can specify a single value or a list of values in square brackets. All values must be nonnegative integers. The default order is zero.
- If you specify a single value, square brackets are optional. The specified lag will be included in the model.
- If you specify a list of positive integer values—for example, [1 3]—the specified lags are included in the model. Duplicate lags are ignored.

DENOMSEASONAL Keyword

The DENOMSEASONAL keyword specifies the denominator order of the transfer function for seasonal models.

- You can specify a single value or a list of values in square brackets. All values must be nonnegative integers. The default order is zero.
- If you specify a single value, square brackets are optional. The specified lag will be included in the model.
- If you specify a list of positive integer values—for example, [1 3]—the specified lags are included in the model. Duplicate lags are ignored.
- An error occurs if DENOMSEASONAL specifies a nonzero value and the season length has not been defined via the DATE command or the SEASONLENGTH keyword.

TRANSFORM Keyword

The TRANSFORM keyword specifies a transformation that is performed on all predictor variables. By default, predictor variables are not transformed.

NONE	*Predictor variables are not transformed.* This setting is the default.
SQRT	*A square root transformation is performed.*
LN	*A natural log transformation is performed.*

DIFF Keyword

The DIFF keyword specifies the order of nonseasonal differencing for predictor variables.

- The order of nonseasonal differencing must be a nonnegative integer. The default order is zero.

DIFFSEASONAL Keyword

The DIFFSEASONAL keyword specifies the order of seasonal differencing for predictor variables.

- The order of seasonal differencing must be a nonnegative integer. The default order is zero.
- DIFFSEASONAL generates an error if the season length has not been defined via the DATE command or the SEASONLENGTH keyword.

DELAY Keyword

The DELAY keyword specifies the delay order for predictor variables.

- The delay order must be a nonnegative integer. The default order is zero.

AUTOOUTLIER Subcommand

The AUTOOUTLIER subcommand specifies whether outlier time points are identified automatically.

- By default, outliers are not identified.
- If identified, outliers are not discarded but are incorporated in the model.
- The AUTOOUTLIER subcommand is ignored with a warning if it is part of a MODEL block that contains an EXSMOOTH subcommand.

Example

```
TSMODEL
  /MODELDETAILS PRINT=PARAMETERS
  /MODEL DEPENDENT=revenue
  /EXPERTMODELER TYPE=[ARIMA]
  /AUTOOUTLIER DETECT=ON.
```

DETECT Keyword

The DETECT keyword controls whether automatic outlier detection is performed.

OFF	*Outliers are not identified.* This setting is the default.
ON	*Outliers are identified.* ON is ignored with a warning if the model type is EXSMOOTH.

TYPE Keyword

The optional TYPE keyword specifies the types of outliers that are identified when DETECT=ON. TYPE is ignored if DETECT=OFF.

- Additive and level shift outliers are identified by default.
- The specification of outlier types overrides the default. That is, if you specify a list of outlier types, additive and level shift outliers are not included unless explicitly requested.

The keyword is followed by an equals sign (=) and one or more of the following options enclosed in square brackets:

ADDITIVE	**Additive.** An outlier that affects a single observation. For example, a data coding error might be identified as an additive outlier. Default if DETECT=ON.
LEVELSHIFT	**Level shift.** An outlier that shifts all observations by a constant, starting at a particular series point. A level shift could result from a change in policy. Default if DETECT=ON.
INNOVATIONAL	**Innovational.** An outlier that acts as an addition to the noise term at a particular series point. For stationary series, an innovational outlier affects several observations. For nonstationary series, it may affect every observation starting at a particular series point.

TRANSIENT	**Transient.** An outlier whose impact decays exponentially to 0.
SEASONALADDITIVE	**Seasonal additive.** An outlier that affects a particular observation and all subsequent observations separated from it by one or more seasonal periods. All such observations are affected equally. A seasonal additive outlier might occur if, beginning in a certain year, sales are higher every January. The keyword generates an error if the season length has not been defined via the DATE command or the SEASONLENGTH keyword.
LOCALTREND	**Local trend.** An outlier that starts a local trend at a particular series point.
ADDITIVEPATCH	**Additive patch.** A group of two or more consecutive additive outliers. Selecting this outlier type results in the detection of individual additive outliers in addition to patches of them.

OUTLIER Subcommand

The OUTLIER subcommand specifies outlier time points to be included in an ARIMA model.

- By default, no time points are modeled as outliers.
- For each outlier, you must specify its time point (location) and type.
- Multiple OUTLIER subcommands can be used to define two or more outliers for an ARIMA model. Duplicate specifications (same location and type) are ignored and a warning is issued.
- A warning occurs and the OUTLIER subcommand is ignored if the subcommand is part of a MODEL block that contains an EXPERTMODELER or EXSMOOTH subcommand.
- If the AUTOOUTLIER and OUTLIER subcommands are both included in a MODEL block containing an ARIMA subcommand, a warning is issued and the OUTLIER specification takes precedence.

Example

```
TSMODEL
  /MODELDETAILS PRINT=PARAMETERS
  /MODEL DEPENDENT=revenue
  /ARIMA AR=[1] MA=[1]
  /OUTLIER LOCATION=[YEAR 2000 MONTH 8] TYPE=LOCALTREND.
```

- A custom ARIMA(1,0,1) model is specified with an outlier of type Local Trend for August, 2000.

LOCATION Keyword

The LOCATION keyword specifies the time point to be treated as an outlier and is required.

- Specify a date in square brackets. If the data are undated, you must specify a case number. Otherwise, specify the outlier location using date keywords and values. For example, LOCATION=[YEAR 2000 MONTH 8] specifies that August, 2000 be treated as an outlier. The following date keywords may be used: CYCLE, YEAR, QUARTER, MONTH, WEEK, DAY, HOUR, MINUTE, SECOND, and OBS. Every keyword in the SPSS date specification must appear in LOCATION. Only keywords that correspond to system date variables may be used, and no date keyword may be used more than once. For more information, see DATE on p. 536.
- A warning is issued if you specify an outlier location that is outside the estimation period or corresponds to a gap in the data. Any such models are ignored.

TYPE Keyword

The TYPE keyword specifies the type of outlier and is required. Specify one of the following types:

ADDITIVE	**Additive.** An outlier that affects a single observation. For example, a data coding error might be identified as an additive outlier.
LEVELSHIFT	**Level shift.** An outlier that shifts all observations by a constant, starting at a particular series point. A level shift could result from a change in policy.
INNOVATIONAL	**Innovational.** An outlier that acts as an addition to the noise term at a particular series point. For stationary series, an innovational outlier affects several observations. For nonstationary series, it may affect every observation starting at a particular series point.
TRANSIENT	**Transient.** An outlier whose impact decays exponentially to 0.
SEASONALADDITIVE	**Seasonal additive.** An outlier that affects a particular observation and all subsequent observations separated from it by one or more seasonal periods. All such observations are affected equally. A seasonal additive outlier might occur if, beginning in a certain year, sales are higher every January. The keyword generates an error if the season length has not been defined via the DATE command or the SEASONLENGTH keyword.
LOCALTREND	**Local trend.** An outlier that starts a local trend at a particular series point.

TSPLOT

```
TSPLOT VARIABLES= variable names

 [/DIFF={1}]
        {n}

 [/SDIFF={1}]
         {n}

 [/PERIOD=n]

 [/{NOLOG**}]
   {LN     }

 [/ID=varname]

 [/MARK={varname} ]
        {date   }

 [/SPLIT {UNIFORM**}]
         {SCALE    }

 [/APPLY [='model name']]
```

For plots with one variable:

```
[/FORMAT=[{NOFILL**}]  [{NOREFERENCE**      }]]
          {BOTTOM  }    {REFERENCE[(value)]}
```

For plots with multiple variables:

```
[/FORMAT={NOJOIN**}]
         {JOIN    }
         {HILO    }
```

**Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Release History

Release 14.0

- For plots with one variable, REFERENCE keyword modified to allow specification of a value.

Example

```
TSPLOT VARIABLES = TICKETS.
```

Overview

TSPLOT produces a plot of one or more time series or sequence variables. You can request natural log and differencing transformations to produce plots of transformed variables. Several plot formats are available.

Options

Modifying the Variables. You can request a natural log transformation of the variables using the LN subcommand and seasonal and nonseasonal differencing to any degree using the SDIFF and DIFF subcommands. With seasonal differencing, you can also specify the periodicity on the PERIOD subcommand.

Plot Format. With the FORMAT subcommand, you can fill in the space on one side of the plotted values on plots with one variable. You can also plot a reference line indicating the variable mean. For plots with two or more variables, you can specify whether you want to join the values for each observation with a vertical line. With the ID subcommand, you can label the horizontal axis with the values of a specified variable. You can mark the onset of an intervention variable on the plot with the MARK subcommand.

Split-File Processing. You can control how data that have been divided into subgroups by a SPLIT FILE command should be plotted using the SPLIT subcommand.

Subcommand Order

- Subcommands can be specified in any order.

Syntax Rules

- VARIABLES can be specified only once.
- Other subcommands can be specified more than once, but only the last specification of each one is executed.

Operations

- Subcommand specifications apply to all variables named on the TSPLOT command.
- If the LN subcommand is specified, any differencing requested on that TSPLOT command is done on the log-transformed variables.
- Split-file information is displayed as part of the subtitle, and transformation information is displayed as part of the footnote.

Limitations

- Maximum of one VARIABLES subcommand. There is no limit on the number of variables named on the list.

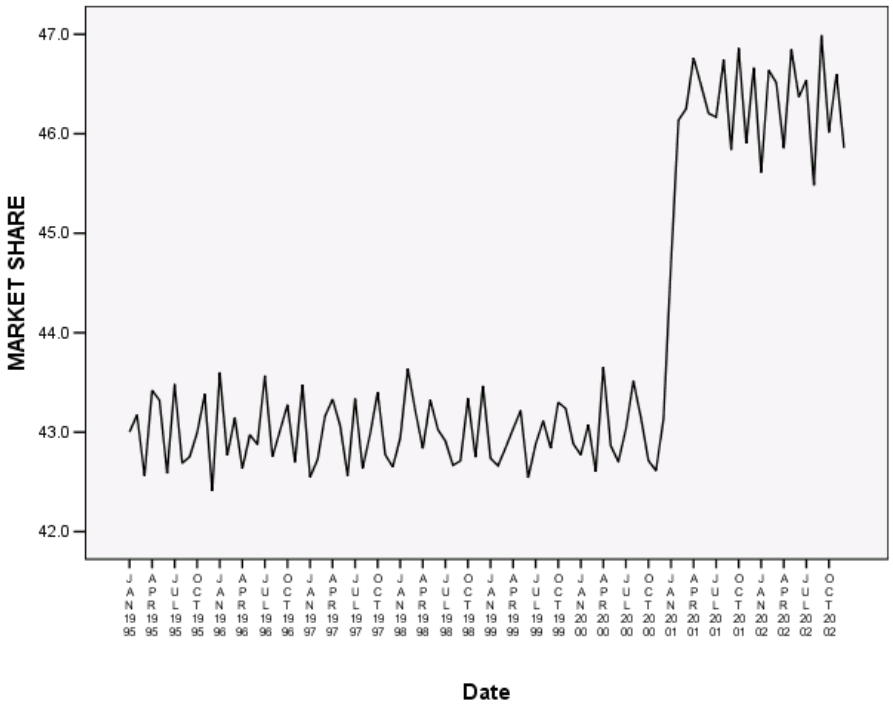
Basic Specification

The basic specification is one or more variable names.

- If the DATE command has been specified, the horizontal axis is labeled with the *DATE_* variable at periodic intervals. Otherwise, sequence numbers are used. The vertical axis is labeled with the value scale of the plotted variable(s).

The following figure shows a default plot with DATE YEAR 1995 MONTH.

Figure 234-1
TSPLOT VARIABLES=SHARE



Example

```
TSPLOT VARIABLES = TICKETS
  /LN
  /DIFF
  /SDIFF
  /PERIOD=12
  /FORMAT=REFERENCE
  /MARK=Y 55 M 6.
```

- This command produces a plot of *TICKETS* after a natural log transformation, differencing, and seasonal differencing have been applied.
- `LN` transforms the data using the natural logarithm (base *e*) of *TICKETS*.
- `DIFF` differences the logged variable once.
- `SDIFF` and `PERIOD` apply one degree of seasonal differencing with a period of 12.
- `FORMAT=REFERENCE` adds a reference line representing the variable mean.
- `MARK` provides a marker on the plot at June 1955. The marker is displayed as a vertical reference line.

VARIABLES Subcommand

`VARIABLES` specifies the names of the variables to be plotted and is the only required subcommand.

DIFF Subcommand

DIFF specifies the degree of differencing used to convert a nonstationary variable to a stationary one with a constant mean and variance before plotting.

- You can specify any positive integer on DIFF.
- If DIFF is specified without a value, the default is 1.
- The number of values plotted decreases by 1 for each degree of differencing.

Example

```
TSPLOT VARIABLES = TICKETS
  /DIFF=2.
```

- In this example, *TICKETS* is differenced twice before plotting.

SDIFF Subcommand

If the variable exhibits a seasonal or periodic pattern, you can use the SDIFF subcommand to seasonally difference the variable before plotting.

- The specification on SDIFF indicates the degree of seasonal differencing and can be any positive integer.
- If SDIFF is specified without a value, the degree of seasonal differencing defaults to 1.
- The number of seasons plotted decreases by 1 for each degree of seasonal differencing.
- The length of the period used by SDIFF is specified on the PERIOD subcommand. If the PERIOD subcommand is not specified, the periodicity established on the TSET or DATE command is used (see the PERIOD subcommand).

PERIOD Subcommand

PERIOD indicates the length of the period to be used by the SDIFF subcommand.

- The specification on PERIOD indicates how many observations are in one period or season and can be any positive integer.
- If PERIOD is not specified, the periodicity established on TSET PERIOD is in effect. If TSET PERIOD is not specified, the periodicity established on the DATE command is used. If periodicity was not established anywhere, the SDIFF subcommand will not be executed.

Example

```
TSPLOT VARIABLES = TICKETS
  /SDIFF=1
  /PERIOD=12.
```

- This command applies one degree of seasonal differencing with 12 observations per season to *TICKETS* before plotting.

LN and NOLOG Subcommands

LN transforms the data using the natural logarithm (base *e*) of the variable and is used to remove varying amplitude over time. NOLOG indicates that the data should not be log transformed. NOLOG is the default.

- If you specify LN on TSPLOT, any differencing requested on that command will be done on the log-transformed variables.
- There are no additional specifications on LN or NOLOG.
- Only the last LN or NOLOG subcommand on a TSPLOT command is executed.
- If a natural log transformation is requested, any value less than or equal to zero is set to system-missing.
- NOLOG is generally used with an APPLY subcommand to turn off a previous LN specification.

Example

```
TSPLOT VARIABLES = TICKETS
  /LN.
```

- In this example, *TICKETS* is transformed using the natural logarithm before plotting.

ID Subcommand

ID names a variable whose values will be used as labels for the horizontal axis.

- The only specification on ID is a variable name. If you have a variable named *ID* in your active dataset, the equals sign (=) after the subcommand is required.
- If the ID subcommand is not used and TSET ID has not been specified, the axis is labeled with the *DATE_* variable created by the DATE command. If the DATE command has not been specified, the observation number is used as the label.

Example

```
TSPLOT VARIABLES = VARA
  /ID=VARB.
```

- In this example, the values of *VARB* will be used to label the horizontal axis of *VARA* at periodic intervals.

FORMAT Subcommand

FORMAT controls the plot format.

- The specification on FORMAT is one of the keywords listed below.

- Keywords NOFILL, BOTTOM, REFERENCE, and NOREFERENCE apply to plots with one variable. NOFILL and BOTTOM are alternatives that indicate how the plot is filled. NOREFERENCE and REFERENCE are alternatives that specify whether a reference line is displayed.
- Keywords JOIN, NOJOIN, and HILO apply to plots with multiple variables and are alternatives. NOJOIN is the default. Only one keyword can be specified on a FORMAT subcommand for plots with multiple variables.

The following formats are available for plots with one variable:

NOFILL *Plot only the values for the variable with no fill.* NOFILL produces a plot with no fill above or below the plotted values. This is the default format when one variable is specified.

BOTTOM *Plot the values for the variable and fill in the area below the curve.* If the plotted variable has missing or negative values, BOTTOM is ignored and the default NOFILL is used instead.

NOREFERENCE *Do not plot a reference line.* This is the default when one variable is specified.

REFERENCE(value) *Plot a reference line at the specified value or at the variable mean if no value is specified.* A fill chart is displayed as an area chart with a reference line and a non-fill chart is displayed as a line chart with a reference line.

Figure 234-2
FORMAT=BOTTOM

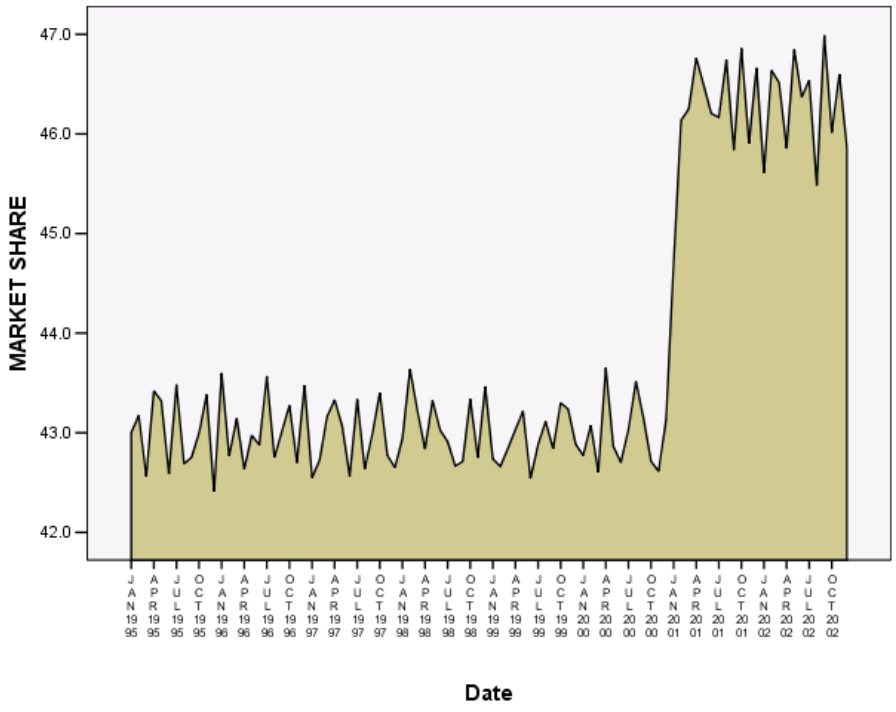


Figure 234-3
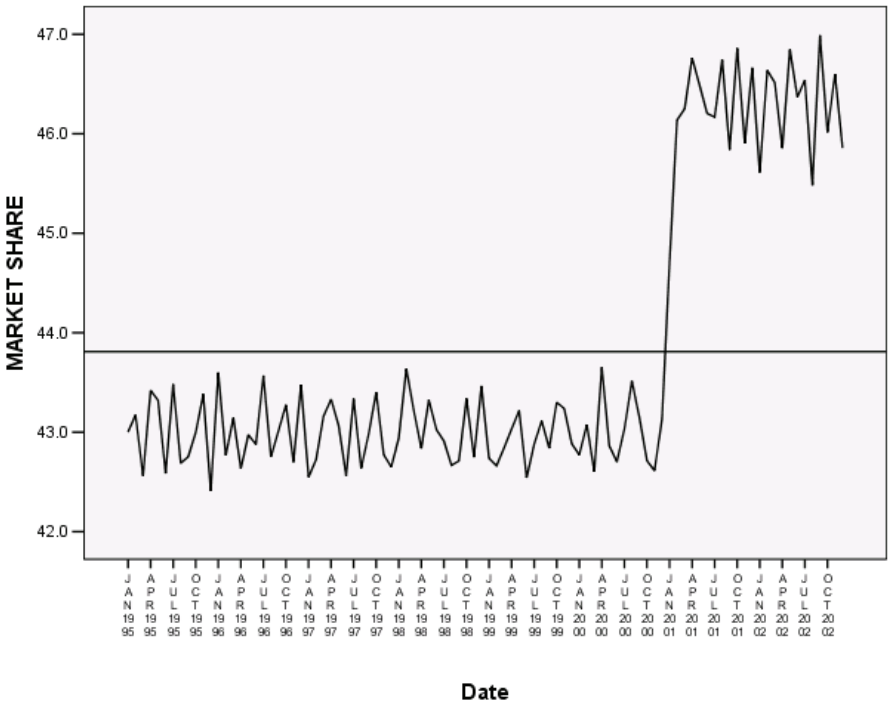
FORMAT=REFERENCE



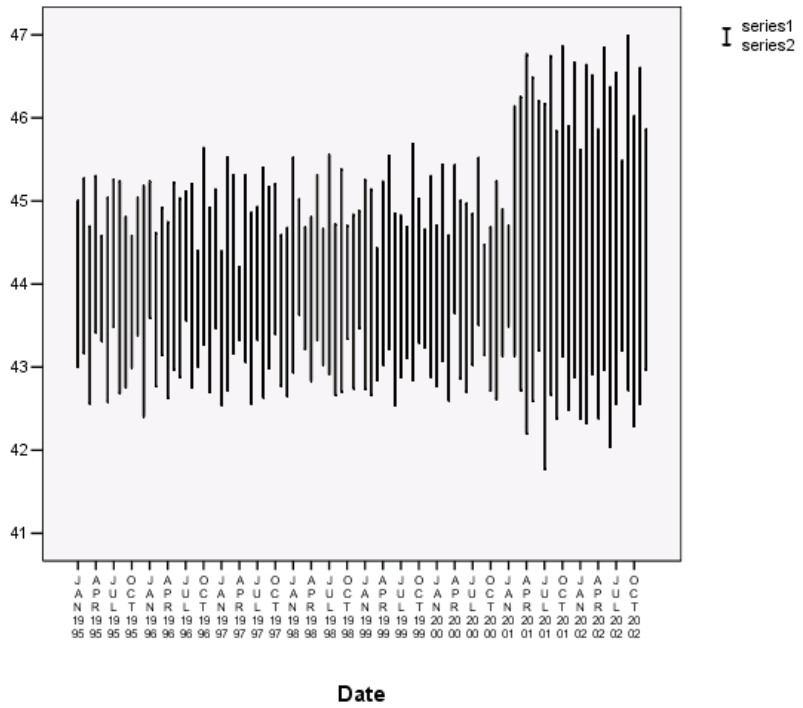
The following formats are available for plots with multiple variables:

NOJOIN *Plot the values of each variable named.* Different colors or line patterns are used for multiple variables. Multiple occurrences of the same value for a single observation are plotted using a dollar sign ($). This is the default format for plots with multiple variables.

JOIN *Plot the values of each variable and join the values for each observation.* Values are plotted as described for `NOJOIN`, and the values for each observation are joined together by a line.

HILO *Plot the highest and lowest values across variables for each observation and join the two values together.* The high and low values are plotted as a horizontal bar and are joined with a line. If more than three variables are specified, `HILO` is ignored and the default `NOJOIN` is used.

Figure 234-4
FORMAT=HILO



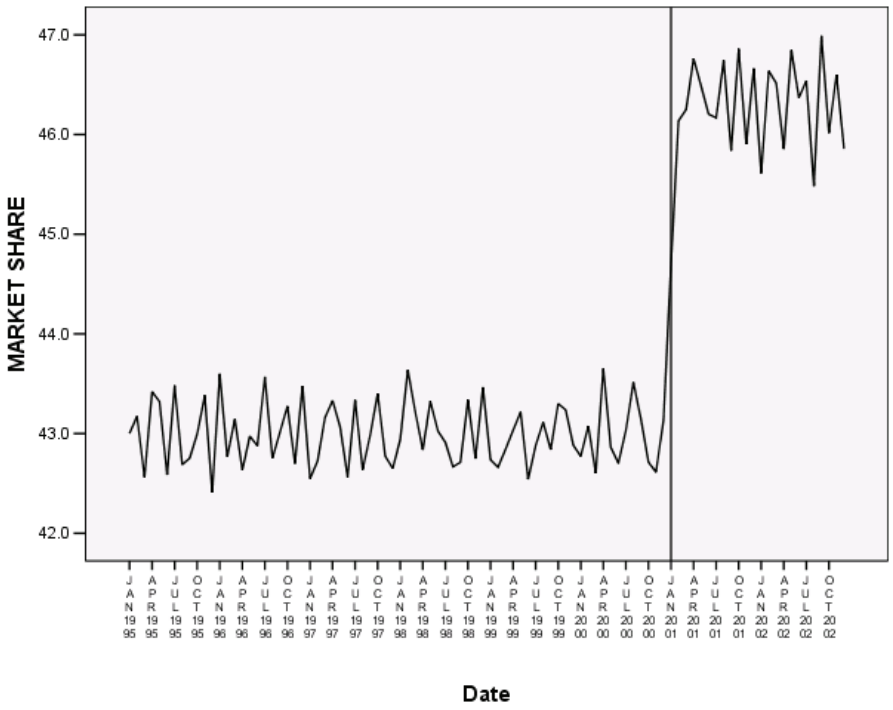
MARK Subcommand

MARK indicates the onset of an intervention variable.

- The onset date is indicated by a vertical reference line.
- The specification on MARK can be either a variable name or an onset date if the *DATE_* variable exists.
- If a variable is named, the plot indicates where the values of that variable change.
- A date specification follows the same format as the DATE command; that is, a keyword followed by a value. For example, the specification for June 1955 is `Y 1955 M 6` (or `Y 55 M 6` if only the last two digits of the year are used on DATE).

The following figure shows a plot with January 2001 marked as the onset date.

Figure 234-5
MARK=Y 2001 M 1



SPLIT Subcommand

SPLIT specifies how to plot data that have been divided into subgroups by a SPLIT FILE command. The default is UNIFORM.

UNIFORM	*Scale uniformly.* The vertical axis is scaled according to the values of the entire dataset.
SCALE	*Scale individually.* The vertical axis is scaled according to the values of each individual subgroup.

- If FORMAT=REFERENCE is specified when SPLIT=SCALE, the reference line is placed at the mean of the subgroup. If FORMAT=REFERENCE is specified when SPLIT=UNIFORM, the reference line is placed at the overall mean.

Example

```
SPLIT FILE BY REGION.
TSPLOT VARIABLES = TICKETS / SPLIT=SCALE.
```

- In this example, the data have been split into subgroups by *REGION*. The plots produced with the SCALE subcommand have vertical axes that are individually scaled according to the values of each particular region.

APPLY Subcommand

APPLY allows you to produce a plot using previously defined specifications without having to repeat the TSPLOT subcommands.

- The only specification on APPLY is the name of a previous model enclosed in quotes. If a model name is not specified, the specifications from the previous TSPLOT command are used.
- To change one or more specifications of the plot, specify the subcommands of only those portions you want to change after the subcommand APPLY.
- If no variables are specified, the variables that were specified for the original plot are used.
- To plot different variables, enter new variable names before or after the APPLY subcommand.

Example

```
TSPLOT VARIABLES = TICKETS
  /LN
  /DIFF=1
  /SDIFF=1
  /PERIOD=12.
TSPLOT VARIABLES = ROUNDTRP
  /APPLY.
TSPLOT APPLY
  /NOLOG.
```

- The first command produces a plot of *TICKETS* after a natural log transformation, differencing, and seasonal differencing have been applied.
- The second command plots the values for *ROUNDTRP* using the same subcommands specified for *TICKETS*.
- The third command produces another plot of *ROUNDTRP* but this time without a log transformation. *ROUNDTRP* is still differenced once and seasonally differenced with a periodicity of 12.

T-TEST

One-sample tests:

```
T-TEST TESTVAL n /VARIABLE=varlist
```

Independent-samples tests:

```
T-TEST GROUPS=varname ({1,2**      }) /VARIABLES=varlist
                      {value       }
                      {value,value}
```

Paired-samples tests:

```
T-TEST PAIRS=varlist [WITH varlist [(PAIRED)]] [/varlist ...]
```

All types of tests:

```
[/MISSING={ANALYSIS**}  [INCLUDE]]
          {LISTWISE  }

[/CRITERIA=CI({0.95**})
              {value }
```

**Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Examples

```
T-TEST GROUPS=WORLD(1,3) /VARIABLES=NTCPRI NTCSAL NTCPUR.

T-TEST PAIRS=TEACHER CONSTRUC MANAGER.
```

Overview

T-TEST compares sample means by calculating Student's *t* and displays the two-tailed probability of the difference between the means. Statistics are available for one-sample (tested against a specified value), independent samples (different groups of cases), or paired samples (different variables). Other procedures that compare group means are ANOVA, ONEWAY, UNIANOVA, GLM, and MANOVA (GLM and MANOVA are available in the Advanced Models option).

Options

Statistics. There are no optional statistics. All statistics available are displayed by default.

Basic Specification

The basic specification depends on whether you want a one-sample test, an independent-samples test or a paired-samples test. For all types of tests, T-TEST displays Student's *t,* degrees of freedom, and two-tailed probabilities, as well as the mean, standard deviation, standard error, and count for each group or variable.

- To request a one-sample test, use the TESTVAL and VARIABLES subcommands. The output includes a One-Sample Statistics table showing univariate statistics and a One-Sample Test table showing the test value, the difference between the sample mean and the test value, and the two-tailed probability level.
- To request an independent-samples test, use the GROUPS and VARIABLES subcommands. The output includes a Group Statistics table showing summary statistics by group for each dependent variable and an Independent-Samples Test table showing both pooled- and separate-variance estimates, along with the *F* value used to test homogeneity of variance and its probability. The two-tailed probability is displayed for the *t* value.
- To request a paired-samples test, use the PAIRS subcommand. The output includes a Paired Statistics table showing univariate statistics by pairs, a Paired Samples Correlations table showing correlation coefficients and two-tailed probability level for a test of the coefficient for each pair, and a Paired Samples Test table showing the paired differences between the means and two-tailed probability levels for a test of the differences.

Subcommand Order

Subcommands can be named in any order.

Operations

- If a variable specified on GROUPS is a long string, only the short-string portion is used to identify groups in the analysis.
- Probability levels are two-tailed. To obtain the one-tailed probability, divide the two-tailed probability by 2.

Limitations

- Maximum of one TESTVAL and one VARIABLES subcommand per one-sample *t* test.
- Maximum of one GROUPS and one VARIABLES subcommand per independent-samples *t* test.

Examples

One-Sample Test

```
T-TEST TESTVAL 28000 /VARIABLES=CHISAL LASAL NYSAL.
```

- This one-sample *t* test compares the means of *CHISAL, LASAL,* and *NYSAL* each with the standard value (28000).

Independent-Samples Test

```
T-TEST GROUPS=WORLD(1,3) /VARIABLES=NTCPRI NTCSAL NTCPUR.
```

- This independent-samples *t* test compares the means of the two groups defined by values 1 and 3 of *WORLD* for variables *NTCPRI, NTCSAL,* and *NTCPUR*.

Paired-Samples Test

```
T-TEST PAIRS=TEACHER CONSTRUC MANAGER.
```

- This paired-samples *t* test compares the means of *TEACHER* with *CONSTRUC*, *TEACHER* with *MANAGER*, and *CONSTRUC* with *MANAGER*.

VARIABLES Subcommand

VARIABLES specifies the dependent variables to be tested in a one-sample or an independent-samples *t* test.

- VARIABLES can specify multiple variables, all of which must be numeric.
- When specified along with TESTVAL, the mean of all cases for each variable is compared with the specified value.
- When specified along with GROUPS, the means of two groups of cases defined by the GROUPS subcommand are compared.
- If both TESTVAL and GROUPS are specified, a one-sample test and an independent-samples test are performed on each variable.

TESTVAL Subcommand

TESTVAL specifies the value with which a sample mean is compared.

- Only one TESTVAL subcommand is allowed.
- Only one value can be specified on the TESTVAL subcommand.

GROUPS Subcommand

GROUPS specifies a variable used to group cases for independent-samples *t* tests.

- GROUPS can specify only one variable, which can be numeric or string.

Any one of three methods can be used to define the two groups for the variable specified on GROUPS:

- Specify a single value in parentheses to group all cases with a value equal to or greater than the specified value into one group and the remaining cases into the other group.
- Specify two values in parentheses to include cases with the first value in one group and cases with the second value in the other group. Cases with other values are excluded.
- If no values are specified on GROUP, T-TEST uses 1 and 2 as default values for numeric variables. There is no default for string variables.

PAIRS Subcommand

PAIRS requests paired-samples *t* tests.

- The minimum specification for a paired-samples test is PAIRS with an analysis list. Only numeric variables can be specified on the analysis list. The minimum analysis list is two variables.
- If keyword WITH is not specified, each variable in the list is compared with every other variable on the list.
- If keyword WITH is specified, every variable to the left of WITH is compared with every variable to the right of WITH. WITH can be used with PAIRED to obtain special pairing.
- To specify multiple analysis lists, use multiple PAIRS subcommands, each separated by a slash. Keyword PAIRS is required only for the first analysis list; a slash can be used to separate each additional analysis list.

(PAIRED) *Special pairing for paired-samples test.* PAIRED must be enclosed in parentheses and must be used with keyword WITH. When PAIRED is specified, the first variable before WITH is compared with the first variable after WITH, the second variable before WITH is compared with the second variable after WITH, and so forth. The same number of variables should be specified before and after WITH; unmatched variables are ignored and a warning message is issued. PAIRED generates an error message if keyword WITH is not specified on PAIRS.

Example

```
T-TEST  PAIRS=TEACHER CONSTRUC MANAGER.
T-TEST  PAIRS=TEACHER MANAGER WITH CONSTRUC ENGINEER.
T-TEST  PAIRS=TEACHER MANAGER WITH CONSTRUC ENGINEER (PAIRED).
```

- The first T-TEST compares *TEACHER* with *CONSTRUC, TEACHER* with *MANAGER*, and *CONSTRUC* with *MANAGER*.
- The second T-TEST compares *TEACHER* with *CONSTRUC*, *TEACHER* with *ENGINEER*, *MANAGER* with *CONSTRUC*, and *MANAGER* with *ENGINEER*. *TEACHER* is not compared with *MANAGER*, and *CONSTRUC* is not compared with *ENGINEER*.
- The third T-TEST compares *TEACHER* with *CONSTRUC* and *MANAGER* with *ENGINEER*.

CRITERIA Subcommand

CRITERIA resets the value of the confidence interval. Keyword CI is required. You can specify a value between 0 and 1 in the parentheses. The default is 0.95.

MISSING Subcommand

MISSING controls the treatment of missing values. The default is ANALYSIS.

- ANALYSIS and LISTWISE are alternatives; however, each can be specified with INCLUDE.

ANALYSIS *Delete cases with missing values on an analysis-by-analysis or pair-by-pair basis.* For independent-samples tests, cases with missing values for either the grouping variable or the dependent variable are excluded from the analysis of that dependent variable. For paired-samples tests, a case with a missing value for either of the variables in a given pair is excluded from the analysis of that pair. This is the default.

LISTWISE *Exclude cases with missing values listwise.* A case with a missing value for any variable specified on either GROUPS or VARIABLES is excluded from any independent-samples test. A case with a missing value for any variable specified on PAIRS is excluded from any paired-samples test.

INCLUDE *Include user-missing values.* User-missing values are treated as valid values.

