SPSS 16.0 Command Syntax Reference

Printed in the United States of America.

Contents

Introduction: A Guide to Command Syntax 1

Add-On Modules 12
Release History 15

Universals 31

Commands 31
- Running Commands 33
- Subcommands 34
- Keywords 34
- Values in Command Specifications 34
- String Values in Command Specifications 35
- Delimiters 35
- Command Order 36

Files 40
- Command File 40
- Journal File 40
- Data Files 41

Variables 43
- Variable Names 43
- Keyword TO 45
- Keyword ALL 46
- Scratch Variables 46
- System Variables 48

Variable Types and Formats 49
- Input and Output Formats 49
- String Variable Formats 50
- Numeric Variable Formats 52
- Date and Time Formats 58
- FORTRAN-like Input Format Specifications 63

Transformation Expressions 63
- Numeric Expressions 64
- Numeric Functions 67
- Arithmetic Functions 67
- Statistical Functions 68
- Random Variable and Distribution Functions 69

Date and Time Functions . . . 93
String Expressions . . . 101
String Functions . . . 101
String/Numeric Conversion Functions . . . 106
LAG Function . . . 106
VALUELABEL Function . . . 107
Logical Expressions . . . 107
Logical Functions . . . 111
Scoring Expressions (SPSS Server) . . . 111
Missing Values . . . 114
Treatment of Missing Values in Arguments . . . 114
Missing Values in Numeric Expressions . . . 116
Missing Values in String Expressions . . . 116
Missing Values in Logical Expressions . . . 116
Missing Value Functions . . . 117

Introduction: A Guide to Command Syntax

The *Command Syntax Reference* is arranged alphabetically by command name to provide quick access to detailed information about each command in the syntax command language. This introduction groups commands into broad functional areas. Some commands are listed more than once because they perform multiple functions, and some older commands that have deprecated in favor of newer and better alternatives (but are still supported) are not included here. Changes to the command syntax language (since SPSS 12.0), including modifications to existing commands and addition of new commands, are provided in the section Release History.

Base System

The Base system contains the core functionality plus a wide range of statistical and charting procedures. There are also numerous add-on modules that contain specialized functionality.

Getting Data

You can read in a variety of data formats, including data files saved in SPSS format, SAS datasets, database tables from many database sources, Excel and other spreadsheets, and text data files with both simple and complex structures.

Command	Description	Page Number
SPSS Data Files		
Get	Reads SPSS-format data files.	on p. 752
Import	Reads portable data files created with the Export command.	on p. 906
Add Files	Combines multiple data files by adding cases.	on p. 132
Match Files	Combines multiple data files by adding variables.	on p. 1035
Update	Replaces values in a master file with updated values.	on p. 1924
Data Files Created by Other Applications		
Get Translate	Reads spreadsheet and dBASE files.	on p. 773
Get Data	Reads Excel files, text data files, and database tables.	on p. 759
Database Tables		
Get Data	Reads Excel files, text data files, and database tables.	on p. 759
Get Capture	Reads database tables.	on p. 756
SAS and Stata Data Files		
Get SAS	Reads SAS dataset and SAS transport files.	on p. 768

Command	Description	Page Number
Get Stata	Reads Stata data files.	on p. 772
Text Data Files		
Get Data	Reads Excel files, text data files, and database tables.	on p. 759
Data List	Reads text data files.	on p. 501
Begin Data-End Data	Used with Data List to read inline text data.	on p. 208
Complex (nested, mixed, grouped, etc.) Text Data Files		
File Type	Defines mixed, nested, and grouped data structures.	on p. 670
Record Type	Used with File Type to read complex text data files.	on p. 1559
Input Program	Generates case data and/or reads complex data files.	on p. 913
End Case	Used with Input Program to define cases.	on p. 621
End File	Used with Input Program to indicate end of file.	on p. 627
Repeating Data	Used with Input Program to read input cases whose records contain repeating groups of data.	on p. 1604
Reread	Used with Input Program to reread a record.	on p. 1644
Keyed Data List	Reads data from nonsequential files: ■ Direct-access files, which provide direct access by a record number. ■ Keyed files, which provide access by a record key.	on p. 921
Point	Used with Keyed Data to establish the location at which sequential access begins (or resumes) in a keyed file.	on p. 1411
Working with Multiple Data Sources		
Dataset Name	Provides the ability to have multiple data sources open at the same time.	on p. 533
Dataset Activate	Makes the named dataset the active dataset.	on p. 522

Saving and Exporting Data

You can save data in numerous formats, including SPSS-format data file, Excel spreadsheet, database table, delimited text, and fixed-format text.