TWOSTEP CLUSTER

```
TWOSTEP CLUSTER

[/CATEGORICAL VARIABLES = varlist]

[/CONTINUOUS VARIABLES = varlist]

[/CRITERIA [INITHRESHOLD({0**  })] [MXBRANCH({8**})]
                        {value}             {n  }
           [MXLEVEL({3**})] ]
                    {n  }

[/DISTANCE {EUCLIDEAN   }]
           {LIKELIHOOD**}

[/HANDLENOISE {0**}]
              {n  }

[/INFILE FILE = filename]

[/MEMALLOCATE {64**}]
              {n   }

[/MISSING {EXCLUDE**}]
          {INCLUDE  }

[/NOSTANDARDIZE [VARIABLES = varlist]]

[/NUMCLUSTERS {AUTO** {15**} [{AIC  }]}]
                      {n   }  {BIC**}
              {FIXED = n              }

[/OUTFILE [MODEL = 'file'] [STATE = 'file']]

[/PRINT [IC] [COUNT] [SUMMARY]]

[/SAVE CLUSTER [VARIABLE = varname]]
```

**Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
TWOSTEP CLUSTER
  /CONTINUOUS VARIABLES = INCOME
  /CATEGORICAL VARIABLES = GENDER RACE
  /PRINT SUMMARY.
```

Overview

TWOSTEP CLUSTER groups observations into clusters based on a nearness criterion. The procedure uses a hierarchical agglomerative clustering procedure in which individual cases are successively combined to form clusters whose centers are far apart. This algorithm is designed to cluster large numbers of cases. It passes the data once to find the cluster centers and again to assign cluster memberships. In addition to the benefit of few data passes, the procedure allows the user to set the amount of memory used by the clustering algorithm.

Basic Features

Cluster Features (CF) Tree. TWOSTEP CLUSTER clusters observations by building a data structure called the **CF tree**, which contains the cluster centers. The CF tree is grown during the first stage of clustering and values are added to its leaves if they are close to the cluster center of a particular leaf.

Distance Measure. Two types of distance measures are offered—the traditional Euclidean distance and the likelihood distance. The former is available when no categorical variables are specified. The latter is especially useful when categorical variables are used. The likelihood function is computed using the normal density for continuous variables and the multinomial probability mass function for categorical variables. All variables are treated as independent.

Tuning the Algorithm. You can control the values of algorithm-tuning parameters with the CRITERIA subcommand.

Noise Handling. The clustering algorithm can optionally retain any outliers that do not fit in the CF tree. If possible, these values will be placed in the CF tree after it is completed. Otherwise, TWOSTEP CLUSTER will discard them after preclustering.

Missing Values. TWOSTEP CLUSTER will delete listwise any records with missing fields.

Numclusters. This subcommand specifies the number of clusters into which the data will be partitioned. The user may tell TWOSTEP CLUSTER to automatically select the number of clusters.

Optional Output. You can specify output to an XML file with the OUTFILE subcommand. The cluster membership for each case used can be saved to the active dataset with the SAVE subcommand.

Weights. TWOSTEP CLUSTER ignores specification on the WEIGHT command.

Basic Specification

- The minimum specification is a list of variables, either categorical or continuous, to be clustered and at least one of the following subcommands: OUTFILE, PRINT, or SAVE.
- The number of clusters may be specified with the NUMCLUSTERS subcommand.
- Unless the NOSTANDARDIZE subcommand is given, TWOSTEP CLUSTER will standardize all continuous variables.
- If DISTANCE is Euclidean, TWOSTEP CLUSTER will accept only continuous variables.

Subcommand Order

- The subcommands can be specified in any order.

Syntax Rules

- Minimum syntax: a variable must be specified.
- Empty subcommands are silently ignored.
- Variables listed in the CONTINUOUS subcommand must be numeric.
- If a subcommand is issued more than once, TWOSTEP CLUSTER will ignore all but the last issue.

Variable List

The variable lists specify those variables to be clustered. The first variable list specifies only continuous variables, and the second list specifies only categorical variables (that is, the two lists are disjoint).

CATEGORICAL Subcommand

The CATEGORICAL subcommand specifies a list of categorical variables.

Example

```
TWOSTEP CLUSTER
  /CATEGORICAL VARIABLES = RACE GENDER CITIZEN
  /PRINT SUMMARY COUNT.
```

This tells TWOSTEP CLUSTER to cluster the categorical variables *RACE*, *GENDER,* and *CITIZEN*. Summary statistics by cluster and cluster frequencies are output in tables.

CONTINUOUS Subcommand

The CONTINUOUS subcommand specifies a list of scale variables.

Example

```
TWOSTEP CLUSTER
  /CATEGORICAL VARIABLES = RACE GENDER CITIZEN
  /CONTINUOUS VARIABLES = INCOME
  /PRINT SUMMARY COUNT.
```

This tells TWOSTEP CLUSTER to cluster the categorical variables *RACE*, *GENDER,* and *CITIZEN*, and the numeric variable *INCOME*. Summary statistics by cluster and cluster frequencies are output in tables.

CRITERIA Subcommand

The CRITERIA subcommand specifies the following settings for the clustering algorithm:

INITTHRESHOLD *The initial threshold used to grow the CF tree.* The default is 0. If inserting a specific case into a leaf of the CF tree would yield tightness less than the threshold, the leaf is not split. If the tightness exceeds the threshold, the leaf is split.

MXBRANCH *The maximum number of child nodes that a leaf node can have.* The default is 8.

MXLEVEL *The maximum number of levels that the CF tree can have.* The default is 3.

DISTANCE Subcommand

The distance subcommand determines how distances will be computed between clusters.

EUCLIDEAN *Use the Euclidean distance to compute distances between clusters.* You may select Euclidean distance if all variables are continuous. TWOSTEP CLUSTER will return a syntax error if you specify Euclidean distance with non-numeric variables.

LIKELIHOOD *Use the minus log-likelihood to compute distances between clusters.* This is the default. The likelihood function is computed assuming all variables are independent. Continuous variables are assumed to be normally distributed, and categorical variables are assumed to be multinomially distributed.

HANDLENOISE Subcommand

The HANDLENOISE subcommand tells TWOSTEP CLUSTER to treat outliers specially during clustering. During growth of the CF tree, this subcommand is relevant only if the CF tree fills. The CF tree is full if it cannot accept any more cases in a leaf node and no leaf node can be split. The default value of HANDLENOISE is 0, equivalent to no noise handling.

- If the CF tree fills and HANDLENOISE is greater than 0, the CF tree will be regrown after placing any data in sparse leaves into their own noise leaf. A leaf is considered sparse if the ratio of the number of cases in the sparse leaf to the number of cases in the largest leaf is less than HANDLENOISE. After the tree is grown, the outliers will be placed in the CF tree, if possible. If not, the outliers are discarded for the second phase of clustering.
- If the CF tree fills and HANDLENOISE is equal to 0, the threshold will be increased and CF tree regrown with all cases. After final clustering, values that cannot be assigned to a cluster are labeled outliers. The outlier cluster is given an identification number of –1. The outlier cluster is not included in the count of the number of clusters; that is, if you specify *n* clusters and noise handling, TWOSTEP CLUSTER will output *n* clusters and one noise cluster.

Example

```
TWOSTEP CLUSTER
  /CATEGORICAL VARIABLES = RACE GENDER CITIZEN
  /CONTINUOUS VARIABLES = INCOME
  /HANDLENOISE 25
  /PRINT SUMMARY COUNT.
```

This tells TWOSTEP CLUSTER to cluster the categorical variables *RACE*, *GENDER* and *CITIZEN*, and the numeric variable *INCOME*. If the CF tree fills, a noise leaf is constructed from cases whose leaves contain fewer than 25 percent of the cases contained by the largest leaf. The CF tree is then regrown, ignoring the noise leaf. After the tree is regrown, cases from the noise leaf are checked to see if they fit any of the leaves in the new tree. Any cases that still do not fit are discarded as outliers. Summary statistics by cluster and cluster frequencies are output in tables.

INFILE Subcommand

The INFILE subcommand causes TWOSTEP CLUSTER to update a cluster model whose CF Tree has been saved as an XML file with the OUTFILE subcommand and STATE keyword. The model will be updated with the data in the active file. The user must supply variable names in the active file in the order they are stored in the XML file. TWOSTEP CLUSTER will update the cluster model in memory only, leaving unaltered the XML file.

- If the INFILE subcommand is given, TWOSTEP CLUSTER will ignore the CRITERIA, DISTANCE, HANDLENOISE and MEMALLOCATE subcommands, if given.

MEMALLOCATE Subcommand

The MEMALLOCATE subcommand specifies the maximum amount of memory in megabytes (MB) that the cluster algorithm should use. If the procedure exceeds this maximum, it will use the disk to store information that will not fit in memory.

- The minimum value that you can specify is 4. If this subcommand is not specified, the default value is 64 MB.
- Consult your system administrator for the largest value you can specify on your system.

MISSING Subcommand

The MISSING subcommand specifies how to handle cases with user-missing values.

- If this subcommand is not specified, the default is EXCLUDE.
- TWOSTEP CLUSTER deletes any case with a system-missing value.
- Keywords EXCLUDE and INCLUDE are mutually exclusive. Only one of them can be specified.

EXCLUDE *Exclude both user-missing and system-missing values.* This is the default.

INCLUDE *User-missing values are treated as valid.* System-missing values cannot be included in the analysis.

NOSTANDARDIZE Subcommand

The NOSTANDARDIZE subcommand will prevent TWOSTEP CLUSTER from standardizing the continuous variables specified with the VARIABLES keyword. If this subcommand is not specified, TWOSTEP CLUSTER will standardize all continuous variables by subtracting the mean and dividing by the standard deviation. If the NOSTANDARDIZE subcommand is given without a variable list, TWOSTEP CLUSTER will not standardize any continuous variables.

NUMCLUSTERS Subcommand

The NUMCLUSTERS subcommand specifies the number of clusters into which the data will be partitioned.

AUTO *Automatic selection of the number of clusters.* Under AUTO, you may specify a maximum number of possible clusters. TWOSTEP CLUSTER will search for the best number of clusters between 1 and the maximum using the criterion that you specify. The criterion for deciding the number of clusters can be either the Bayesian Information Criterion (BIC) or Akaike Information Criterion (AIC). TWOSTEP CLUSTER will find at least one cluster if the AUTO keyword is given.

FIXED *User-specified number of clusters.* Specify a positive integer.

Examples

```
TWOSTEP CLUSTER
  /CONTINUOUS VARIABLES = INCOME
  /CATEGORICAL VARIABLES = GENDER RACE
  /NUMCLUSTERS AUTO 10 AIC
  /PRINT SUMMARY COUNT.
```

TWOSTEP CLUSTER uses the variables *RACE*, *GENDER* and *INCOME* for clustering. Specifications on the NUMCLUSTERS subcommand will instruct the procedure to automatically search for the number of clusters using the Akaike Information Criterion and require the answer to lie between 1 and 10.

```
TWOSTEP CLUSTER
  /CONTINUOUS VARIABLES = INCOME
  /CATEGORICAL VARIABLES = RACE GENDER
  /NUMCLUSTERS FIXED 7
  /PRINT SUMMARY COUNT.
```

Here the procedure will find exactly seven clusters.

OUTFILE Subcommand

The OUTFILE subcommand directs TWOSTEP CLUSTER to write its output to the specified filename as XML.

MODEL *Save the final model output.*

STATE *Save the CF tree.* Use the STATE keyword if you want to update the model later.

You must supply a valid filename on your operating system. We recommend specifying the full path of the filename.

PRINT Subcommand

The PRINT subcommand causes TWOSTEP CLUSTER to print tables related to each cluster.

IC *Information criterion.* Prints the chosen information criterion (AIC or BIC) for different numbers of clusters. If this keyword is specified when the AUTO keyword is not used with the NUMCLUSTERS subcommand, TWOSTEP CLUSTER will skip this keyword and issue a warning. TWOSTEP CLUSTER will ignore this keyword if AUTO 1 is specified in the NUMCLUSTERS subcommand.

SUMMARY *Descriptive statistics by cluster.* This option prints two tables describing the variables in each cluster. In one table, means and standard deviations are reported for continuous variables. The other table reports frequencies of categorical variables. All values are separated by cluster.

COUNT *Cluster frequencies.* This option prints a table containing a list of clusters and how many observations are in each cluster.

SAVE Subcommand

The SAVE subcommand allows you to save cluster output to the active dataset.

CLUSTER *Save the cluster identification.* The cluster number for each case is saved; the user may specify a variable name using the VARIABLE keyword, otherwise, it is saved to *TSC_n*, where *n* is a positive integer indicating the ordinal of the SAVE operation completed by this procedure in a given session.

UNIANOVA

```
UNIANOVA dependent var [BY factor list [WITH covariate list]]

[/RANDOM=factor factor...]

[/REGWGT=varname]

[/METHOD=SSTYPE({1  })]

[/EMMEANS=TABLES({OVERALL         })] [COMPARE ADJ([LSD] [BONFERRONI] [SIDAK])]
                 {factor        }
                 {factor*factor...}

 [/SAVE=[tempvar [(name)]] [tempvar [(name)]]...]

 [/OUTFILE=[{COVB ('savfile'|'dataset')}]
            {CORB ('savfile'|'dataset')}
           [EFFECT('savfile'|'dataset')] [DESIGN('savfile'|'dataset')]

 [/DESIGN={[INTERCEPT...]    }]
          {[effect effect...]}
```

** Default if the subcommand or keyword is omitted.

Temporary variables (tempvar) are:

```
PRED, WPRED, RESID, WRESID, DRESID, ZRESID, SRESID, SEPRED, COOK, LEVER
```

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
UNIANOVA YIELD BY SEED FERT
  /DESIGN.
```

Overview

This section describes the use of UNIANOVA for univariate analyses. The UNIANOVA procedure provides regression analysis and analysis of variance for one dependent variable by one or more factors and/or variables.

Options

Design Specification. You can specify which terms to include in the design on the DESIGN subcommand. This allows you to estimate a model other than the default full factorial model, incorporate factor-by-covariate interactions or covariate-by-covariate interactions, and indicate nesting of effects.

Contrast Types. You can specify contrasts other than the default deviation contrasts on the CONTRAST subcommand.

Optional Output. You can choose from a wide variety of optional output on the PRINT subcommand. Output appropriate to univariate designs includes descriptive statistics for each cell, parameter estimates, Levene's test for equality of variance across cells, partial eta-squared for each effect and each parameter estimate, the general estimable function matrix, and a contrast coefficients table (**L'** matrix). The OUTFILE subcommand allows you to write out the covariance or correlation matrix, the design matrix, or the statistics from the between-subjects ANOVA table into a separate SPSS data file.

Using the EMMEANS subcommand, you can request tables of estimated marginal means of the dependent variable and their standard deviations. The SAVE subcommand allows you to save predicted values and residuals in weighted or unweighted and standardized or unstandardized forms. You can specify different means comparison tests for comparing all possible pairs of cell means using the POSTHOC subcommand. In addition, you can specify your own hypothesis tests by specifying an **L** matrix and a **K** matrix to test the univariate hypothesis **LB** = **K**.

Basic Specification

- The basic specification is a variable list identifying the dependent variable, the factors (if any), and the covariates (if any).

- By default, UNIANOVA uses a model that includes the intercept term, the covariate (if any), and the full factorial model, which includes all main effects and all possible interactions among factors. The intercept term is excluded if it is excluded in the model by specifying the keyword EXCLUDE on the INTERCEPT subcommand. Sums of squares are calculated and hypothesis tests are performed using type-specific estimable functions. Parameters are estimated using the normal equation and a generalized inverse of the SSCP matrix.

Subcommand Order

- The variable list must be specified first.
- Subcommands can be used in any order.

Syntax Rules

- For many analyses, the UNIANOVA variable list and the DESIGN subcommand are the only specifications needed.
- If you do not enter a DESIGN subcommand, UNIANOVA will use a full factorial model, with main effects of covariates, if any.
- At least one dependent variable must be specified, and at least one of the following must be specified: INTERCEPT, a factor, or a covariate. The design contains the intercept by default.
- If more than one DESIGN subcommand is specified, only the last one is in effect.
- Dependent variables and covariates must be numeric, but factors can be numeric or string variables.
- If a string variable is specified as a factor, only the first eight characters of each value are used in distinguishing among values.
- If more than one MISSING subcommand is specified, only the last one is in effect.
- The following words are reserved as keywords or internal commands in the UNIANOVA procedure:

  INTERCEPT, BY, WITH, ALL, OVERALL, WITHIN

  Variable names that duplicate these words should be changed before you run UNIANOVA.

Limitations

- Any number of factors can be specified, but if the number of factors plus the number of split variables exceeds 18, the Descriptive Statistics table is not printed even when you request it.
- Memory requirements depend primarily on the number of cells in the design. For the default full factorial model, this equals the product of the number of levels or categories in each factor.

Example

```
UNIANOVA YIELD BY SEED FERT WITH RAINFALL
  /PRINT=DESCRIPTIVE PARAMETER
  /DESIGN.
```

- *YIELD* is the dependent variable; *SEED* and *FERT* are factors; *RAINFALL* is a covariate.

- The PRINT subcommand requests the descriptive statistics for the dependent variable for each cell and the parameter estimates, in addition to the default tables Between-Subjects Factors and Univariate Tests.
- The DESIGN subcommand requests the default design, a full factorial model with a covariate. This subcommand could have been omitted or could have been specified in full as

```
/DESIGN = INTERCEPT RAINFALL, SEED, FERT, SEED BY FERT.
```

UNIANOVA Variable List

The variable list specifies the dependent variable, the factors, and the covariates in the model.

- The dependent variable must be the first specification on UNIANOVA.
- The names of the factors follow the dependent variable. Use the keyword BY to separate the factors from the dependent variable.
- Enter the covariates, if any, following the factors. Use the keyword WITH to separate covariates from factors (if any) and the dependent variable.

Example

```
UNIANOVA DEPENDNT BY FACTOR1 FACTOR2, FACTOR3.
```

- In this example, three factors are specified.
- A default full factorial model is used for the analysis.

Example

```
UNIANOVA Y BY A WITH X
  /DESIGN.
```

- In this example, the DESIGN subcommand requests the default design, which includes the intercept term, the covariate *X*, and the factor *A*.

RANDOM Subcommand

RANDOM allows you to specify which effects in your design are random. When the RANDOM subcommand is used, a table of expected mean squares for all effects in the design is displayed, and an appropriate error term for testing each effect is calculated and used automatically.

- Random always implies a univariate mixed-model analysis.
- If you specify an effect on RANDOM, higher-order effects containing the specified effect (excluding any effects containing covariates) are automatically treated as random effects.
- The keyword INTERCEPT and effects containing covariates are not allowed on this subcommand.
- When the RANDOM subcommand is used, the appropriate error terms for the hypothesis testing of all effects in the model are automatically computed and used.
- More than one RANDOM subcommand is allowed. The specifications are accumulated.

Example

```
UNIANOVA DEP BY A B
  /RANDOM = B
  /DESIGN = A,B, A*B.
```

- In the example, effects *B* and *A*B* are considered as random effects. Notice that if only effect *B* is specified in the RANDOM subcommand, *A*B* is automatically considered as a random effect.
- The hypothesis testing for each effect (*A*, *B*, and *A*B*) in the design will be carried out using the appropriate error term, which is calculated automatically.

REGWGT Subcommand

The only specification on REGWGT is the name of the variable containing the weights to be used in estimating a weighted least-squares model.

- Specify a numeric weight variable name following the REGWGT subcommand. Only observations with positive values in the weight variable will be used in the analysis.
- If more than one REGWGT subcommand is specified, only the last one is in effect.

Example

```
UNIANOVA OUTCOME BY TREATMNT
  /REGWGT WT.
```

- The procedure performs a weighted least-squares analysis. The variable *WT* is used as the weight variable.

METHOD Subcommand

METHOD controls the computational aspects of the UNIANOVA analysis. You can specify one of four different methods for partitioning the sums of squares. If more than one METHOD subcommand is specified, only the last one is in effect.

SSTYPE(1) *Type I sum-of-squares method.* The Type I sum-of-squares method is also known as the hierarchical decomposition of the sum-of-squares method. Each term is adjusted only for the terms that precede it on the DESIGN subcommand. Under a balanced design, it is an orthogonal decomposition, and the sums of squares in the model add up to the total sum of squares.

SSTYPE(2) *Type II sum-of-squares method.* This method calculates the sum of squares of an effect in the model adjusted for all other "appropriate" effects. An appropriate effect is one that corresponds to all effects that do not contain the effect being examined.

For any two effects *F1* and *F2* in the model, *F1* is said to be **contained** in *F2* under the following three conditions: 1) both effects *F1* and *F2* have the same covariate, if any, 2) *F2* consists of more factors than *F1*, and 3) all factors in *F1* also appear in *F2*. The intercept effect is treated as contained in all of the pure factor effects. However, it is not contained in any effect involving a covariate. No effect is contained in the intercept effect. Thus, for any one effect *F* of interest, all other effects in the model can be classified as in one of the following two groups: the effects that do not contain *F* or the effects that contain *F*.

If the model is a main-effects design (that is, only main effects are in the model), the Type II sum-of-squares method is equivalent to the regression approach sums of squares. This means that each main effect is adjusted for every other term in the model.

SSTYPE(3) *Type III sum-of-squares method.* This is the default. This method calculates the sum of squares of an effect *F* in the design as the sum of squares adjusted for any other effects that do not contain it, and *orthogonal* to any effects (if any) that contain it. The Type III sums of squares have one major advantage—they are invariant with respect to the cell frequencies as long as the general form of estimability remains constant. Hence, this type of sums of squares is often used for an unbalanced model with no missing cells. In a factorial design with no missing cells, this method is equivalent to the Yates' weighted squares of means technique, and it also coincides with the overparameterized $\sum$-restricted model.

SSTYPE(4) *Type IV sum-of-squares method.* This method is designed for a situation in which there are missing cells. For any effect *F* in the design, if *F* is not contained in any other effect, then Type IV = Type III = Type II. When *F* is contained in other effects, then Type IV distributes the contrasts being made among the parameters in *F* to all higher-level effects equitably.

Example

```
UNIANOVA DEP BY A B C
  /METHOD=SSTYPE(3)
  /DESIGN=A, B, C.
```

- The design is a main-effects model.
- The METHOD subcommand requests that the model be fitted with Type III sums of squares.

INTERCEPT Subcommand

INTERCEPT controls whether an intercept term is included in the model. If more than one INTERCEPT subcommand is specified, only the last one is in effect.

INCLUDE *Include the intercept term.* The intercept (constant) term is included in the model. This is the default.

EXCLUDE *Exclude the intercept term.* The intercept term is excluded from the model. Specification of the keyword INTERCEPT on the DESIGN subcommand overrides INTERCEPT = EXCLUDE.

MISSING Subcommand

By default, cases with missing values for any of the variables on the UNIANOVA variable list are excluded from the analysis. The MISSING subcommand allows you to include cases with user-missing values.

- If MISSING is not specified, the default is EXCLUDE.
- Pairwise deletion of missing data is not available in UNIANOVA.

- Keywords INCLUDE and EXCLUDE are mutually exclusive.
- If more than one MISSING subcommand is specified, only the last one is in effect.

EXCLUDE *Exclude both user-missing and system-missing values.* This is the default when MISSING is not specified.

INCLUDE *User-missing values are treated as valid.* System-missing values cannot be included in the analysis.

CRITERIA Subcommand

CRITERIA controls the statistical criteria used to build the models.

- More than one CRITERIA subcommand is allowed. The specifications are accumulated. Conflicts across CRITERIA subcommands are resolved using the conflicting specification given on the last CRITERIA subcommand.
- The keyword must be followed by a positive number in parentheses.

EPS(n) *The tolerance level in redundancy detection.* This value is used for redundancy checking in the design matrix. The default value is 1E–8.

ALPHA(n) *The alpha level.* This keyword has two functions. First, it gives the alpha level at which the power is calculated for the *F* test. Once the noncentrality parameter for the alternative hypothesis is estimated from the data, then the power is the probability that the test statistic is greater than the critical value under the alternative hypothesis. The second function of alpha is to specify the level of the confidence interval. If the alpha level specified is *n*, the value (1−n)×100 indicates the level of confidence for all individual and simultaneous confidence intervals generated for the specified model. The value of *n* must be between 0 and 1, exclusive. The default value of alpha is 0.05. This means that the default power calculation is at the 0.05 level, and the default level of the confidence intervals is 95%, since (1−0.05)×100=95.

PRINT Subcommand

PRINT controls the display of optional output.

- Some PRINT output applies to the entire UNIANOVA procedure and is displayed only once.
- Additional output can be obtained on the EMMEANS, PLOT, and SAVE subcommands.
- Some optional output may greatly increase the processing time. Request only the output you want to see.
- If no PRINT command is specified, default output for a univariate analysis includes a factor information table and a Univariate Tests table (ANOVA) for all effects in the model.
- If more than one PRINT subcommand is specified, only the last one is in effect.

The following keywords are available for UNIANOVA univariate analyses.

DESCRIPTIVES *Basic information about each cell in the design.* Observed means, standard deviations, and counts for the dependent variable in all cells. The cells are constructed from the highest-order crossing of the factors. If the number of factors plus the number of split variables exceeds 18, the Descriptive Statistics table is not printed.

HOMOGENEITY *Tests of homogeneity of variance.* Levene's test for equality of variances for the dependent variable across all level combinations of the factors. If there are no factors, this keyword is not valid.

PARAMETER *Parameter estimates.* Parameter estimates, standard errors, *t* tests, and confidence intervals for each test.

OPOWER *Observed power.* The observed power for each test.

LOF *Lack of fit.* Lack of fit test that allows you to determine if the current model adequately accounts for the relationship between the response variable and the predictors.

ETASQ Partial eta-squared (η^2). This value is an overestimate of the actual effect size in an *F* test. It is defined as

$$\eta^2 = \frac{dfh \times F}{dfh \times F + dfe}$$

where *F* is the test statistic and *dfh* and *dfe* are its degrees of freedom and degrees of freedom for error. The keyword EFSIZE can be used in place of ETASQ.

GEF *General estimable function table.* This table shows the general form of the estimable functions.

TEST(LMATRIX) *Set of contrast coefficients (L) matrices.* The transpose of the **L** matrix (**L'**) is displayed. This set always includes one matrix displaying the estimable function for each effect appearing or implied in the DESIGN subcommand. Also, any **L** matrices generated by the LMATRIX or CONTRAST subcommands are displayed. TEST(ESTIMABLE) can be used in place of TEST(LMATRIX).

Example

```
UNIANOVA DEP BY A B WITH COV
  /PRINT=DESCRIPTIVE, TEST(LMATRIX), PARAMETER
  /DESIGN.
```

- Since the design in the DESIGN subcommand is not specified, the default design is used. In this case, the design includes the intercept term, the covariate *COV*, and the full factorial terms of *A* and *B*, which are *A*, *B*, and *A*B*.
- For each combination of levels of *A* and *B*, the descriptive statistics of *DEP* are displayed.
- The set of **L** matrices that generates the sums of squares for testing each effect in the design is displayed.
- The parameter estimates, their standard errors, *t* tests, confidence intervals, and the observed power for each test are displayed.

PLOT Subcommand

PLOT provides a variety of plots useful in checking the assumptions needed in the analysis. The PLOT subcommand can be specified more than once. All of the plots requested on each PLOT subcommand are produced.

Use the following keywords on the PLOT subcommand to request plots:

SPREADLEVEL *Spread-versus-level plots.* Plots of observed cell means versus standard deviations, and versus variances.

RESIDUALS *Observed by predicted by standardized residuals plot.* A plot is produced for each dependent variable. In a univariate analysis, a plot is produced for the single dependent variable.

PROFILE *Line plots of dependent variable means for one-way, two-way, or three-way crossed factors.* The PROFILE keyword must be followed by parentheses containing a list of one or more factor combinations. All factors specified (either individual or crossed) must be made up of only valid factors on the factor list. Factor combinations on the PROFILE keyword may use an asterisk (*) or the keyword BY to specify crossed factors. A factor cannot occur in a single factor combination more than once.

The order of factors in a factor combination is important, and there is no restriction on the order of factors. If a single factor is specified after the PROFILE keyword, a line plot of estimated means at each level of the factor is produced. If a two-way crossed factor combination is specified, the output includes a multiple-line plot of estimated means at each level of the first specified factor, with a separate line drawn for each level of the second specified factor. If a three-way crossed factor combination is specified, the output includes multiple-line plots of estimated means at each level of the first specified factor, with separate lines for each level of the second factor, and separate plots for each level of the third factor.

Example

```
UNIANOVA DEP BY A B
  /PLOT = SPREADLEVEL PROFILE(A A*B A*B*C)
  /DESIGN.
```

Assume each of the factors *A*, *B*, and *C* has three levels.

- Spread-versus-level plots are produced showing observed cell means versus standard deviations and observed cell means versus variances.
- Five profile plots are produced. For factor *A*, a line plot of estimated means at each level of *A* is produced (one plot). For the two-way crossed factor combination *A*B*, a multiple-line plot of estimated means at each level of *A*, with a separate line for each level of *B*, is produced (one plot). For the three-way crossed factor combination *A*B*C*, a multiple-line plot of estimated means at each level of *A*, with a separate line for each level of *B*, is produced for each of the three levels of *C* (three plots).

TEST Subcommand

The TEST subcommand allows you to test a hypothesis term against a specified error term.

- TEST is valid only for univariate analyses. Multiple TEST subcommands are allowed, each executed independently.
- You must specify both the hypothesis term and the error term. There is no default.
- The hypothesis term is specified before the keyword VS. It must be a valid effect specified or implied on the DESIGN subcommand.
- The error term is specified after the keyword VS. You can specify either a linear combination or a value. The linear combination of effects takes the general form: `coefficient*effect +/– coefficient*effect ....`
- All effects in the linear combination must be specified or implied on the DESIGN subcommand. Effects specified or implied on DESIGN but not listed after VS are assumed to have a coefficient of 0.
- Duplicate effects are allowed. UNIANOVA adds coefficients associated with the same effect before performing the text. For example, the linear combination `5*A–0.9*B–A` will be combined to `4*A–0.9B`.
- A coefficient can be specified as a fraction with a positive denominator—for example, 1/3 or –1/3, but 1/–3 is invalid.
- If you specify a value for the error term, you must specify the degrees of freedom after the keyword DF. The degrees of freedom must be a positive real number. DF and the degrees of freedom are optional for a linear combination.

Example

```
UNIANOVA DEP BY A B
  /TEST = A VS B + A*B
  /DESIGN = A, B, A*B.
```

- *A* is tested against the pooled effect of *B* + *A*B*.

LMATRIX Subcommand

The LMATRIX subcommand allows you to customize your hypotheses tests by specifying the **L** matrix (contrast coefficients matrix) in the general form of the linear hypothesis **LB** = **K**, where **K** = **0** if it is not specified on the KMATRIX subcommand. The vector **B** is the parameter vector in the linear model.

- The basic format for the LMATRIX subcommand is an optional label in quotation marks, an effect name or the keyword ALL, and a list of real numbers. There can be multiple effect names (or the keyword ALL) and number lists.
- The optional label is a string with a maximum length of 255 characters. Only one label can be specified.
- Only valid effects appearing or implied on the DESIGN subcommand can be specified on the LMATRIX subcommand.
- The length of the list of real numbers must be equal to the number of parameters (including the redundant ones) corresponding to that effect. For example, if the effect *A*B* takes up six columns in the design matrix, then the list after *A*B* must contain exactly six numbers.

- A number can be specified as a fraction with a positive denominator—for example, 1/3 or –1/3, but 1/–3 is invalid.
- A semicolon (;) indicates the end of a row in the **L** matrix.
- When ALL is specified, the length of the list that follows ALL is equal to the total number of parameters (including the redundant ones) in the model.
- Effects appearing or implied on the DESIGN subcommand must be explicitly specified here.
- Multiple LMATRIX subcommands are allowed. Each is treated independently.

Example

```
UNIANOVA DEP BY A B
  /LMATRIX = "B1 vs B2 at A1"
              B 1 -1 0 A*B 1 -1 0 0 0 0 0 0 0
  /LMATRIX = "Effect A"
              A 1 0 -1
              A*B 1/3  1/3  1/3
                   0    0    0
                 -1/3 -1/3 -1/3;
              A 0 1 -1
              A*B  0    0    0
                  1/3  1/3  1/3
                 -1/3 -1/3 -1/3
  /LMATRIX = "B1 vs B2 at A2"
             ALL  0
                  0  0  0
                  1 -1  0
                  0  0  0  1 -1  0 0  0  0
  /DESIGN = A, B, A*B.
```

Assume that factors *A* and *B* each have three levels. There are three LMATRIX subcommands; each is treated independently.

- **B1 versus B2 at A1.** In the first LMATRIX subcommand, the difference is tested between levels 1 and 2 of effect *B* when effect *A* is fixed at level 1. Since there are three levels each in effects *A* and *B*, the interaction effect *A*B* takes up nine columns in the design matrix.
- **Effect A.** In the second LMATRIX subcommand, effect *A* is tested. Since there are three levels in effect *A*, at most two independent contrasts can be formed; thus, there are two rows in the L matrix, which are separated by a semicolon (;). The first row tests the difference between levels 1 and 3 of effect *A*, while the second row tests the difference between levels 2 and 3 of effect *A*.
- **B1 versus B2 at A2.** In the last LMATRIX subcommand, the keyword ALL is used. The first 0 corresponds to the intercept effect; the next three zeros correspond to effect *A*.

KMATRIX Subcommand

The KMATRIX subcommand allows you to customize your hypothesis tests by specifying the **K** matrix (contrast results matrix) in the general form of the linear hypothesis **LB** = **K**. The vector **B** is the parameter vector in the linear model.

- The default **K** matrix is a zero matrix; that is, **LB** = **0** is assumed.
- For the KMATRIX subcommand to be valid, at least one of the following subcommands must be specified: the LMATRIX subcommand or the INTERCEPT = INCLUDE subcommand.

- If KMATRIX is specified but LMATRIX is not specified, the LMATRIX is assumed to take the row vector corresponding to the intercept in the estimable function, provided the subcommand INTERCEPT = INCLUDE is specified. In this case, the **K** matrix can be only a scalar matrix.
- If KMATRIX and LMATRIX are specified, then the number of rows in the requested **K** and **L** matrices must be equal. If there are multiple LMATRIX subcommands, then all requested **L** matrices must have the same number of rows, and **K** must have the same number of rows as these **L** matrices.
- A semicolon (;) can be used to indicate the end of a row in the **K** matrix.
- If more than one KMATRIX subcommand is specified, only the last one is in effect.

Example

```
UNIANOVA DEP BY A B
  /LMATRIX = "Effect A"
             A 1  0 -1; A 1 -1  0
  /LMATRIX = "Effect B"
             B 1  0 -1; B 1 -1  0
  /KMATRIX = 0; 0
  /DESIGN = A B.
```

In this example, assume that factors *A* and *B* each have three levels.

- There are two LMATRIX subcommands; both have two rows.
- The first LMATRIX subcommand tests whether the effect of *A* is 0, while the second LMATRIX subcommand tests whether the effect of *B* is 0.
- The KMATRIX subcommand specifies that the **K** matrix also has two rows, each with value 0.

CONTRAST Subcommand

CONTRAST specifies the type of contrast desired among the levels of a factor. For a factor with *k* levels or values, the contrast type determines the meaning of its *k*−1 degrees of freedom.

- Specify the factor name in parentheses following the subcommand CONTRAST.
- You can specify only one factor per CONTRAST subcommand, but you can enter multiple CONTRAST subcommands.
- After closing the parentheses, enter an equals sign followed by one of the contrast keywords.
- This subcommand creates an **L** matrix such that the columns corresponding to the factor match the contrast given. The other columns are adjusted so that the **L** matrix is estimable.

The following contrast types are available:

DEVIATION *Deviations from the grand mean.* This is the default for factors. Each level of the factor except one is compared to the grand mean. One category (by default, the last) must be omitted so that the effects will be independent of one another. To omit a category other than the last, specify the number of the omitted category (which is not necessarily the same as its value) in parentheses after the keyword DEVIATION. For example,

```
UNIANOVA Y BY B /CONTRAST(B)=DEVIATION(1).
```

Suppose factor *B* has three levels, with values 2, 4, and 6. The specified contrast omits the first category, in which *B* has the value 2. Deviation contrasts are not orthogonal.

POLYNOMIAL *Polynomial contrasts.* This is the default for within-subjects factors. The first degree of freedom contains the linear effect across the levels of the factor, the second contains the quadratic effect, and so on. In a balanced design, polynomial contrasts are orthogonal. By default, the levels are assumed to be equally spaced; you can specify unequal spacing by entering a metric consisting of one integer for each level of the factor in parentheses after the keyword `POLYNOMIAL`. (All metrics specified cannot be equal; thus, (1, 1, . . . 1) is not valid.) For example,

```
UNIANOVA RESPONSE BY STIMULUS /CONTRAST(STIMULUS) =
POLYNOMIAL(1,2,4).
```

Suppose that factor *STIMULUS* has three levels. The specified contrast indicates that the three levels of *STIMULUS* are actually in the proportion 1:2:4. The default metric is always (1, 2, . . . *k*), where *k* levels are involved. Only the relative differences between the terms of the metric matter; (1, 2, 4) is the same metric as (2, 3, 5) or (20, 30, 50) because, in each instance, the difference between the second and third numbers is twice the difference between the first and second.

DIFFERENCE *Difference or reverse Helmert contrasts.* Each level of the factor except the first is compared to the mean of the previous levels. In a balanced design, difference contrasts are orthogonal.

HELMERT *Helmert contrasts.* Each level of the factor except the last is compared to the mean of subsequent levels. In a balanced design, Helmert contrasts are orthogonal.

SIMPLE *Each level of the factor except the last is compared to the last level.* To use a category other than the last as the omitted reference category, specify its number (which is not necessarily the same as its value) in parentheses following the keyword `SIMPLE`. For example,

```
UNIANOVA Y BY B /CONTRAST(B)=SIMPLE(1).
```

Suppose that factor *B* has three levels with values 2, 4, and 6. The specified contrast compares the other levels to the first level of *B*, in which *B* has the value 2. Simple contrasts are not orthogonal.

REPEATED *Comparison of adjacent levels.* Each level of the factor except the first is compared to the previous level. Repeated contrasts are not orthogonal.

SPECIAL *A user-defined contrast.* Values specified after this keyword are stored in a matrix in column major order. For example, if factor *A* has three levels, then `CONTRAST(A)=SPECIAL(1 1 1 1 -1 0 0 1 -1)` produces the following contrast matrix:

1 1 0 1 –1 1 1 0 –1

Orthogonal contrasts are particularly useful. In a balanced design, contrasts are orthogonal if the sum of the coefficients in each contrast row is 0 and if, for any pair of contrast rows, the products of corresponding coefficients sum to 0. `DIFFERENCE`, `HELMERT`, and `POLYNOMIAL` contrasts always meet these criteria in balanced designs.

Example

```
UNIANOVA DEP BY FAC
  /CONTRAST(FAC)=DIFFERENCE
  /DESIGN.
```

- Suppose that the factor *FAC* has five categories and therefore four degrees of freedom.
- CONTRAST requests DIFFERENCE contrasts, which compare each level (except the first) with the mean of the previous levels.

POSTHOC Subcommand

POSTHOC allows you to produce multiple comparisons between means of a factor. These comparisons are usually not planned at the beginning of the study but are suggested by the data in the course of study.

- Post hoc tests are computed for the dependent variable. The alpha value used in the tests can be specified by using the keyword ALPHA on the CRITERIA subcommand. The default alpha value is 0.05. The confidence level for any confidence interval constructed is $(1-\alpha) \times 100$. The default confidence level is 95.
- Only factors appearing in the factor list are valid in this subcommand. Individual factors can be specified.
- You can specify one or more effects to be tested. Only fixed main effects appearing or implied on the DESIGN subcommand are valid test effects.
- Optionally, you can specify an effect defining the error term following the keyword VS after the test specification. The error effect can be any single effect in the design that is not the intercept or a main effect named on a POSTHOC subcommand.
- A variety of multiple comparison tests are available. Some tests are designed for detecting homogeneity subsets among the groups of means, some are designed for pairwise comparisons among all means, and some can be used for both purposes.
- For tests that are used for detecting homogeneity subsets of means, non-empty group means are sorted in ascending order. Means that are not significantly different are included together to form a homogeneity subset. The significance for each homogeneity subset of means is displayed. In a case where the numbers of valid cases are not equal in all groups, for most post hoc tests, the harmonic mean of the group sizes is used as the sample size in the calculation. For QREGW or FREGW, individual sample sizes are used.
- For tests that are used for pairwise comparisons, the display includes the difference between each pair of compared means, the confidence interval for the difference, and the significance. The sample sizes of the two groups being compared are used in the calculation.
- Output for tests specified on the POSTHOC subcommand are available according to their statistical purposes. The following table illustrates the statistical purpose of the post hoc tests:

Post Hoc Tests	**Statistical Purpose**	
Keyword	**Homogeneity Subsets Detection**	**Pairwise Comparison and Confidence Interval**
LSD		Yes
SIDAK		Yes
BONFERRONI		Yes
GH		Yes
T2		Yes

Post Hoc Tests	Statistical Purpose	
Keyword	**Homogeneity Subsets Detection**	**Pairwise Comparison and Confidence Interval**
T3		Yes
C		Yes
DUNNETT		Yes*
DUNNETTL		Yes*
DUNNETTR		Yes*
SNK	Yes	
BTUKEY	Yes	
DUNCAN	Yes	
QREGW	Yes	
FREGW	Yes	
WALLER	Yes†	
TUKEY	Yes	Yes
SCHEFFE	Yes	Yes
GT2	Yes	Yes
GABRIEL	Yes	Yes

* Only CIs for differences between test group means and control group means are given.