Command	Description	Page Number
Saving Data in SPSS Format		
Save	Saves the active dataset in SPSS format.	on p. 1661
Xsave	Saves data in SPSS format without requiring a separate data pass.	on p. 2011
Export	Saves data in portable format.	on p. 640
Save Dimensions	Saves a data file in SPSS format and a metadata file in Dimensions MDD format for use in Dimensions applications.	on p. 1668
Saving Data as Text		

Command	Description	Page Number
Write	Saves data as fixed-format text.	on p. 1987
Save Translate	Saves data as tab-delimited text and comma-delimted (CSV) text.	on p. 1675
Saving Data in Spreadsheet Format		
Save Translate	Saves data in Excel and other spreadsheet formats and dBASE format.	on p. 1675
Writing Data Back to a Database Table		
Save Translate	Replaces or appends to existing database tables or creates new database tables.	on p. 1675

Data Definition

An SPSS-format data file can contain more than simply data values. The SPSS **dictionary** can contain a variety of metadata attributes, including measurement level, display format, descriptive variable and value labels, and special codes for missing values.

Command	Description	Page Number
Apply Dictionary	Applies variable and file-based dictionary information from an external SPSS-format data file.	on p. 193
Datafile Attribute	Creates user-defined attributes that can be saved with the data file.	on p. 519
Variable Attribute	Creates user-defined variable attributes that can be saved with variables in the data file.	on p. 1957
Variable Labels	Assigns descriptive labels to variables.	on p. 1960
Value Labels	Assigns descriptive labels to data values.	on p. 1946
Add Value Labels	Assigns descriptive labels to data values.	on p. 139
Variable Level	Specifies the level of measurement (nominal, ordinal, or scale).	on p. 1962
Missing Values	Specifies values to be treated as missing.	on p. 1113
Rename	Changes variable names.	on p. 1602
Formats	Changes variable print and write formats.	on p. 694
Print Formats	Changes variable print formats.	on p. 1465
Write Formats	Changes variable write formats.	on p. 1992
Variable Alignment	Specifies the alignment of data values in the Data Editor.	on p. 1956
Variable Width	Specifies the column width for display of variables in the Data Editor.	on p. 1963
Mrsets	Defines and saves multiple response set information.	on p. 1168

Data Transformations

You can perform data transformations ranging from simple tasks, such as collapsing categories for analysis, to more advanced tasks, such as creating new variables based on complex equations and conditional statements.

Command	Description	Page Number
Autorecode	Recodes the values of string and numeric variables to consecutive integers.	on p. 200
Compute	Creates new numeric variables or modifies the values of existing string or numeric variables.	on p. 293
Count	Counts occurrences of the same value across a list of variables.	on p. 325
Create	Produces new series as a function of existing series.	on p. 340
Date	Generates date identification variables.	on p. 536
Leave	Suppresses reinitialization and retains the current value of the specified variable or variables when the program reads the next case.	on p. 936
Numeric	Declares new numeric variables that can be referred to before they are assigned values.	on p. 1277
Rank	Produces new variables containing ranks, normal scores, and Savage and related scores for numeric variables.	on p. 1523
Recode	Changes, rearranges, or consolidates the values of an existing variable.	on p. 1553
RMV	Replaces missing values with estimates computed by one of several methods.	on p. 1651
String	Declares new string variables.	on p. 1768
Temporary	Signals the beginning of temporary transformations that are in effect only for the next procedure.	on p. 1794
TMS Begin	Indicates the beginning of a block of transformations to be exported to a file in PMML format (with SPSS extensions).	on p. 1800
TMS End	Marks the end of a block of transformations to be exported as PMML.	on p. 1807
TMS Merge	Merges a PMML file containing exported transformations with a PMML model file.	on p. 1809

File Information

You can add descriptive information to a data file and display file and data attributes for the active dataset or any selected SPSS-format data file.

Command	Description	Page Number
Add Documents	Saves a block of text of any length in an SPSS-format data file.	on p. 130
Display	Displays information from the dictionary of the active dataset.	on p. 598

Command	Description	Page Number
Document	Saves a block of text of any length in an SPSS-format data file.	on p. 617
Drop Documents	Deletes all text added with Document or Add Documents.	on p. 619
Sysfile Info	Displays complete dictionary information for all variables in a specified SPSS-format data file.	on p. 1791

File Transformations

Data files are not always organized in the ideal form for your specific needs. You may want to combine data files, sort the data in a different order, select a subset of cases, or change the unit of analysis by grouping cases together. A wide range of file transformation capabilities is available.

Command	Description	Page Number
Delete Variables	Deletes variables from the data file.	on p. 564
Sort Cases	Reorders the sequence of cases based on the values of one or more variables.	on p. 1733
Weight	Case replication weights based on the value of a specified variable.	on p. 1979
Select Subsets of Cases		
Filter	Excludes cases from analysis without deleting them from the file.	on p. 684
N of Cases	Deletes all but the first *n* cases in the data file.	on p. 1210
Sample	Selects a random sample of cases from the data file, deleting unselected cases.	on p. 1659
Select If	Selects cases based on logical conditions, deleting unselected cases.	on p. 1698
Split File	Splits the data into separate analysis groups based on values of one or more split variables.	on p. 1765
Use	Designates a range of observations for time series procedures.	on p. 1931
Change File Structure		
Aggregate	Aggregates groups of cases or creates new variables containing aggregated values.	on p. 142
Casestovars	Restructures complex data that has multiple rows for a case.	on p. 227
Varstocases	Restructures complex data structures in which information about a variable is stored in more than one column.	on p. 1964
Flip	Transposes rows (cases) and columns (variables).	on p. 690
Merge Data Files		
Add Files	Combines multiple SPSS-format data files by adding cases.	on p. 132
Match Files	Combines multiple SPSS-format data file by adding variables.	on p. 1035
Update	Replaces values in a master file with updated values.	on p. 1924

Programming Structures

As with other programming languages, the command syntax contains standard programming structures that can be used to do many things. These include the ability to perform actions only if some condition is true (if/then/else processing), repeat actions, create an array of elements, and use loop structures.