† No significance for Waller test is given.

- Tests that are designed for homogeneity subset detection display the detected homogeneity subsets and their corresponding significances.
- Tests that are designed for both homogeneity subset detection and pairwise comparison display both kinds of output.
- For the DUNNETT, DUNNETTL, and DUNNETTR keywords, only individual factors can be specified.
- The default reference category for DUNNETT, DUNNETTL, and DUNNETTR is the last category. An integer greater than 0 within parentheses can be used to specify a different reference category. For example, POSTHOC = A (DUNNETT(2)) requests a DUNNETT test for factor *A*, using the second level of *A* as the reference category.
- The keywords DUNCAN, DUNNETT, DUNNETTL, and DUNNETTR must be spelled out in full; using the first three characters alone is not sufficient.
- If the REGWT subcommand is specified, weighted means are used in performing post hoc tests.
- Multiple POSTHOC subcommands are allowed. Each specification is executed independently so that you can test different effects against different error terms.

SNK *Student-Newman-Keuls procedure based on the Studentized range test.*

TUKEY *Tukey's honestly significant difference.* This test uses the Studentized range statistic to make all pairwise comparisons between groups.

BTUKEY *Tukey's* b. Multiple comparison procedure based on the average of Studentized range tests.

DUNCAN *Duncan's multiple comparison procedure based on the Studentized range test*.

SCHEFFE *Scheffé's multiple comparison* t *test.*

DUNNETT(refcat) *Dunnett's two-tailed* t *test*. Each level of the factor is compared to a reference category. A reference category can be specified in parentheses. The default reference category is the last category. This keyword must be spelled out in full.

DUNNETTL(refcat) *Dunnett's one-tailed* t *test*. This test indicates whether the mean at any level (except the reference category) of the factor is *smaller* than that of the reference category. A reference category can be specified in parentheses. The default reference category is the last category. This keyword must be spelled out in full.

DUNNETTR(refcat) *Dunnett's one-tailed* t *test*. This test indicates whether the mean at any level (except the reference category) of the factor is *larger* than that of the reference category. A reference category can be specified in parentheses. The default reference category is the last category. This keyword must be spelled out in full.

BONFERRONI *Bonferroni* t *test*. This test is based on Student's *t* statistic and adjusts the observed significance level for the fact that multiple comparisons are made.

LSD *Least significant difference* t *test*. Equivalent to multiple *t* tests between all pairs of groups. This test does not control the overall probability of rejecting the hypotheses that some pairs of means are different, while in fact they are equal.

SIDAK *Sidak* t *test*. This test provides tighter bounds than the Bonferroni test.

GT2 *Hochberg's GT2.* Pairwise comparisons test based on the Studentized maximum modulus test. Unless the cell sizes are extremely unbalanced, this test is fairly robust even for unequal variances.

GABRIEL *Gabriel's pairwise comparisons test based on the Studentized maximum modulus test.*

FREGW *Ryan-Einot-Gabriel-Welsch's multiple stepdown procedure based on an* F *test.*

QREGW *Ryan-Einot-Gabriel-Welsch's multiple stepdown procedure based on the Studentized range test.*

T2 *Tamhane's T2.* Tamhane's pairwise comparisons test based on a *t* test. This test can be applied in situations where the variances are unequal.

T3 *Dunnett's T3.* Pairwise comparisons test based on the Studentized maximum modulus. This test is appropriate when the variances are unequal.

GH *Games and Howell's pairwise comparisons test based on the Studentized range test.* This test can be applied in situations where the variances are unequal.

C *Dunnett's C.* Pairwise comparisons based on the weighted average of Studentized ranges. This test can be applied in situations where the variances are unequal.

WALLER(kratio) *Waller-Duncan* t *test.* This test uses a Bayesian approach. It is restricted to cases with equal sample sizes. For cases with unequal sample sizes, the harmonic mean of the sample size is used. The *k*-ratio is the Type 1/Type 2 error seriousness ratio. The default value is 100. You can specify an integer greater than 1 within parentheses.

EMMEANS Subcommand

EMMEANS displays estimated marginal means of the dependent variable in the cells (with covariates held at their overall mean value) and their standard errors for the specified factors. Note that these are predicted, not observed, means. The estimated marginal means are calculated using a modified definition by Searle, Speed, and Milliken (1980).

- TABLES, followed by an option in parentheses, is required. COMPARE is optional; if specified, it must follow TABLES.
- Multiple EMMEANS subcommands are allowed. Each is treated independently.
- If identical EMMEANS subcommands are specified, only the last identical subcommand is in effect. EMMEANS subcommands that are redundant but not identical (for example, crossed factor combinations such as *A*B* and *B*A*) are all processed.

TABLES(option)

Table specification. Valid options are the keyword OVERALL, factors appearing on the factor list, and crossed factors constructed of factors on the factor list. Crossed factors can be specified using an asterisk (*) or the keyword BY. All factors in a crossed factor specification must be unique.

If OVERALL is specified, the estimated marginal means of the dependent variable are displayed, collapsing over factors.

If a factor, or a crossing of factors, is specified on the TABLES keyword, UNIANOVA collapses over any other factors before computing the estimated marginal means for the dependent variable.

COMPARE(factor)
ADJ(method)

Main- or simple-main-effects omnibus tests and pairwise comparisons of the dependent variable. This option gives the mean difference, standard error, significance, and confidence interval for each pair of levels for the effect specified in the TABLES command, as well as an omnibus test for that effect. If only one factor is specified on TABLES, COMPARE can be specified by itself; otherwise, the factor specification is required. In this case, levels of the specified factor are compared with each other for each level of the other factors in the interaction.

The optional ADJ keyword allows you to apply an adjustment to the confidence intervals and significance values to account for multiple comparisons. Methods available are LSD (no adjustment), BONFERRONI, or SIDAK.

If OVERALL is specified on TABLES, COMPARE is invalid.

Example

```
UNIANOVA DEP BY A B
  /EMMEANS = TABLES(A*B) COMPARE(A) ADJ(LSD)
  /DESIGN.
```

- The output of this analysis includes a pairwise comparisons table for the dependent variable *DEP*.
- Assume that *A* has three levels and *B* has two levels. The first level of *A* is compared with the second and third levels, the second level with the first and third levels, and the third level with the first and second levels. The pairwise comparison is repeated for the two levels of *B*.

SAVE Subcommand

Use SAVE to add one or more residual or fit values to the active dataset.

- Specify one or more temporary variables, each followed by an optional new name in parentheses.
- WPRED and WRESID can be saved only if REGWGT has been specified.
- Specifying a temporary variable on this subcommand results in a variable being added to the active data file for each dependent variable.
- You can specify variable names for the temporary variables. These names must be unique, valid variable names.
- If new names are not specified, UNIANOVA generates a rootname using a shortened form of the temporary variable name with a suffix.
- If more than one SAVE subcommand is specified, only the last one is in effect.

PRED	*Unstandardized predicted values.*
WPRED	*Weighted unstandardized predicted values.* Available only if REGWGT has been specified.
RESID	*Unstandardized residuals.*
WRESID	*Weighted unstandardized residuals.* Available only if REGWGT has been specified.
DRESID	*Deleted residuals.*
ZRESID	*Standardized residuals.*
SRESID	*Studentized residuals.*
SEPRED	*Standard errors of predicted value.*
COOK	*Cook's distances.*
LEVER	*Uncentered leverage values.*

OUTFILE Subcommand

The OUTFILE subcommand writes an SPSS-format data file that can be used in other procedures.

- You must specify a keyword on OUTFILE. There is no default.
- You must specify a quoted file specification or a previously declared dataset name (DATASET DECLARE command), enclosed in quotes. The asterisk (*) is not allowed.
- If you specify more than one keyword, a different file specification is required for each.
- If more than one OUTFILE subcommand is specified, only the last one is in effect.
- For COVB or CORB, the output will contain, in addition to the covariance or correlation matrix, three rows for each dependent variable: a row of parameter estimates, a row of residual degrees of freedom, and a row of significance values for the *t* statistics corresponding to the parameter estimates. All statistics are displayed separately by split.

COVB ('savfile'|'dataset')	*Writes the parameter covariance matrix.*
CORB ('savfile'|'dataset')	*Writes the parameter correlation matrix.*

EFFECT ('savfile'|'dataset')	*Writes the statistics from the between-subjects ANOVA table.*
DESIGN ('savfile'|'dataset')	*Writes the design matrix.* The number of rows equals the number of cases, and the number of columns equals the number of parameters. The variable names are *DES_1*, *DES_2*, *..., DES_p*, where *p* is the number of the parameters.

DESIGN Subcommand

DESIGN specifies the effects included in a specific model. The cells in a design are defined by all of the possible combinations of levels of the factors in that design. The number of cells equals the product of the number of levels of all the factors. A design is *balanced* if each cell contains the same number of cases. UNIANOVA can analyze both balanced and unbalanced designs.

- Specify a list of terms to be included in the model, separated by spaces or commas.
- The default design, if the DESIGN subcommand is omitted or is specified by itself, is a design consisting of the following terms in order: the intercept term (if INTERCEPT=INCLUDE is specified), next the covariates given in the covariate list, and then the full factorial model defined by all factors on the factor list and excluding the intercept.
- To include a term for the main effect of a factor, enter the name of the factor on the DESIGN subcommand.
- To include the intercept term in the design, use the keyword INTERCEPT on the DESIGN subcommand. If INTERCEPT is specified on the DESIGN subcommand, the subcommand INTERCEPT=EXCLUDE is overridden.
- To include a term for an interaction between factors, use the keyword BY or the asterisk (*) to join the factors involved in the interaction. For example, *A*B* means a two-way interaction effect of *A* and *B*, where *A* and *B* are factors. *A*A* is not allowed because factors inside an interaction effect must be distinct.
- To include a term for nesting one effect within another, use the keyword WITHIN or a pair of parentheses on the DESIGN subcommand. For example, *A(B)* means that *A* is nested within *B*. The expression *A(B)* is equivalent to the expression *A WITHIN B*. When more than one pair of parentheses is present, each pair of parentheses must be enclosed or nested within another pair of parentheses. Thus, *A(B)(C)* is not valid.
- Multiple nesting is allowed. For example, *A(B(C))* means that *B* is nested within *C*, and *A* is nested within *B(C)*.
- Interactions between nested effects are not valid. For example, neither *A(C)*B(C)* nor *A(C)*B(D)* is valid.
- To include a covariate term in the design, enter the name of the covariate on the DESIGN subcommand.
- Covariates can be connected, but not nested, through the * operator to form another covariate effect. Therefore, interactions among covariates such as *X1*X1* and *X1*X2* are valid, but not *X1(X2)*. Using covariate effects such as *X1*X1*, *X1*X1*X1*, *X1*X2*, and *X1*X1*X2*X2* makes fitting a polynomial regression model easy in UNIANOVA.

- Factor and covariate effects can be connected only by the * operator. Suppose *A* and *B* are factors, and *X1* and *X2* are covariates. Examples of valid factor-by-covariate interaction effects are *A*X1*, *A*B*X1*, *X1*A(B)*, *A*X1*X1*, and *B*X1*X2*.
- If more than one `DESIGN` subcommand is specified, only the last one is in effect.

Example

```
UNIANOVA Y BY A B C WITH X
  /DESIGN A B(A) X*A.
```

- In this example, the design consists of a main effect *A*, a nested effect *B* within *A*, and an interaction effect of a covariate *X* with a factor *A*.

UPDATE

```
UPDATE FILE={master file}
            {*          }

 [/RENAME=(old varnames=new varnames)...]

 [/IN=varname]

  /FILE={transaction file1}
        {*                 }

 [/FILE=transaction file2]

  /BY key variables

 [/MAP]

 [/KEEP={ALL**  }] [/DROP=varlist]
        {varlist}
```

**Default if the subcommand is omitted.

Example

```
UPDATE FILE='/data/maillist.sav'
  /FILE='/data/newlist.sav'
  /BY=ID.
```

Overview

UPDATE replaces values in a master file with updated values recorded in one or more files called transaction files. Cases in the master file and transaction file are matched according to a key variable.

The master file and the transaction files must be SPSS-format data files or datasets available in the current session, including the active dataset. UPDATE replaces values and creates a new active dataset, which replaces the original active dataset.

UPDATE is designed to update values of existing variables for existing cases. Use MATCH FILES to add new variables to an SPSS-format data file and ADD FILES to add new cases.

Options

Variable Selection. You can specify which variables from each input file are included in the new active dataset using the DROP and KEEP subcommands.

Variable Names. You can rename variables in each input file before combining the files using the RENAME subcommand. This permits you to combine variables that are the same but whose names differ in different input files, or to separate variables that are different but have the same name.

Variable Flag. You can create a variable that indicates whether a case came from a particular input file using IN. You can use the FIRST or LAST subcommand to create a variable that flags the first or last case of a group of cases with the same value for the key variable.

Variable Map. You can request a map showing all variables in the new active dataset, their order, and the input files from which they came using the MAP subcommand.

Basic Specification

The basic specification is two or more FILE subcommands and a BY subcommand.

- The first FILE subcommand must specify the master file. All other FILE subcommands identify the transaction files.
- BY specifies the key variables.
- All files must be sorted in ascending order by the key variables.
- By default, all variables from all input files are included in the new active dataset.

Subcommand Order

- The master file must be specified first.
- RENAME and IN must immediately follow the FILE subcommand to which they apply.
- BY must follow the FILE subcommands and any associated RENAME and IN subcommands.
- MAP, DROP, and KEEP must be specified after all FILE and RENAME subcommands.

Syntax Rules

- BY can be specified only once. However, multiple variables can be specified on BY. All files must be sorted in ascending order by the key variables named on BY.
- The master file cannot contain duplicate values for the key variables.
- RENAME can be repeated after each FILE subcommand and applies only to variables in the file named on the immediately preceding FILE subcommand.
- MAP can be repeated as often as needed.

Operations

- UPDATE reads all input files named on FILE and builds a new active dataset that replaces active dataset. The new active dataset is built when the data are read by one of the procedure commands or the EXECUTE, SAVE, or SORT CASES command.
- The new active dataset contains complete dictionary information from the input files, including variable names, labels, print and write formats, and missing-value indicators. The new active dataset also contains the documents from each input file, unless the DROP DOCUMENTS command is used.
- UPDATE copies all variables in order from the master file, then all variables in order from the first transaction file, then all variables in order from the second transaction file, and so on.
- Cases are updated when they are matched on the BY variable(s). If the master and transaction files contain common variables for matched cases, the values for those variables are taken from the transaction file, provided that the values are not missing or blanks. Missing or blank values in the transaction files are not used to update values in the master file.

- When UPDATE encounters duplicate keys within a transaction file, it applies each transaction sequentially to that case to produce one case per key value in the resulting file. If more than one transaction file is specified, the value for a variable comes from the last transaction file with a nonmissing value for that variable.
- Variables that are in the transaction files but not in the master file are added to the master file. Cases that do not contain those variables are assigned the system-missing value (for numerics) or blanks (for strings).
- Cases that are in the transaction files but not in the master file are added to the master file and are interleaved according to their values for the key variables.
- If the active dataset is named as an input file, any N and SAMPLE commands that have been specified are applied to the active dataset before files are combined.
- The TEMPORARY command cannot be in effect if the active dataset is used as an input file.

Limitations

- A maximum of one BY subcommand. However, BY can specify multiple variables.

Examples

Basic Example

```
UPDATE FILE='/data/mailist.sav'
  /FILE='/data/newlist.sav'
  /BY=ID.
```

- *mailist.sav* is specified as the master file. *newlist.sav* is the transaction file. *ID* is the key variable.
- Both *mailist.sav* and *newlist.sav* must be sorted in ascending order of *ID*.
- If *newlist.sav* has cases or nonmissing variables that are not in *mailist.sav*, the new cases or variables are added to the resulting file.

Using Multiple Key Variables

```
SORT CASES BY LOCATN DEPT.
UPDATE  FILE='/data/master.sav' /FILE=* /BY LOCATN DEPT
  /KEEP AVGHOUR AVGRAISE LOCATN DEPT SEX HOURLY RAISE /MAP.
SAVE OUTFILE='/data/personnel.sav'.
```

- SORT CASES sorts the active dataset in ascending order of the variables to be named as key variables on UPDATE.
- UPDATE specifies *master.sav* as the master file and the sorted active dataset as the transaction file. The file *master.sav* must also be sorted by *LOCATN* and *DEPT*.
- BY specifies the key variables *LOCATN* and *DEPT*.
- KEEP specifies the subset and order of variables to be retained in the resulting file.
- MAP provides a list of the variables in the resulting file and the two input files.
- SAVE saves the resulting file as an SPSS-format data file.

FILE Subcommand

FILE identifies each input file. At least two FILE subcommands are required on UPDATE: one specifies the master file and the other a transaction file. A separate FILE subcommand must be used to specify each transaction file.

- The first FILE subcommand must specify the master file.
- An asterisk on FILE refers to the active dataset.
- The files must be SPSS-format data files or datasets available in the current session. File specifications should be enclosed in quotes.
- All files must be sorted in ascending order according to the variables specified on BY.
- The master file cannot contain duplicate values for the key variables. However, transaction files can and often do contain cases with duplicate keys (see "Operations").

Text Data Files

You can update data from text data files — or from any data format that SPSS can read — using defined datasets.

Example

```
DATA LIST FILE='/data/update.txt'
  ID 1-3 NAME 5-17 (A) ADDRESS 19-28 (A) ZIP 30-34.
SORT CASES BY ID.
DATASET NAME updatefile.
GET FILE='/maillist.sav'.
SORT CASES BY ID.
DATASET NAME=masterfile.
UPDATE FILE='masterfile'
 /RENAME=(STREET=ADDRESS)
 /FILE='updatefile'
 /BY=ID /MAP.
```

BY Subcommand

BY specifies one or more identification, or key, variables that are used to match cases between files.

- BY must follow the FILE subcommands and any associated RENAME and IN subcommands.
- BY specifies the names of one or more key variables. The key variables must exist in all input files and have the same names in all of the files. The key variables can be string variables (long strings are allowed).
- All input files must be sorted in ascending order of the key variables. If necessary, use SORT CASES before UPDATE.
- Missing values for key variables are handled like any other values.
- The key variables in the master file must identify unique cases. If duplicate cases are found, the program issues an error and UPDATE is not executed. The system-missing value is treated as one single value.

RENAME Subcommand

RENAME renames variables on the input files *before* they are processed by UPDATE. RENAME must follow the FILE subcommand that contains the variables to be renamed.

- RENAME applies only to the immediately preceding FILE subcommand. To rename variables from more than one input file, specify a RENAME subcommand after each FILE subcommand.
- Specifications for RENAME consist of a left parenthesis, a list of old variable names, an equals sign, a list of new variable names, and a right parenthesis. The two variable lists must name or imply the same number of variables. If only one variable is renamed, the parentheses are optional.
- More than one rename specification can be specified on a single RENAME subcommand, each enclosed in parentheses.
- The TO keyword can be used to refer to consecutive variables in the file and to generate new variable names.
- RENAME takes effect immediately. Any KEEP and DROP subcommands entered prior to a RENAME must use the old names, while KEEP and DROP subcommands entered after a RENAME must use the new names.
- All specifications within a single set of parentheses take effect simultaneously. For example, the specification RENAME (A,B = B,A) swaps the names of the two variables.
- Variables cannot be renamed to scratch variables.
- Input SPSS-format data files are not changed on disk; only the copy of the file being combined is affected.

Example

```
UPDATE FILE='/data/master.sav' /FILE=CLIENTS
  /RENAME=(TEL_NO, ID_NO = PHONE, ID)
  /BY ID.
```

- UPDATE updates the master phone list by using current information from the file *CLIENTS*.
- Two variables on *CLIENTS* are renamed prior to the match. *TEL_NO* is renamed *PHONE* to match the name used for phone numbers in the master file. *ID_NO* is renamed *ID* so that it will have the same name as the identification variable in the master file and can be used on the BY subcommand.
- The old variable names are listed before the equals sign, and the new variable names are listed in the same order after the equals sign. The parentheses are required.
- The BY subcommand matches cases according to client ID numbers.

DROP and KEEP Subcommands

DROP and KEEP are used to include a subset of variables in the resulting file. DROP specifies a set of variables to exclude, and KEEP specifies a set of variables to retain.

- DROP and KEEP do not affect the input files on disk.
- DROP and KEEP must follow all FILE and RENAME subcommands.

- DROP and KEEP must specify one or more variables. If RENAME is used to rename variables, specify the new names on DROP and KEEP.
- DROP cannot be used with variables created by the IN subcommand.
- The keyword ALL can be specified on KEEP. ALL must be the last specification on KEEP, and it refers to all variables not previously named on KEEP.
- KEEP can be used to change the order of variables in the resulting file. With KEEP, variables are kept in the order in which they are listed on the subcommand. If a variable is named more than once on KEEP, only the first mention of the variable is in effect; all subsequent references to that variable name are ignored.
- Multiple DROP and KEEP subcommands are allowed. Specifying a variable that is not in the active dataset or that has been dropped because of a previous DROP or KEEP subcommand results in an error and the UPDATE command is not executed.

Example

```
UPDATE FILE='/data/mailist.sav' /FILE='/data/newlist.sav' /RENAME=(STREET=ADDRESS)
  /BY ID /KEEP=NAME ADDRESS CITY STATE ZIP ID.
```

- KEEP specifies the variables to keep in the result file. The variables are stored in the order specified on KEEP.

IN Subcommand

IN creates a new variable in the resulting file that indicates whether a case came from the input file named on the preceding FILE subcommand. IN applies only to the file specified on the immediately preceding FILE subcommand.

- IN has only one specification, the name of the flag variable.
- The variable created by IN has the value 1 for every case that came from the associated input file and the value 0 if the case came from a different input file.
- Variables created by IN are automatically attached to the end of the resulting file and cannot be dropped.

Example

```
UPDATE  FILE=WEEK10 /FILE=WEEK11 /IN=INWEEK11 /BY=EMPID.
```

- IN creates the variable *INWEEK11*, which has the value 1 for all cases in the resulting file that came from the input file *WEEK11* and the value 0 for those cases that were not in file *WEEK11*.

MAP Subcommand

MAP produces a list of the variables in the new active dataset and the file or files from which they came. Variables are listed in the order in which they appear in the resulting file. MAP has no specifications and must be placed after all FILE, RENAME, and IN subcommands.

- Multiple MAP subcommands can be used. Each MAP shows the current status of the active dataset and reflects only the subcommands that precede the MAP subcommand.

- To obtain a map of the resulting file in its final state, specify `MAP` last.
- If a variable is renamed, its original and new names are listed. Variables created by `IN` are not included in the map, since they are automatically attached to the end of the file and cannot be dropped.

USE

```
USE [{start date       }] [THRU [{end date       }]]
     {start case number}         {end case number}
     {FIRST            }         {LAST           }

    [ALL]
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Example

```
USE Y 1960.
```

Overview

USE designates a range of observations to be used with time series procedures.

Basic Specification

The basic specification is either the start of the range, the end of the range, or both. You can also simply specify the keyword THRU or ALL.

- The default start is the first observation in the file, and the default end is the last observation.
- The keyword THRU is required if the end of the range is specified.
- The keyword ALL defines a USE range starting with the first observation and ending with the last observation in the series. It can be specified to restore processing to the entire series.
- The keyword THRU by itself is the same as specifying the keyword ALL.

Operations

- USE is ignored by the utility procedures CREATE and RMV. These procedures process all of the available data.
- The DATE command turns off all existing USE and PREDICT specifications.
- FILTER and USE are mutually exclusive. USE automatically turns off any previous FILTER command, and FILTER automatically turns off any previous USE command.
- USE remains in effect in a session until it is changed by another USE command or until a new DATE or FILTER command is issued.
- Any data selection specified on USE is in effect until the next USE command, the next DATE command, or the end of the session. SPSS-format data files are not affected by the USE command.

Limitations

- A maximum of one range (one start and/or one end) can be specified.

Syntax Rules

- The start and end can be specified as either DATE specifications or case (observation) numbers.
- DATE specifications and case numbers cannot be mixed on a USE command.
- Any observation within the file can be used as the start or end as long as the starting observation comes before the end observation.

DATE Specifications

- A DATE specification consists of DATE keywords and values (see DATE). These specifications must correspond to existing DATE variables.
- If more than one DATE variable exists, the highest-order one must be used in the specification.
- Values on the keyword YEAR must have the same format (two or four digits) as the YEAR specifications on the DATE command.

Case Specifications

- The case number specification is the sequence number of the case (observation) as it is read by the program.

Keywords FIRST and LAST

- The start can also be specified with the keyword FIRST, and the end, with the keyword LAST. These keywords designate the first and last cases in the file, respectively.
- The keywords FIRST and LAST can be used along with either DATE or case specifications.

Examples

```
USE ALL.
```

- This command includes all observations in the file in the USE range.
- This specification is the same as USE THRU or USE FIRST THRU LAST.

```
USE Y 1960.
```

- This command selects observations starting with a *YEAR_* value of 1960 through the last observation in the file. It is equivalent to USE Y 1960 THRU LAST.

```
USE THRU D 5.
```

- This command selects all cases from the first case in the file to the last one with a *DAY_* value of 5. It is equivalent to USE FIRST THRU D 5.

```
USE THRU 5.
```

- This command selects cases starting with the first case and ending with the fifth case.

```
USE Y 1955 M 6 THRU Y 1960 M 6.
```

- This selects cases from June, 1955, through June, 1960.

```
USE W 16 D 3 THRU W 48 D 3.
```

- This example selects cases from day 3 of week 16 through day 3 of week 48.

```
USE CYCLE 2 OBS 4 THRU CYCLE 2 OBS 17.
```

- This example selects observations 4 through 17 of the second cycle.

VALIDATEDATA

VALIDATEDATA is available in the Data Preparation option.

```
VALIDATEDATA        [VARIABLES=varlist]
                    [ID=varlist]
                    [CROSSVARRULES=rulelist]
 [/VARCHECKS        [STATUS={ON**}]
                            {OFF }
                    [PCTMISSING={70**   }]
                                {number }
                    [PCTEQUAL={95**  }]
                              {number}
                    [PCTUNEQUAL={90**  }]
                                {number}
                    [CV={0.001**}]
                        {number }
                    [STDDEV={0**   }]]
                            {number}
 [/IDCHECKS         [INCOMPLETE**] [DUPLICATE**] [NONE]]
 [/CASECHECKS       [REPORTEMPTY={YES**}] [SCOPE={ANALYSISVARS}]]
                              {NO   }          {ALLVARS     }
 [/RULESUMMARIES    [BYVARIABLE**] [BYRULE] [NONE]]
 [/CASEREPORT       DISPLAY={YES**}
                            {NO   }
                    [MINVIOLATIONS={1**    }]
                                   {integer}
                    [CASELIMIT={FIRSTN({500**  })}]]
                                       {integer}
                               {NONE             }
 [/SAVE             [EMPTYCASE[(varname)]]
                    [INCOMPLETEID[(varname)]]
                    [DUPLICATEID[(varname)]]
                    [RULEVIOLATIONS[(varname)]]]
```

** Default if the subcommand or keyword is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Release History

Release 14.0

- Command introduced.

Example

```
VALIDATEDATA VARIABLES=ALL.
```

Overview

The VALIDATEDATA procedure identifies suspicious and invalid cases, variables, and data values in the active dataset.

The procedure can summarize two types of validation rules. Single-variable rules consist of a fixed set of checks that are applied to individual data values, such as range checks. Cross-variable rules are user-specified rules that typically examine combinations of data values for two or more variables.

Options

Analysis Variables. The procedure can identify variables that have a high proportion of missing values as well as variables that are constant (or nearly so). You can set the maximum acceptable percentage of missing values as well as thresholds for considering categorical and scale variables as constants.

Case Identifiers. The procedure can identify incomplete and duplicate case identifiers. A single variable or a combination of variables can be treated as the identifier for a case.

Cases. The procedure can identify empty cases. A case can be regarded as empty if all analysis variables are blank or missing or all non-ID variables are blank or missing.

Single-Variable Rules. Single-variable validation rules can be summarized by variable and rule. Single-variable rules are defined using the `DATAFILE ATTRIBUTE` command and are linked to analysis variables using the `VARIABLE ATTRIBUTE` command.

Cross-Variable Rules. The procedure can summarize violations of cross-variable validation rules. Cross-variable rules are defined using the `DATAFILE ATTRIBUTE` command.

Saved Variables. You can save variables that identify suspicious cases and values in the active dataset.

Basic Specification

- The minimum specification is a list of analysis variables, case identifier variables, or cross-variable rules.
- By default, if you specify analysis variables, the procedure reports all analysis variables that have a high proportion of missing values, as well as analysis variables that are constant or nearly so. If single-variable validation rules are defined for analysis variables, the procedure reports rule violations for each variable.
- By default, if case identifier variables are specified, the procedure reports all incomplete and duplicate case identifiers.
- If you specify cross-variable rules, the procedure reports the total number of cases that violated each rule.
- If you specify single-variable or cross-variable rules, a casewise report is shown that lists the first 500 cases that violated at least one validation rule.
- Empty cases are identified by default.

Syntax Rules

- Each subcommand is global and can be used only once.
- Subcommands can be used in any order.
- An error occurs if a keyword or attribute is specified more than once within a subcommand.

- Equals signs and slashes shown in the syntax chart are required.
- Subcommand names and keywords must be spelled out in full.
- Empty subcommands generate a procedure error.

Operations

- The procedure honors `SPLIT FILE` specifications. Split variables are filtered out of all variable lists.
- The procedure treats user- and system-missing values as missing values.
- An error occurs if no procedure output is requested.

Limitations

- The weight variable, if specified, is ignored with a warning.

Validation Rules

- `VALIDATEDATA` ignores invalid rules and links with a warning.
- If an analysis variable is linked to multiple rules, `VALIDATEDATA` applies the rules independently; it does not check for conflicts or redundancies among the constituent rules.
- A rule outcome variable must be associated with each rule that indicates which cases violated the rule. Outcome variables are created outside the `VALIDATEDATA` procedure and should be coded such that 1 indicates an invalid value or combination of values and 0 indicates a valid value.
- An error occurs if the same outcome variable is referenced by two or more rules.
- Values of all outcome variables are assumed to be current with respect to the active dataset.

Examples

Default Analysis Variable Validation

```
VALIDATEDATA VARIABLES=ALL.
```

- The only specification is a list of analysis variables (all variables in the active dataset).
- The procedure reports all variables with a high proportion of missing values, as well as variables that are constant or nearly so.
- In addition, empty cases are identified.

Default Case Identifier Variable Validation

```
VALIDATEDATA ID=Firstname Lastname.
```

- Two case identifier variables are specified.
- By default, the procedure reports cases having incomplete or duplicate case identifiers. The combination of *Firstname* and *Lastname* values is treated as a case identifier.
- In addition, empty cases are identified.

Non-Default Analysis and Case Identifier Variable Validation

```
VALIDATEDATA VARIABLES=Satis1 Satis2 Satis3
            ID=Firstname Lastname
 /VARCHECKS STATUS=ON PCTMISSING=30
 /IDCHECKS DUPLICATE
 /SAVE EMPTYCASE.
```

- Three ordinal satisfaction variables (*Satis1*, *Satis2*, *Satis3*) are specified as analysis variables.
- ID specifies two case identifier variables, *Firstname* and *Lastname*.
- VARCHECKS reports analysis variables with more than 30% missing values. By default, the procedure also reports categorical analysis variables if more than 95% of their cases fall into a single category.
- IDCHECKS reports cases that have duplicate case identifiers and turns off the default check for incomplete case identifiers.
- Empty cases are identified by default.
- SAVE saves a variable to the active dataset that indicates which cases are empty.

Using Single-Variable Validation Rules

```
DATAFILE ATTRIBUTE
 ATTRIBUTE=$VD.SRule[1] ("Label='Likert 1 to 5',"+
                         "Description='Likert 5-point scale',"+
                         "Type='Numeric',"+
                         "Domain='Range',"+
                         "FlagUserMissing='No',"+
                         "FlagSystemMissing='No',"+
                         "FlagBlank='No',"+
                         "Minimum='1',"+
                         "Maximum='5',"+
                         "FlagNoninteger='Yes'").

COMPUTE Likert1to5_Satis_=NOT(Satis LE 5 AND Satis GE 1 AND
                              Satis=TRUNC(Satis)).
VARIABLE ATTRIBUTE
  VARIABLES= Likert1to5_Satis_
  ATTRIBUTE=$VD.RuleOutcomeVar("Yes").

VARIABLE ATTRIBUTE
  VARIABLES=Satis
  ATTRIBUTE=$VD.SRuleRef[1]("Rule='$VD.SRule[1]',"+
                            "OutcomeVar='Likert1to5_Satis_'").

VALIDATEDATA VARIABLES=Satis
 /CASEREPORT DISPLAY=YES CASELIMIT=NONE
 /SAVE RULEVIOLATIONS.
```

- DATAFILE ATTRIBUTE defines a single-variable validation rule named *$VD.SRule[1]*. The rule flags any value that is not an integer within the range 1 to 5.
- The first VARIABLE ATTRIBUTE command links the rule to the variable *Satis*. It also references an outcome variable where 1 indicates an invalid value for the variable *Satis*.
- COMPUTE creates the rule outcome variable.
- The second VARIABLE ATTRIBUTE command marks *Likert1to5_Satis_* as an outcome variable in the data dictionary.

- VALIDATEDATA specifies *Satis* as an analysis variable. In addition to performing default checks for constants, variables with a large proportion of missing values, and empty cases, the procedure summarizes violations of single-variable validation rules defined for *Satis*.
- CASEREPORT reports all cases having a rule violation.
- SAVE saves a variable to the active dataset that indicates the total number of validation rule violations per case.

Using Cross-Variable Validation Rules

```
DATAFILE ATTRIBUTE
 ATTRIBUTE=$VD.CRule[1]("Label='Pregnant Male',"+
                        "Expression='Sex =''Male'' AND Pregnant ''Yes'''',"+
                        "OutcomeVar='PregnantMale_'").

COMPUTE PregnantMale_= Sex ='Male' AND Pregnant = 'Yes'.
VARIABLE ATTRIBUTE
  VARIABLES=PregnantMale_
  ATTRIBUTE=$VD.RuleOutcomeVar("Yes").