Command	Description	Page Number
Break	Used with Loop and Do If-Else If to control looping that cannot be fully controlled with conditional clauses.	on p. 215
Do If-Else If	Conditionally executes one or more transformations based on logical expressions.	on p. 601
Do Repeat	Repeats the same transformations on a specified set of variables.	on p. 611
If	Conditionally executes a single transformation based on logical conditions.	on p. 877
Loop	Performs repeated transformations specified by the commands within the loop until they reach a specified cutoff.	on p. 971
Vector	Associates a vector name with a set of variables or defines a vector of new variables.	on p. 1971

Programming Utilities

Command	Description	Page Number
Define	Defines a program macro.	on p. 545
Echo	Displays a specified text string as text output.	on p. 620
Execute	Forces the data to be read and executes the transformations that precede it in the command sequence.	on p. 639
Host	Executes external commands at the operating system level.	on p. 873
Include	Includes commands from the specified file.	on p. 910
Insert	Includes commands from the specified file.	on p. 917
Script	Runs the specified script file.	on p. 1692

General Utilities

Command	Description	Page Number
Cache	Creates a copy of the data in temporary disk space for faster processing.	on p. 216
Clear Transformations	Discards all data transformation commands that have accumulated since the last procedure.	on p. 273
Erase	Deletes the specified file.	on p. 629
File Handle	Assigns a unique file handle to the specified file.	on p. 666
New File	Creates a blank, new active dataset.	on p. 1222
Permissions	Changes the read/write permissions for the specified file.	on p. 1390
Preserve	Stores current Set command specifications that can later be restored by the Restore command.	on p. 1446

Command	Description	Page Number
Print	Prints the values of the specified variables as text output.	on p. 1456
Print Eject	Displays specified information at the top of a new page of the output.	on p. 1462
Print Space	Displays blank lines in the output.	on p. 1468
Restore	Restores Set specifications that were stored by Preserve.	on p. 1650
Set	Customizes program default settings.	on p. 1710
Show	Displays current settings, many of which are set by the Set command.	on p. 1728
Subtitle	Inserts a subtitle on each page of output.	on p. 1770
Title	Inserts a title on each page of output.	on p. 1798

Matrix Operations

Command	Description	Page Number
Matrix	Using matrix programs, you can write your own statistical routines in the compact language of matrix algebra.	on p. 1044
Matrix Data	Reads raw matrix materials and converts them to a matrix data file that can be read by procedures that handle matrix materials.	on p. 1087
Mconvert	Converts covariance matrix materials to correlation matrix materials or vice versa.	on p. 1105

Output Management System

The Output Management System (OMS) provides the ability to automatically write selected categories of output to different output files in different formats, including SPSS data file format, HTML, XML, and text.

Command	Description	Page Number
OMS	Controls the routing and format of output. Output can be routed to external files in XML, HTML, text, and SAV (SPSS-format data file) formats.	on p. 1284
OMSEnd	Ends active OMS commands.	on p. 1313
OMSInfo	Displays a table of all active OMS commands.	on p. 1315
OMSLog	Creates a log of OMS activity.	on p. 1316

Output Documents

These commands control Viewer windows and files.

Command	Description	Page Number
Output Activate	Controls the routing of output to Viewer output documents.	on p. 1340
Output Close	Closes the specified Viewer document.	on p. 1343
Output Display	Displays a table of all open Viewer documents.	on p. 1345

Command	Description	Page Number
Output Name	Assigns a name to the active Viewer document. The name is used to refer to the output document in subsequent Output commands.	on p. 1346
Output New	Creates a new Viewer output document, which becomes the active output document.	on p. 1348
Output Open	Opens a Viewer document, which becomes the active output document. You can use this command to append output to an existing output document.	on p. 1346
Output Save	Saves the contents of an open output document to a file.	on p. 1354

Charts

Command	Description	Page Number
Caseplot	Casewise plots of sequence and time series variables.	on p. 217
Graph	Bar charts, pie charts, line charts, histograms, scatterplots, etc.	on p. 842
GGraph	Bar charts, pie charts, line charts, scatterplots, custom charts.	on p. 781
Igraph	Bar charts, pie charts, line charts, histograms, scatterplots, etc.	on p. 883
Pplot	Probability plots of sequence and time series variables.	on p. 1415
ROC	Receiver operating characteristic (ROC) curve and an estimate of the area under the curve.	on p. 1655
Spchart	Control charts, including X-Bar, r, s, individuals, moving range, and u.	on p. 1737
Xgraph	Creates 3-D bar charts, population pyramids, and dot plots.	on p. 1995

Reports

In addition to the commands listed here, the Tables option provide many advanced reporting capabilities. For more information, see Add-On Modules on p. 12.