VALIDATEDATA CROSSVARRULES=$VD.CRule[1]
 /CASECHECKS REPORTEMPTY=NO.
```

- DATAFILE ATTRIBUTE defines the cross-variable rule *$VD.CRule[1]*.
- COMPUTE creates the outcome variable *PregnantMale_* referenced by the cross-variable rule. For *PregnantMale_* , values of 1 identify cases containing males coded as being pregnant.
- VARIABLE ATTRIBUTE marks *PregnantMale_* as an outcome variable in the data dictionary.
- VALIDATEDATA specifies *$VD.CRule[1]* as a cross-variable rule to be summarized. The procedure reports the total number of pregnant males in the active dataset.
- CASECHECKS turns off the default check for empty cases.
- By default, the first 500 cases that violated at least one validation rule are listed.

Variable Lists

You must specify VARIABLES, ID, or CROSSVARRULES.

VARIABLES Keyword

The VARIABLES list specifies analysis variables to be validated.

- Specify one or more analysis variables. ALL and TO can be used to refer to all variables or a range of variables, respectively.
- Repeated instances of the same variable are filtered out of the list.
- Rule outcome variables are filtered out of the list.

ID Keyword

The ID list specifies case ID variables to be validated. ID variables are also used to label casewise output.

- Specify one or more variables. If two or more ID variables are specified, the combination of their values is treated as a case identifier.
- Repeated instances of the same variable are filtered out of the list.
- Rule outcome variables are filtered out of the list.

CROSSVARRULES Keyword

The CROSSVARRULES keyword specifies cross-variable rules to be summarized.

- Specify one or more cross-variable rules of the form *$VD.CRule[n]*, where *n* is a positive integer. Alternatively, you can provide a list of integers, where 1 means *$VD.CRule[1]*, 2 means *$VD.CRule[2]*, etc.
- The list accepts the keyword ALL, which signifies all cross-variable rules recorded in the data dictionary.
- Repeated instances of the same rule are filtered out of the list.
- A warning occurs if a specified rule does not exist. The rule is ignored.

VARCHECKS Subcommand

The VARCHECKS subcommand specifies checks to be performed on analysis variables. The subcommand is ignored if no analysis variables are defined.

STATUS *Perform variable checks.* By default, variable checks are performed. To turn off variable checks, specify STATUS=NO; any other VARCHECKS keywords are then ignored.

PCTMISSING *Maximum percentage of missing values.* Reports analysis variables with a percentage of missing values greater than the specified value. The specified value must be a positive number less than or equal to 100. The default value is 70.

PCTEQUAL *Maximum percentage of cases representing a single category.* Reports categorical analysis variables with a percentage of cases representing a single nonmissing category greater than the specified value. The specified value must be a positive number less than or equal to 100. The default value is 95. The percentage is based on cases with nonmissing values of the variable. PCTEQUAL is ignored if no categorical analysis variables are specified.

PCTUNEQUAL *Percentage of categories containing only one case in a categorical variable.* If the percentage of an analysis variable's categories containing only one case is greater than the specified value, the variable is reported. The specified value must be a positive number less than or equal to 100. The default value is 90. PCTUNEQUAL is ignored if no categorical analysis variables are specified.

CV *Minimum absolute coefficient of variation.* A variable's coefficient of variation is defined as its standard deviation divided by its mean. If the absolute value of the coefficient of variation is less than the specified value, the variable is reported.

This setting applies only to continuous predictors and only if the mean is non-zero. The specified value must be a non-negative number. Specifying 0 turns off the coefficient of variation check. The default value is 0.001. CV is ignored if no scale analysis variables are specified.

STDDEV *Minimum standard deviation.* Reports variables whose standard deviation is less than the specified value. This setting applies only to scale analysis variables. The specified value must be a non-negative number. The default value is 0, which, in effect, turns off the standard deviation check. STDDEV is ignored if no scale analysis variables are specified.

IDCHECKS Subcommand

The IDCHECKS subcommand specifies checks to be performed on case identifiers. The subcommand is ignored if no ID variables are specified.

INCOMPLETE *Incomplete case identifiers.* Reports cases with incomplete case identifiers. For a particular case, an identifier is considered incomplete if the value of any ID variable is blank or missing. Default.

DUPLICATE *Duplicate case identifiers.* Reports cases with duplicate case identifiers. Incomplete identifiers are excluded from the set of possible duplicates. Default.

NONE *Case identifiers are not validated.*

CASECHECKS Subcommand

The CASECHECKS subcommand specifies checks to be performed on cases in the active dataset.

REPORTEMPTY Keyword

Empty cases are identified by default. To turn off the check for empty cases, specify REPORTEMPTY=NO.

SCOPE Keyword

The SCOPE keyword controls which variables are considered when the procedure determines whether a case is empty. SCOPE is ignored if REPORTEMPTY=NO.

ANALYSISVARS *Procedure considers analysis variables only.* A case is considered empty if values of all analysis variables are blank or missing. This is the default if analysis variables are specified. ANALYSISVARS is ignored if no analysis variables are specified.

ALLVARS *Procedure considers all variables.* A case is regarded as empty if all variables in the active dataset are blank or missing. This is the default if no analysis variables are specified. ID variables, split file variables, and rule outcome variables are always disregarded when determining whether a case is empty.

RULESUMMARIES Subcommand

The RULESUMMARIES subcommand is used to summarize violations of single-variable validation rules.

- By default, single-variable rule violations are summarized by analysis variable.

- Cross-variable validation rules are always summarized by rule.
- RULESUMMARIES generates a warning if summaries are requested but single-variable validation rules are not defined for at least one analysis variable.

BYVARIABLE	*Summarize by variable.* For each analysis variable, shows all single-variable validation rules that were violated and the number of values that violated each rule. Also reports the total number of single-variable rule violations for each variable. This is the default.
BYRULE	*Summarize by rule.* For each single-variable validation rule, reports variables that violated the rule and the number of invalid values per variable. Also reports the total number of values that violated each rule across variables.
NONE	*No summaries are produced for single-variable rules.* An error occurs if NONE is specified along with any other RULESUMMARIES keyword.

CASEREPORT Subcommand

The CASEREPORT subcommand is used to obtain a report that lists validation rule violations for individual cases.

- The case report includes violations of single-variable and cross-variable rules.
- CASEREPORT is ignored if no single-variable or cross-variable rules are applied.

DISPLAY Keyword

- The case report is shown by default. To turn off the report, specify DISPLAY=NO.
- If you specify a case identifier, it is used to label cases in the report. Cases are also identified by case number.

MINVIOLATIONS Keyword

- MINVIOLATIONS specifies the minimum number of rule violations required for a case to be included in the report. Specify a positive integer.
- The default is 1 violation.
- MINVIOLATIONS is ignored if DISPLAY=NO.

CASELIMIT Keyword

- The CASELIMIT keyword specifies the maximum number of cases included in the case report. By default the maximum is 500.
- To change the maximum number of cases in the report, specify FIRSTN followed by a positive integer in parentheses.
- NONE turns off the case limit. All cases that meet the MINVIOLATIONS threshold are reported.
- CASELIMIT is ignored if DISPLAY=NO.

SAVE Subcommand

The SAVE subcommand specifies optional variables to save. Specify one or more keywords, each followed by an optional variable name.

- The name, if specified, must be enclosed in parentheses—for example, `EMPTYCASE(Empty)`—and must be a valid variable name.
- If you do not specify a variable name, the procedure uses a default name.
- If the default name is used and it conflicts with that of an existing variable, a suffix is added to make the name unique.
- If you specify a name and it conflicts with that of an existing variable, an error occurs.

EMPTYCASE	*Empty case indicator.* Empty cases are assigned the value 1. All other cases are coded 0. The default rootname is *EmptyCase*. Values of `EMPTYCASE` reflect the scope specified via the `CASECHECKS` subcommand.
INCOMPLETEID	*Incomplete ID indicator.* Cases with empty or incomplete case identifiers are assigned a value 1. All other cases are coded 0. The default rootname is *IncompleteID*.
DUPLICATEID	*Duplicate ID group.* Cases that have the same case identifier (other than cases with incomplete identifiers) are assigned the same group number. Cases with unique or incomplete identifiers are coded 0. The default rootname is *DuplicateIDGroup*.
RULEVIOLATIONS	*Total count of single-variable and cross-variable validation rule violations.* The default rootname is *ValidationRuleViolations*. Ignored if no single-variable or cross-variable validation rules are applied.

Single-Variable Validation Rules

To use a single-variable validation rule with the `VALIDATEDATA` procedure requires:

1. A rule definition (using the `DATAFILE ATTRIBUTE` command).

Defining a Single-Variable Validation Rule

Single-variable validation rules are attributes of the data file and are generally defined according to the following syntax diagram:

```
DATAFILE ATTRIBUTE
  ATTRIBUTE=$VD.SRule[n]("Label='value',"+
                         "Description='value',"+
                         "Type='{Numeric}',"+
                                {String }
                                {Date   }
                         "Format='dateformat'"+
                         "Domain='{Range}',"+
                                  {List }
                         "FlagUserMissing='{Yes}'"+
                                           {No }
                         "FlagSystemMissing='{Yes}'"+
                                            {No }
                         "FlagBlank='{Yes}'"+
                                    {No }

  -- when Domain='Range' --
                         "Minimum='value',"+
                         "Maximum='value',"+
                         "FlagUnlabeled='{Yes}'"+
                                        {No }
                         "FlagNoninteger='{Yes}'"+
                                         {No }
```

```
-- when Domain='List' --
                        "List='value1' 'value2' ... 'valuen'"+
                        "CaseSensitive='{Yes}'"+
                                       {No }
                        ").
```

- Single-variable rule attribute names must be of the form *$VD.SRule[n]*, where *n* is a positive integer.
- Each rule specification includes a comma-separated list of properties that define the rule. Except where noted in the following table, each property is required. The order in which properties appear does not matter. Unrecognized rule properties are ignored. If the same property appears more than once in a rule specification, the value for the last one is honored.

Table 240-1
Properties for single-variable rule attributes

Label	The label is text that uniquely identifies the rule among single-variable and cross-variable rules. It cannot be the null string. Leading and trailing blanks are trimmed for the purpose of determining the uniqueness of the label.
Description	Any text (optional).
Type	This is the type of variable to which the rule can be applied. Select from Numeric, String, and Date. It is used by `VALIDATEDATA` to ensure that the rule is internally consistent and appropriate for the variable to which it is applied.
Format	This allows you to select the date format for rules that can be applied to date variables. Specify any SPSS date or time format. For more information, see Date and Time Formats on p. 58. This property is not required if *Type* is not *Date*.
FlagUserMissing	Controls whether user-missing values are flagged as invalid. Specify *Yes* or *No*.
FlagSystemMissing	Controls whether system-missing values are flagged as invalid. This does not apply to string rule types. Specify *Yes* or *No*.
FlagBlank	Controls whether blank—that is, completely empty—string values are flagged as invalid. This does not apply to non-string rule types. Specify *Yes* or *No*.
Domain	You can specify the valid values either as a *Range* or a *List* of values. "Range" properties are ignored if `Domain='List'`, and "List" properties are ignored if `Domain='Range'`.
Minimum	This property is optional**. Its value must be consistent with the rule type and format and be less than or equal to *Maximum*. The value is ignored if null. It cannot have a noninteger value if `FlagNoninteger='Yes'`.
Maximum	This property is optional**. Its value must be consistent with the rule type and format and be greater than or equal to *Minimum*. The value is ignored if null. It cannot have a non-integer value if `FlagNoninteger='Yes'`.
FlagUnlabeled	Controls whether unlabeled values are flagged as invalid. Specify *Yes* or *No*.
FlagNoninteger	Controls whether non-integer values are flagged as invalid. Specify *Yes* or *No*.
List	Specify one or more values consistent with the rule type and format. Null strings are ignored. Each item in the list must be quoted.
CaseSensitive	Controls whether case matters when string data values are checked against the list of acceptable values. Specify *Yes* or *No*.

** Range properties are optional if `Domain='Range'`. However, if `Domain='Range'` and *FlagUserMissing*, *FlagSystemMissing*, and *FlagBlank* are all set to *No*, then *Minimum* or *Maximum* must be specified or *FlagUnlabeled* or *FlagNoninteger* must be *Yes*. Otherwise, no values would be validated when the rule is applied.

2. A rule outcome variable (using COMPUTE and VARIABLE ATTRIBUTE).

Creating a Rule Outcome Variable

Rule outcome variables are generated to validate values of variables and are generally defined according to the following syntax diagram:

```
COMPUTE outcomevar1=expression for analysisvar1.
COMPUTE outcomevar2=...

VARIABLE ATTRIBUTE
  VARIABLES=outcomevarlist
  ATTRIBUTE=$VD.RuleOutcomeVar("Yes").
```

- The COMPUTE expression for each outcome variable should generate the value 1 for invalid cases of a variable, according to the associated single-variable rule definition.
- The rule outcome variable is marked as such using the VARIABLE ATTRIBUTE command. Rule outcome variable attribute names must be *$VD.RuleOutcomeVar* with the property *Yes*.

3. A link between the analysis and outcome variable (using VARIABLE ATTRIBUTE).

Linking Analysis and Outcome Variables

Single-variable rule links are attributes of the analysis variables and are generally defined according to the following syntax diagram:

```
VARIABLE ATTRIBUTE
  VARIABLES=analysisvar1
  ATTRIBUTE=$VD.SRuleRef[n]("Rule='$VD.SRule[n]',"+
                            "OutcomeVar='outcomevar1'")
  /VARIABLES=analysisvar2...
```

- Single-variable rule link attribute names must be of the form *$VD.SRuleRef[n]*, where *n* is a positive integer.
- The *Rule* and *OutcomeVar* properties are required. The order in which they appear does not matter. Unrecognized rule properties are ignored. If the same property appears more than once in a rule specification, the value for the last one is honored.

Table 240-2
Properties for single-variable rule link attributes

Rule	An existing single-variable validation rule whose *Type* property is consistent with that of the variable to which it is linked. String rules can be applied to string variables.
Outcomevar	A rule outcome variable associated with the analysis variable.

Cross-Variable Validation Rules

To use a cross-variable validation rule with the VALIDATEDATA procedure requires:

1. A rule definition (using the DATAFILE ATTRIBUTE command).

Creating a Rule Definition

Cross-variable validation rules are attributes of the data file and are generally defined according to the following syntax diagram:

```
DATAFILE ATTRIBUTE
 ATTRIBUTE=$VD.CRule[1]("Label='value',"+
                        "Expression='value'."+
                        "OutcomeVar='outcomevar'").
```

Cross-variable rule attribute names must be of the form *$VD.CRule[n]*, where *n* is a positive integer.

- Each rule specification includes a list of properties that define the rule. Each property is required. The order in which properties appear does not matter. Unrecognized rule properties are ignored. If the same property appears more than once in a rule specification, the value for the last one is honored.

Table 240-3
Properties for cross-variable rule attributes

Label	The label is text that uniquely identifies the rule among single-variable and cross-variable rules. It cannot be the null string. Leading and trailing blanks are trimmed for the purpose of determining the uniqueness of the label.
Expression	The expression must be valid command syntax for the right side of a COMPUTE statement. Any variables used in the expression must exist in the data file.
OutcomeVar	A rule outcome variable associated with the cross-variable rule.

2. A rule outcome variable (using COMPUTE and VARIABLE ATTRIBUTE).

Creating a Rule Outcome Variable

```
COMPUTE outcomevar = expression.

VARIABLE ATTRIBUTE
  VARIABLES=outcomevar
  ATTRIBUTE=$VD.RuleOutcomeVar("Yes").
```

- The COMPUTE expression for each outcome variable should generate the value 1 for invalid cases. It should be equivalent to the *Expression* in the cross-variable rule definition.
- The rule outcome variable is marked as such using the VARIABLE ATTRIBUTE command. Rule outcome variable attribute names must be *$VD.RuleOutcomeVar* with the property *Yes*.

VALUE LABELS

```
VALUE LABELS varlist value 'label' value 'label'... [/varlist...]
             [/datevarlist 'value' 'label'...]
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Release History

Release 14.0

- The maximum length of a value label is extended to 120 bytes (previous limit was 60 bytes).

Release 16.0

- Limitation preventing assignment of missing values to strings with a defined width greater than eight bytes removed.

Example

```
VALUE LABELS JOBGRADE 'P' 'Parttime Employee' 'C' 'Customer Support'.
```

Overview

`VALUE LABELS` deletes all existing value labels for the specified variable(s) and assigns new value labels. `ADD VALUE LABELS` can be used to add new labels or alter labels for specified values without deleting other existing labels.

Basic Specification

The basic specification is a variable name and the individual values with their assigned labels.

Syntax Rules

- Labels can be assigned to any previously defined variables.
- It is not necessary to enter value labels for all values for a variable.
- Each value label must be enclosed in quotes. For string variables, the values themselves must also be quotes.
- For date format variables (for example, `DATE`, `ADATE`), values expressed in date formats must be enclosed in quotes, and values must be expressed in the same date format as the defined date format for the variable.
- Value labels can contain any characters, including blanks. To enter an apostrophe as part of a label, enclose the label in double quotes or enter two apostrophes (two single quotes). For more information, see String Values in Command Specifications on p. 35.
- Each value label can be up to 120 bytes long.

- The same labels can be assigned to the values of different variables by specifying a list of variable names. For string variables, the variables specified must be of equal length.
- Multiple sets of variable names and value labels can be specified on one VALUE LABELS command as long as the sets are separated by slashes.
- To continue a label from one command line to the next, specify a plus (+) sign before the continuation of the label. Each string segment of the label must be enclosed in quotes. To insert a blank between the strings, the blank must be included in the label specification.
- To control line wrapping of labels in pivot tables and charts, insert \n as part of the label wherever you want a line break. The \n is not displayed in output; it is interpreted as a line-break character. (*Note*: Labels will *always* wrap wherever \n appears in the defined label even if there is enough space to display the label without wrapping.)

Operations

- Unlike most transformations, VALUE LABELS takes effect as soon as it is encountered in the command sequence. Thus, special attention should be paid to its position among commands. For more information, see Command Order on p. 36.
- VALUE LABELS deletes all previously assigned value labels for the specified variables.
- The value labels assigned are stored in the dictionary of the working file and are automatically displayed on the output from many procedures.
- If a specified value is longer than the format of the variable, the program will be unable to read the full value and may not be able to assign the value label correctly.
- If the value specified for a string variable is shorter than the format of the variable, the value specification is right-padded without warning.

Examples

Assigning Value Labels to Multiple Variables

```
VALUE LABELS V1 TO V3 1 'Officials & Managers'
                      6 'Service Workers'
                /V4 'N' 'New Employee'.
```

- Labels are assigned to the values 1 and 6 for the variables between and including *V1* and *V3* in the active dataset.
- Following the required slash, a label for the value *N* of *V4* is specified. *N* is a string value and must be enclosed in quotes.
- If labels exist for the values 1 and 6 on *V1* to *V3* and the value *N* on *V4*, they are changed in the dictionary of the working file. If labels do not exist for these values, new labels are added to the dictionary.
- Existing labels for values other than 1 and 6 on *V1* to *V3* and the value *N* on *V4* are deleted.

Combining Strings to Construct Value Labels

```
VALUE LABELS  OFFICE88 1 "EMPLOYEE'S OFFICE ASSIGNMENT PRIOR"
   + " TO 1988".
```

- The label for *OFFICE88* is created by combining two strings with the plus sign. The blank between PRIOR and TO must be included in the first or second string to be included in the label.

Value Labels for String Variables

```
VALUE LABELS=STATE REGION 'U' "UNKNOWN".
```

- The label *UNKNOWN* is assigned to the value *U* for both *STATE* and *REGION*.
- *STATE* and *REGION* must be string variables of equal length. If *STATE* and *REGION* have unequal lengths, a separate specification must be made for each, as in

```
VALUE LABELS STATE 'U' "UNKNOWN" / REGION 'U' "UNKNOWN".
```

Using Value Labels with DATA LIST

```
DATA LIST / CITY 1-8(A) STATE 10-12(A).
VALUE LABELS  STATE 'TEX' "TEXAS" 'TEN' "TENNESSEE"
                    'MIN' "MINNESOTA".
BEGIN DATA
AUSTIN   TEX
MEMPHIS  TEN
ST. PAUL MIN
END DATA.
FREQUENCIES VARIABLES=STATE.
```

- The DATA LIST command defines two variables. *CITY* is eight characters wide and *STATE* is three characters. The values are included between the BEGIN DATA and END DATA commands.
- The VALUE LABELS command assigns labels to three values of variable *STATE*. Each value and each label is specified in quotes.
- The format for the variable *STATE* must be at least three characters wide because the specified values, *TEX*, *TEN*, and *MIN*, are three characters. If the format for *STATE* were two characters, the program would issue a warning. This would occur even though the values named on VALUE LABELS and the values after BEGIN DATA agree.

Forcing Value Labels to Wrap

```
VALUE LABELS myvar 1 "A long value label \n that always wraps".
FREQUENCIES myvar.
```

Figure 241-1
Using \n to wrap value labels

A Fairly Long Label That Always Wraps

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	A long value label that always wraps	1	100.0	100.0	100.0

VARCOMP

VARCOMP is available in the Advanced Models option.

```
VARCOMP dependent variable BY factor list [WITH covariate list]

  /RANDOM = factor [factor ...]

 [/METHOD = {MINQUE({1})**}]
                   {0}
             {ML           }
             {REML         }
             {SSTYPE({3})  }
                     {1}

 [/INTERCEPT = {INCLUDE**}]
               {EXCLUDE    }

 [/MISSING = {EXCLUDE**}]
             {INCLUDE  }

 [/REGWGT = varname]

 [/CRITERIA = [CONVERGE({1.0E-8**})] [EPS({1.0E-8**})] [ITERATE({50**})]]
                        {n       }        {n       }             {n   }

 [/PRINT = [EMS] [HISTORY({1**})] [SS]]
                          {n  }

 [/OUTFILE = [VAREST] [{COVB}] ('savfile'|'dataset') ]
                       {CORB}

 [/DESIGN = {[INTERCEPT] [effect effect ...]}]
```

** Default if the subcommand or keyword is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
VARCOMP Y1 BY B C WITH X1 X2
 /RANDOM = C.
```

Overview

The VARCOMP procedure estimates variance components for mixed models. Following the general linear model approach, VARCOMP uses indicator variable coding to construct a design matrix and then uses one of the four available methods to estimate the contribution of each random effect to the variance of the dependent variable.

Options

Regression Weights. You can use the REGWGT subcommand to specify regression weights for the model.

Estimation Methods. You can use the METHOD subcommand to use one of the four methods that are available for estimating variance components.

Tuning the Algorithm. You can control the values of algorithm-tuning parameters with the CRITERIA subcommand.

Optional Output. You can request additional output using the PRINT subcommand.

Saving the Results. You can save the variance component estimates and their asymptotic covariance matrix (if produced) to an external data file.

Basic Specification

The basic specification is one dependent variable and one or more factor variables (that define the crosstabulation) and one or more factor variables on the RANDOM subcommand (to classify factors into either fixed or random factors). By default, VARCOMP uses the minimum norm quadratic unbiased estimator with unit prior weights to estimate variance components. Default output includes a factor-level information table and a variance component estimates table.

Subcommand Order

- The variable specification must come first.
- Other subcommands can be specified in any order.

Syntax Rules

- Only one dependent variable can be specified.
- At least one factor must be specified after BY.
- At least one factor must be specified on the RANDOM subcommand.

Example

```
VARCOMP
  amtspent  BY storeid   shopfor usecoup
  /RANDOM = storeid
  /METHOD = SSTYPE (3)
  /PRINT = SS
  /PRINT = EMS
  /DESIGN = shopfor usecoup shopfor*usecoup storeid
  /INTERCEPT = INCLUDE .
```

- The procedure fits a model to *amtspent* using *storeid*, *shopfor*, and *usecoup* as factors.
- RANDOM identifies *storeid* as a random effect.
- METHOD specifies ANOVA estimation using Type III sums of squares.
- PRINT requests tabular display of the sums of squares and expected mean squares.
- DESIGN indicates that the model fit is a factorial model for the fixed effects, plus a main-effects term for the random effect. The intercept is included.

Variable List

The variable list specifies the dependent variable and the factors in the model.

- The dependent variable must be the first specification on VARCOMP.
- The factors follow the dependent variable and are separated from it by the keyword BY.
- The covariates, if any, follow the factors and are separated from the dependent variable and the factors by the keyword WITH.
- The dependent variable and the covariates must be numeric, but the factor variables can be either numeric or string.

RANDOM Subcommand

The RANDOM subcommand allows you to specify random factors.

- You must specify at least one RANDOM subcommand with one random factor.
- You can specify multiple random factors on a RANDOM subcommand. You can also use multiple RANDOM subcommands. Specifications are accumulative.
- Only factors that are listed after the keyword BY in the variable list are allowed on the RANDOM subcommand.
- If you specify a factor on RANDOM, all effects containing the factor are automatically declared as random effects.

Example

```
VARCOM Y BY DRUG SUBJECT
 /RANDOM = SUBJECT
 /DESIGN = DRUG DRUG*SUBJECT.
```

- This example specifies a mixed model where *DRUG* is the fixed factor and *SUBJECT* is a random factor.
- The default method MINQUE(1) is used to estimate the contribution of the random effect DRUG*SUBJECT to the variance of the dependent variable.

METHOD Subcommand

The METHOD subcommand offers four different methods for estimating the variances of the random effects. If more than one METHOD subcommand is specified, only the last subcommand is in effect. If the subcommand is not specified, the default method MINQUE(1) is used. METHOD cannot be specified without a keyword.

MINQUE(n) *Minimum norm quadratic unbiased estimator.* This method is the default method. When $n = 0$, zero weight is assigned to the random effects and unit weight is assigned to the residual term. When n = 1, unit weight is assigned to both the random effects and the residual term. By default, $n = 1$.

ML *Maximum likelihood method.* Parameters of the fixed effects and variances of the random effects are estimated simultaneously. However, only the variances are reported.

REML *Restricted maximum likelihood method.* Variances of the random effects are estimated based on residuals of the model after adjusting for the fixed effects.

SSTYPE(n) *ANOVA method.* The ANOVA method equates the expected mean squares of the random effects to their observed mean squares. Their variances are then estimated by solving a system of linear equations. The expected mean squares are computed based on the chosen type of sum of squares. Two types are available in VARCOMP: Type I ($n = 1$) and Type III ($n = 3$). Type III is the default option for this method.

INTERCEPT Subcommand

The INTERCEPT subcommand controls whether an intercept term is included in the model. If more than one INTERCEPT subcommand is specified, only the last subcommand is in effect.

INCLUDE *Include the intercept term.* The intercept (constant) term is included in the model. This setting is the default when INTERCEPT is not specified.

EXCLUDE *Exclude the intercept term.* The intercept (constant) term is excluded from the model. EXCLUDE is ignored if you specify the keyword INTERCEPT on the DESIGN subcommand.

MISSING Subcommand

By default, cases with missing values for any of the variables on the VARCOMP variable list are excluded from the analyses. The MISSING subcommand allows you to include cases with user-missing values.

- Pairwise deletion of missing data is not available in VARCOMP.
- If more than one MISSING subcommand is specified, only the last subcommand is in effect.

EXCLUDE *Exclude both user-missing and system-missing values.* This setting is the default when MISSING is not specified.

INCLUDE *Treat user-missing values as valid.* System-missing values cannot be included in the analysis.

REGWGT Subcommand

REGWGT specifies the weight variable. Values of this variable are used as regression weights in a weighted least squares model.

- Specify one numeric variable name on the REGWGT subcommand.
- Cases with nonpositive values in the regression weight variable are excluded from the analyses.
- If more than one variable is specified on the same REGWGT subcommand, only the last variable is in effect.
- If more than one REGWGT subcommand is specified, only the last subcommand is in effect.

CRITERIA Subcommand

The CRITERIA subcommand specifies numerical tolerance for checking singularity and offers control of the iterative algorithm that is used for ML or REML estimation.

- Multiple CRITERIA subcommands are allowed.
- The last specified value for any keyword takes effect. If no value is specified, the default is used.

EPS(n) *Epsilon value that is used as tolerance in checking singularity.* The value for *n* must be a positive value. The default is 1.0E-8.

CONVERGE(n) *Convergence criterion.* Convergence is assumed if the relative change in the objective function is less than the specified value. The value for *n* must be a positive value. The default is 1.0E-8. This process is available only if you specify ML or REML on the METHOD subcommand.

ITERATE(n) *Maximum number of iterations*. The value for *n* must be a positive integer. The default is 50. This process is available only if you specify ML or REML on the METHOD subcommand.

PRINT Subcommand

The PRINT subcommand controls the display of optional output. If PRINT is not specified, the default output includes a factor information table and a variance component estimates table.

- For the maximum likelihood (ML) and restricted maximum likelihood (REML) methods, an asymptotic covariance matrix of the variance estimates table is also displayed.
- If more than one PRINT subcommand is specified, the specifications are accumulated. However, if you specify the keyword HISTORY more than once but with different values for *n*, the last specification is in effect.

EMS *Expected mean squares*. This output shows expected mean squares of all of the effects. This process is available only if you specify SSTYPE(n) on the METHOD subcommand.

HISTORY(n) *Iteration history*. The table contains the objective function value and variance component estimates at every *n* iteration. The value for *n* must be a positive integer. The default is 1. The last iteration is always printed if HISTORY is specified on PRINT. This process is available only if you specify ML or REML on the METHOD subcommand.

SS *Sums of squares*. The table contains sums of squares, degrees of freedom, and mean squares for each source of variation. This process is available only if you specify SSTYPE(n) on the METHOD subcommand.

OUTFILE Subcommand

The OUTFILE subcommand writes the variance component estimates to a data file or a previously declared dataset (DATASET DECLARE command) that can be used in other procedures. For the ML and REML methods, OUTFILE can also write the asymptotic covariance or correlation matrix. If more than one OUTFILE subcommand is specified, the last specification is in effect.

- OUTFILE writes to an external data file or previously declared dataset. You must specify a quoted file specification or dataset name in parentheses.

- COVB and CORB are available only if you specify ML or REML on the METHOD subcommand.
- COVB and CORB are mutually exclusive; only one of them can be specified on an OUTFILE subcommand.

VAREST *Variance component estimates.* A variable will be created to contain the estimates, and another variable will be created to hold the labels of the variance components.

COVB *Covariance matrix*. This matrix is the asymptotic covariance matrix of the variance component estimates. One variable is created for each variance component.

CORB *Correlation matrix*. This matrix is the asymptotic correlation matrix of the variance component estimates. One variable is created for each variance component.

('savfile'|'dataset') *Output file specification or previously declared dataset name*. Specify a quoted file specification or dataset name, enclosed in parentheses. The variance component estimates and the asymptotic covariance or correlation matrix (if requested) are written to the same file.

DESIGN Subcommand

The DESIGN subcommand specifies the effects in a model. DESIGN can be specified anywhere after the variable list. If more than one DESIGN subcommand is specified, only the last subcommand is in effect.

- Specify a list of effect terms to be included in the design. Each term must be separated from the next term by a comma or a space. Valid specifications include the keyword INTERCEPT, factors, covariates, and interaction or nested terms.
- The factors and covariates must have been specified on the variable list.
- If a factor is specified on the RANDOM subcommand, all effects that include that factor are random effects.
- If the DESIGN subcommand is omitted or specified without any term, the default design is generated. The default design includes the intercept term (if INTERCEPT=EXCLUDE is not specified), the covariates (if any) in the order in which they are specified on the variable list, the main factorial effects, and all orders of factor-by-factor interaction.

INTERCEPT *Include the intercept term.* Specifying INTERCEPT on DESIGN explicitly includes the intercept term, regardless of the specification on the INTERCEPT subcommand.

BY *Interaction.* You can also use the asterisk (*). Interaction terms can be formed among factors, among covariates, and between factors and covariates.

Factors inside an interaction effect must be distinct. For factors *A, B,* and *C,* expressions like A*C*A or A*A are invalid.

Covariates inside an interaction effect do not have to be distinct. For covariate *X*, X*X is the product of *X* and itself. This is equivalent to a covariate whose values are the square of the values of *X*.

WITHIN *Nesting*. You can also use a pair of parentheses. Factors and covariates can be nested within factors, but no effects can be nested within covariates. Suppose that *A* and *B* are factors and *X* and *Y* are covariates. Both A(B) and X(B) are valid, but X(Y) is not valid.

Factors inside a nested effect must be distinct. Expressions like A(A) are invalid.

Multiple-level nesting is supported. For example, `A(B(C))` or `A WITHIN B WITHIN C` means that factor *B* is nested within factor *C*, and factor *A* is nested within *B(C)*. The expression `A(B)(C)` is invalid.

Nesting within an interaction effect is valid. For example, `A(B*C)` means that factor *A* is nested within *B*C* while `X(A*B)` means that covariate *X* is nested within *A*B*.

Interactions among nested effects are allowed. For example, `A*B(C)` means interaction between *A* and *B* within levels of *C*. `X*Y(A)` means the product of *X* and *Y* nested within levels of *C*. The expression `A(C)*B(C)` is invalid.

Example

```
VARCOM Y BY DRUG SUBJECT WITH X
 /RANDOM = SUBJECT
 /DESIGN = DRUG SUBJECT DRUG*SUBJECT X*SUBJECT.
```

- The `DESIGN` subcommand specifies two main effects and two interaction terms.
- All effects that involve the factor *SUBJECT* are assumed to be random.

VARIABLE ALIGNMENT

```
VARIABLE ALIGNMENT varlist ({LEFT  }) ... [/varlist...]
                           {CENTER}
                           {RIGHT }
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Example

```
VARIABLE ALIGNMENT sales95 sales96 (LEFT)
  /id gender (RIGHT).
```

Overview

`VARIABLE ALIGNMENT` specifies the alignment of data values in the Data Editor. It has no effect on the format of the variables or the display of the variables or values in other windows or printed results.

Basic Specification

The basic specification is a variable name and the keyword `LEFT`, `RIGHT`, or `CENTER` in parentheses.

VARIABLE ATTRIBUTE

```
VARIABLE ATTRIBUTE
         VARIABLES=varlist
         ATTRIBUTE=name('value') name('value')...
                   arrayname[1]('value') arrayname[2]('value')...
         DELETE=name name...
                arrayname[n] arrayname...
         /VARIABLES...
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Release History

Release 14.0

- Command introduced.

Example

```
VARIABLE ATTRIBUTE VARIABLES=Age Gender Region
  ATTRIBUTE=DemographicVars ('1').
```

Overview

VARIABLE ATTRIBUTE provides you with the ability to define your own variable attributes and assign attribute values to variables in the active dataset. For example, you could create a variable attribute that identifies the type of response for survey questions (e.g., single selection, multiple selection, fill-in-the-blank) or the formulas used for computed variables.

- User-defined variable attributes are saved with the data file in the data dictionary.
- The VARIABLE ATTRIBUTE command takes effect immediately, updating the data dictionary without requiring a data pass.
- You can display a list of data file and variable attributes with DISPLAY ATTRIBUTES. For more information, see DISPLAY on p. 598.

Basic Specification

The basic specification is:

- The VARIABLES subcommand followed by an equals sign (=) and a list of valid variables.
- The ATTRIBUTE keyword followed by an equals sign (=) and one or more attribute names that follow variable naming rules, with each attribute name followed by a quoted attribute value enclosed in parentheses.

or

- The DELETE keyword followed by an equals sign (=) and a list of defined attribute names or attribute arrays.

Syntax Rules

- The VARIABLES subcommand is required.
- All subcommands and keywords (VARIABLES, ATTRIBUTE, DELETE) must be followed by an equals sign (=).
- Each ATTRIBUTE keyword must be followed by a name that follows variable naming rules and a single, quoted attribute value enclosed in parentheses. For more information, see Variable Names on p. 43.
- Attribute names that begin with @ cannot be displayed in Variable View of the Data Editor and are not displayed by DISPLAY DICTIONARY or DISPLAY ATTRIBUTES. They can only be displayed with DISPLAY @ATTRIBUTES.
- Attribute names that begin with a dollar sign ($) are reserved for internal SPSS use.
- All attribute values must be quoted (single or double quotes), even if the values are numbers.
- Attribute values can be up to 32,767 bytes in length.

Attribute Arrays

If you append an integer enclosed in square brackets to the end of an attribute name, the attribute is interpreted as an array of attributes. For example,

```
VARIABLE ATTRIBUTE VARIABLES=Age
  ATTRIBUTE=MyAttribute[99]('not quite 100').
```

will create 99 attributes—*MyAttribute[01]* through *MyAttribute[99]*—and will assign the value "not quite 100" to the last one.

- Array subscripts (the value enclosed in square brackets) must be integers greater than 0. (Array subscript numbering starts with 1, not 0.)
- If the root name of an attribute array is the same as an existing attribute name for any variables specified on the VARIABLES subcommand, the attribute array replaces the existing attribute for those variables (and vice versa). If no value is assigned to the first element in the array (subscript [1]), the original attribute value is used for that element value.

With the DELETE keyword, the following rules apply to attribute arrays:

- If you specify DELETE followed by an array rootname and no value in square brackets, all attributes in the array are deleted.
- If you specify DELETE with an array name followed by an integer value in square brackets, the specified array element is deleted and the integer values for all subsequent attributes in the array (in numeric order) are changed to reflect the new order of array elements.

Example

```
VARIABLE ATTRIBUTE
  VARIABLES=Age Income1 Income2 Income3
  ATTRIBUTE=AnswerFormat('Fill-in')
  /VARIABLES=Gender OwnHome MortgageType
  ATTRIBUTE=AnswerFormat('Single select')
  /VARIABLES=AvgIncome
  ATTRIBUTE=AnswerFormat('Computed value')
```

```
  /VARIABLES=AvgIncome
   ATTRIBUTE=Formula('mean(Income1, Income2, Income3)')
   /VARIABLES=AvgIncome
   ATTRIBUTE=DerivedFrom[1]('Income1')
   DerivedFrom[2]('Income2')
   DerivedFrom[3]('Income3').
DISPLAY ATTRIBUTES.
```

- The variables *Age*, *Income1*, *Income2*, and *Income3* are assigned the variable attribute *AnswerFormat* with a value of *Fill-in*.
- The variables *Gender*, *OwnHome*, and *MortgageType* are assigned the variable attribute *AnswerFormat* with a value of *Single select*.
- The variable *AvgIncome* is assigned the variable attribute *AnswerFormat* with a value of *Computed value*.
- The variable *AvgIncome* is assigned the variable attribute *Formula*, with a value the describes the formula used to calculate the value of this variable.
- The variable *AvgIncome* is assigned the variable attribute array *DerivedFrom*, and each array value identifies one of the variables used to calculate the value of *AvgIncome*.
- `DISPLAY ATTRIBUTES` lists the variable attributes for each variable in the active dataset.

Figure 244-1
Variable attributes

Variable Attributes

Variable	Attribute	Value
Age	AnswerFormat	Fill-in
Gender	AnswerFormat	Single select
Income1	AnswerFormat	Fill-in
Income2	AnswerFormat	Fill-in
Income3	AnswerFormat	Fill-in
OwnHome	AnswerFormat	Single select
MortgageType	AnswerFormat	Single select
AvgIncome	AnswerFormat	Computed value
	DerivedFrom[1]	Income1
	DerivedFrom[2]	Income2
	DerivedFrom[3]	Income3
	Formula	mean(Income1, Income2, Income3)

VARIABLE LABELS

```
VARIABLE LABELS varname 'label' [/varname...]
```

Example

```
VARIABLE LABELS YRHIRED 'YEAR OF FIRST HIRING'.
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Overview

VARIABLE LABELS assigns descriptive labels to variables in the active dataset.

Basic Specification

The basic specification is a variable name and the associated label in quotes.

Syntax Rules

- Labels can be added to any previously defined variable. It is not necessary to enter labels for all variables in the active dataset.
- Each variable label must be enclosed in quotes.
- Variable labels can contain any characters, including blanks. To enter an apostrophe as part of a label, enclose the label in double quotes or enter a two apostrophes (two single quotes). For more information, see String Values in Command Specifications on p. 35.
- Each variable label can be up to 255 bytes long, although some procedures print fewer than the 255 bytes. All statistical procedures display at least 40 bytes.
- Multiple variables can be assigned labels on a single VARIABLE LABELS command. Only one label can be assigned to each variable, and each label can apply to only one variable.
- To continue a label from one command line to the next, specify a plus (+) sign before the continuation of the label. Each string segment of the label must be enclosed in quotes. To insert a blank between the strings, the blank must be included in the label specification.
- To control line wrapping of labels in pivot tables and charts, insert \n as part of the label wherever you want a line break. The \n is not displayed in output; it is interpreted as a line-break character. (*Note*: Labels will *always* wrap wherever \n appears in the defined label, even if there is enough space to display the label without wrapping.)

Operations

- Unlike most transformations, VARIABLE LABELS takes effect as soon as it is encountered in the command sequence. Thus, special attention should be paid to its position among commands. For more information, see Command Order on p. 36.

- Variable labels are automatically displayed in the output from many procedures and are stored in the dictionary of the active dataset.
- VARIABLE LABELS can be used for variables that have no previously assigned variable labels. If a variable has a previously assigned variable label, the new label replaces the old label.

Examples

Assigning Variable Labels to Multiple Variables

```
VARIABLE LABELS  YRHIRED 'YEAR OF FIRST HIRING'
  DEPT88 'DEPARTMENT OF EMPLOYMENT IN 1988'
  SALARY88 'YEARLY SALARY IN 1988'
  JOBCAT 'JOB CATEGORIES'.
```

- Variable labels are assigned to the variables *YRHIRED*, *DEPT88*, *SALARY88*, and *JOBCAT*.

Combining Strings to Construct Variable Labels

```
VARIABLE LABELS  OLDSAL "EMPLOYEE'S GROSS SALARY PRIOR"
   + " TO 1988".
```

- The label for *OLDSAL* is created by combining two strings with the plus sign. The blank between PRIOR and TO must be included in the first or second string to be included in the label.

Forcing Variable Labels to Wrap

```
VARIABLE LABELS myvar "A Fairly Long Label \n That Always Wraps".
FREQUENCIES myvar.
```

Figure 245-1
Using \n to wrap variable labels

A Fairly Long Label
That Always Wraps

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	1.00	1	100.0	100.0	100.0

VARIABLE LEVEL

```
VARIABLE LEVEL varlist ({SCALE  }) ... [/varlist...]
                        {ORDINAL}
                        {NOMINAL}
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Example

```
VARIABLE LEVEL sales95 sales96 (SCALE)
    /region division (NOMINAL)
    /expense (ORDINAL).
```

Overview

`VARIABLE LEVEL` specifies the level of measurement for variables.

Basic Specification

The basic specification is a variable name, followed by a measurement level enclosed in parentheses. The measurement level can be:

NOMINAL	A variable can be treated as nominal when its values represent categories with no intrinsic ranking; for example, the department of the company in which an employee works. Examples of nominal variables include region, zip code, or religious affiliation.
ORDINAL	A variable can be treated as ordinal when its values represent categories with some intrinsic ranking; for example, levels of service satisfaction from highly dissatisfied to highly satisfied. Examples of ordinal variables include attitude scores representing degree of satisfaction or confidence and preference rating scores.
SCALE	A variable can be treated as scale when its values represent ordered categories with a meaningful metric, so that distance comparisons between values are appropriate. Examples of scale variables include age in years and income in thousands of dollars.

VARIABLE WIDTH

```
VARIABLE WIDTH varlist (n) ... [/varlist...]
```

Example

```
VARIABLE WIDTH sales95 sales96 (10)
  /id gender (2).
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Overview

`VARIABLE WIDTH` specifies the column width for the display of variables in the Data Editor. It has no effect on the format of the variable or the display of the variable or values in other windows or printed results.

Basic Specification

The basic specification is a variable name and a positive integer in parentheses for the column width.

VARSTOCASES

```
VARSTOCASES

/MAKE new variable ["label"] [FROM] varlist [/MAKE ...]

[/INDEX = {new variable ["label"]                                    }]
          {new variable ["label"] (make variable name)               }
          {new variable ["label"] (n) new variable ["label"](n) ...}

[/ID = new variable ["label"]]

[/NULL = {DROP**}]
         {KEEP  }

[/COUNT=new variable ["label"]]

[/KEEP={ALL**  }] [/DROP=varlist]
       {varlist}
```

**Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
VARSTOCASES /MAKE newvar FROM var1 TO var4.
```

Overview

A **variable** contains information that you want to analyze, such as a measurement or a test score. A **case** is an observation, such as an individual or an institution. In a simple data structure, each variable is a single **column** in your data. So if you are measuring test scores, for example, all test score values would appear in only one column. In a simple data structure, each case is a single **row** in your data. So if you were measuring scores for all students in a class, there would be a row for each student.

VARSTOCASES restructures **complex** data structures (in which information about a variable is stored in more than one column) into a data file in which those measurements are organized into separate rows of a single column. It replaces the active dataset.

You can use VARSTOCASES to restructure data files in which repeated measurements of a single case were recorded in one row into a new data file in which each measurement for a case appears in a new row.

Options

Creating New Variables. You can create an **identification** variable that identifies the row in the original data file that was used to create a group of new rows, a **count** variable that contains the number of new rows generated by a row in the original data, and one or more **index** variables that identify the original variable from which the new row was created.

Variable Selection. You can use the DROP and KEEP subcommands to specify which variables from the original data file are included in the new data file.

Basic Specification

The basic specification is one or more MAKE subcommands, each of which specifies a list of variables to be combined into a single variable in which each value is displayed on a separate row.

Subcommand Order

Subcommands can be specified in any order.

Syntax Rules

- The MAKE subcommand is required and can be specified as many times as needed.
- The rest of the subcommands can be specified only once.

Operations

- **Row order.** New rows are created in the order in which the variables are specified on the FROM list.
- **Propagated variables.** Variables that are not named on the MAKE or DROP subcommands are kept in the new data file. Their values are propagated for each new row.
- **Split file processing.** The SPLIT FILE command does not affect the results of VARSTOCASES. If split file processing is in effect, it will remain in effect in the new data file unless a variable that is used to split the file is named on the MAKE or DROP subcommands.
- **Weighted files.** The WEIGHT command does not affect the results of VARSTOCASES. If original data are weighted, the new data will be weighted unless the variable that is used to split the file is named on the MAKE or DROP subcommands.
- **Selected cases.** The FILTER and USE commands do not affect the results of VARSTOCASES. It processes all cases.

Limitations

The TEMPORARY command cannot be in effect when VARSTOCASES is executed.

Example

The following is the LIST output for a data file where repeated measurements for the same case are stored in variables on a single row:

```
caseid          var1         var2         var3    var4

001              .00          .05         5.00    3.00
002             7.00         1.00         5.00    4.00
003             6.00         3.00         6.00    2.00
```

The command:

```
VARSTOCASES
    /MAKE newvar FROM var1 TO var4.
```

creates a new variable, *newvar*, using the values of *var1* through *var4*. The LIST output for the new active dataset is as follows:

```
caseid      newvar

001            .00
001            .05
001           5.00
001           3.00
002           7.00
002           1.00
002           5.00
002           4.00
003           6.00
003           3.00
003           6.00
003           2.00
```

The values for the new variable *newvar* are the values from *var1* through *var4* from the original data. There are now four rows for each case—one row for each variable that was named on the FROM list.

MAKE Subcommand

The MAKE subcommand names, and optionally labels, the new variable to be created from the variables on the FROM list.

- One new variable is required on each MAKE subcommand. It must have a unique name.
- The label for the new variable is optional and, if specified, must be enclosed in quotes.
- The new variable will have the values of the variables listed on the FROM list. For each case in the original data, one new row will be created for each variable on the FROM list.
- All of the variables on the FROM list are required to be of the same type. For example, they must all be numeric or they must all be string.
- The dictionary information for the new variable (for example, value labels and format) is taken from the first variable in the FROM list. If string variables of different lengths are specified, the longest length is used.
- Rows are created in the order in which variables appear on the FROM list.
- Variables that appear on the FROM list will not appear in the new data file.
- Variables that are kept in the new data file and not named on the FROM list will have their values propagated for each new row.
- When multiple MAKE subcommands are used, a variable may not appear on more than one FROM list.
- A variable may be listed more than once on a FROM list. Its values are repeated.
- When multiple MAKE subcommands are used, the FROM lists must all contain the same number of variables (variables that are listed more than once must be included in the count).

ID Subcommand

The ID subcommand creates a new variable that identifies the permanent case sequence number (*$casenum*) of the original row that was used to create the new rows. Use the ID subcommand when the original data file does not contain a variable that identifies cases.

- One new variable is named on the ID subcommand. It must have a unique name.
- The label for the new variable is optional and, if specified, must be enclosed in quotes.
- The format of the new variable is F8.0.

INDEX Subcommand

In the original data file, a case appears on a single row. In the new data file, that case will appear on multiple rows. The INDEX subcommand creates a new variable that sequentially identifies a group of new rows based on the original variables from which it was created.

- You can choose among three types of indices—a simple numeric index, an index that lists the variables on a FROM list, or multiple numeric indices.
- New variable(s) are named on the INDEX subcommand. A new variable must have a unique name.
- The label for the new variable is optional and, if specified, must be enclosed in quotes.

Simple Numeric Index

A simple numeric index numbers the rows sequentially within a new group.

- The basic specification is /INDEX=ivar, where *ivar* is a name for the new index variable.
- The new index variable starts with 1 and increments each time a FROM variable is encountered in a row in the original file. After the last FROM variable is encountered, the index restarts at 1.
- Gaps in the index sequence can occur if null data are dropped.

Example

```
VARSTOCASES
    /MAKE newvar FROM var1 TO var4
    /INDEX=ivar.
```

```
caseid      ivar    newvar

001            1       .00
001            2       .05
001            3      5.00
001            4      3.00
002            1      7.00
002            2      1.00
002            3      5.00
002            4      4.00
003            1      6.00
003            2      3.00
003            3      6.00
003            4      2.00
```

Variable Name Index

A variable name index works like the simple numeric index, except that it lists the name of the original FROM variable instead of a sequential number.

- The basic specification is /INDEX=ivar (make variable name), where *ivar* is the name for the new index variable and *make variable name* is the name of a variable on the MAKE subcommand from which the index is to be constructed.
- The new index variable is a string that lists the name of the FROM variable from which the new row was created.

Example

```
VARSTOCASES
    /MAKE newvar FROM var1 TO var4
    /INDEX=ivar (newvar).
```

```
caseid      ivar    newvar

001         VAR1       .00
001         VAR2       .05
001         VAR3      5.00
001         VAR4      3.00
002         VAR1      7.00
002         VAR2      1.00
002         VAR3      5.00
002         VAR4      4.00
003         VAR1      6.00
003         VAR2      3.00
003         VAR3      6.00
003         VAR4      2.00
```

Multiple Numeric Indices

Multiple numeric indices are used to identify groups of new rows that share a particular combination of factors. You can create multiple numeric indices if the original variables are ordered so that levels of a given factor are grouped together.

- The basic specification is /INDEX=ivar(n) ivar(n) . . ., where *ivar* is the name of the new index for a factor and *n* is the number of factor levels represented in the variable group for which the index is being constructed.
- The last index specified varies the fastest.

Example

```
       B1      B2

A1    .00     .05

A2   5.00    3.00
```

- Data were collected for a designed experiment with two levels of factor A and two levels of factor B. The table shows the data for the first case.

```
caseid     v_a1b1    v_a1b2    v_a2b1    v_a2b2
001           .00       .05      5.00      3.00
```

- The original data file is structured so that each case has one variable for each combination of factors. Note that factor B varies fastest.

```
VARSTOCASES
    /MAKE newvar FROM v_a1b1 TO v_a2b2
    /INDEX=a(2) b(2).

caseid      a     b    newvar

001         1     1       .00
001         1     2       .05
001         2     1      5.00
001         2     2      3.00
```

- The command restructures the data file and creates two indices, *A* and *B*.

NULL Subcommand

The NULL subcommand checks each potential new row for **null** values. A null value is a system-missing or blank value. By default, VARSTOCASES does not add a new row that contains null values for all variables created by MAKE subcommands. You can change the default null-value treatment with the NULL subcommand.

DROP *Do not include a new row when all MAKE variables are null.* A potential new row with null values for all of the variables created by MAKE subcommands is excluded from the new data file. This is the default. With this option, you may want to create a count variable to keep track of new rows because cases in the original data file are not guaranteed to appear in the new data file.

KEEP *Include a new row when all MAKE variables are null.* A potential new row with null values for all of the variables created by the MAKE subcommand is included in the new data. With this option, you may not need a count variable to keep track of cases because each row in the original data will result in a consistent number of rows in the new data file.

COUNT Subcommand

When there are no null data, VARSTOCASES generates *n* new rows for each row in the original data file, where *n* is the number of variables on the FROM list(s). When the original data file contains null values and you drop them, it is possible to generate a different number of rows for a given subject in the original data file. The COUNT subcommand creates a new variable that contains the number of new rows generated by the original subject.

- One new variable is named on the COUNT subcommand. It must have a unique name.
- The label for the new variable is optional and, if specified, must be enclosed in quotes.
- The format of the new variable is F4.0.

DROP and KEEP Subcommands

The DROP and KEEP subcommands are used to include only a subset of variables in the new active dataset. The DROP subcommand specifies a set of variables to exclude and the KEEP subcommand specifies a set of variables to retain. Variables not specified on the KEEP subcommand are dropped.

- DROP and KEEP cannot be used with variables that appear on a FROM list.

- DROP and KEEP are mutually exclusive. Only one DROP or one KEEP subcommand can be used on the VARSTOCASES command.
- KEEP affects the order of variables in the new data file. The order of the variables kept in the new data file is the order in which they are named on the KEEP subcommand.

Example

```
VARSTOCASES
    /MAKE newvar FROM var1 to var4
    /DROP caseid.
```

- *Caseid* is dropped from the new data file. The new data file contains one variable, *newvar*.

VECTOR

```
VECTOR  {vector  name=varname TO varname}  [/vector  name...]
        {vector  name(n  [format])      }
```

This command does not read the active dataset. It is stored, pending execution with the next command that reads the dataset. For more information, see Command Order on p. 36.

Example

```
VECTOR V=V1 TO V6.
```

Overview

VECTOR associates a vector name with a set of existing variables or defines a vector of new variables. A vector is a set of variables that can be referred to using an index. The vector can refer to either string or numeric variables, and the variables can be permanent or temporary.

For each variable in the reference list, VECTOR generates an element. Element names are formed by adding a subscript in parentheses to the end of the vector name. For example, if the vector *AGES* has three elements, the element names are *AGES(1)*, *AGES(2)*, and *AGES(3)*. Although the VECTOR command has other uses within the transformation language, it is most often used with LOOP structures because the indexing variable on LOOP can be used to refer to successive vector elements.

Options

File Structures. VECTOR can be used with the END CASE command to restructure data files. You can build a single case from several cases or, conversely, you can build several cases from a single case (see the examples for the END CASE command on p. 622).

Short-Form Vectors. VECTOR can be used to create a list of new variables and the vector that refers to them simultaneously. VECTOR in the short form can be used to establish the dictionary order of a group of variables before they are defined on a DATA LIST command (see "VECTOR: Short Form" on p. 1973).

Basic Specification

- The basic specification is VECTOR, a vector name, a required equals sign, and the list of variables that the vector refers to. The TO keyword must be used to specify the variable list, and it defines a variable list based on file order.
- For the short form of VECTOR, the basic specification is VECTOR, an alphabetical prefix, and, in parentheses, the number of variables to be created.

Syntax Rules

- Multiple vectors can be created on the same command by using a slash to separate each set of specifications.

- Variables specified on VECTOR must already be defined unless the short form of VECTOR is used to create variables (see "VECTOR: Short Form" on p. 1973).
- The TO convention must be used to specify the variable list. Thus, variables specified must be consecutive and must be from the same dictionary, permanent or scratch.
- A single vector must comprise all numeric variables or all string variables. The string variables must have the same length.
- A scalar (a variable named on NUMERIC), a function, and a vector can all have the same name, for example *MINI*. The scalar can be identified by the lack of a left parenthesis following the name. Where a vector has the same name as a function (or the abbreviation of a function), the vector name takes precedence (see the example on name conflicts in "VECTOR: Short Form" on p. 1973).
- Vector element names must always be specified with a subscript in parentheses.

Operations

- VECTOR takes effect as soon as it is encountered in the command sequence, unlike most transformations, which do not take effect until the data are read. Thus, special attention should be paid to its position among commands. For more information, see Command Order on p. 36.
- VECTOR is in effect only until the first procedure that follows it. The vector must be redeclared to be reused.
- Vectors can be used in transformations but not in procedures.

Examples

Example

```
DATA LIST FREE /height age weight.
BEGIN DATA
1 2 3
END DATA.
VECTOR x=height TO weight.
VECTOR y=age TO weight.
VECTOR z=age TO height.
```

- The list of variables specified with TO defines a list of variables in file order.
- Vector *x* contains the variables *height, age,* and *weight*.
- Vector *y* contains the variables *age* and *weight*.
- The last VECTOR command generates an error because *height* comes before *age* in file order.

Example

```
* Replace a case's missing values with the mean of all
  nonmissing values for that case.

DATA LIST FREE /V1 V2 V3 V4 V5 V6 V7 V8.
MISSING VALUES V1 TO V8 (99).
COMPUTE MEANSUB=MEAN(V1 TO V8).

VECTOR V=V1 TO V8.
LOOP #I=1 TO 8.
```

```
+  DO IF MISSING (V(#I)).
+  COMPUTE V(#I)=MEANSUB.
+  END IF.
END LOOP.

BEGIN DATA
1 99 2 3 5 6 7  8
2  3 4 5 6 7 8  9
2  3 5 5 6 7 8 99
END DATA.
LIST.
```

- The first COMPUTE command calculates the variable *MEANSUB* as the mean of all nonmissing values for each case.
- VECTOR defines the vector *V* with the original variables as its elements.
- For each case, the loop is executed once for each variable. The COMPUTE command within the loop is executed only when the variable has a missing value for that case. COMPUTE replaces the missing value with the value of *MEANSUB*.
- For the first case, the missing value for the variable *V2* is changed to the value of *MEANSUB* for that case. The missing value for the variable *V8* for the third case is changed to the value of *MEANSUB* for that case.

For additional examples of VECTOR, see the examples for the END CASE command on p. 622 and the IF command on p. 878.

VECTOR: Short Form

VECTOR can be used to create a list of new variables and the vector that refers to them simultaneously. The short form of VECTOR specifies a prefix of alphanumeric characters followed, in parentheses, by the length of the vector (the number of variables to be created).

- The new variable names must not conflict with existing variables. If the prefix starts with the # character, the new variables are created according to the rules for scratch variables.
- More than one vector of the same length can be created by naming two or more prefixes before the length specification.
- By default, variables created with VECTOR receive F8.2 formats. Alternative formats for the variables can be specified by including a format specification with the length specification within the parentheses. The format and length can be specified in either order and must be separated by at least one space or comma. If multiple vectors are created, the assigned format applies to all of them unless you specify otherwise.

Creating a Vector from a Set of New Scratch Variables

```
VECTOR #WORK(10).
```

- The program creates the vector *#WORK*, which refers to 10 scratch variables: *#WORK1, #WORK2,* and so on, through *#WORK10*. Thus, the element *#WORK(5)* of the vector is the variable *#WORK5*.

Creating Multiple Vectors of the Same Length

```
VECTOR X,Y(5).
```

- VECTOR creates the vectors *X* and *Y*, which refer to the new variables *X1* through *X5* and *Y1* through *Y5*, respectively.

Specifying the Format of Vector Variables

```
VECTOR X(6,A5).
```

- VECTOR assigns an A5 format to the variables *X1* through *X6*.

Creating Multiple Vectors of Different Lengths and Formats

```
VECTOR X,Y(A5,6) Z(3,F2).
```

- VECTOR assigns A5 formats to the variables *X1* to *X6* and *Y1* to *Y6*, and F2 formats to the variables *Z1* to *Z3*. It doesn't matter whether the format or the length is specified first within the parentheses.

Predetermining Variable Order Using the Short Form of VECTOR

```
INPUT PROGRAM.
VECTOR X Y (4,F8.2).
DATA LIST / X4 Y4 X3 Y3 X2 Y2 X1 Y1 1-8.
END INPUT PROGRAM.

PRINT /X1 TO X4  Y1 TO Y4.
BEGIN DATA
49382716
49382716
49382716
END DATA.
```

- The short form of VECTOR is used to establish the dictionary order of a group of variables before they are defined on a DATA LIST command. To predetermine variable order, both VECTOR and DATA LIST must be enclosed within the INPUT PROGRAM and END INPUT PROGRAM commands.
- The order of the variables in the active dataset will be *X1*, *X2*, *X3*, and *X4*, and *Y1*, *Y2*, *Y3*, and *Y4*, even though they are defined in a different order on DATA LIST.
- The program reads the variables with the F1 format specified on DATA LIST. It writes the variables with the output format assigned on VECTOR (F8.2).
- Another method for predetermining variable order is to use NUMERIC (or STRING if the variables are string variables) before the DATA LIST command (see the example on variable order for the NUMERIC command on p. 1278). The advantage of using NUMERIC or STRING is that you can assign mnemonic names to the variables.

Name Conflicts in Vector Assignments

```
INPUT PROGRAM.
NUMERIC MIN MINI_A MINI_B MINIM(F2).
COMPUTE MINI_A = MINI(2).  /*MINI is function MINIMUM.
VECTOR MINI(3,F2).
```

```
DO REPEAT I = 1 TO 3.
+  COMPUTE MINI(I) = -I.
END REPEAT.
COMPUTE MIN = MIN(1).      /*The second MIN is function MINIMUM.
COMPUTE MINI_B = MINI(2). /*MINI now references vector MINI
COMPUTE MINIM = MINIM(3). /*The second MINIM is function MINIMUM.
END CASE.
END FILE.
END INPUT PROGRAM.
```

- In this example, there are potential name conflicts between the scalars (the variables named on NUMERIC), the vectors (named on VECTOR), and the statistical function MINIMUM.
- A name that is not followed by a left parenthesis is treated as a scalar.
- When a name followed by a left parenthesis may refer to a vector element or a function, precedence is given to the vector.

VECTOR outside a Loop Structure

VECTOR is most commonly associated with the loop structure, since the index variable for LOOP can be used as the subscript. However, the subscript can come from elsewhere, including from the data.

Example

```
* Create a single case for each of students 1, 2, and 3.

DATA LIST /STUDENT 1 SCORE 3-4 TESTNUM 6.
BEGIN DATA
1 10 1
1 20 2
1 30 3
1 40 4
2 15 2
2 25 3
3 40 1
3 55 3
3 60 4
END DATA.

VECTOR RESULT(4).
COMPUTE RESULT(TESTNUM)=SCORE.

AGGREGATE OUTFILE=*/BREAK=STUDENT
        /RESULT1 TO RESULT4=MAX(RESULT1 TO RESULT4).

PRINT FORMATS RESULT1 TO RESULT4 (F2.0).
PRINT /STUDENT RESULT1 TO RESULT4.
EXECUTE.
```

- Data are scores on tests recorded in separate cases along with a student identification number and a test number. In this example, there are four possible tests for three students. Not all students took every test.
- The vector *RESULT* creates the variables *RESULT1* through *RESULT4*.

- For each case, COMPUTE assigns the *SCORE* value to one of the four vector variables, depending on the value of *TESTNUM*. The other three vector variables for each case keep the system-missing value they were initialized to.
- Aggregating by the variable *STUDENT* creates new cases, as shown by the output from the PRINT command. The MAX function in AGGREGATE returns the maximum value across cases with the same value for *STUDENT*. If a student has taken a particular test, the one valid value is returned as the value for the variable *RESULT1*, *RESULT2*, *RESULT3*, or *RESULT4*.

Figure 249-1
PRINT output after aggregating

```
 1 10 20 30 40
 2  . 15 25  .
 3 40  . 55 60
```

VERIFY

```
VERIFY [VARIABLES=series name]
```

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
VERIFY.
```

Overview

VERIFY produces a report on the status of the most current DATE, USE, and PREDICT specifications. The report lists the first and last observations in the active dataset, the current USE and PREDICT ranges, and any anomalies in the DATE variables. The number of missing values and the values of the first and last observations in the file and in the USE and PREDICT ranges can also be displayed for a specified series.

VERIFY should be used before a time series procedure whenever there is a possibility that DATE variables or USE and PREDICT ranges have been invalidated. In particular, the active dataset should be verified after you have modified the file structure with commands such as SELECT IF, SORT CASES, and AGGREGATE.

Options

If a series is specified after VERIFY, the values of the first and last observations in the file and in the USE and PREDICT periods are reported for that series. In addition, the number of observations in the active dataset that have missing values for that series is displayed. This can be useful for determining the USE ranges that do not include any missing values.

Basic Specification

The basic specification is the command keyword VERIFY.

- VERIFY displays the first and last observations in the active dataset and in the USE and PREDICT ranges. This information is presented by case number and by the values of the DATE variables.
- For DATE variables, VERIFY reports the number of missing or invalid values. In addition, DATE variables that are not properly nested within the next higher-level DATE variable, that have start or end values other than those expected at the beginning or end of a cycle, or that increment by more than the expected increment are flagged with an asterisk next to the problem. An explanation of the problem is given.

Operations

- VERIFY reports on cases remaining after any preceding SELECT IF commands.

- The USE and PREDICT ranges are defined by the last USE and PREDICT commands specified before the VERIFY command. If USE and PREDICT have not been specified, the USE range is the entire series, and the PREDICT range does not exist.

Limitations

- A maximum of 1 VARIABLES subcommand. Only one series can be specified on VARIABLES.

VARIABLES Subcommand

VARIABLES names a series to include in the report and is optional. The actual keyword VARIABLES can be omitted.

- The series named on VARIABLES must be numeric. The *DATE_* series is non-numeric and cannot be specified.
- Only one VARIABLES subcommand can be specified, and it can name only one series.

Examples

```
VERIFY.
```

- This command produces a report on the status of the most recent DATE, USE, and PREDICT specifications, as well as the first and last valid cases in the file.

```
VERIFY VARIABLE=STOCK.
```

- In addition to the default VERIFY information, this command displays information on the series *STOCK*, including the values of the first and last cases and how many values in that series are missing.

WEIGHT

```
WEIGHT  {BY  varname}
        {OFF        }
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Example

```
WEIGHT BY V1.
```

Overview

WEIGHT gives cases different weights (by simulated replication) for statistical analysis. WEIGHT can be used to weight a sample up to population size for reporting purposes or to replicate an example from a table or other aggregated data. With WEIGHT, you can arithmetically alter the sample size or its distribution.

To apply weights resulting from your sampling design, see the Complex Samples option.

Basic Specification

The basic specification is keyword BY followed by the name of the weight variable. Cases are weighted according to the values of the specified variable.

Syntax Rules

- Only one numeric variable can be specified. The variable can be a precoded weighting variable, or it can be computed with the transformation language.
- WEIGHT cannot be placed within a FILE TYPE–END FILE TYPE or INPUT PROGRAM–END INPUT PROGRAM structure. It can be placed nearly anywhere following these commands in a transformation program. For more information, see Commands and Program States on p. 2025.

Operations

- Unlike most transformations, WEIGHT takes effect as soon as it is encountered in the command sequence. Thus, special attention should be paid to its position among commands. For more information, see Command Order on p. 36.
- Weighting is permanent during a session unless it is preceded by a TEMPORARY command, changed by another WEIGHT command, or turned off with the WEIGHT OFF specification.
- Each WEIGHT command overrides the previous one.
- WEIGHT uses the value of the specified variable to arithmetically replicate cases for subsequent procedures. Cases are not physically replicated.
- Weight values do not need to be integer.

- Cases with missing or nonpositive values for the weighting variable are treated as having a weight of 0 and are thus invisible to statistical procedures. They are not used in calculations even where unweighted counts are specified. These cases do remain in the file, however, and are included in case listings and saved when the file is saved.
- A file saved when weighting is in effect maintains the weighting.
- If the weighted number of cases exceeds the sample size, tests of significance are inflated; if it is smaller, they are deflated.

Examples

```
WEIGHT BY V1.
FREQ VAR=V2.
```

- The frequency counts for the values of variable *V2* will be weighted by the values of variable *V1*.

```
COMPUTE WVAR=1.
IF (GROUP EQ 1) WVAR=.5.
WEIGHT BY WVAR.
```

- Variable *WVAR* is initialized to 1 with the `COMPUTE` command. The `IF` command changes the value of *WVAR* to 0.5 for cases where *GROUP* equals 1.
- Subsequent procedures will use a case base in which cases from group 1 count only half as much as other cases.

WLS

WLS is available in the Regression Models option.

```
WLS VARIABLES= dependent varname WITH independent varnames

 [/SOURCE=varname]

 [/DELTA=[{1.0**                  }]]
          {value list             }
          {value TO value BY value}

 [/WEIGHT=varname]

 [/{CONSTANT**}
   {NOCONSTANT}

 [/PRINT={BEST}]
         {ALL }

 [/SAVE = WEIGHT]

 [/APPLY['model name']]
```

**Default if the subcommand or keyword is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
WLS VARIABLES = VARY WITH VARX VARZ
  /SOURCE=VARZ
  /DELTA=2.
```

Overview

WLS (weighted least squares) estimates regression models with different weights for different cases. Weighted least squares should be used when errors from an ordinary regression are heteroscedastic—that is, when the size of the residual is a function of the magnitude of some variable, termed the **source**.

The WLS model is a simple regression model in which the residual variance is a function of the source variable, up to some power transform indicated by a delta value. For fuller regression results, save the weights produced by WLS and specify that weight variable on the REGWGT subcommand in REGRESSION.

Options

Calculated and Specified Weights. WLS can calculate the weights based on a source variable and delta values (subcommands SOURCE and DELTA), or it can apply existing weights contained in a series (subcommand WEIGHT). If weights are calculated, each weight value is calculated as the source series value raised to the negative delta value.

New Variables. You can change NEWVAR settings on the TSET command prior to WLS to evaluate the regression coefficients and log-likelihood function without saving the weight variable, or save the new values to replace the values saved earlier, or save the new values without erasing values saved earlier (see the TSET command). You can also use the SAVE subcommand on WLS to override the NONE or the default CURRENT settings on NEWVAR for the current procedure.

Statistical Output. You can change the PRINT setting on the TSET command prior to WLS to display regression coefficients or the list of log-likelihood functions at each delta value, or to limit the output to only the regression statistics for the delta value at which the log-likelihood function is maximized (see the TSET command). You can also use the PRINT subcommand to override the PRINT setting on the TSET command for the current procedure and obtain regression coefficients at each value of delta in addition to the default output.

Basic Specification

- The basic specification is the VARIABLES subcommand specifying one dependent variable, the keyword WITH, and one or more independent variables. Weights are calculated using the first independent variable as the source variable and a default delta value of 1.
- The default output for calculated weights displays the log-likelihood function for each value of delta. For the value of delta at which the log-likelihood function is maximized, the displayed summary regression statistics include R, R^2, adjusted R^2, standard errors, analysis of variance, and t tests of the individual coefficients. A variable named *WGT#1* containing the calculated weights is automatically created, labeled, and added to the active dataset.

Syntax Rules

- VARIABLES can be specified only once.
- DELTA can be specified more than once. Each specification will be executed.
- If other subcommands are specified more than once, only the last specification of each one is executed.
- You can specify either SOURCE and DELTA, or just the WEIGHT subcommand. You cannot specify all three, and you cannot specify WEIGHT with SOURCE or with DELTA.

Subcommand Order

- Subcommands can be specified in any order.

Operations

- If neither the WEIGHT subcommand nor the SOURCE and DELTA subcommands are specified, a warning is issued and weights are calculated using the default source and delta value.
- Only one *WGT#1* variable is created per procedure. If more than one delta value is specified, the weights used when the log-likelihood function is maximized are the ones saved as *WGT#1*.
- *WGT#1* is not created when the WEIGHT subcommand is used.
- The WEIGHT command specifies case replication weights, which are *not* the same as the weights used in weighted least squares. If the WEIGHT command and WLS WEIGHT subcommand are both specified, both types of weights are incorporated in WLS.

- WLS uses listwise deletion of missing values. Whenever one variable is missing a value for a particular observation, that observation will not be included in any computations.

Limitations

- Maximum one VARIABLES subcommand.
- Maximum one dependent variable on the VARIABLES subcommand. There is no limit on the number of independent variables.
- Maximum 150 values specified on the DELTA subcommand.

Example

```
WLS VARIABLES = VARY WITH VARX VARZ
  /SOURCE=VARZ
  /DELTA=2.
```

- This command specifies a weighted least-squares regression in which *VARY* is the dependent variable and *VARX* and *VARZ* are the independent variables.
- *VARZ* is identified as the source of heteroscedasticity.
- Weights will be calculated using a delta value of 2. Thus, the weights will equal $VARZ^{-2}$.

VARIABLES Subcommand

VARIABLES specifies the variable list and is the only required subcommand.

SOURCE Subcommand

SOURCE is used in conjunction with the DELTA subcommand to compute weights. SOURCE names the variable that is the source of heteroscedasticity.

- The only specification on SOURCE is the name of a variable to be used as the source of heteroscedasticity.
- Only one source variable can be specified.
- If neither SOURCE nor WEIGHT is specified, the first independent variable specified on the VARIABLES subcommand is assumed to be the source variable.

DELTA Subcommand

DELTA, alias POWER, is used in conjunction with the SOURCE subcommand to compute weights. DELTA specifies the values to use in computing weights. The weights are equal to 1/(SOURCE raised to the DELTA power).

- The specification on DELTA is a list of possible delta values and/or value grids.
- Multiple values and grids can be specified on one DELTA subcommand.
- Delta values can be any value in the range of –6.5 to +7.5. Values below this range are assigned the minimum (–6.5), and values above are assigned the maximum (7.5).

- A grid is specified by naming the starting value, the keyword TO, an ending value, the keyword BY, and an increment value. Alternatively, the keyword BY and the increment value can be specified after the starting value.
- More than one DELTA subcommand can be specified; each subcommand will be executed.
- If DELTA is not specified, the delta value defaults to 1.0.

Example

```
WLS VARIABLES = X1 WITH Y1 Z1
  /SOURCE=Z1
  /DELTA=0.5.
```

- In this example, weights are calculated using the source variable *Z1* and a delta value of 0.5. Thus, the weights are `1/(SQRT (Z1))`.

Example

```
WLS VARIABLES = SHARES WITH PRICE
  /DELTA=0.5 TO 2.5 BY 0.5.
```

- In this example, several regression equations will be fit, one for each value of delta.
- Weights are calculated using the source variable *PRICE* (the default).
- The delta values start at 0.5 and go up to 2.5, incrementing by 0.5. This specification is equivalent to 0.5 BY 0.5 TO 2.5.
- The weights that maximize the log-likelihood function will be saved as variable *WGT#1*.

WEIGHT Subcommand

WEIGHT specifies the variable containing the weights to be used in weighting the cases. WEIGHT is an alternative to computing the weights using the SOURCE and DELTA subcommands. If a variable containing weights is specified, the output includes the regression coefficients, log-likelihood function, and summary regression statistics such as R, R^2, adjusted R^2, standard errors, analysis of variance, and t tests of the coefficients. Since no new weights are computed, no new variable is created.

- The only specification on WEIGHT is the name of the variable containing the weights. Typically, *WGT* variables from previous WLS procedures are used.
- Only one variable can be specified.

Example

```
WLS VARIABLES = SHARES WITH PRICE
  /WEIGHT=WGT_1.
```

- This WLS command uses the weights contained in variable *WGT_1* to weight cases.

CONSTANT and NOCONSTANT Subcommands

Specify CONSTANT or NOCONSTANT to indicate whether a constant term should be estimated in the regression equation. The specification of either subcommand overrides the CONSTANT setting on the TSET command for the current procedure.

- CONSTANT is the default and specifies that the constant term is used as an instrument.
- NOCONSTANT eliminates the constant term.

SAVE Subcommand

SAVE saves the weight variable generated during the current session to the end of the active dataset. The default name *WGT_n* will be generated, where *n* increments to make the variable name unique. The only specification on SAVE is WEIGHT. The specification overrides the NONE or the default CURRENT setting on NEWVAR for the current procedure.

PRINT Subcommand

PRINT can be used to override the PRINT setting on the TSET command for the current procedure. Two keywords are available.

BEST	*Display coefficients for the best weight only.* This is the default.
ALL	*Display coefficients for all weights.*

APPLY Subcommand

- The APPLY subcommand allows you to use a previously defined WLS model without having to repeat the specifications.
- The only specification on APPLY is the name of a previous model in quotes. If a model name is not specified, the model specified on the previous WLS command is used.
- To change one or more model specifications, specify the subcommands of only those portions you want to change after the APPLY subcommand.
- If no variables are specified on the command, the variables that were originally specified with the model being reapplied are used.

Example

```
WLS VARIABLES = X1 WITH Y1
  /SOURCE=Y1
  /DELTA=1.5.
WLS APPLY
  /DELTA=2.
```

- The first command produces a weighted least-squares regression of *X1*, with *Y1* as the source variable and delta equal to 1.5.
- The second command uses the same variable and source but changes the delta value to 2.

Example

```
WLS VARIABLES = X1 WITH Y1 Z1
  /SOURCE=Z1
  /DELTA=1 TO 3 BY 0.5
WLS APPLY
  /WEIGHT=WGT#1.
```

- The first command regresses *X1* on *Y1* and *Z1*, using *Z1* as the source variable. The delta values range from 1 to 3, incrementing by 0.5.
- The second command again regresses *X1* on *Y1* and *Z1*, but this time applies the values of *WGT#1* as the weights.

WRITE

```
WRITE [OUTFILE='file'] [ENCODING='encoding specification']
  [RECORDS={1}] [{NOTABLE}]
                              {n}   {TABLE  }

 /{1    } varlist [{col location [(format)]}] [varlist...]
  {rec #}          {(format list)          }
                   {*                      }

 [/{2    }...]
   {rec #}
```

This command does not read the active dataset. It is stored, pending execution with the next command that reads the dataset. For more information, see Command Order on p. 36.

Release History

Release 16.0

- ENCODING subcommand added for Unicode support.

Example

```
WRITE OUTFILE="/data/personnel.txt' / MOHIRED YRHIRED DEPT SALARY NAME.
EXECUTE.
```

Overview

WRITE writes files in a machine-readable format that can be used by other software applications. When used for this purpose, the OUTFILE subcommand is required. If OUTFILE is not specified, the output from WRITE that can be displayed is included with the output from your session in a format similar to that used by the PRINT command.

Options

Formats. You can specify formats for the variables.

Strings. You can include strings within the variable specifications. The strings can be used to label values or to add extra space between values.

Multiple Lines per Case. You can write variables on more than one line for each case. See the RECORDS subcommand.

Output File. You can direct the output to a specified file using the OUTFILE subcommand.

Summary Table. You can display a table that summarizes the variable formats with the TABLE subcommand.

Subcommand Order

Subcommands can be specified in any order. However, all subcommands must be used before the slash that precedes the first variable list.

Basic Specification

The basic specification is a slash followed by a variable list. The values for all of the variables specified on the list are included with the rest of the output from your session.

Syntax Rules

- A slash must precede the variable specifications. The first slash begins the definition of the first (and possibly only) line per case of the WRITE output.
- Specified variables must already exist, but they can be numeric, string, scratch, temporary, or system variables. Subscripted variable names, such as *X(1)* for the first element in vector *X* cannot be used.
- Keyword ALL can be used to write the values of all user-defined variables in the active dataset.