Command	Description	Page Number
OLAP Cubes	Summary statistics for scale variables within categories defined by one or more categorical grouping variables.	on p. 1279
Summarize	Individual case listing and group summary statistics.	on p. 1772
List	Individual case listing.	on p. 939
Report	Individual case listing and group summary statistics.	on p. 1618

Descriptive Statistics

Command	Description	Page Number
Crosstabs	Crosstabulations (contingency tables) and measures of association.	on p. 349

Command	Description	Page Number
Descriptives	Univariate statistics, including the mean, standard deviation, and range.	on p. 565
Examine	Descriptive statistics, stem-and-leaf plots, histograms, boxplots, normal plots, robust estimates of location, and tests of normality.	on p. 630
Frequencies	Tables of counts and percentages and univariate statistics, including the mean, median, and mode.	on p. 697
Ratio Statistics	Descriptive statistics for the ratio between two variables.	on p. 1529

Compare Means

Command	Description	Page Number
Means	Group means and related univariate statistics for dependent variables within categories of one or more independent variables.	on p. 1108
Oneway	One-way analysis of variance.	on p. 1318
TTest	One sample, independent samples, and paired samples *t* tests.	on p. 1892

General Linear Model

In addition to the command(s) listed here, the Advanced Models option provides more advanced general linear model features. For more information, see Add-On Modules on p. 12.

Command	Description	Page Number
Unianova	Regression analysis and analysis of variance for one dependent variable by one or more factors and/or variables.	on p. 1904

Correlate

Command	Description	Page Number
Correlations	Pearson correlations with significance levels, univariate statistics, covariances, and cross-product deviations.	on p. 309
Nonpar Corr	Rank-order correlation coefficients: Spearman's rho and Kendall's tau-*b*, with significance levels.	on p. 1252
Partial Corr	Partial correlation coefficients between two variables, adjusting for the effects of one or more additional variables.	on p. 1372
Proximities	Measures of similarity, dissimilarity, or distance between pairs of cases or pairs of variables.	on p. 1482

Nonparametric Tests

Command	Description	Page Number
Nonpar Corr	Rank-order correlation coefficients: Spearman's rho and Kendall's tau-*b*, with significance levels.	on p. 1252
Npar Tests	Collection of one-sample, independent samples, and related samples nonparametric tests.	on p. 1258

Regression

In addition to the commands listed here, the Regression Models option provides more advanced regression analysis features. For more information, see Add-On Modules on p. 12.

Command	Description	Page Number
Regression	Multiple regression equations and associated statistics and plots.	on p. 1569
Plum	Analyzes the relationship between a polytomous ordinal dependent variable and a set of predictors.	on p. 1403
Curvefit	Fits selected curves to a line plot.	on p. 494

Classification

In addition to the commands listed here, the Classification Trees option provides additional classification methods. For more information, see Add-On Modules on p. 12.

Command	Description	Page Number
Cluster	Hierarchical clusters of items based on distance measures of dissimilarity or similarity. The items being clustered are usually cases, although variables can also be clustered.	on p. 274
Quick Cluster	When the desired number of clusters is known, this procedure groups cases efficiently into clusters.	on p. 1516
Twostep Cluster	Groups observations into clusters based on a nearness criterion. The procedure uses a hierarchical agglomerative clustering procedure in which individual cases are successively combined to form clusters whose centers are far apart.	on p. 1897
Discriminant	Classifies cases into one of several mutually exclusive groups based on their values for a set of predictor variables.	on p. 580

Data Reduction

In addition to the command(s) listed here, the Categories option provides data reduction methods. For more information, see Add-On Modules on p. 12.

Command	Description	Page Number
Factor	Identifies underlying variables, or factors, that explain the pattern of correlations within a set of observed variables.	on p. 649

Scale

In addition to the commands listed here, the Categories option provides additional scaling methods. For more information, see Add-On Modules on p. 12.

Scale	Description	Page Number
ALSCAL	Multidimensional scaling (MDS) and multidimensional unfolding (MDU) using an alternating least-squares algorithm.	on p. 160
Reliability	Estimates reliability statistics for the components of multiple-item additive scales.	on p. 1593

Multiple Response

In addition to the command(s) listed here, the Tables option also provides methods for defining and reporting multiple-response data. For more information, see Add-On Modules on p. 12.

Command	Description	Page Number
Mult Response	Frequency tables and crosstabulations for multiple-response data.	on p. 1172

Time Series

The Base system provides some basic time series functionality, including a number of time series chart types. Extensive time series analysis features are provided in the Trends option. For more information, see Add-On Modules on p. 12.