Operations

- WRITE is executed once for each case constructed from the data file.
- Values are written to the file as the data are read.
- WRITE is a transformation and will not be executed unless it is followed by a procedure or the EXECUTE command.
- When writing to an external file with the OUTFILE subcommand, line/record width can be up to 2.1 billion bytes. When writing to the Viewer, however (when there is no OUTFILE subcommand), if a line width exceeds the line width defined by SET WIDTH, an error results and the WRITE command is not executed. The maximum line width you can specify with SET WIDTH is 255 bytes.
- There are no carriage control characters in the output file generated by WRITE.
- User-missing values are written just like valid values. System-missing values are represented by blanks.
- If you are writing a file to be used on another system, you should take into account that some data types cannot be read by all computers.
- If long records are less convenient than short records with multiple records per case, you can write out a case identifier and insert a string as a record identification number. The receiving system can then check for missing record numbers (see Strings on p. 1990 for an example).

Examples

Writing a Specific Set of Variables

```
WRITE OUTFILE="/data/personnel.txt' / MOHIRED YRHIRED DEPT SALARY NAME.
FREQUENCIES VARIABLES=DEPT.
```

- WRITE writes values for each variable on the variable list to file *personnel.txt*. The FREQUENCIES procedure reads the data and causes WRITE to be executed.
- All variables are written with their dictionary formats.

Writing All Variables

```
WRITE OUTFILE='/data/personnel.txt' /ALL.
EXECUTE.
```

- WRITE writes values for all user-defined variables in the active dataset to file *personnel.txt*. The EXECUTE command executes WRITE.

Formats

By default, WRITE uses the dictionary write formats. You can specify formats for some or all variables specified on WRITE. For a string variable, the specified format must have the same width as that of the dictionary format.

- Format specifications can be either column-style or FORTRAN-like (see DATA LIST). The column location specified with column-style formats or implied with FORTRAN-like formats refers to the column in which the variable will be written.
- A format specification following a list of variables applies to all the variables in the list. Use an asterisk to prevent the specified format from applying to variables preceding the asterisk. The specification of column locations implies a default print format, and that format will apply to all previous variables if no asterisk is used.
- All available formats can be specified on WRITE. Note that hex and binary formats use different widths. For example, the AHEX format must have a width twice that of the corresponding A format. For more information on specifying formats and on the formats available, see DATA LIST and Variable Types and Formats on p. 49.
- Format specifications are in effect only for the WRITE command. They do not change the dictionary write formats.
- To specify a blank between variables in the output, use a string (see Strings on p. 1990), specify blank columns in the format, or use an X or T format element in the WRITE specifications (see DATA LIST for information on X and T).

Example

```
WRITE OUTFILE='/data/personnel.txt' / TENURE (F2.0) ' ' MOHIRED YRHIRED DEPT *
        SALARY85 TO SALARY88 (4(DOLLAR8,1X)) NAME.
EXECUTE.
```

- Format F2.0 is specified for *TENURE*. A blank between quotes is specified as a string after *TENURE* to separate values of *TENURE* from those of *MOHIRED*.
- *MOHIRED, YRHIRED,* and *DEPT* are written with default formats because the asterisk prevents them from receiving the DOLLAR8 format specified for *SALARY85* to *SALARY88*. The 1X format element is specified with DOLLAR8 to add one blank after each value of *SALARY85* to *SALARY88*.
- *NAME* uses the default dictionary format.

Strings

You can specify strings within the variable list. Strings must be enclosed in quotes.

- If a format is specified for a variable list, the application of the format is interrupted by a specified string. Thus, the string has the same effect within a variable list as an asterisk.

Example

```
WRITE OUTFILE='/data/personnel.txt'
  /EMPLOYID '1' MOHIRED YRHIRED SEX AGE JOBCAT NAME
  /EMPLOYID '2' DEPT86 TO DEPT88 SALARY86 TO SALARY88.
EXECUTE.
```

- Strings are used to assign the constant 1 to record 1 of each case, and 2 to record 2 to provide record identifiers in addition to the case identifier *EMPLOYID*.

RECORDS Subcommand

RECORDS indicates the total number of lines written per case. The number specified on RECORDS is informational only. The actual specification that causes variables to be written on a new line is a slash within the variable specifications. Each new line is requested by another slash.

- RECORDS must be specified before the slash that precedes the start of the variable specifications.
- The only specification on RECORDS is an integer to indicate the number of records for the output. If the number does not agree with the actual number of records indicated by slashes, the program issues a warning and ignores the specification on RECORDS.
- Specifications for each line of output must begin with a slash. An integer can follow the slash, indicating the line on which values are to be written. The integer is informational only. It cannot be used to rearrange the order of records in the output. If the integer does not agree with the actual record number indicated by the number of slashes in the variable specifications, the integer is ignored.
- A slash that is not followed by a variable list generates a blank line in the output.

Examples

```
WRITE OUTFILE='/data/personnel.txt' RECORDS=2
  /EMPLOYID NAME DEPT
  /EMPLOYID TENURE SALARY.
EXECUTE.
```

- WRITE writes the values of an individual's name and department on one line, tenure and salary on the next line, and the employee identification number on both lines.

```
WRITE OUTFILE='/data/personnel.txt' RECORDS=2
  /1 EMPLOYID NAME DEPT
  /2 EMPLOYID TENURE SALARY.
EXECUTE.
```

- This command is equivalent to the command in the preceding example.

```
WRITE OUTFILE='/data/personnel.txt' / EMPLOYID NAME DEPT / EMPLOYID TENURE SALARY.
```

```
EXECUTE.
```

- This command is equivalent to the commands in both preceding examples.

OUTFILE Subcommand

OUTFILE specifies the target file for the output from the WRITE command. By default, the output is included with the rest of the output from the session.

- OUTFILE must be specified before the slash that precedes the start of the variable specifications.

Example

```
WRITE OUTFILE='/data/writeout.txt'
   /1 EMPLOYID DEPT SALARY /2 NAME.
EXECUTE.
```

- OUTFILE specifies *writeout.txt* as the file that receives the WRITE output.

ENCODING Subcommand

ENCODING specifies the encoding format of the file. The keyword is followed by an equals sign and a quoted encoding specification.

- In Unicode mode, the default is UTF8. For more information, see SET command, UNICODE subcommand.
- In code page mode, the default is the current locale setting. For more information, see SET command, LOCALE subcommand.
- The quoted encoding value can be: Locale (the current locale setting), UTF8, UTF16, UTF16BE (big endian), UTF16LE (little endian), a numeric Windows code page value (for example, '1252'), or an IANA code page value (for example, 'iso8859-1' or cp1252).
- If there is no OUTFILE subcommand, the ENCODING subcommand is ignored.

TABLE Subcommand

TABLE requests a table showing how the variable information is formatted. NOTABLE is the default.

- TABLE must be specified before the slash that precedes the start of the variable specifications.

Example

```
WRITE OUTFILE='/data/personnel.txt' TABLE
  /1 EMPLOYID DEPT SALARY /2  NAME.
EXECUTE.
```

- TABLE requests a summary table describing the WRITE specifications.

WRITE FORMATS

```
WRITE FORMATS varlist (format) [varlist...]
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Example

```
WRITE FORMATS SALARY (DOLLAR8)
            / HOURLY (DOLLAR7.2)
            / RAISE BONUS (PCT2).
```

Overview

WRITE FORMATS changes variable write formats. Write formats are output formats and control the form in which values are written by the WRITE command.

WRITE FORMATS changes only write formats. To change print formats, use the PRINT FORMATS command. To change both the print and write formats with a single specification, use the FORMATS command. For information on assigning input formats during data definition, see DATA LIST. For detailed information on available formats and specifications, see Variable Types and Formats.

Basic Specification

The basic specification is a variable list followed by the new format specification in parentheses. All specified variables receive the new format.

Syntax Rules

- You can specify more than one variable or variable list, followed by a format in parentheses. Only one format can be specified after each variable list. For clarity, each set of specifications can be separated by a slash.
- You can use keyword TO to refer to consecutive variables in the active dataset.
- The specified width of a format must include enough positions to accommodate any punctuation characters such as decimal points, commas, dollar signs, or date and time delimiters. (This differs from assigning an *input* format on DATA LIST, where the program automatically expands the input format to accommodate punctuation characters in output.)
- Custom currency formats (CCw, CCw.d) must first be defined on the SET command before they can be used on WRITE FORMATS.
- For string variables, you can only use WRITE FORMATS to switch between A and AHEX formats. WRITE FORMATS cannot be used to change the length of string variables. To change the length of a string variable, declare a new variable of the desired length with the STRING command and then use COMPUTE to copy values from the existing string into the new variable.

Operations

- Unlike most transformations, WRITE FORMATS takes effect as soon as it is encountered in the command sequence. Special attention should be paid to its position among commands. For more information, see Command Order on p. 36.
- Variables not specified on WRITE FORMATS retain their current formats in the active dataset. To see the current formats, use the DISPLAY command.
- The new write formats are changed only in the active dataset and are in effect for the duration of the session or until changed again with a WRITE FORMATS or FORMATS command. Write formats in the original data file (if one exists) are not changed, unless the file is resaved with the SAVE or XSAVE command.
- New numeric variables created with transformation commands are assigned default print and write formats of F8.2 (or the format specified on the FORMAT subcommand of SET). The WRITE FORMATS command can be used to change the new variable's write formats.
- New string variables created with transformation commands are assigned the format specified on the STRING command that declares the variable. WRITE FORMATS cannot be used to change the format of a new string variable.
- Date and time formats are effective only with the LIST and TABLES procedures and the PRINT and WRITE transformation commands. All other procedures use F format regardless of the date and time formats specified. For more information, see Date and Time Formats on p. 58.
- If a numeric data value exceeds its width specification, the program attempts to write some value nevertheless. First the program rounds decimal values, then removes punctuation characters, then tries scientific notation, and finally, if there is still not enough space, produces asterisks indicating that a value is present but cannot be written in the assigned width.

Examples

Specifying Write Formats for Multiple Variables

```
WRITE FORMATS SALARY (DOLLAR8)
              / HOURLY (DOLLAR7.2)
              / RAISE BONUS (PCT2).
```

- The write format for *SALARY* is changed to DOLLAR with eight positions, including the dollar sign and comma when appropriate. An eight-digit number would require a DOLLAR11 format specification: eight characters for the digits, two characters for commas, and one character for the dollar sign.
- The write format for *HOURLY* is changed to DOLLAR with seven positions, including the dollar sign, decimal point, and two decimal places.
- The write format for both *RAISE* and *BONUS* is changed to PCT with two positions: one for the percentage and one for the percent sign.

Changing the Default Format of a New Variable

```
COMPUTE V3=V1 + V2.
WRITE FORMATS V3 (F3.1).
```

- COMPUTE creates the new numeric variable *V3*. By default, *V3* is assigned an F8.2 format.

- WRITE FORMATS changes the write format for *V3* to F3.1.

Working With Custom Currency Formats

```
SET CCA='-/-.Dfl ..-'.
WRITE FORMATS COST (CCA14.2).
```

- SET defines a European currency format for the custom currency format type CCA.
- WRITE FORMATS assigns the write format CCA to variable *COST*. See the SET command for more information on custom currency formats.

XGRAPH

XGRAPH is available only on systems with high-resolution graphics capabilities.

Note: Square brackets used in the XGRAPH syntax chart are required parts of the syntax and are not used to indicate optional elements. Any equals signs (=) displayed in the syntax chart are required. All subcommands except the chart expression in the first line are optional.

```
XGRAPH CHART=yvars BY xvars BY zvars

  /BIN START={AUTO**} SIZE={AUTO**   }
             {x     }      {WIDTH (x)}
                           {COUNT (n)}

  /DISPLAY DOT={ASYMMETRIC**}
               {SYMMETRIC   }
               {FLAT        }

  /DISTRIBUTION TYPE=NORMAL

  /COORDINATE SPLIT={NO**}
                    {YES }

  /ERRORBAR {CI     {(95)}}
                    {(n) }
            {STDDEV {(2) }}
                    {(n) }
            {SE     {(2) }}
                    {(n) }

  /MISSING USE={LISTWISE**  } REPORT={NO**}
               {VARIABLEWISE}        {YES }

  /PANEL COLVAR=varlist COLOP={CROSS**} ROWVAR=varlist ROWOP={CROSS**}
                              {NEST   }                     {NEST   }

  /TEMPLATE FILE='filespec'

  /TITLES TITLE='line' 'line2' SUBTITLE='line1'
          FOOTNOTE='line1' 'line2'
```

** Default if the subcommand is omitted.

yvars defines the *y* dimension and has the general form:

```
(varname [function] [data_element_type] + ...) > {varname {[COLOR]  }}
                                                 {[PATTERN]}
                                                 {1       {[COLOR]  }}
                                                          {[PATTERN]}
```

xvars and zvars define the *x* and *z* dimensions and have the general form:

```
{varname {[c]}              } > varname {[COLOR]  }
         {[s]}}                         {[PATTERN]}
{$CASENUM [LABEL=varname]   }
{1                          }
```

The + operator blends the *y*-axis to accommodate all the *y*-axis variables. It is used when separate variables are displayed on the same axis. The number 1 is a placeholder for the variables on the axis. The > operator stacks data elements on the *y*-axis and clusters data elements on the *x*-axis and *z*-axis. [c] or [s] indicates whether the variable should be treated as categorical or scale. $CASENUM is used when individual cases are displayed on the same axis.

Summary functions available for yvars: VALUE, COUNT, PCT, CUPCT, CUFREQ, MINIMUM, MAXIMUM, VALIDN, SUM, CSUM, MEAN, STDDEV, VARIANCE, MEDIAN, GMEDIAN, MODE, PTILE(x), GPTILE(x), PLT(x), PGT(x), NLT(x), NGT(x), PIN(x1,x2), and NIN(x1,x2).

Data element types available for yvars: BAR, HISTOBAR, and POINT.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Release History

Release 13.0

- Command introduced.

Example

```
XGRAPH CHART=([COUNT] [BAR]) BY jobcat [c] BY gender [c].
```

Overview

XGRAPH generates a high-resolution chart by computing statistics from variables in the active dataset and constructing the chart according to your specification. The chart can be a 3-D bar chart, population pyramid, or dot plot. The chart is displayed where high-resolution display is available and can be edited with the Chart Editor and saved in an Output file.

Note: Although you can create other charts with XGRAPH, these are not currently supported.

Basic Specification

The basic specification is the command name followed by a chart expression. The chart expression must identify one or more variables and a data element for the chart.

Syntax Rules

- The chart expression is required and must appear first. It can optionally be preceded by CHART=. If CHART is used, the = must be present. All other subcommands are optional.
- After the chart expression, subcommands can appear in any order.
- Only a single instance of each subcommand is allowed.
- Subcommand names and keywords must be spelled in full.
- Required square brackets cannot be merged for different types of specifications. For example, when a summary function and a data element are adjacent, they cannot be merged. That is, [VALUE] [BAR] cannot be written as [VALUE BAR].

Limitations

- XGRAPH does not produce charts with more than 1,000,000 data values.
- When a weight is in effect and the ERRORBAR subcommand is used on a chart that displays medians, counts, or percentages, the case weights must be integers.

CHART Expression

The **chart expression** defines the data and the role of that data in the chart. It also specifies the data element type and any clustering and stacking. For clustered and stacked charts, the chart expression specifies whether color or patterns are used to distinguish the clustered and stacked groups. For charts of individual cases (that is, when `$CASENUM` defines a categorical axis), the chart expression can also specify a label variable.

- The `CHART` keyword is optional. If it is used, it must be followed by an equals sign (=).
- The order within the chart expression matters. The `yvars` (the *y* dimension) must be first, followed by `xvars` and then `zvars`.
- The final `BY` variable is used as the splitter variable in a population pyramid when the `COORDINATE` subcommand specifies `SPLIT`.
- There is a limit to the number of stack and cluster specifications. There can be two clusters, or one stack and one cluster.

Functions

Functions must be enclosed in square brackets.

Value function:

The `VALUE` function yields the value of the specified *y*-axis variable for each case. It always produces one data element for each case.

Aggregation functions:

Two groups of aggregation functions are available: count functions and summary functions.

Count functions:

COUNT	*Frequency of cases in each category.*
PCT	*Frequency of cases in each category expressed as a percentage of the whole.*
CUPCT	*Cumulative percentage sorted by category value.*
CUFREQ	*Cumulative frequency sorted by category value.*

- Count functions yield the count or percentage of valid cases within categories determined by the `xvars` and the `zvars`, as in:

```
XGRAPH ([PCT] [BAR]) BY jobcat [c] BY gender [c].
```

- Count functions do not operate on a variable.
- Count functions do not have any arguments.

Summary functions:

MINIMUM	*Minimum value of the variable.*
MAXIMUM	*Maximum value of the variable.*

VALIDN	*Number of cases for which the variable has a nonmissing value.*
SUM	*Sum of the values of the variable.*
CUSUM	*Sum of the summary variable accumulated across values of the category variable.*
MEAN	*Mean.*
STDDEV	*Standard deviation.*
VARIANCE	*Variance.*
MEDIAN	*Median.*
GMEDIAN	*Group median.*
MODE	*Mode.*
PTILE(x)	X*th percentile value of the variable. X* must be greater than 0 and less than 100.
PLT(x)	*Percentage of cases for which the value of the variable is less than* x.
PGT(x)	*Percentage of cases for which the value of the variable is greater than* x.
NLT(x)	*Number of cases for which the value of the variable is less than* x.
NGT(x)	*Number of cases for which the value of the variable is greater than* x.
PIN(x1,x2)	*Percentage of cases for which the value of the variable is greater than or equal to* x1 *and less than or equal to* x2. *x1* cannot exceed *x2*.
NIN(x1,x2)	*Number of cases for which the value of the variable is greater than or equal to* x1 *and less than or equal to* x2. *x1* cannot exceed *x2*.

- Summary functions operate on summary variables (variables that record continuous values, like age or expenses). To use a summary function, specify the name of one or more variables before the name of the function and the data element type, both of which are in square brackets, as in:

```
XGRAPH (salary [SUM] [BAR]) BY jobcat[c] BY gender[c].
```

- You can specify a list of variables on which the function operates, as in:

```
XGRAPH ((salary + salbegin) [SUM] [BAR]) BY jobcat[c] BY gender[c].
```

  This syntax is equivalent to:

```
XGRAPH (salary [SUM] [BAR] + salbegin [SUM] [BAR]) BY jobcat[c] BY
gender[c].
```

Data Element Types

The data element type is a basic description of how the data are represented on the chart.

BAR	*Draws a bar data element.* Bars show the results of a summary function. Used for 3-D bar charts and population pyramids that show the distribution of a categorical variable.
HISTOBAR	*Draws a histogram data element.* Histogram data elements show the counts in a range of cases. A range of cases is called a bin. Used for population pyramids.
POINT	*Draws a point marker.* A point marker shows a case with a specific *x*-axis value. Used for dot plots.

Measurement Level

The chart expression allows the user to specify a measurement level for BY variables. If measurement level is not specified, the following occurs:

- In a chart of BAR elements, xvars and zvars are treated as categorical.
- In a chart of HISTOBAR elements, xvars is treated as scale. zvars is treated as categorical, because the COORDINATE subcommand and SPLIT keyword are always used.
- In charts of POINT elements, the measurement level is obtained from the SPSS data dictionary for each variable. If no measurement levels have been defined, numeric variables are treated as scale and string variables are treated as categorical.

[c] *Specifies that the variable is treated as a categorical variable.*

[s] *Specifies that the variable is treated as a scale variable.*

Variable Placeholder

When summaries of separate variables are used to define a categorical axis, clustering, or stacking, 1 must be used as a variable placeholder.

1 *Uses the separate variables specified in yvars as categories on the axis, cluster categories, or stack categories. Must be defined as an integer (no decimal places).*

Examples

```
XGRAPH CHART=((salary + salbegin) [MEAN] [BAR]) BY 1 BY gender[c].
```

- Separate variables appear on the *y*-axis.

```
XGRAPH CHART=((salary + salbegin) [MEAN] [BAR]) BY gender[c] BY 1.
```

- Separate variables appear on the *z*-axis.

Case Numbers

Whenever the VALUE function is used, one categorical axis consists of cases, which are identified by a sequential number.

$CASENUM *Uses the sequential numbering of selected cases as the categories on the axis.* This is not the actual case number.

Example

```
XGRAPH CHART=(salary [VALUE]) BY gender[c] BY $CASENUM.
```

Blending, Clustering, and Stacking

Blending on an axis is indicated by +. This is used when separate variables are displayed on the same axis.

Clustering and stacking are indicated by >. On the *x*- or *z*-axis, this indicates clustering. On the *y*-axis, this indicates stacking. Stacking is allowed with one clustering variable; or two clustering variables are allowed, one on the *x*-axis and one on the *z*-axis.

+ *Scales the axis to accommodate all of the variables on that dimension.*

> *Stacks groups on the y-axis, and clusters groups on the x- and z-axes.*

Stacking Example

```
XGRAPH CHART=(salary [MEAN] [BAR]) > educ BY jobcat[c] by gender[c].
```

Clustering Example

```
XGRAPH CHART=(salary [MEAN] [BAR]) BY jobcat[c] > educ by gender[c].
```

When you use clustering or stacking, you can specify how the clusters and stacks are differentiated in the chart.

[COLOR] *Uses color to differentiate the clusters or stacks.*

[PATTERN] *Uses pattern to differentiate the clusters or stacks.*

[COLOR] and [PATTERN] follow these rules:

- The actual colors and patterns are specified in the Options. You can access these by choosing Options from the Edit menu. Then click the Charts tab.
- [COLOR] and [PATTERN] follow the stacking or clustering variable in the chart expression.
- If the specification is omitted, color is used to differentiate the clusters or stacks. The color cycle starts over for each dimension.
- If neither [COLOR] nor [PATTERN] is specified, XGRAPH uses the Style Cycle Preference specified by the Options.
- If [COLOR] or [PATTERN] is specified for both dimensions, these specifications are honored. The color or pattern cycle starts over for each dimension.
- If [COLOR] or [PATTERN] is specified for only one dimension, the specification is honored, and the other dimension uses the other specification.

Example

```
XGRAPH CHART=(salary [MEAN] [BAR]) BY jobcat[c] > educ[PATTERN]
by gender[c].
```

Labels

On categorical charts of individual cases, you can specify a labeling variable by using `[LABEL=varname]` in the chart expression. `[LABEL=varname]` follows `$CASENUM` in the chart expression.

[LABEL=varname] *The variable whose values are used as the tick labels instead of the case number.*

Example

```
XGRAPH CHART=(salary [VALUE] [BAR]) BY $CASENUM[LABEL=gender]
> jobcat BY educ.
```

BIN Subcommand

For population pyramids, the `BIN` subcommand controls the starting point and size of the bins. The bins are the bars in the chart and represent a group of data values. For example, if there are four bins in a chart and the values range from 0-100, the bin width is 25. Therefore, all points with values of 0-24 would be in the first bin, those with values of 25-49 would be in the second bin, and so on. Each keyword is followed by an equals sign (=) and the value for that keyword.

Example

```
XGRAPH CHART=([HISTOBAR]) BY age[s] BY gender[c]
  /COORDINATE SPLIT=YES
  /BIN START=30 SIZE=WIDTH(5).
```

- The first bin begins at age 30.
- Each bin includes cases with *age* values that span 5 years.
- So the first bin contains the cases with ages 30-34, the second bin contains the cases with ages 35-39, and so on.

START Keyword

The `START` keyword specifies the starting value of the first bin in the chart.

AUTO *Adjust the starting value of the first bin according to the data values.* The starting value is set so the first bin includes the lowest data value and the bin boundaries are at good values. This is the default.

value *User-specified starting value.* The value can be set lower than the lowest data value so the first bin includes values that are not in the dataset. For example, if the lowest value in the dataset is 6, the starting value can be set to 0 so the values of 0–5 are included in the first bin.

Note: If the variable being binned is a date, the starting value must be a data literal in quotes and in the date format specified for the variable in the SPSS data dictionary (for example, 'January 1, 2001').

SIZE Keyword

The SIZE keyword specifies the width of the bins. The width can be determined by an exact value or by the number of bins (fewer bins result in wider bins).

AUTO	*Adjust bin width according to the data values.* The size is set so the bins are neither too few nor too narrow. This is the default.
WIDTH (value)	*User-specified value for the bin width.* *Note*: If the variable being binned is a date, the width must be specified in quotes and in the duration format ddd hh:mm (for example, '30 12:00' for bin widths of 30 days and 12 hours). The hh:mm portion of the duration format is optional.
COUNT (value)	*User-specified value for the number of bins.*

DISPLAY Subcommand

DISPLAY controls how the data elements are displayed. Currently this subcommand applies to dot plots.

DOT Keyword

The DOT keyword controls the display of points in a dot plot.

ASYMMETRIC	*Stack the points on the x-axis.* This is the default.
SYMMETRIC	*Arrange the points symmetrically across a central horizontal line in the chart.* In other words, the point stacks are vertically centered.
FLAT	*Do not stack the points.*

DISTRIBUTION Subcommand

The DISTRIBUTION subcommand adds distribution curves to the chart. This subcommand applies to population pyramids.

Example

```
XGRAPH CHART=([HISTOBAR]) BY age[s] BY gender[c]
  /DISTRIBUTION TYPE=NORMAL
  /COORDINATE SPLIT=YES.
```

TYPE Keyword

The TYPE keyword specifies the type of distribution to draw on the chart. The keyword is followed by an equals sign (=) and the value for that keyword.

NORMAL	*Display a normal curve on the chart.* The normal curve uses the data mean and standard deviation as parameters. This is the default.

COORDINATE Subcommand

The COORDINATE subcommand specifies the coordinate system for the chart. Currently this subcommand is used to create population pyramids.

SPLIT Keyword

The SPLIT keyword specifies whether zvars (the variable after the last BY in the chart expression) is used to split the chart and create a population pyramid. The keyword is followed by an equals sign (=) and the value for that keyword.

Note: The SPLIT keyword is not the same as the PANEL subcommand. The keyword splits the chart before it is paneled.

NO *Do not split the chart.* This is the default.

YES *Split the chart and create a population pyramid.*

ERRORBAR Subcommand

The ERRORBAR subcommand adds errors bars to the chart. Error bars indicate the variability of the summary statistic being displayed. The length of the error bar on either side of the summary statistic represents a confidence interval or a specified number of standard errors or standard deviations. Currently, XGRAPH supports error bars for COUNT and population pyramids.

The keywords are not followed by an equals sign (=). They are followed by a value in parentheses.

Example

```
XGRAPH CHART=([COUNT] [BAR]) BY agecat[c] BY gender[c]
  /COORDINATE SPLIT=YES
  /ERRORBAR CI(95).
```

CI Keyword

(value) *The percentage of the confidence interval to use as the length of the error bars.*

STDDEV Keyword

(value) *A multiplier indicating the number of standard deviations to use as the length of the error bars.*

SE Keyword

(value) *A multiplier indicating the number of standard errors to use as the length of the error bars.*

MISSING Subcommand

MISSING controls the treatment of missing values in the chart drawn by XGRAPH.

- For an aggregated categorical chart, if every aggregated series is empty in a category, the empty category is excluded.

Each keyword in the subcommand is followed by an equals sign (=) and the value for that keyword.

USE Keyword

The USE keyword controls the exclusion of cases with missing values. Excluded cases are excluded from computations and charts. USE applies to variables used in summary functions for a chart.

LISTWISE *Exclude a case with a missing value for any dependent variable.* This is the default.

VARIABLEWISE *Exclude a case with a missing value for the dependent variable being analyzed.*

REPORT Keyword

The REPORT keyword specifies whether to report on missing values by creating missing-values categories in the chart. REPORT applies only to categorical variables, including paneling variables and the splitter variable in a population pyramid.

NO *Do not create a missing-values categories.* This is the default.

YES *Create a missing-values categories.*

PANEL Subcommand

The PANEL subcommand specifies the variables and method used for paneling.

Each keyword in the subcommand is followed by an equals sign (=) and the value for that keyword.

COLVAR and ROWVAR Keywords

The COLVAR and ROWVAR keywords identify the column and row variables, respectively. Each category in a column variable appears as a vertical column in the resulting chart. Each category in a row variable appears as a horizontal row in the resulting chart.

- If multiple variables are specified for a keyword, the COLOP and ROWOP keywords can be used to change the way in which variable categories are rendered in the chart.
- The ROWVAR keyword is not available for population pyramids.

varlist *The list of variables used for paneling.*

Examples

```
XGRAPH CHART=([COUNT] [BAR]) BY educ [c] BY gender [c]
  /PANEL COLVAR=minority.
```

- There are two columns in the resulting paneled chart, one for minorities and one for non-minorities.
- Because there is only one paneling variable, there are only as many panels as there are variable values. Therefore, there are two panels.

```
XGRAPH CHART=([COUNT] [BAR]) BY educ [c] BY gender [c]
  /PANEL COLVAR=minority ROWVAR=jobcat.
```

- There are two columns in the resulting paneled chart (for the *minority* variable values) and three rows (for the *jobcat* variable values).

COLOP and ROWOP Keywords

The COLOP and ROWOP keywords specify the paneling method for the column and row variables, respectively. These keywords have no effect on the chart if there is only one variable in the rows and/or columns. They also have no effect if the data are not nested.

CROSS *Cross variables in the rows or columns.* When the variables are crossed, a panel is created for every combination of categories in the variables. For example, if the categories in one variable are A and B and the categories in another variable are 1 and 2, the resulting chart will display a panel for the combinations of A and 1; A and 2; B and 1; and B and 2. A panel can be empty if the categories in that panel do not cross (for example, if there are no cases in the B category *and* the 1 category). This is the default.

NEST *Nest variables in the rows or columns.* When the variables are nested, a panel is created for each category that is nested in the parent category. For example, if the data contain variables for states and cities, a panel is created for each city and the relevant state. However, panels are not created for cities that are not in certain states, as would happen with CROSS. See the following example. When nesting, make sure the variables specified for ROWVAR or COLVAR are in the correct order. Parent variables precede the child variables.

Example

Assume data like the following data:

Table 255-1
Nested data

state	city	temperature
NJ	Springfield	70
MA	Springfield	60
IL	Springfield	50
NJ	Trenton	70
MA	Boston	60

You can create a paneled chart from this data with the following syntax:

```
XGRAPH ([POINT]) BY temperature
  /PANEL COLVAR=state city COLOP=CROSS.
```

The command crosses every variable value to create the panels. Because not every state contains every city, the resulting paneled chart will contain blank panels. For example, there will be a blank panel for Springfield and New Jersey. In this dataset, the *city* variable is really nested in the *state* variable. To nest the variables in the panels and eliminate any blank panels, use the following syntax:

```
XGRAPH ([POINT]) BY temperature
  /PANEL COLVAR=state city COLOP=NEST.
```

TEMPLATE Subcommand

TEMPLATE uses an existing file as a template and applies it to the chart requested by the current XGRAPH command. The template overrides the default settings that are used to create any chart, and the specifications on the current XGRAPH command override the template. Templates are created in the Chart Editor by saving an existing chart as a template.

Example

```
XGRAPH CHART=([COUNT] [BAR]) BY jobcat [c] BY gender [c].
  /TEMPLATE FILE='mytemplate.sgt'.
```

FILE Keyword

The FILE keyword specifies the template file. The keyword is followed by an equals sign (=) and a file specification enclosed in quotes.

filespec *Applies the specified template file to the chart being created.*

TITLES Subcommand

The TITLES subcommand specifies the titles, subtitles, and footnotes. These are lines of text at the top or bottom of the chart.

- At least one keyword should be specified if the TITLES subcommand is used; otherwise the subcommand is treated as blank.
- If the subcommand is blank, an error is issued.
- Each line of text must be enclosed in quotes. The maximum length of any line is 255 bytes.
- When a keyword is specified with no text, an error is issued.

The following symbols can be used within the lines of text. Each must be specified using an opening right parenthesis and uppercase letters.

)DATE *Displays the current date as a locale-appropriate date stamp that includes the year, month, and day.*

)TIME *Displays the current time as a locale-appropriate time stamp.*

)CHART *Displays the chart expression used to create the chart, stripped of measurement levels, statistics specifications, and* CHART=. If variable labels are available, they are used instead of the variable names in the chart expression.

Example

```
XGRAPH CHART=([COUNT] [BAR]) BY jobcat [c] BY gender [c]
  /TITLES TITLE='Counts by Job Category and Gender' 'Date: )DATE'.
```

TITLE Keyword

'line1' 'line2' *The lines of text in the title.* The title appears above the chart. Up to two lines can be specified.

SUBTITLE Keyword

'line1' *The line of text in the subtitle.* The subtitle appears below the title. Only one line can be specified.

FOOTNOTE Keyword

'line1' 'line2' *The lines of text in the footnote.* The footnote appears below the chart. Up to two lines can be specified.

3-D Bar Examples

A 3-D bar chart is a bar chart with two categorical axes (*x* and *z*). The height of the bars is determined by a summary function. The categories on the *x*- and *z*-axes can be values of categorical variables, separate variables, or individual cases.

Examples of Summaries for Groups of Cases

```
XGRAPH CHART=([COUNT] [BAR]) BY jobcat[c] by gender[c].
```

- The bars in the chart represent counts for males and females in each job category.

```
XGRAPH CHART=(salary [MEAN] [BAR])> educ[PATTERN] BY jobcat[c] >
minority[COLOR] by gender[c].
```

- The bars in the chart represent the mean salary for males and females in each job category clustered by minority membership.
- The bars are also stacked by education level.
- Clusters are distinguished by color, and stacks are distinguished by pattern.

Example of Summaries of Separate Variables by Group

```
XGRAPH CHART=((salary + salbegin) [MEAN] [BAR]) BY 1 BY gender[c].
```

- The bars in the chart represent the mean current salary and mean beginning salary for males and females.
- The blending operator (+) indicates that the chart is for separate variables.
- The `1` placeholder indicates the axis on which the separate variables appear.

- The variables appear on the *x*-axis, and the gender categories are on the *z*-axis.

Examples of Individual Cases in Groups

```
XGRAPH CHART=(salary [VALUE] [BAR]) BY gender[c] BY $CASENUM.
```

- The bars in the chart represent the current salary for each case with the cases grouped by gender.
- VALUE is the only function available when creating charts of individual cases.

Examples for Values of Individual Cases for Separate Variables

```
XGRAPH CHART=((salary + salbegin) [VALUE] [BAR]) BY $CASENUM BY 1.
```

- The bars in the chart represent the value of the current salary and the value of the beginning salary for every case.
- The cases are on the *x*-axis, and the variables are on the *z*-axis.

```
XGRAPH CHART=((salary + salbegin) [VALUE] [BAR]) BY
$CASENUM[LABEL=gender] BY 1.
```

- This is the same as the previous example except that the bars are labeled by gender.

Population Pyramid Examples

A population pyramid uses bars to show the shape of a distribution split by a categorical variable. The variable used for the distribution can be a scale or categorical. When the variable is scale, the data element type must be HISTOBAR. When the variable is categorical, the data element type is BAR.

Example Using Continuous Data

```
XGRAPH CHART=([HISTOBAR]) BY age[s] BY gender[c]
  /COORDINATE SPLIT=YES.
```

- The bars in the chart represent the number of cases in each *age* bin.
- The population pyramid is split by gender.

Example Using Categorical Data

```
XGRAPH CHART=([COUNT] [BAR]) BY agecat[c] BY gender[c]
  /COORDINATE SPLIT=YES.
```

- The *agecat* variable has categories for different age groups.
- The bars in the chart represent the number of cases in each *agecat* category. This is not necessarily the same as the previous example because the size of the bins and the size of the categories might not match.

Example Using Pre-Aggregated Data

```
XGRAPH CHART=(population [SUM] [BAR]) BY agecat[c] BY gender[c]
```

```
/COORDINATE SPLIT=YES.
```

- The bars in the chart represent the number of cases in each *agecat* category.
- The data include a *population* variable that specifies the count for each *agecat* category for each gender. In other words, the data are pre-aggregated.

Example Using Pre-Aggregated Data Without a Categorical Splitter Variable

In the previous example, there was a categorical variable to use as the splitter variable. In some census data, the data are not organized in this manner. Instead of a splitter variable, there is one variable for each split value. An example follows:

Table 255-2
Pre-aggregated data without a categorical splitter variable

agecat	malepop	femalepop
1	247	228
2	306	300
3	311	303

Data in this format needs to be restructured by using the VARSTOCASES command:

```
VARSTOCASES /ID = id
  /MAKE population FROM malepop femalepop
  /INDEX = gender(2)
  /KEEP = agecat
  /NULL = KEEP.
```

Running this command results in the following. The splitter variable is *gender*.

Table 255-3
Pre-aggregated data with a categorical splitter variable

id	agecat	gender	population
1	1	1	247
1	1	2	228
2	2	1	306
2	2	2	300
3	3	1	311
3	3	2	303

Now a population pyramid can be created using the categorical splitter variable:

```
XGRAPH (population [SUM] [BAR]) BY agecat[c] BY gender[c]
  /COORDINATE SPLIT=YES.
```

Dot Plot Examples

A dot plot shows the value in one dimension (the *x*-axis) of each selected case. The variable on the *x*-axis can be scale or categorical.

```
XGRAPH CHART=([POINT]) BY jobcat[c].
```

- The chart shows cases represented as points.
- Cases are stacked at each *jobcat* value. So, if there are three categories for `jobcat`, there are only three stacks.

```
XGRAPH CHART=([POINT]) BY salary[s].
```

- Cases are stacked at each *salary* value. The *x*-axis is a continuous range of values.

```
XGRAPH CHART=([POINT]) BY salary[s]
  /DISPLAY DOT=SYMMETRIC.
```

- Same as the previous example except the stacked dots are centered vertically in the chart.

XSAVE

```
XSAVE OUTFILE='filespec'

 [/KEEP={ALL**  }] [/DROP=varlist]
        {varlist}

 [/RENAME=(old varlist=new varlist)...]