Command	Description	Page Number
ACF	Displays and plots the sample autocorrelation function of one or more time series.	on p. 123
CCF	Displays and plots the cross-correlation functions of two or more time series.	on p. 263
PACF	Displays and plots the sample partial autocorrelation function of one or more time series.	on p. 1366
Tsplot	Plot of one or more time series or sequence variables.	on p. 1882
Fit	Displays a variety of descriptive statistics computed from the residual series for evaluating the goodness of fit of models.	on p. 687
Predict	Specifies the observations that mark the beginning and end of the forecast period.	on p. 1425
Tset	Sets global parameters to be used by procedures that analyze time series and sequence variables.	on p. 1852
Tshow	Displays a list of all of the current specifications on the Tset, Use, Predict, and Date commands.	on p. 1855
Verify	Produces a report on the status of the most current Date, Use, and Predict specifications.	on p. 1977

Scoring

The following commands work only with SPSS Server and the SPSS batch facility (SPSSB) that accompanies SPSS Server.

Command	Description	Page Number
Model Handle	Reads an external XML file containing specifications for a predictive model.	on p. 1161
Model Close	Discards cached models and their associated model handle names.	on p. 1160
Model List	Lists the model handles currently in effect.	on p. 1165

Add-On Modules

Add-on modules are not included with the Base system. The commands available to you will depend on your software license.

Advanced Models

Command	Description	Page Number
GLM	General Linear Model. A general procedure for analysis of variance and covariance, as well as regression.	on p. 798
Genlin	Generalized Linear Model. Genlin allows you to fit a broad spectrum of "generalized" models in which the distribution of the error term need not be normal and the relationship between the dependent variable and predictors need only be linear through a specified transformation.	on p. 705
Varcomp	Estimates variance components for mixed models.	on p. 1949
Mixed	The mixed linear model expands the general linear model used in the GLM procedure in that the data are permitted to exhibit correlation and non-constant variability.	on p. 1116
Genlog	A general procedure for model fitting, hypothesis testing, and parameter estimation for any model that has categorical variables as its major components.	on p. 741
Hiloglinear	Fits hierarchical loglinear models to multidimensional contingency tables using an iterative proportional-fitting algorithm.	on p. 856
Survival	Actuarial life tables, plots, and related statistics.	on p. 1778
Coxreg	Cox proportional hazards regression for analysis of survival times.	on p. 327
KM	Kaplan-Meier (product-limit) technique to describe and analyze the length of time to the occurrence of an event.	on p. 927

Regression Models

Command	Description	Page Number
Logistic Regression	Regresses a dichotomous dependent variable on a set of independent variables.	on p. 943
Nomreg	Fits a multinomial logit model to a polytomous nominal dependent variable.	on p. 1239
NLR, CNLR	Nonlinear regression is used to estimate parameter values and regression statistics for models that are not linear in their parameters.	on p. 1223
WLS	Weighted Least Squares. Estimates regression models with different weights for different cases.	on p. 1981
2SLS	Two-stage least-squares regression.	on p. 118

Tables

Command	Description	Page Number
Ctables	Produces tables in one, two, or three dimensions and provides a great deal of flexibility for organizing and displaying the contents.	on p. 466

Classification Trees

Command	Description	Page Number
Tree	Tree-based classification models.	on p. 1811

Categories

Command	Description	Page Number
Catreg	Categorical regression with optimal scaling using alternating least squares.	on p. 252
CatPCA	Principal components analysis.	on p. 235
Overals	Nonlinear canonical correlation analysis on two or more sets of variables.	on p. 1357
Correspondence	Displays the relationships between rows and columns of a two-way table graphically by a scatterplot matrix.	on p. 314
Multiple Correspondence	Quantifies nominal (categorical) data by assigning numerical values to the cases (objects) and categories, such that objects within the same category are close together and objects in different categories are far apart.	on p. 1182
Proxscal	Multidimensional scaling of proximity data to find a least-squares representation of the objects in a low-dimensional space.	on p. 1499

Complex Samples

Command	Description	Page Number
CSPlan	Creates a complex sample design or analysis specification.	on p. 432
CSSelect	Selects complex, probability-based samples from a population.	on p. 451
CSDescriptives	Estimates means, sums, and ratios, and computes their standard errors, design effects, confidence intervals, and hypothesis tests.	on p. 380
CSTabulate	Frequency tables and crosstabulations, and associated standard errors, design effects, confidence intervals, and hypothesis tests.	on p. 460
CSGLM	Linear regression analysis, and analysis of variance and covariance.	on p. 386
CSLogistic	Logistic regression analysis on a binary or multinomial dependent variable using the generalized link function.	on p. 400
CSOrdinal	Fits a cumulative odds model to an ordinal dependent variable for data that have been collected according to a complex sampling design.	on p. 415

Neural Networks

Command	Description	Page Number
MLP	Fits flexible predictive model for one or more target variables, which can be categorical or scale, based upon the values of factors and covariates.	on p. 1137
RBF	Fits flexible predictive model for one or more target variables, which can be categorical or scale, based upon the values of factors and covariates. Generally trains faster than MLP at the slight cost of some model flexibility.	on p. 1534