 [/MAP] [/{COMPRESSED  }]
          {UNCOMPRESSED}

 [/PERMISSIONS={READONLY }
               {WRITEABLE}
```

**Default if the subcommand is omitted.

This command does not read the active dataset. It is stored, pending execution with the next command that reads the dataset. For more information, see Command Order on p. 36.

Example

```
XSAVE OUTFILE='/data/empl.sav'.
```

Overview

XSAVE produces an SPSS-format data file. An SPSS-format data file contains data plus a dictionary. The dictionary contains a name for each variable in the data file plus any assigned variable and value labels, missing-value flags, and variable print and write formats. The dictionary also contains document text created with the DOCUMENTS command.

SAVE also creates SPSS-format data files. The principal difference is that XSAVE is not executed until data are read for the next procedure, while SAVE is executed by itself. Thus, XSAVE can reduce processing time by consolidating two data passes into one.

See SAVE TRANSLATE for information on saving data files that can be used by other programs.

Options

Variable Subsets and Order. You can save a subset of variables and reorder the variables that are saved using the DROP and KEEP subcommands.

Variable Names. You can rename variables as they are copied into the SPSS-format data file using the RENAME subcommand.

Variable Map. To confirm the names and order of the variables saved in the SPSS-format data file, use the MAP subcommand. MAP displays the variables saved in the SPSS-format data file next to their corresponding names in the active dataset.

Data Compression. You can write the data file in compressed or uncompressed form using the COMPRESSED or UNCOMPRESSED subcommand.

Basic Specification

The basic specification is the OUTFILE subcommand, which specifies a name for the SPSS-format data file to be saved.

Subcommand Order

- Subcommands can be specified in any order.

Syntax Rules

- OUTFILE is required and can be specified only once. If OUTFILE is specified more than once, only the last OUTFILE specification is in effect.
- KEEP, DROP, RENAME, and MAP can be used as many times as needed.
- Only one of the subcommands COMPRESSED or UNCOMPRESSED can be specified per XSAVE command.
- Documentary text can be dropped from the active dataset with the DROP DOCUMENTS command.
- XSAVE cannot appear within a DO REPEAT–END REPEAT structure.
- Multiple XSAVE commands writing to the same file are not permitted.

Operations

- Unlike the SAVE command, XSAVE is a transformation command and is executed when the data are read for the next procedure.
- The new SPSS-format data file dictionary is arranged in the same order as the active dataset dictionary unless variables are reordered with the KEEP subcommand. Documentary text from the active dataset dictionary is always saved unless it is dropped with the DROP DOCUMENTS command before XSAVE.
- New variables created by transformations and procedures previous to the XSAVE command are included in the new SPSS-format data file, and variables altered by transformations are saved in their modified form. Results of any temporary transformations immediately preceding the XSAVE command are included in the file; scratch variables are not.
- SPSS-format data files are binary files designed to be read and written by SPSS only. SPSS-format data files can be edited only with the UPDATE command. Use the MATCH FILES and ADD FILES commands to merge SPSS-format data files.
- The active dataset is still available for transformations and procedures after XSAVE is executed.
- XSAVE processes the dictionary first and displays a message that indicates how many variables will be saved. Once the data are written, XSAVE indicates how many cases were saved. If the second message does not appear, the file was probably not completely written.

Limitations

- Maximum of 10 XSAVE commands are allowed within a single set of transformations.

Examples

Using XSAVE to Consolidate Two Data Passes Into One

```
GET FILE='/data/hubempl.sav'.
XSAVE OUTFILE='/data/empl88.sav'
  /RENAME=(AGE=AGE88) (JOBCAT=JOBCAT88).
MEANS RAISE88 BY DEPT88.
```

- The GET command retrieves the SPSS-format data file *hubempl.sav*.
- The RENAME subcommand renames variable *AGE* to *AGE88* and variable *JOBCAT* to *JOBCAT88*.
- XSAVE is not executed until the program reads the data for procedure MEANS. The program saves file *empl88.sav* and generates a MEANS table in a single data pass.
- After MEANS is executed, the *hubempl.sav* file is still the active dataset. Variables *AGE* and *JOBCAT* retain their original names in the active dataset.

Using Temporary Transformations With XSAVE

```
GET FILE=hubempl.sav.
TEMPORARY.
RECODE DEPT85 TO DEPT88 (1,2=1) (3,4=2) (ELSE=9).
VALUE LABELS DEPT85 TO DEPT88 1 'MANAGEMENT' 2 'OPERATIONS' 3 'UNKNOWN'.
XSAVE OUTFILE='/data/hubtemp.sav'.
CROSSTABS DEPT85 TO DEPT88 BY JOBCAT.
```

- Both the saved data file and the CROSSTABS output will reflect the temporary recoding and labeling of the department variables.
- If SAVE were specified instead of XSAVE, the data would be read twice instead of once and the CROSSTABS output would not reflect the recoding.

OUTFILE Subcommand

OUTFILE specifies the SPSS-format data file to be saved. OUTFILE is required and can be specified only once. If OUTFILE is specified more than once, only the last OUTFILE is in effect. The file specification should be enclosed in quotes.

DROP and KEEP Subcommands

DROP and KEEP are used to save a subset of variables. DROP specifies the variables not to save in the new data file, while KEEP specifies the variables to save in the new data file; variables not named on KEEP are dropped.

- Variables can be specified in any order. The order of variables on KEEP determines the order of variables in the SPSS-format data file. The order on DROP does not affect the order of variables in the SPSS-format data file.
- Keyword ALL on KEEP refers to all remaining variables not previously specified on KEEP. ALL must be the last specification on KEEP.
- If a variable is specified twice on the same subcommand, only the first mention is recognized.

- Multiple DROP and KEEP subcommands are allowed. Specifying a variable that is not in the active dataset or that has been dropped because of a previous DROP or KEEP subcommand results in an error, and the XSAVE command is not executed.
- Keyword TO can be used to specify a group of consecutive variables in the SPSS-format data file.

Dropping a Range of Variables

```
XSAVE OUTFILE='/data/hubtemp.sav'
  /DROP=DEPT79 TO DEPT84 SALARY79.
CROSSTABS DEPT85 TO DEPT88 BY JOBCAT.
```

- The SPSS-format data file is saved as *hubtemp.sav*. All variables between and including *DEPT79* and *DEPT84*, as well as *SALARY79*, are excluded from the SPSS-format data file. All other variables are saved.

Specifying Variable Order With XSAVE

```
GET FILE='/data/prsnl.sav'.
COMPUTE  TENURE=(12-CMONTH +(12*(88-CYEAR)))/12.
COMPUTE  JTENURE=(12-JMONTH +(12*(88-JYEAR)))/12.
VARIABLE LABELS   TENURE 'Tenure in Company'
                  JTENURE 'Tenure in Grade'.
XSAVE OUTFILE='/data/prsnl88.sav' /DROP=GRADE STORE
 /KEEP=LNAME NAME TENURE JTENURE ALL.
REPORT FORMAT=AUTO /VARS=AGE TENURE JTENURE SALARY
 /BREAK=DIVISION /SUMMARY=MEAN.
```

- Variables *TENURE* and *JTENURE* are created by COMPUTE commands and assigned variable labels by the VARIABLE LABELS command. *TENURE* and *JTENURE* are added to the end of the active dataset.
- DROP excludes variables *GRADE* and *STORE* from file *PRSNL88*. KEEP specifies that *LNAME, NAME, TENURE*, and *JTENURE* are the first four variables in file *prsnl88.sav*, followed by all remaining variables not specified on DROP. These remaining variables are saved in the same sequence as they appear in the original file.

RENAME Subcommand

RENAME changes the names of variables as they are copied into the new SPSS-format data file.

- The specification on RENAME is a list of old variable names followed by an equals sign and a list of new variable names. The same number of variables must be specified on both lists. Keyword TO can be used on the first list to refer to consecutive variables in the active dataset and on the second list to generate new variable names. The entire specification must be enclosed in parentheses.
- Alternatively, you can specify each old variable name individually, followed by an equals sign and the new variable name. Multiple sets of variable specifications are allowed. The parentheses around each set of specifications are optional.
- RENAME does not affect the active dataset. However, if RENAME precedes DROP or KEEP, variables must be referred to by their new names on DROP or KEEP.
- Old variable names do not need to be specified according to their order in the active dataset.

- Name changes take place in one operation. Therefore, variable names can be exchanged between two variables.
- Multiple RENAME subcommands are allowed.

Examples

```
XSAVE OUTFILE='/data/empl88.sav'
  /RENAME  AGE=AGE88 JOBCAT=JOBCAT88.
CROSSTABS DEPT85 TO DEPT88 BY JOBCAT.
```

- RENAME specifies two name changes for file *empl88.sav*: *AGE* is renamed to *AGE88* and *JOBCAT* is renamed to *JOBCAT88*.

```
XSAVE OUTFILE='/data/empl88.sav'
  /RENAME (AGE JOBCAT=AGE88 JOBCAT88).
CROSSTABS DEPT85 TO DEPT88 BY JOBCAT.
```

- The name changes are identical to those in the previous example: *AGE* is renamed to *AGE88* and *JOBCAT* is renamed to *JOBCAT88*. The parentheses are required with this method.

MAP Subcommand

MAP displays a list of the variables in the SPSS-format data file and their corresponding names in the active dataset.

- The only specification is keyword MAP. There are no additional specifications.
- Multiple MAP subcommands are allowed. Each MAP subcommand maps the results of subcommands that precede it, but not results of subcommands that follow it.

Example

```
GET FILE='/data/hubempl.sav'.
XSAVE OUTFILE='/data/empl88.sav'
 /RENAME=(AGE=AGE88) (JOBCAT=JOBCAT88)
 /KEEP=LNAME NAME JOBCAT88 ALL /MAP.
MEANS RAISE88 BY DEPT88.
```

- MAP is used to confirm the new names for *AGE* and *JOBCAT* and the order of variables in the *empl88.sav* file (*LNAME, NAME,* and *JOBCAT88*, followed by all remaining variables from the active dataset).

COMPRESSED and UNCOMPRESSED Subcommands

COMPRESSED saves the file in compressed form. UNCOMPRESSED saves the file in uncompressed form. In a compressed file, small integers (from –99 to 155) are stored in one byte instead of the eight bytes used in an uncompressed file.

- The only specification is the keyword COMPRESSED or UNCOMPRESSED. There are no additional specifications.
- Compressed data files occupy less disk space than do uncompressed data files.

- Compressed data files take longer to read than do uncompressed data files.
- The GET command, which reads SPSS-format data files, does not need to specify whether the files it reads are compressed or uncompressed.

Only one COMPRESSED or UNCOMPRESSED subcommand can be specified per XSAVE command. COMPRESSED is usually the default, though UNCOMPRESSED may be the default on some systems.

PERMISSIONS Subcommand

The PERMISSIONS subcommand sets the operating system read/write permissions for the file.

READONLY *File permissions are set to read-only for all users.* The file cannot be saved using the same file name with subsequent changes unless the read/write permissions are changed in the operating system or the subsequent XSAVE command specifies PERMISSIONS=WRITEABLE.

WRITEABLE *File permissions are set to allow writing for the file owner.* If file permissions were set to read-only for other users, the file remains read-only for them.

Your ability to change the read/write permissions may be restricted by the operating system.

Appendix

A

IMPORT/EXPORT Character Sets

Communication-formatted portable files do not use positions 1–63 in the following table. Tape-formatted portable files use the complete table. See the *EXPORT* command for a description of the two types of files.

Appendix

B

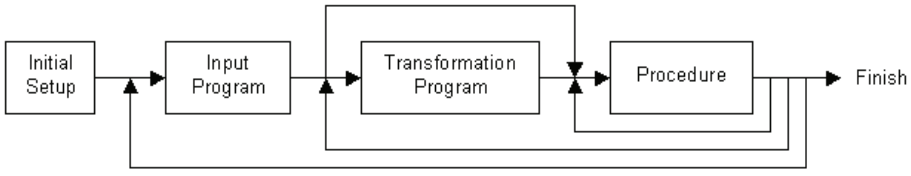
Commands and Program States

Command order is determined only by the system's need to know and do certain things in logical sequence. You cannot label a variable before the variable exists in the file. Similarly, you cannot transform or analyze data before a active dataset is defined. This appendix briefly describes how the program handles various tasks in a logical sequence. It is not necessary to understand the program states in order to construct a command file, but some knowledge of how the program works will help you considerably when you encounter a problem or try to determine why the program doesn't seem to want to accept your commands or seems to be carrying out your instructions incorrectly.

Program States

To run a program session, you need to define your active dataset, transform the data, and then analyze it. This order conforms very closely to the order the program must follow as it processes your commands. Specifically, the program checks command order according to the program state through which it passes. The **program state** is a characteristic of the program before and after a command is encountered. There are four program states. Each session starts in the **initial state**, followed by the **input program state**, the **transformation state**, and the **procedure state.** The four program states in turn enable the program to set up the environment, read data, modify data, and execute a procedure. The figure shows how the program moves through these states. The program determines the current state from the commands that it has already encountered and then identifies which commands are allowed in that state.

Figure B-1
Program States



A session must go through initial, input program, and procedure states to be a complete session. Since all sessions start in the initial state, you need to be concerned primarily with what commands you need to define your active dataset and to analyze the data. The following commands define a very minimal session:

```
GET FILE=DATAIN.
FREQUENCIES VARIABLES=ALL.
```

The GET command defines the active dataset and the FREQUENCIES command reads the data file and analyzes it. Thus, the program goes through the required three states: initial, input, and procedure.

Typically, a session also goes through the transformation state, but it can be skipped as shown in the example above and in the diagram in the preceding figure. Consider the following example:

```
TITLE 'PLOT FOR COLLEGE SURVEY'.

DATA LIST FILE=TESTDATA
 /AGE 1-3 ITEM1 TO ITEM3 5-10.

VARIABLE LABELS ITEM1 'Opinion on level of defense spending'
  ITEM2 'Opinion on level of welfare spending'
  ITEM3 'Opinion on level of health spending'.
VALUE LABELS ITEM1 TO ITEM3 -1 'Disagree' 0 'No opinion' 1 'Agree'.
MISSING VALUES AGE(-99,-98) ITEM1 TO ITEM3 (9).
RECODE ITEM1 TO ITEM3 (0=1) (1=0) (2=-1) (9=9) (ELSE=SYSMIS).
RECODE AGE (MISSING=9) (18 THRU HI=1) (LO THRU 18=0) INTO VOTER.
PRINT /$CASENUM 1-2 AGE 4-6 VOTER 8-10.
VALUE LABELS VOTER 0 'Under 18' 1 '18 or over'.
MISSING VALUES VOTER (9).
PRINT FORMATS VOTER (F1.0).

FREQUENCIES VARIABLES=VOTER, ITEM1 TO ITEM3.
```

The program starts in the initial state, where it processes the TITLE command. It then moves into the input state upon encountering the DATA LIST command. The program can then move into either the transformation or procedure state once the DATA LIST command has been processed.

In this example, the program remains in the transformation state after processing each of the commands from VARIABLE LABELS through PRINT FORMATS. The program then moves into the procedure state to process the FREQUENCIES command. As shown in the preceding figure, the program can repeat the procedure state if it encounters a second procedure. The program can return to the transformation state if it encounters additional transformation commands following the first procedure. Finally, in some sessions the program can return to the input program state when it encounters commands such as FILE TYPE or MATCH FILES.

Determining Command Order

The table "Commands and program states" shows where specific commands can be placed in the command file in terms of program states and what happens when the program encounters a command in each of the four program states. If a column contains a dash, the command is accepted in that program state and it leaves the program in that state. If one of the words *INIT*, *INPUT*, *TRANS*, or *PROC* appears in the column, the command is accepted in the program state indicated by the column heading, but it moves the program into the state indicated by *INIT*, *INPUT*, *TRANS*, or *PROC*. Asterisks in a column indicate errors when the program encounters the command in that program state. Commands marked with the dagger (†) in the column for the procedure state clear the active dataset.

The table shows six groups of commands: utility, file definition, input program, data transformation, restricted transformation, and procedure commands. These groups are discussed in the following sections.

To read the table, first locate the command. If you simply want to know where in the command stream it can go, look for columns without asterisks. For example, the COMPUTE command can be used when the program is in the input program state, the transformation state, or the procedure state, but it will cause an error if you try to use it in the initial state. If you want to know what can follow a command, look at each of the four columns next to the command. If the column is dashed, any commands not showing asterisks in the column for that program state can follow the command. If the column contains one of the words *INIT*, *INPUT*, *TRANS*, or *PROC,* any command not showing asterisks in the column for the program state indicated by that word can follow the command.

For example, if you want to know what commands can follow the INPUT PROGRAM command, note first that it is allowed only in the initial or procedure states. Then note that INPUT PROGRAM puts the program into the input program state wherever it occurs legally. This means that commands with dashes or words in the *INPUT* column can follow the INPUT PROGRAM command. This includes all the utility commands, the DATA LIST command, input program commands, and transformation commands like COMPUTE. Commands that are not allowed after the INPUT PROGRAM command are most of the file definition commands that are their own input program (such as GET), restricted transformations (such as SELECT IF), and procedures.

Unrestricted Utility Commands

Most utility commands can appear in any state. The table "Commands and program states" shows this by the absence of asterisks in the columns.

The dashed lines indicate that after a utility command is processed, the program remains in the same state it was in before the command execution. *INIT*, *TRANS*, or *PROC* indicates that the command moves the program to that state. For example, if the program is in the procedure state, `N OF CASES` moves the program to the transformation state. The `FINISH` command terminates

command processing wherever it appears. Any commands appearing after FINISH will not be read and therefore will not cause an error.

File Definition Commands

You can use most of the file definition commands in the initial state, the transformation state, and the procedure state. Most of these commands cause errors if you try to use them in the input program state. However, DATA LIST and KEYED DATA LIST can be and often are used in input programs.

After they are used in the initial state, most file definition commands move the program directly to the transformation state, since these commands are the entire input program. FILE TYPE and INPUT PROGRAM move the program into the input program state and require input program commands to complete the input program. Commands in the table "Commands and program states" marked with a dagger (†) clear the active dataset.

Input Program Commands

The commands associated with the complex file facility (FILE TYPE, RECORD TYPE, and REPEATING DATA) and commands associated with the INPUT PROGRAM command are allowed only in the input program state.

The END CASE, END FILE, POINT, RECORD TYPE, REPEATING DATA, and REREAD commands leave the program in the input program state. The two that move the program on to the transformation state are END FILE TYPE for input programs initiated with FILE TYPE and END INPUT PROGRAM for those initiated with INPUT PROGRAM.

Transformation Commands

The entire set of transformation commands from ADD VALUE LABELS to XSAVE can appear in the input program state as part of an input program, in the transformation state, or in the procedure state. When you use transformation commands in the input program state or the transformation state, the program remains in the same state it was in before the command. When the program is in the procedure state, these commands move the program back to the transformation state.

Transformation commands and some file definition and input program commands can be categorized according to whether they are **declarative**, **status-switching**, or **executable**. Declarative commands alter the active dataset dictionary but do not affect the data. Status-switching commands change the program state but do not affect the data. Executable commands alter the data. The following table lists these commands and indicates which of the three categories applies.

Table B-2
Taxonomy of transformation commands

Command	Type	Command	Type
ADD FILES	Exec*	LEAVE	Decl
ADD VALUE LABELS	Decl	LOOP	Exec
APPLY DICTIONARY	Decl	MATCH FILES	Exec*

Command	Type	Command	Type
BREAK	Exec	MISSING VALUES	Decl
COMPUTE	Exec	N OF CASES	Decl
COUNT	Exec	NUMERIC	Decl
DATA LIST	Exec*	POINT	Exec
DO IF	Exec	PRINT, PRINT EJECT	Exec
DO REPEAT	Decl†	PRINT FORMATS	Decl
ELSE	Exec	PRINT SPACE	Exec
ELSE IF	Exec	RECODE	Exec
END CASE	Exec	RECORD TYPE	Exec
END FILE	Exec	REFORMAT	Exec
END FILE TYPE	Stat	REPEATING DATA	Exec*
END IF	Exec	REREAD	Exec
END INPUT PROGRAM	Stat	SAMPLE	Exec
END LOOP	Exec	SELECT IF	Exec
END REPEAT	Decl†	SPLIT FILE	Decl
FILE TYPE	Stat**	STRING	Decl
FILTER	Exec	TEMPORARY	Stat
FORMATS	Decl	VALUE LABELS	Decl
GET	Exec*	VARIABLE LABELS	Decl
GET CAPTURE	Exec*	VECTOR	Decl
GET OSIRIS	Exec*	WEIGHT	Decl
IF	Exec	WRITE	Exec
INPUT PROGRAM	Stat	WRITE FORMATS	Decl
KEYED DATA LIST	Exec*	XSAVE	Exec

* This command is also declarative.

**This command is also executable and declarative.

†This command does not fit into these categories; however, it is neither executable nor status-switching, so it is classified as declarative.

Restricted Transformations

Commands REFORMAT, SAMPLE, SELECT IF, and TEMPORARY are restricted transformation commands because they are allowed in either the transformation state or the procedure state but cannot be used in the input program state.

If you use restricted transformation commands in the transformation state, the program remains in the transformation state. If you use them in the procedure state, they move the program back to the transformation state.

Procedures

The procedures and the BEGIN DATA, EXECUTE, EXPORT, LIST, SAVE, SAVE SCSS, SAVE TRANSLATE, and SORT CASES commands cause the data to be read. These commands are allowed in either the transformation state or the procedure state.

When the program is in the transformation state, these commands move the program to the procedure state. When you use these commands in the procedure state, the program remains in that state.

Appendix
C

Defining Complex Files

Most data files have a rectangular, case-ordered structure and can be read with the DATA LIST command. This chapter illustrates the use of commands for defining complex, nonrectangular files.

- **Nested** files contain several types of records with a hierarchical relationship among the record types. You can define nested files with the FILE TYPE NESTED command.
- **Grouped** files have several records per case, and a case's records are grouped together in a file. You can use DATA LIST and FILE TYPE GROUPED to define grouped files.
- In a **mixed** file, different types of cases have different kinds of records. You can define mixed files with the FILE TYPE MIXED command.
- A record in a **repeating data** file contains information for several cases. You can use the REPEATING DATA command to define files with repeating data.

It is a good idea to read the descriptions of the FILE TYPE and REPEATING DATA commands before proceeding.

Rectangular File

The following figure shows contents of data file *RECTANG.DAT*, which contains 1988 sales data for salespeople working in different territories. Year, region, and unit sales are recorded for each salesperson. Like most data files, the sales data file has a **rectangular** format, since information on a record applies only to one case.

Figure C-1
File RECTANG.DAT

```
1988 CHICAGO   JONES    900
1988 CHICAGO   GREGORY  400
1988 BATON ROUGE RODRIGUEZ 300
1988 BATON ROUGE SMITH    333
1988 BATON ROUGE GRAU     100
```

Since the sales data are rectangular, you can use the DATA LIST command to define these data:

```
DATA LIST FILE='RECTANG.DAT'
 / YEAR     1-4
   REGION   6-16(A)
   SALESPER 18-26(A)
   SALES    29-31.
```

- DATA LIST defines the variable *YEAR* in columns 1 through 4 and string variable *REGION* in columns 6 through 16 in file *RECTANG.DAT*. The program also reads variables *SALESPER* and *SALES* on each record.
- The LIST output below shows the contents of each variable.

Figure C-2
LIST output for RECTANG.DAT

```
YEAR REGION     SALESPER  SALES

1988 CHICAGO    JONES     900
1988 CHICAGO    GREGORY   400
1988 BATON ROUGE RODRIGUEZ 300
1988 BATON ROUGE SMITH     333
1988 BATON ROUGE GRAU      100
```

Nested Files

In a nested file, information on some records applies to several cases. The 1988 sales data are arranged in nested format in the figure below. The data contain three kinds of records. A code in the first column indicates whether a record is a year (Y), region (R), or person record (P).

Figure C-3
File NESTED.DAT

```
Y  1988
R  CHICAGO
P  JONES    900
P  GREGORY  400
R  BATON ROUGE
P  RODRIGUEZ 300
P  SMITH    333
P  GRAU     100
```

The record types are related to each other hierarchically. Year records represent the highest level in the hierarchy, since the year value 1988 applies to each salesperson in the file (only one year record is used in this example). Region records are intermediate-level records; region names apply to salesperson records that occur before the next region record in the file. For example, Chicago applies to salespersons Jones and Gregory. Baton Rouge applies to Rodriguez, Smith, and Grau. Person records represent the lowest level in the hierarchy. The information they contain—salesperson and unit sales—defines a case. Nested file structures minimize redundant information in a data file. For example, 1988 and Baton Rouge appear several times in the rectangular file, but only once in the nested file.

Since each record in the nested file has a code that indicates record type, you can use the FILE TYPE and RECORD TYPE commands to define the nested sales data:

```
FILE  TYPE  NESTED  FILE='NESTED.DAT' RECORD=#TYPE 1 (A)

RECORD TYPE 'Y'.
DATA LIST /  YEAR 5-8.

RECORD TYPE 'R'.
DATA LIST  / REGION 5-15 (A).
```

```
RECORD TYPE 'P'.
DATA LIST / SALESPER 5-15 (A) SALES 20-23

END FILE TYPE.
```

- `FILE TYPE` indicates that data are in nested form in the file *NESTED.DAT*.
- `RECORD` defines the record type variable as string variable *#TYPE* in column 1. *#TYPE* is defined as scratch variable so it won't be saved in the active dataset.
- One pair of `RECORD TYPE` and `DATA LIST` statements is specified for each record type in the file. The first pair of `RECORD TYPE` and `DATA LIST` statements defines the variable *YEAR* in columns 5 through 8 on every year record. The second pair defines the string variable *REGION* on region records. The final pair defines *SALESPER* and *SALES* on person records.
- The order of `RECORD TYPE` statements defines the hierarchical relationship among the records. The first `RECORD TYPE` defines the highest-level record type. The next `RECORD TYPE` defines the next highest level, and so forth. The last `RECORD TYPE` defines a case in the active dataset.
- `END FILE TYPE` signals the end of file definition.
- In processing nested data, the program reads each record type you define. Information on the highest and intermediate-level records is spread to cases to which the information applies. The output from the `LIST` command is identical to that for the rectangular file.

Nested Files with Missing Records

In a nested file, some cases may be missing one or more record types defined in `RECORD TYPE` commands. For example, in the figure below the region record for salespersons Jones and Gregory is missing.

Figure C-4
File NESTED.DAT with missing records

```
Y 1988
P JONES    900
P GREGORY  400
R BATON ROUGE
P RODRIGUEZ 300
P SMITH    333
P GRAU     100
```

The program assigns missing values to variables that are not present for a case. Using the modified *NESTED.DAT* file, the commands in the previous example produce the output shown below. You can see that the program assigned missing values to *REGION* for Jones and Gregory.

Figure C-5
LIST output for nested data with missing records

```
YEAR REGION    SALESPER  SALES

1988       JONES    900
1988       GREGORY  400
```

```
1988 BATON ROUGE RODRIGUEZ 300
1988 BATON ROUGE SMITH     333
1988 BATON ROUGE GRAU      100
```

You may want to examine cases with missing records, since these cases may indicate data errors. If you add the `MISSING=WARN` subcommand to your `FILE TYPE` command, the program prints a warning message when a case is missing a defined record type. For example, the program would print two warnings when processing data in *NESTED.DAT* with missing records. When `MISSING` is set to `WARN`, cases are built in the same way as when the default setting (`NOWARN`) is in effect.

Grouped Data

In a grouped file, a case has several records that are grouped together in the file. You can use `DATA LIST` to define a grouped file if each case has the same number of records and records appear in the same order for each case. You can use `FILE TYPE GROUPED` whether the number of records per case and record order are fixed or vary. However, `FILE TYPE GROUPED` requires that each record have a case identifier and a record code.

Using DATA LIST

The following table shows the organization of a grouped data file containing school subject scores for three students. Each student has three data records, and each record contains a score. The first record for each student also contains a case identifier. Records for each case are grouped together. Student 1 records appear first, followed by records for student 2 and student 3.

Record order determines whether a score is a reading, math, or science score. The reading score appears on the first record for a case, the math score appears on the second record, and the science score appears on the third record.

Table C-1
Data for GROUPED.DAT

Student	Score
1	58
	59
	97
2	43
	88
	45
3	67
	75
	90

Since each case has the same number of records and record order is fixed across cases, you can use `DATA LIST` to define the student data:

```
DATA LIST FILE='GROUPED.DAT' RECORDS=3
 /STUDENT 1 READING 5-6
 /MATH    5-6
```

```
 /SCIENCE 5-6.

LIST.
```

- `DATA LIST` indicates that data are in file *GROUPED.DAT*.
- `RECORDS` defines three records per case. The program reads student ID number (*STUDENT*) and reading score (*READING*) in the first record for a case. Math and science scores are read in the second and third records.
- The output from the `LIST` command is shown below.

Figure C-6
LIST output for GROUPED.DAT

```
STUDENT READING MATH SCIENCE

      1      58   59      97
      2      43   88      45
      3      67   75      90
```

Using FILE TYPE GROUPED

To use `FILE TYPE GROUPED` to define a grouped file, each record must have a case identifier and a record code. In the following commands, each data record contains a student ID number coded 1, 2, or 3 and a code indicating whether the score on that record is a reading (R), math (M), or science (S) score:

```
FILE TYPE GROUPED RECORD=#REC 3(A)  CASE=STUDENT 1.

RECORD TYPE 'R'.
DATA LIST / READING 5-6.

RECORD TYPE 'M'.
DATA LIST / MATH 5-6.

RECORD TYPE 'S'.
DATA LIST / SCIENCE 5-6.

END FILE TYPE.

BEGIN DATA
1 R 58
1 M 59
1 S 97
2 R 43
2 M 88
2 S 45
3 R 67
3 M 75
3 S 90
END DATA.

LIST.
```

- `FILE TYPE` indicates that data are in grouped format. `RECORD` defines the variable containing record codes as string variable *#REC* in column 3. `CASE` defines the case identifier variable *STUDENT* in the first column of each record.

- One pair of RECORD TYPE and DATA LIST statements appears for each record type in the file. The program reads reading score in every R record, math score in M records, and science score in S records.
- END FILE TYPE signals the end of file definition.
- BEGIN DATA and END DATA indicate that data are inline.
- The output from LIST is identical to the output using DATA LIST.

FILE TYPE GROUPED is most useful when record order varies across cases and when cases have missing or duplicate records. In the modified data shown below, only case 1 has all three record types. Also, record order varies across cases. For example, the first record for case 1 is a science record, whereas the first record for cases 2 and 3 is a reading record.

Table C-2
Modified grouped data file

Student	Subject	Score
1	S	97
1	R	58
1	M	59
2	R	43
3	R	67
3	M	75

You can use the same FILE TYPE commands as above to read the modified file. As shown in the output from LIST below, the program assigns missing values to variables that are missing for a case.

Figure C-7
LIST output for GROUPED.DAT

```
STUDENT READING MATH SCIENCE

  1    58   59    97
  2    43    .     .
  3    67   75     .
```

By default, the program generates a warning message when a case is missing a defined record type in a grouped file or when a record is not in the same order as in RECORD TYPE commands. Thus, four warnings are generated when the commands for the previous example are used to read the modified *GROUPED.DAT* file. You can suppress these warnings if you add the optional specifications MISSING=NOWARN and ORDERED=NO on your FILE TYPE command.

In the modified *GROUPED.DAT* file, the case identifier *STUDENT* appears in the same column position in each record. When the location of the case identifier varies for different types of records, you can use the CASE option of the RECORD TYPE command to specify different column positions for different records. For example, suppose the case identifier appears in first column position on reading and science records and in column 2 in math records. You could use the following commands to define the data:

```
FILE TYPE GROUPED RECORD=#REC 3(A)  CASE=STUDENT 1.
```

```
RECORD TYPE 'R'.
DATA LIST / READING 5-6.

RECORD TYPE 'M' CASE=2.
DATA LIST / MATH 5-6.

RECORD TYPE 'S'.
DATA LIST / SCIENCE 5-6.

END FILE TYPE.

BEGIN DATA
1 S 97
1 R 58
 1M 59
2 R 43
3 R 67
 3M 75
END DATA.

LIST.
```

- `FILE TYPE` indicates that the data are in grouped format. `RECORD` defines the variable containing record codes as string variable *#REC*. `CASE` defines the case identifier variable as *STUDENT* in the first column of each record.
- One pair of `RECORD TYPE` and `DATA LIST` statements is coded for each record type in the file.
- The `CASE` specification on the `RECORD TYPE` statement for math records overrides the `CASE` value defined on `FILE TYPE`. Thus, the program reads *STUDENT* in column 2 in math records and column 1 in other records.
- `END FILE TYPE` signals the end of file definition.
- `BEGIN DATA` and `END DATA` indicate that data are inline.
- The output from `LIST` is identical to the output above.

Mixed Files

In a mixed file, different types of cases have different kinds of records. You can use `FILE TYPE MIXED` to read each record or a subset of records in a mixed file.

Reading Each Record in a Mixed File

The following table shows test data for two hypothetical elementary school students referred to a remedial education teacher. Student 1, who was thought to need special reading attention, took reading tests (word identification and comprehension tests). The second student completed writing tests (handwriting, spelling, vocabulary, and grammar tests). Test code (READING or WRITING) indicates whether the record contains reading or writing scores.

Table C-3
Academic test data for two students

Student 1

Test	ID	Grade	Word	Compre
READING	1	04	65	35

Student 2

Test	ID	Grade	Handwrit	Spelling	Vocab	Grammar
WRITING	2	03	50	55	30	25

The following commands define the test data:

```
FILE TYPE MIXED RECORD=TEST 1-7(A).

RECORD TYPE 'READING'.
DATA LIST / ID  9-10 GRADE  12-13 WORD 15-16 COMPRE 18-19.

RECORD TYPE 'WRITING'.
DATA LIST / ID  9-10 GRADE 12-13 HANDWRIT 15-16 SPELLING 18-19
            VOCAB 21-22 GRAMMAR  24-25.
END FILE TYPE.

BEGIN DATA
READING 1  04 65 35
WRITING 2  03 50 55 30 25
END DATA.

LIST.
```

- `FILE TYPE` specifies that the data contain mixed record types. `RECORD` reads the record identifier (variable *TEST*) in columns 1 through 7.
- One pair of `RECORD TYPE` and `DATA LIST` statements is coded for each record type in the file. The program reads variables *ID*, *GRADE, WORD,* and *COMPRE* in the record in which the value of *TEST* is READING, and *ID*, *GRADE, HANDWRIT, SPELLING, VOCAB,* and *GRAMMAR* in the WRITING record.
- `END FILE TYPE` signals the end of file definition.
- `BEGIN DATA` and `END DATA` indicate that data are inline. Data are mixed, since some column positions contain different variables for the two cases. For example, word identification score is recorded in columns 15 and 16 for student 1. For student 2, handwriting score is recorded in these columns.
- The following figure shows the output from `LIST`. Missing values are assigned for variables that are not recorded for a case.

Figure C-8
LIST output for mixed file

```
TEST    ID GRADE WORD COMPRE HANDWRIT SPELLING VOCAB GRAMMAR

READING 1   4 65   35    .    .    .    .
WRITING 2   3 .    .     50    55    30    25
```

Reading a Subset of Records in a Mixed File

You may want to process a subset of records in a mixed file. The following commands read only the data for the student who took reading tests:

```
FILE TYPE MIXED RECORD=TEST 1-7(A).
```

```
RECORD TYPE 'READING'.
DATA LIST / ID      9-10
            GRADE  12-13
            WORD   15-16
            COMPRE 18-19.

RECORD TYPE 'WRITING'.
DATA LIST / ID        9-10
            GRADE    12-13
            HANDWRIT 15-16
            SPELLING 18-19
            VOCAB    21-22
            GRAMMAR  24-25.

END FILE TYPE.

BEGIN DATA
READING 1  04 65 35
WRITING 2  03 50 55 30 25
END DATA.

LIST.
```

- `FILE TYPE` specifies that data contain mixed record types. `RECORD` defines the record identification variable as *TEST* in columns 1 through 7.
- `RECORD TYPE` defines variables on reading records. Since the program skips all record types that are not defined by default, the case with writing scores is not read.
- `END FILE TYPE` signals the end of file definition.
- `BEGIN DATA` and `END DATA` indicate that data are inline. Data are identical to those in the previous example.
- The following figure shows the output from `LIST`.

Figure C-9
LIST output for reading record

```
TEST   ID GRADE WORD COMPRE

READING 1  4 65  35
```

Repeating Data

You can use the `REPEATING DATA` command to read files in which each record contains repeating groups of variables that define several cases. Command syntax depends on whether the number of repeating groups is fixed across records.

Fixed Number of Repeating Groups

The following table shows test score data for students in three classrooms. Each record contains a classroom number and two pairs of student ID and test score variables. For example, in class 101, student 182 has a score of 12 and student 134 has a score of 53. In class 103, student 15 has a score of 87 and student 203 has a score of 69. Each pair of ID and score variables is a repeating group, since these variables appear twice on each record.

Table C-4
Data in REPEAT.DAT file

Class	ID	Score	ID	Score
101	182	12	134	53
102	99	112	200	150
103	15	87	203	69

The following commands generate a active dataset in which one case is built for each occurrence of *SCORE* and *ID*, and classroom number is spread to each case on a record.

```
INPUT PROGRAM.
DATA LIST /  CLASS 3-5.
REPEATING DATA STARTS=6 / OCCURS=2
 /DATA STUDENT 1-4 SCORE 5-8.
END INPUT PROGRAM.

BEGIN DATA
  101 182  12 134  53
  102  99 112 200 150
  103  15  87 203  69
END DATA.

LIST.
```

- `INPUT PROGRAM` signals the beginning of data definition.
- `DATA LIST` defines variable *CLASS*, which is spread to each student on a classroom record.
- `REPEATING DATA` specifies that the input file contains repeating data. `STARTS` indicates that repeating data begin in column 6. `OCCURS` specifies that the repeating data group occurs twice in each record.
- `DATA` defines variables that are repeated (*STUDENT* and *SCORE*). The program begins reading the first repeating data group in column 6 (the value of `STARTS`). Since the value of `OCCURS` is 2, the program reads the repeating variables a second time, beginning in the next available column (column 14).
- `END INPUT PROGRAM` signals the end of data definition.
- `BEGIN DATA` and `END DATA` specify that data are inline.
- The output from `LIST` is shown below. Each student is a separate case.

Figure C-10
LIST output for repeating data

```
CLASS STUDENT SCORE
101    182    12
101    134    53
102     99   112
102    200   150
103     15    87
103    203    69
```

Varying Number of Repeating Groups

To use REPEATING DATA to define a file in which the number of repeating data groups varies across records, your data must contain a variable indicating the number of repeating data groups on a record. The following commands define such a file:

```
INPUT PROGRAM.
DATA LIST /  #NUM 1 CLASS 3-5.
REPEATING DATA STARTS=6 / OCCURS=#NUM
 /DATA STUDENT 1-4 SCORE 5-8.
END INPUT PROGRAM.

BEGIN DATA
3 101 182  12 134  53 199  30
2 102  99 112 200 150
1 103  15  87
END DATA.

LIST.
```

- INPUT PROGRAM signals the beginning of data definition.
- DATA LIST defines variables *CLASS* in columns 3 through 5 and *#NUM*, a scratch variable in column 1 that contains the number of repeating data groups in a record.
- REPEATING DATA specifies that the input file contains repeating data. STARTS indicates that repeating data begin in column 6. OCCURS sets the number of repeating groups on a record equal to the value of *#NUM*.
- DATA defines variables that are repeated. Since *#NUM* is 3 in the first and third records, the program reads three sets of *STUDENT* and *SCORE* variables in these records. *STUDENT* and *SCORE* are read twice in record 2.
- END INPUT PROGRAM signals the end of data definition.
- Data appear between BEGIN DATA and END DATA.
- The following figure shows the output from LIST.

Figure C-11
LIST output

CLASS	STUDENT	SCORE
101	182	12
101	134	53
101	199	30
102	99	112
103	15	87

If your data file does not have a variable indicating the number of repeating data groups per record, you can use the LOOP and REREAD commands to read the data, as in:

```
INPUT PROGRAM.
DATA LIST /   CLASS 3-5 #ALL 6-29 (A).
LEAVE CLASS.

LOOP #I = 1 TO 17  BY 8 IF SUBSTR(#ALL, #I, 8) NE ''.
-  REREAD COLUMN = #I + 5.
-  DATA LIST / STUDENT 1-4 SCORE 5-8.
-  END CASE.
END LOOP.
```

```
END INPUT PROGRAM.

BEGIN DATA
  101 182  12 134  53 199  30
  102  99 112 200 150
  103  15  87
END DATA.

LIST.
```

- `INPUT PROGRAM` signals the beginning of data definition.
- `DATA LIST` reads *CLASS* and *#ALL*, a temporary string variable that contains all of the repeating data groups for a classroom record. The column specifications for *#ALL* (6 through 29) are wide enough to accommodate the classroom record with the most repeating data groups (record 1).
- `LOOP` and `END LOOP` define an index loop. As the loop iterates, the program successively reads eight-character segments of *#ALL*, each of which contains a repeating data group or an empty field. The program reads the first eight characters of *#ALL* in the first iteration, the second eight characters in the second iteration, and so forth. The loop terminates when the program encounters an empty segment, which means that there are no more repeating data groups on a record.
- In each iteration of the loop in which an *#ALL* segment is not empty, `DATA LIST` reads *STUDENT* and *SCORE* in a classroom record. The program begins reading these variables in the first record, in the starting column specified by `REREAD COLUMN`. For example, in the first iteration, the program reads *STUDENT* and *SCORE* beginning in column 6. In the second iteration, the program reads *STUDENT* and *SCORE* starting in column 14 of the same record. When all repeating groups have been read for a record, loop processing begins on the following record.
- `END CASE` creates a new case for each repeating group.
- `REREAD` causes `DATA LIST` to read repeating data groups in the same record in which it last read *CLASS*. Without `REREAD`, each execution of `DATA LIST` would begin on a different record.
- `LEAVE` preserves the value of `CLASS` across the repeating data groups on a record. Thus, the same class number is read for each student on a classroom record.
- `INPUT PROGRAM` signals the beginning of data definition.
- `BEGIN DATA` and `END DATA` indicate that the data are inline. The data are identical to those in the previous example except that they do not contain a variable indicating the number of repeating groups per record.
- These commands generate the same output as shown in the figure above.

Appendix
D

Using the Macro Facility

A macro is a set of commands that generates customized command syntax. Using macros can reduce the time and effort needed to perform complex and repetitive data analysis tasks.

Macros have two parts: a **macro definition**, which indicates the beginning and end of the macro and gives a name to the macro, and a **macro body**, which contains regular commands or macro commands that build command syntax. When a macro is invoked by the **macro call**, syntax is generated in a process called **macro expansion**. Then the generated syntax is executed as part of the normal command sequence.

This chapter shows how to construct macros that perform three data analysis tasks. In the first example, macros facilitate a file-matching task. In Example 2, macros automate a specialized statistical operation (testing a sample correlation coefficient against a nonzero population correlation coefficient). Macros in Example 3 generate random data. As shown in the following table, each example demonstrates various features of the macro facility. For information on specific macro commands, see the `DEFINE` command.

Table D-1
Macro features

	Example 1	**Example 2**	**Example 3**
Macro argument			
Keyword	x	x	x
Default values	x		x
None	x		x
String manipulation	x		x
Looping			
Index	x		x
List processing		x	
Direct assignment	x		x

Example 1: Automating a File-Matching Task

The following figure shows a listing of 1988 sales data for salespeople working in different regions. The listing shows that salesperson Jones sold 900 units in the Chicago sales territory, while Rodriguez sold 300 units in Baton Rouge.

Figure D-1
Listing of data file SALES88.SAV

```
YEAR REGION     SALESPER  SALES
```

```
1988 CHICAGO    JONES     900
1988 CHICAGO    GREGORY   400
1988 BATON ROUGE RODRIGUEZ 300
1988 BATON ROUGE SMITH     333
1988 BATON ROUGE GRAU      100
```

You can use command syntax shown below to obtain each salesperson's percentage of total sales for their region.

Figure D-2
Commands for obtaining sales percentages

```
GET FILE = 'SALES88.SAV'.

SORT CASES BY REGION.

AGGREGATE OUTFILE = 'TOTALS.SAV'
 /PRESORTED
 /BREAK = REGION
 /TOTAL@ = SUM(SALES).

MATCH FILES FILE=*
 /TABLE = 'TOTALS.SAV'
 /BY REGION.

COMPUTE PCT = 100 * SALES / TOTAL@.

TITLE 1988 DATA.
LIST.
```

- The `GET` command opens *SALES88.SAV*, an SPSS-format data file. This file becomes the active dataset.
- `SORT CASES` sorts the active dataset in ascending alphabetical order by *REGION*.
- The `AGGREGATE` command saves total sales (variable *TOTAL@*) for each region in file *TOTALS.SAV*.
- `MATCH FILES` appends the regional totals to each salesperson's record in the active dataset. (See the `MATCH FILES` command for more information on matching files.)
- `COMPUTE` obtains the percentage of regional sales (*PCT*) for each salesperson.
- The `LIST` command output displayed below shows that Rodriguez sold 41% of the products sold in Baton Rouge. Gregory accounted for 31% of sales in the Chicago area.

Figure D-3
Listing of data file SALES88.SAV

```
YEAR REGION     SALESPER  SALES  TOTAL@   PCT

1988 BATON ROUGE RODRIGUEZ  300   733.00   41.00
1988 BATON ROUGE SMITH      333   733.00   45.00
1988 BATON ROUGE GRAU       100   733.00   14.00
1988 CHICAGO    JONES       900  1300.00   69.00
1988 CHICAGO    GREGORY     400  1300.00   69.00
```

The following figure shows a macro that issues the commands for obtaining sales percentages. The macro consists of the commands that produce sales percentages imbedded between macro definition commands `DEFINE` and `!ENDDEFINE`.

Figure D-4
!TOTMAC macro

```
DEFINE !TOTMAC ().

GET FILE = 'SALES88.SAV'.

SORT CASES BY REGION.

AGGREGATE OUTFILE = 'TOTALS.SAV'
 /PRESORTED
 /BREAK = REGION
 /TOTAL@ = SUM(SALES).

MATCH FILES FILE = *
 /TABLE = 'TOTALS.SAV'
 /BY REGION.

COMPUTE PCT = 100 * SALES / TOTAL@.

TITLE 1988 DATA.
LIST.

!ENDDEFINE.

!TOTMAC.
```

- Macro definition commands `DEFINE` and `!ENDDEFINE` signal the beginning and end of macro processing. `DEFINE` also assigns the name `!TOTMAC` to the macro (the parentheses following the name of the macro are required). The macro name begins with an exclamation point so that the macro does not conflict with that of an existing variable or command. Otherwise, if the macro name matched a variable name, the variable name would invoke the macro whenever the variable name appeared in the command stream.
- Commands between `DEFINE` and `!ENDDEFINE` constitute the macro body. These commands, which produce sales percentages, are identical to the commands in Figure D-2.
- The final statement, `!TOTMAC`, is the **macro call**, which invokes the macro. When the program reads the macro call, it issues the commands in the macro body. Then these commands are executed, generating identical output.

While the macro shows you how to construct a simple macro, it doesn't reduce the number of commands needed to calculate regional percentages. However, you can use macro features such as looping to minimize coding in more complicated tasks. For example, let's say that in addition to the 1988 data, you have sales data for 1989 (*SALES89.SAV),* and each file contains the variables *REGION*, *SALESPER*, and *SALES*. The modified `!TOTMAC` macro below calculates regional sales percentages for each salesperson for 1988 and 1989.

Figure D-5
!TOTMAC macro with index loop

```
DEFINE !TOTMAC ().

!DO !I = 88 !TO 89.

- GET FILE = !CONCAT('SALES', !I, '.SAV').
- SORT CASES BY REGION.
- AGGREGATE OUTFILE = 'TOTALS.SAV'
    /PRESORTED
    /BREAK = REGION
    /TOTAL@ = SUM(SALES).
- MATCH FILES FILE = *
    /TABLE = 'TOTALS.SAV'
    /BY REGION.
- COMPUTE PCT= 100 * SALES / TOTAL@.
- !LET !YEAR = !CONCAT('19',!I).
- TITLE !YEAR DATA.
- LIST.
!DOEND.

!ENDDEFINE.

!TOTMAC.
```

- `DEFINE` and `!ENDDEFINE` signal the beginning and end of macro processing.
- Commands `!DO` and `!DOEND` define an **index loop**. Commands between `!DO` and `!DOEND` are issued once in each iteration of the loop. The value of **index variable** `!I`, which changes in each iteration, is 88 in the first iteration and 89 in the second (final) iteration.
- In each iteration of the loop, the `GET` command opens an SPSS-format data file. The name of the file is constructed using the **string manipulation function** `!CONCAT`, which creates a string that is the concatenation of SALES, the value of the index variable, and *.sav*. Thus the file *SALES88.SAV* is opened in the first iteration.
- Commands between `AGGREGATE` and `COMPUTE` calculate percentages on the active dataset. These commands are identical to those in Figure D-4.
- Next, a customized title is created. In the first iteration, the **direct assignment** command `!LET` assigns a value of 1988 to the macro variable `!YEAR`. This variable is used in the `TITLE` command on the following line to specify a title of *1988 DATA*.
- The `LIST` command displays the contents of each variable.
- In the second iteration of the loop, commands display percentages for the 1989 data file. The output from the `!TOTMAC` macro is shown below. Note that the listing for 1988 data is the same as before.

Figure D-6
Regional sales percentages for 1988 and 1989

```
1988 DATA

YEAR REGION    SALESPER  SALES  TOTAL@    PCT
```

```
1988 BATON ROUGE RODRIGUEZ  300   733.00   41.00
1988 BATON ROUGE SMITH      333   733.00   45.00
1988 BATON ROUGE GRAU       100   733.00   14.00
1988 CHICAGO    JONES       900  1300.00   69.00
1988 CHICAGO    GREGORY     400  1300.00   69.00

1989 DATA
YEAR REGION     SALESPER SALES   TOTAL@    PCT
1989 BATON ROUGE GRAU      320   1459.00   22.00
1989 BATON ROUGE SMITH     800   1459.00   55.00
1989 BATON ROUGE RODRIGUEZ 339   1459.00   23.00
1989 CHICAGO    JONES      300   1439.00   21.00
1989 CHICAGO    STEEL      899   1439.00   62.00
1989 CHICAGO    GREGORY    240   1439.00   17.00
```

Let's look at another application of the `!TOTMAC` macro, one that uses **keyword arguments** to make the application more flexible. The following figure shows the number of absences for students in two classrooms. Let's say you want to calculate deviation scores indicating how many more (or fewer) times a student was absent than the average student in his or her classroom. The first step in obtaining deviation scores is to compute the average number of absences per classroom. We can use the `!TOTMAC` macro to compute classroom means by modifying the macro so that it computes means and uses the absences data file *(SCHOOL.SAV)* as input.

Figure D-7
Listing of file SCHOOL.SAV

```
CLASS STUDENT ABSENT
 101  BARRY G   3
 101  JENNI W   1
 101  ED F      2
 101  JOHN 0    8
 102  PAUL Y    2
 102  AMY G     3
 102  JOHN D   12
 102  RICH H    4
```

The `!TOTMAC` macro below can produce a variety of group summary statistics such as sum, mean, and standard deviation for any SPSS-format data file. In the macro call you specify values of keyword arguments indicating the data file (`FILE`), the break (grouping) variable (`BREAKVR`), the summary function (`FUNC`), and the variable to be used as input to the summary function (`INVAR`). For example, to obtain mean absences for each classroom, we specify *SCHOOL.SAV* as the data file, *CLASS* as the break variable, `MEAN` as the summary function, and *ABSENT* as the variable whose values are to be averaged.

Figure D-8
!TOTMAC macro with keyword arguments

```
DEFINE !TOTMAC ( BREAKVR = !TOKENS(1)
        /FUNC = !TOKENS(1)
        /INVAR = !TOKENS(1)
        /TEMP = !TOKENS(1) !DEFAULT(TOTALS.SAV)
```

```
        /FILE = !CMDEND).
GET FILE = !FILE.
SORT CASES BY !BREAKVR.
AGGREGATE OUTFILE = '!TEMP'
  /PRESORTED
  /BREAK = !BREAKVR
  /!CONCAT(!FUNC,'@') = !FUNC(!INVAR).

MATCH FILES FILE = *
  /TABLE = '!TEMP'
  /BY !BREAKVR.

!ENDDEFINE.

!TOTMAC BREAKVR=CLASS FUNC=MEAN INVAR=ABSENT FILE=SCHOOL.SAV.

COMPUTE DIFF = ABSENT-MEAN@.

LIST.

!TOTMAC BREAKVR=REGION FUNC=SUM INVAR=SALES FILE=SALES89.SAV.

COMPUTE PCT = 100 * SALES / SUM@.

LIST.
```

- The syntax for declaring keyword arguments follows the name of the macro in `DEFINE`.
- `!TOKENS(1)` specifies that the value of an argument is a string following the name of the argument in the macro call. Thus the first macro call specifies CLASS as the value of `BREAKVR`, MEAN as the value of `FUNC`, and ABSENT as the value of `INVAR`.
- `!CMDEND` indicates that the value for `FILE` is the remaining text in the macro call (*SCHOOL.SAV*).
- `TEMP` is an optional argument that names an intermediate file to contain the summary statistics. Since `TEMP` is not assigned a value in the macro call, summary statistics are written to the default intermediate file *(TOTALS.SAV)*.
- In the body of the macro, `GET FILE` opens *SCHOOL.SAV*.
- `SORT CASES` sorts the file by *CLASS*.
- `AGGREGATE` computes the mean number of absences for each class. The name of the variable containing the means (*MEAN@*) is constructed using the `!CONCAT` function, which concatenates the value of `FUNC` and the @ symbol.
- `MATCH FILES` appends the means to student records.
- `COMPUTE` calculates the deviation from the classroom mean for each student (variable *DIFF*).

- LIST displays the deviation scores, as shown in the output below. For example, John D., who was absent 12 times, had 6.75 more absences than the average student in classroom 102. Rich H., who was absent 4 times, had 1.25 fewer absences than the average student in classroom 102.
- The second macro call and remaining commands generate regional sales percentages for the 1989 sales data. As shown below, percentages are identical to those displayed in the bottom half of Figure D-6.

Figure D-9
Student absences and 1989 sales percentages

```
CLASS STUDENT ABSENT MEAN@   DIFF
 101  BARRY G   3   3.50   -.50
 101  JENNI W   1   3.50  -2.50
 101  ED F      2   3.50  -1.50
 101  JOHN 0    8   3.50   4.50
 102  PAUL Y    2   5.25  -3.25
 102  AMY G     3   5.25  -2.25
 102  JOHN D   12   5.25   6.75
 102  RICH H    4   5.25  -1.25

1989 DATA
YEAR REGION     SALESPER SALES   TOTAL@    PCT
1989 BATON ROUGE GRAU     320   1459.00   22.00
1989 BATON ROUGE SMITH    800   1459.00   55.00
1989 BATON ROUGE RODRIGUEZ 339   1459.00   23.00
1989 CHICAGO    JONES     300   1439.00   21.00
1989 CHICAGO    STEEL     899   1439.00   62.00
1989 CHICAGO    GREGORY   240   1439.00   17.00
```

You can modify the macro call to specify a different data file, input variable, break variable, or summary statistic. To get a different summary statistic (such as standard deviation), change the value of FUNC (see the AGGREGATE command for more information on summary functions available in the AGGREGATE procedure).

Example 2: Testing Correlation Coefficients

While the program provides a large variety of statistical procedures, some specialized operations require the use of COMPUTE statements. For example, you may want to test a sample correlation coefficient against a population correlation coefficient. When the population coefficient is nonzero, you can compute a *Z* statistic to test the hypothesis that the sample and population values are equal. The formula for *Z* is

$$Z = \frac{0.5 \ln\left[\frac{1+r}{1-r}\right] - 0.5 \ln\left[\frac{1+p_0}{1-p_0}\right]}{1/\left(\sqrt{n-3}\right)}$$

where *r* is the sample correlation coefficient, p_0 is the population coefficient, *n* is the size of the sample from which *r* is obtained, and *ln* signifies the natural logarithm function. *Z* has approximately the standard normal distribution.

Let's say you want to test an *r* of 0.66 obtained from a sample of 30 cases against a population coefficient of 0.85. The following figure shows commands for displaying *Z* and its two-tailed probability.

Figure D-10
Commands for computing Z statistic

```
DATA LIST FREE / R N P.

BEGIN DATA
.66 30 .85
END DATA.

COMPUTE #ZR = .5* (LN ((1 + R) / (1 - R))).
COMPUTE #ZP = .5* (LN ((1 + P) / (1 - P))).

COMPUTE Z = (#ZR-#ZP)/(1/(SQRT(N-3))).
COMPUTE PROB = 2*(1-CDFNORM(ABS(Z))).

FORMAT PROB (F8.3).
LIST.
```

- `DATA LIST` defines variables containing the sample correlation coefficient *(R)*, sample size (*N)*, and population correlation coefficient (*P)*.
- `BEGIN DATA` and `END DATA` indicate that data are inline.
- `COMPUTE` statements calculate *Z* and its probability. Variables *#ZR* and *#ZP* are scratch variables used in the intermediate steps of the calculation.
- The `LIST` command output is shown below. Since the absolute value of *Z* is large and the probability is small, we reject the hypothesis that the sample was drawn from a population having a correlation coefficient of 0.85.

Figure D-11
Z statistic and its probability

```
 R     N    P     Z  PROB
.66  30.00  .85  -2.41  .016
```

If you use the *Z* test frequently, you may want to construct a macro like that shown below. The `!CORRTST` macro computes *Z* and probability values for a sample correlation coefficient, sample size, and population coefficient specified as values of keyword arguments.

Figure D-12
!CORRTST macro

```
DEFINE !CORRTST ( R = !TOKENS(1)
        /N = !TOKENS(1)
        /P = !TOKENS(1)).
INPUT PROGRAM.
- END CASE.
- END FILE.
```

```
END INPUT PROGRAM.

COMPUTE #ZR = .5* (LN ((1 + !R) / (1 - !R))).
COMPUTE #ZP = .5* (LN ((1 + !P) / (1 - !P))).

COMPUTE Z = (#ZR-#ZP) / (1/(SQRT(!N-3))).
COMPUTE PROB = 2*(1-CDFNORM(ABS(Z))).
FORMAT PROB(F8.3).

TITLE SAMPLE R=!R, N=!N, POPULATION COEFFICIENT=!P.

LIST.

!ENDDEFINE.

!CORRTST R=.66 N=30 P=.85.
!CORRTST R=.50 N=50 P=.85.
```

- `DEFINE` names the macro as `!CORRTST` and declares arguments for the sample correlation coefficient `(R)`, the sample size `(N)`, and the population correlation coefficient `(P)`.
- `!TOKENS(1)` specifies that the value of an argument is a string that follows the name of the argument in the macro call. Thus the first macro call specifies values of 0.66, 30, and 0.85 for `R`, `N`, and `P`.
- Commands between `INPUT PROGRAM` and `END INPUT PROGRAM` create an active dataset with one case. `COMPUTE` statements calculate the *Z* statistic and its probability using the values of macro arguments `R`, `N`, and `P`. (`INPUT PROGRAM` commands would not be needed if `COMPUTE` statements operated on values in an existing file or inline data, rather than macro arguments.)
- A customized `TITLE` shows displays the values of macro arguments used in computing *Z*.
- The `LIST` command displays *Z* and its probability.
- The `!CORRTST` macro is called twice. The first invocation tests an *r* of 0.66 from a sample of 30 cases against a population coefficient of 0.85 (this generates the same *Z* value and probability as shown earlier). The second macro call tests an *r* of 0.50 from a sample of 50 cases against the same population correlation coefficient. The output from these macro calls is shown below.

Figure D-13
Output from !CORRTST

```
SAMPLE R= .66 , N= 30 , POPULATION COEFFICIENT= .85

    Z    PROB
 -2.41    .016

SAMPLE R= .50 , N= 50 , POPULATION COEFFICIENT= .85

    Z    PROB
 -4.85    .000
```

The following figure shows a modified !CORRTST macro that you can use to test a sample *r* against each coefficient in a *list* of population coefficients.

Figure D-14
!CORRTST macro with list-processing loop

```
DEFINE !CORRTST (R = !TOKENS(1)
        /N = !TOKENS(1)
        /P = !CMDEND).
- INPUT PROGRAM.
-  END CASE.
-  END FILE.
- END INPUT PROGRAM.

!DO !I !IN (!P).
- COMPUTE #ZR = .5* (LN ((1 + !R) / (1 - !R))).
- COMPUTE #ZP = .5* (LN ((1 + !I) / (1 - !I))).

- COMPUTE Z = (#ZR-#ZP)/(1/(SQRT(!N-3))).

- COMPUTE PROB=2*(1-CDFNORM(ABS(Z))).
- FORMAT PROB(F8.3).
- TITLE SAMPLE R=!R, N=!N, POPULATION COEFFICIENT=!I.
- LIST.
!DOEND.

!ENDDEFINE.

!CORRTST R=.66 N=30 P=.20 .40 .60 .80 .85 .90.
```

- DEFINE names the macro as !CORRTST and declares arguments for the sample correlation coefficient (R), the sample size (N), and the population correlation coefficient (P).
- !TOKENS(1) specifies that the value of an argument is a string that follows the name of the argument in the macro call. Thus, the macro call specifies the value of R as 0.66 and N as 0.30.
- !CMDEND indicates that the value for P is the remaining text in the macro call. Thus the value of P is a list containing the elements 0.20, 0.40, 0.60, 0.80, 0.85, and 0.90.
- Commands !DO !IN and !DOEND define a **list-processing loop**. Commands in the loop compute one *Z* statistic for each element in the list of population coefficients. For example, in the first iteration *Z* is computed using 0.20 as the population coefficient. In the second iteration 0.40 is used. The same sample size (30) and *r* value (0.66) are used for each *Z* statistic.
- The output from the macro call is shown below. One *Z* statistic is displayed for each population coefficient.

Figure D-15
Output from modified !CORRTST macro

```
SAMPLE R= .66 , N= 30 , POPULATION COEFFICIENT= .20

    Z    PROB
 3.07    .002
```

```
SAMPLE R= .66 , N= 30 , POPULATION COEFFICIENT= .40

    Z    PROB
 1.92    .055

SAMPLE R= .66 , N= 30 , POPULATION COEFFICIENT= .60

    Z    PROB
  .52    .605

SAMPLE R= .66 , N= 30 , POPULATION COEFFICIENT= .80

    Z    PROB
-1.59    .112

SAMPLE R= .66 , N= 30 , POPULATION COEFFICIENT= .85

    Z    PROB
-2.41    .016

SAMPLE R= .66 , N= 30 , POPULATION COEFFICIENT= .90

    Z    PROB
-3.53    .000
```

Example 3: Generating Random Data

You can use command syntax to generate variables that have approximately a normal distribution. Commands for generating five standard normal variables (*X1* through *X5*) for 1000 cases are shown in the following figure. As shown in the output below, each variable has a mean of approximately 0 and a standard deviation of approximately 1.

Figure D-16
Data-generating commands

```
INPUT PROGRAM.
-  VECTOR X(5).
-     LOOP #I = 1 TO 1000.
-        LOOP #J = 1 TO 5.
-          COMPUTE X(#J) = NORMAL(1).
-        END LOOP.
-        END CASE.
-     END LOOP.
-     END FILE.
END INPUT PROGRAM.

DESCRIPTIVES VARIABLES X1 TO X5.
```

Figure D-17
Descriptive statistics for generated data

Variable	Mean	Std Dev	Minimum	Maximum	Valid N	Label
X1	-.01	1.02	-3.11	4.15	1000	
X2	.08	1.03	-3.19	3.22	1000	
X3	.02	1.00	-3.01	3.51	1000	
X4	.03	1.00	-3.35	3.19	1000	
X5	-.01	.96	-3.34	2.91	1000	

The `!DATAGEN` macro below issues the data-generating commands shown above.

Figure D-18
!DATAGEN macro

```
DEFINE !DATAGEN ().

INPUT PROGRAM.
-  VECTOR X(5).
-    LOOP #I = 1 TO 1000.
-      LOOP #J = 1 TO 5.
-        COMPUTE X(#J) = NORMAL(1).
-      END LOOP.
-      END CASE.
-    END LOOP.
-    END FILE.
END INPUT PROGRAM.

DESCRIPTIVES VARIABLES X1 TO X5.

!ENDDEFINE.

!DATAGEN.
```

The data-generating commands are imbedded between macro definition commands. The macro produces the same data and descriptive statistics as shown above.

You can tailor the generation of normally distributed variables if you modify the `!DATAGEN` macro so it will accept keyword arguments, as shown in the following figure. The macro allows you to specify the number of variables and cases to be generated and the approximate standard deviation.

Figure D-19
!DATAGEN macro with keyword arguments

```
DEFINE !DATAGEN ( OBS =!TOKENS(1) !DEFAULT(1000)
          /VARS =!TOKENS(1) !DEFAULT(5)
          /SD =!CMDEND !DEFAULT(1)).
INPUT PROGRAM.
-  VECTOR X(!VARS).
-    LOOP #I = 1 TO !OBS.
-      LOOP #J = 1 TO !VARS.
-        COMPUTE X(#J) = NORMAL(!SD).
-      END LOOP.
```

```
-       END CASE.
-     END LOOP.
-     END FILE.
END INPUT PROGRAM.

!LET !LIST = !NULL.
!DO  !I = 1 !TO !VARS.
-  !LET !LIST = !CONCAT(!LIST, ' ', X, !I).
!DOEND.

DESCRIPTIVES VARIABLES !LIST.

!ENDDEFINE.

!DATAGEN OBS=500 VARS=2 SD=1.
!DATAGEN.
```

- The `DEFINE` statement declares arguments that specify the number of cases (`OBS`), variables (`VARS`), and standard deviation (`SD`). By default, the macro creates 1000 cases with 5 variables that have a standard deviation of 1.
- Commands between `INPUT PROGRAM` and `END INPUT PROGRAM` generate the new data using values of the macro arguments.
- Commands `!LET` and `!DO/!DOEND` construct a variable list (`!LIST`) that is used in `DESCRIPTIVES`. The first `!LET` command initializes the list to a null (blank) string value. For each new variable, the index loop adds to the list a string of the form *X1*, *X2, X3*, and so forth. Thus, `DESCRIPTIVES` requests means and standard deviations for each new variable.
- The first macro call generates 500 cases with two standard normal variables. The second call requests the default number of variables, cases, and standard deviation. Descriptive statistics (not shown) are also computed for each variable.

As shown in the following figure, you can declare additional keyword arguments that allow you to specify the distribution (normal or uniform) of the generated data and a parameter value that is used as the standard deviation (for normally distributed data) or a range (for uniformly distributed data).

Figure D-20
!DATAGEN macro with additional keyword arguments

```
DEFINE !DATAGEN (OBS   =!TOKENS(1) !DEFAULT(1000)
          /VARS  =!TOKENS(1) !DEFAULT(5)
          /DIST  =!TOKENS(1) !DEFAULT(NORMAL)
          /PARAM =!TOKENS(1) !DEFAULT(1)).
INPUT PROGRAM.
-  VECTOR X(!VARS).
-     LOOP #I = 1 TO !OBS.
-       LOOP #J = 1 TO !VARS.
-          COMPUTE X(#J) = !DIST(!PARAM).
-       END LOOP.
-       END CASE.
-     END LOOP.
-     END FILE.
END INPUT PROGRAM.
```

```
!LET !LIST = !NULL.
!DO  !I = 1 !TO !VARS.
-   !LET !LIST = !CONCAT(!LIST, ' ', X, !I).
!DOEND.

DESCRIPTIVES VARIABLES !LIST.
!ENDDEFINE.

!DATAGEN OBS=500 VARS=2 DIST=UNIFORM PARAM=2.
```

- The `DEFINE` statement declares arguments `OBS`, `VARS`, `DIST`, and `PARAM`. `OBS` and `VARS` represent the number of observations and cases to be generated. Arguments `DIST` and `PARAM` specify the shape and parameter of the distribution of generated data. By default, the macro generates 1000 observations with 5 standard normal variables.
- Statements between `INPUT PROGRAM` and `END INPUT PROGRAM` generate the new data using values of macro arguments.
- Remaining commands in the body of the macro obtain descriptive statistics for generated variables.
- The macro call in creates two approximately uniformly distributed variables with a range of 2. The output from the macro call is shown below.

Figure D-21
Descriptive statistics for uniform variables

				Valid		
Variable	Mean	Std Dev	Minimum	Maximum	N	Label
X1	.99	.57	.00	2.00	500	
X2	1.00	.57	.00	2.00	500	

Appendix

E

Canonical Correlation and Ridge Regression Macros

Two macro routines are installed with the Base system for performing canonical correlation and ridge regression. Macros are inherently less robust than regular commands. Error checking is minimal, and small errors produce large numbers of uninformative messages, giving little clue to the real cause of the problem. Syntax must be entered exactly as documented:

- Enter subcommands in the order shown.
- Do not include a slash before the first subcommand.
- Enter keywords exactly as shown. Do not abbreviate them, and do not extend them (even if they look like abbreviations).
- Do not omit equal signs, but do not add them if none is displayed in the syntax diagram.
- Remember that these "command names" are actually macro calls, which are expanded into (lengthy) sequences of commands and Matrix language statements. The command name should not appear anywhere within the specifications of the command, for example within a variable name.
- These macros create new files in the current directory. If you do not have write permission to the current directory (this can happen if you are running the program on a network), change the current directory. You can do this by opening or saving a file on your own hard disk.
- You cannot run these macros if split-file processing is in effect.

Canonical Correlation Macro

```
INCLUDE '[installdir]/Canonical correlation.sps'.
CANCORR SET1=varlist1 /
        SET2=varlist2 / .
The two variable lists must be separated with a slash.
[installdir] is the installation directory.
```

Ridge Regression Macro

```
INCLUDE '[installdir]/Ridge regression.sps'.
RIDGEREG DEP=varname /ENTER = varlist
 [/START={0**}] [/STOP={1**}] [/INC={0.05**}]
          {value}         {value}        {value   }
 [ /K=value] .
[installdir] is the installation directory.
```

Appendix

F

File Specifications for Predictive Enterprise Repository Objects

Access to a Predictive Enterprise Repository is available with the SPSS Adaptor for Predictive Enterprise Services option. Once a connection to a repository has been established, you can use a file specification for a repository object on nearly any SPSS keyword or subcommand where a file specification can be provided (including, but not limited to FILE, INFILE, or OUTFILE). File specifications for repository objects can also be used in procedure dialog boxes that allow manual entry of a file specification—for example, XML model files or plan files for complex samples analyses.

A Predictive Enterprise Repository file specification has the following form:

```
SPSSCR://{directory path and/or file specification}

         [{#M.versionmarker}]
          {#L.versionlabel }

         [#D.description]
         [#K.keywords   ]
```

Basic Specification

The basic specification is the scheme name SPSSCR (short for *SPSS Content Repository*), followed by a colon, one or two slashes (forward or backward), and a directory path or file: for example:

```
GET FILE='SPSSCR://spss/data/mydata.sav'.
```

- A repository file specification is included on a GET command. The latest version of the file */spss/data/mydata.sav* will be retrieved from the currently connected repository.

Syntax Rules

- Paths can be specified with forward slashes (/) or backslashes (\).
- The optional components of a file specification—version marker (#M), version label (#L), description (#D), and keywords (#K)—can be specified in any order.
- When including an optional component, the character sequence that specifies the component—for example, #L—must be followed by a period (.).
- You can include multiple optional components in a single specification—for example, version label and description. The character sequence that specifies each component serves to delimit adjacent components—for example, #L.development#D.Customer Lifetime Value.

File Extensions

Files are stored to the repository with an associated MIME type that specifies the type of file; for example, SPSS-format data, or viewer output. Including a file extension, such as *.sav* or *.spv*, is not necessary in order for the correct MIME type to be determined; however, it is recommended.

- File extensions are not added to filenames when storing to a repository. For example, the following SAVE command results in the creation of a repository object with a MIME type of SPSS-format data, and a fully qualified path of */spss/data/mydata*, but no *sav* extension.

```
SAVE OUTFILE='SPSSCR://spss/data/mydata'.
```

- When retrieving repository objects, you must specify the filename exactly as provided when the file was stored. If the file was stored with an extension, then you must supply the extension. If the file was stored without an extension then do not include one.

Permissions

- The PERMISSIONS, SAVE, and XSAVE commands will generate errors if you attempt to set permissions for repository objects. Permissions for repository objects are set with the PER ATTRIBUTES command or using administration tools included with Predictive Enterprise Services.
- The ERASE FILE command will generate an error if you attempt to delete a repository object.

Versions

By default, the latest version is returned when a file is retrieved. You can optionally specify a particular version to retrieve by including the version marker or version label, if one exists, for the desired version. Version markers and labels are always ignored if the specification describes a directory path, as opposed to a specific file.

Version label (#L). A label is used to easily identify a version; for example, *production* or *development*. You can attach a label to a version when storing and specify a version by its label when retrieving.

- Two versions of an object cannot have the same label. When storing an object, if you specify a label that is currently in use by a previous version, the label will be removed from the previous version and associated with the one you are storing.
- The version label, if provided, is displayed in the Label column in the Select Version dialog box.

Version marker (#M). The version marker consists of an integer version number followed by a time stamp that uniquely specifies a version—for example, *1:2006-07-26 15:19:49.237*.

- Use of the version marker applies only to file retrieval. It is ignored if included in a file specification when storing to a repository—an object being stored always becomes the latest version and is time stamped by the system.
- The version marker is displayed in the Version column in the Select Version dialog box.

Examples

```
*Associate a label with a version when storing.
```

```
SAVE OUTFILE='SPSSCR://spss/data/mydata.sav#L.production'.
```

- The active dataset is saved to the file */spss/data/mydata.sav* in the current repository. The label *production* is associated with this version of the file.

```
*Retrieve a labelled version.
GET FILE='SPSSCR://spss/data/mydata.sav#L.development'.
```

- The version of */spss/data/mydata.sav* with the label *development* is retrieved from the current repository.

```
*Retrieve a version using its version marker.
OUTPUT OPEN FILE=
   'SPSSCR://spss/output/myoutput.spv#M.0:2006-07-26 15:18:15.862'.
```

- The version of the output file */spss/output/myoutput.spv* with version marker *0:2006-07-26 15:18:15.862* is retrieved.

Description (#D)

A text description can be specified when storing a new object or when storing a new version of an existing object that doesn't already have a description.

- A description is honored only when storing an object and is ignored if the object already has a description (existing descriptions can't be changed).
- A description is always ignored if the specification describes a directory path, as opposed to a specific file.

Example

```
SAVE OUTFILE=
   'SPSSCR://spss/data/mydata.sav#L.development#D.Customer Lifetime Value'.
```

- The active dataset is saved to the file */spss/data/mydata.sav* in the current repository. The label *development* is associated with this version and the description *Customer Lifetime Value* is associated with the file. Spaces are allowed as part of the description.

Keywords (#K)

One or more keywords can be specified when storing a new object, or when storing a new version of an existing object that doesn't already have keywords.

- Multiple keywords should be separated by semicolons. Blank spaces at the beginning and end of each keyword are ignored, but blank spaces within keywords are honored.
- Keywords are honored only when storing an object and are ignored if the object already has keywords.
- Keywords are always ignored if the specification describes a directory path, as opposed to a specific file.

Example

```
OUTPUT SAVE NAME=CLV OUTFILE=
   'SPSSCR://spss/output/clv.spv#K.customer;value'.
```

- The output document named *CLV* is saved to */spss/output/clv.spv* in the current repository. The keywords *customer* and *value* are associated with the file.

Using File Handles for Repository Locations

You can define a file handle to a file or a directory in a repository and use that file handle when storing or retrieving.

```
*Define and use a file handle for a directory.
FILE HANDLE cust /NAME='SPSSCR://CustomerValue'.
GET FILE='cust/data2002.sav'.
```

- The handle *cust* is associated with the repository directory */CustomerValue*, and the `GET` command retrieves the latest version of the file *data2002.sav* from this directory in the current repository.

```
*Define and use a file handle for a specific file.
FILE HANDLE cust /NAME='SPSSCR://CustomerValue/data2002.sav'.
GET FILE='cust'.
```

- The handle *cust* is associated with the repository file */CustomerValue/data2002.sav*, and the `GET` command retrieves the latest version of this file from the current repository.

Setting the Working Directory to a Repository Location

You can use the `CD` command to set the working directory to a directory in the currently connected repository.

```
CD 'SPSSCR://CustomerValue'.
GET FILE='data2002.sav'.
```

- The working directory is set to the repository directory */CustomerValue*, and the `GET` command retrieves the latest version of the file *data2002.sav* from this directory in the current repository.