Trends

Command	Description	Page Number
Season	Estimates multiplicative or additive seasonal factors.	on p. 1693
Spectra	Periodogram and spectral density function estimates for one or more series.	on p. 1757
Tsapply	Loads existing time series models from an external file and applies them to data.	on p. 1838
Tsmodel	Estimates exponential smoothing, univariate Autoregressive Integrated Moving Average (ARIMA), and multivariate ARIMA (or transfer function models) models for time series, and produces forecasts.	on p. 1856

Conjoint

Command	Description	Page Number
Conjoint	Analyzes score or rank data from full-concept conjoint studies.	on p. 299
Orthoplan	Orthogonal main-effects plan for a full-concept conjoint analysis.	on p. 1335
Plancards	Full-concept profiles, or cards, from a plan file for conjoint analysis.	on p. 1391

Missing Values Analysis

Command	Description	Page Number
MVA	Missing Value Analysis. Describes missing value patterns and estimates (imputes) missing values.	on p. 1196

Data Preparation

Command	Description	Page Number
Detectanomaly	Searches for unusual cases based on deviations from the norms of their cluster groups.	on p. 571
Validatedata	Identifies suspicious and invalid cases, variables, and data values in the active dataset.	on p. 1934
Optimal Binning	Discretizes scale "binning input" variables to produce categories that are "optimal" with respect to the relationship of each binning input variable with a specified categorical guide variable.	on p. 1328

Adaptor for Predictive Enterprise Services

Command	Description	Page Number
PER Attributes	Sets attributes for an object in a Predictive Enterprise Repository.	on p. 1380
PER Connect	Establishes a connection to a Predictive Enterprise Repository and logs in the user.	on p. 1384
PER Copy	Copies an arbitrary file from the local file system to a Predictive Enterprise Repository or copies a file from a Predictive Enterprise Repository to the local file system.	on p. 1387

Release History

This section details changes to the command syntax language occurring after SPSS release 12.0. Information is organized alphabetically by command and changes for a given command are grouped by release. For commands introduced after 12.0, the introductory release is noted. Additions of new functions (used for instance with COMPUTE) and changes to existing functions are detailed under the heading *Functions*, located at the end of this section.

AGGREGATE

Release 13.0

- MODE keyword introduced.
- OVERWRITE keyword introduced.

ALTER TYPE

Release 16.0

- Command introduced.

APPLY DICTIONARY

Release 14.0

- ATTRIBUTES keyword introduced on FILEINFO and VARINFO subcommands.

AUTORECODE

Release 13.0

- BLANK subcommand introduced.
- GROUP subcommand introduced.
- APPLY TEMPLATE and SAVE TEMPLATE subcommands introduced.

BEGIN GPL

Release 14.0

- Command introduced.

BEGIN PROGRAM

Release 14.0

- Command introduced.

CASEPLOT

Release 14.0

- For plots with one variable, new option to specify a value with the REFERENCE keyword on the FORMAT subcommand.

CATPCA

Release 13.0

- NDIM keyword introduced on PLOT subcommand.
- The maximum label length on the PLOT subcommand is increased to 64 for variable names, 255 for variable labels, and 60 for value labels (previous value was 20).

CATREG

Release 13.0

- The maximum category label length on the PLOT subcommand is increased to 60 (previous value was 20).

CD

Release 13.0

- Command introduced.

CORRESPONDENCE

Release 13.0

- For the NDIM keyword on the PLOT subcommand, the default is changed to all dimensions.
- The maximum label length on the PLOT subcommand is increased to 60 (previous value was 20).

CSGLM

Release 13.0

- Command introduced.

CSLOGISTIC

Release 13.0

- Command introduced.

CSORDINAL

Release 15.0

- Command introduced.

CTABLES

Release 13.0

- HSUBTOTAL keyword introduced on the CATEGORIES subcommand.

Release 14.0

- INCLUDEMRSETS keyword introduced on the SIGTEST and COMPARETEST subcommands.

- CATEGORIES keyword introduced on the SIGTEST and COMPARETEST subcommands.
- MEANSVARIANCE keyword introduced on the COMPARETEST subcommand.

DATA LIST

Release 16.0

- ENCODING subcommand added for Unicode support.

DATAFILE ATTRIBUTE

Release 14.0

- Command introduced.

DATASET ACTIVATE

Release 14.0

- Command introduced.

DATASET CLOSE

Release 14.0

- Command introduced.

DATASET COPY

Release 14.0

- Command introduced.

DATASET DECLARE

Release 14.0

- Command introduced.

DATASET DISPLAY

Release 14.0

- Command introduced.

DATASET NAME

Release 14.0

- Command introduced.

DEFINE-!ENDDEFINE

Release 14.0

- For syntax processed in interactive mode, modifications to the macro facility may affect macro calls occurring at the end of a command. For more information, see Overview on p. 546.

DETECTANOMALY

Release 14.0

- Command introduced.

DISPLAY

Release 14.0

- `ATTRIBUTES` keyword introduced.

Release 15.0

- `@ATTRIBUTES` keyword introduced.

DO REPEAT-END REPEAT

Release 14.0

- `ALL` keyword introduced.

EXTENSION

Release 16.0

- Command introduced.

FILE HANDLE

Release 13.0

- The `NAME` subcommand is modified to accept a path and/or file.

Release 16.0

- `ENCODING` subcommand added for Unicode support.

FILE TYPE

Release 16.0

- `ENCODING` subcommand added for Unicode support.

GENLIN

Release 15.0

- Command introduced.

Release 16.0

- Added multinomial and tweedie distributions; added MLE estimation option for ancillary parameter of negative binomial distribution (MODEL subcommand, DISTRIBUTION keyword). Notes related to the addition of the new distributions added throughout.
- Added cumulative Cauchit, cumulative complementary log-log, cumulative logit, cumulative negative log-log, and cumulative probit link functions (MODEL subcommand, LINK keyword).
- Added likelihood-ratio chi-square statistics as an alternative to Wald statistics (CRITERIA subcommand, ANALYSISTYPE keyword).
- Added profile likelihood confidence intervals as an alternative to Wald confidence intervals (CRITERIA subcommand, CITYPE keyword).
- Added option to specify initial value for ancillary parameter of negative binomial distribution (CRITERIA subcommand, INITIAL keyword).
- Changed default display of the likelihood function for GEEs to show the full value instead of the kernel (CRITERIA subcommand, LIKELIHOOD keyword).

GET DATA

Release 13.0

- ASSUMEDSTRWIDTH subcommand introduced for TYPE=ODBC.

Release 14.0

- ASSUMEDSTRWIDTH subcommand extended to TYPE=XLS.
- TYPE=OLEDB introduced.

Release 15.0

- ASSUMEDSTRWIDTH subcommand extended to TYPE=OLEDB.

Release 16.0

- TYPE=XLSX and TYPE=XLSM introduced.

GET STATA

Release 14.0

- Command introduced.

GGRAPH

Release 14.0

- Command introduced.

Release 15.0

- `RENAME` syntax qualifier deprecated.
- `COUNTCI`, `MEDIANCI`, `MEANCI`, `MEANSD`, and `MEANSE` functions introduced.

GRAPH

Release 13.0

- `PANEL` subcommand introduced.
- `INTERVAL` subcommand introduced.

HOST

Release 13.0

- Command introduced.

INCLUDE

Release 16.0

- `ENCODING` keyword added for Unicode support.

INSERT

Release 13.0

- Command introduced.

Release 16.0

- `ENCODING` keyword added for Unicode support.

KEYED DATA LIST

Release 16.0

- `ENCODING` subcommand added for Unicode support.

LOGISTIC REGRESSION

Release 13.0

- `OUTFILE` subcommand introduced.

Release 14.0

- Modification to the method of recoding string variables. For more information, see Overview on p. 944.

MISSING VALUES

Release 16.0

- Limitation preventing assignment of missing values to strings with a defined width greater than eight bytes removed.

MLP

Release 16.0

- Command introduced.

MODEL CLOSE

Release 13.0

- Command introduced.

MODEL HANDLE

Release 13.0

- Command introduced.

MODEL LIST

Release 13.0

- Command introduced.

MRSETS

Release 14.0

- `LABELSOURCE` keyword introduced on `MDGROUP` subcommand.
- `CATEGORYLABELS` keyword introduced on `MDGROUP` subcommand.

MULTIPLE CORRESPONDENCE

Release 13.0

- Command introduced.

NAIVEBAYES

Release 14.0

- Command introduced.

NOMREG

Release 13.0

- ENTRYMETHOD keyword introduced on STEPWISE subcommand.
- REMOVALMETHOD keyword introduced on STEPWISE subcommand.
- IC keyword introduced on PRINT subcommand.

Release 15.0

- ASSOCIATION keyword introduced on PRINT subcommand.

OMS

Release 13.0

- TREES keyword introduced on SELECT subcommand.
- IMAGES, IMAGEROOT, CHARTSIZE, and IMAGEFORMAT keywords introduced on DESTINATION subcommand.

Release 14.0

- XMLWORKSPACE keyword introduced on DESTINATION subcommand.

Release 16.0

- IMAGEFORMAT=VML introduced for FORMAT=HTML on DESTINATION subcommand.
- IMAGEMAP keyword introduced for FORMAT=HTML on DESTINATION subcommand.
- FORMAT=SPV introduced for saving output in Viewer format.
- CHARTFORMAT keyword introduced.
- TREEFORMAT keyword introduced.
- TABLES keyword introduced.
- FORMAT=SVWSOXML is no longer supported.

OPTIMAL BINNING

Release 15.0

- Command introduced.

OUTPUT ACTIVATE

Release 15.0

- Command introduced.

OUTPUT CLOSE

Release 15.0

- Command introduced.

OUTPUT DISPLAY

Release 15.0

- Command introduced.

OUTPUT NAME

Release 15.0

- Command introduced.

OUTPUT NEW

Release 15.0

- Command introduced.

Release 16.0

- `TYPE` keyword is obsolete and is ignored.

OUTPUT OPEN

Release 15.0

- Command introduced.

OUTPUT SAVE

Release 15.0

- Command introduced.

Release 16.0

- `TYPE` keyword introduced.

PER ATTRIBUTES

Release 16.0

- Command introduced.

PER CONNECT

Release 15.0

- Command introduced.

PER COPY

Release 16.0

- Command introduced.

PLANCARDS

Release 14.0

- PAGINATE subcommand is obsolete and no longer supported.

PLS

Release 16.0

- Command introduced.

POINT

Release 16.0

- ENCODING subcommand added for Unicode support.

PREFSCAL

Release 14.0

- Command introduced.

PRINT

Release 16.0

- ENCODING subcommand added for Unicode support.

PRINT EJECT

Release 16.0

- ENCODING subcommand added for Unicode support.

PRINT SPACE

Release 16.0

- ENCODING subcommand added for Unicode support.

RBF

Release 16.0

- Command introduced.

REGRESSION

Release 13.0

- PARAMETER keyword introduced on OUTFILE subcommand.

REPEATING DATA

Release 16.0

- ENCODING subcommand added for Unicode support.

SAVE DIMENSIONS

Release 15.0

- Command introduced.

SAVE TRANSLATE

Release 14.0

- Value STATA added to list for TYPE subcommand.
- EDITION subcommand introduced for TYPE=STATA.
- SQL subcommand introduced.
- MISSING subcommand introduced.
- Field/column names specified on the RENAME subcommand can contain characters (for example, spaces, commas, slashes, plus signs) that are not allowed in SPSS variable names.
- Continuation lines for connection strings on the CONNECT subcommand do not need to begin with a plus sign.

Release 15.0

- ENCRYPTED subcommand introduced.
- Value CSV added to list for TYPE subcommand.
- TEXTOPTIONS subcommand introduced for TYPE=CSV and TYPE=TAB.

Release 16.0

- VERSION=12 introduced for writing data in Excel 2007 XLSX format with TYPE=XLS.

SELECTPRED

Release 14.0

- Command introduced.

SET

Release 13.0

- RNG and MTINDEX subcommands introduced.
- Default for MXERRS subcommand increased to 100.
- SORT subcommand introduced.
- LOCALE subcommand introduced.

Release 14.0

- Default for WORKSPACE subcommand increased to 6148.

Release 15.0

- LABELS replaces VALUES as the default for the TNUMBERS subcommand.
- JOURNAL subcommand is obsolete and no longer supported.
- Value EXTERNAL added to list for SORT subcommand, replacing the value SPSS as the default. Value SS is deprecated.

Release 16.0

- MCACHE subcommand introduced.
- THREADS subcommand introduced.
- UNICODE subcommand introduced.

SHOW

Release 13.0

- BLKSIZE and BUFNO subcommands are obsolete and no longer supported.
- SORT subcommand introduced.

Release 15.0

- TMSRECORDING subcommand introduced.

Release 16.0

- UNICODE subcommand introduced.
- MCACHE subcommand introduced.
- THREADS subcommand introduced.

SORT VARIABLES

Release 16.0.

- Command introduced.

SPCHART

Release 15.0

- (XBARONLY) keyword introduced on XR and XS subcommands.
- RULES subcommand introduced.
- ID subcommand introduced.

TMS BEGIN

Release 15.0

- Command introduced.

Release 16.0

- Added support for new string functions `CHAR.CONCAT`, `CHAR.LENGTH`, and `CHAR.SUBSTR` within `TMS` blocks.

TMS END

Release 15.0

- Command introduced.

TMS MERGE

Release 15.0

- Command introduced.

TREE

Release 13.0

- Command introduced.

TSAPPLY

Release 14.0

- Command introduced.

TSMODEL

Release 14.0

- Command introduced.

TSPLOT

Release 14.0

- For plots with one variable, `REFERENCE` keyword modified to allow specification of a value.

VALIDATEDATA

Release 14.0

- Command introduced.

VALUE LABELS

Release 14.0

- The maximum length of a value label is extended to 120 bytes (previous limit was 60 bytes).

Release 16.0

- Limitation preventing assignment of missing values to strings with a defined width greater than eight bytes removed.

VARIABLE ATTRIBUTE

Release 14.0

- Command introduced.

WRITE

Release 16.0

- `ENCODING` subcommand added for Unicode support.

XGRAPH

Release 13.0

- Command introduced.

Functions

Release 13.0

- `APPLYMODEL` and `STRAPPLYMODEL` functions introduced.
- `DATEDIFF` and `DATESUM` functions introduced.

Release 14.0

- `REPLACE` function introduced.
- `VALUELABEL` function introduced.

Release 16.0

- `CHAR.INDEX` function introduced.
- `CHAR.LENGTH` function introduced.
- `CHAR.LPAD` function introduced.
- `CHAR.MBLEN` function introduced.
- `CHAR.RINDEX` function introduced.
- `CHAR.RPAD` function introduced.
- `CHAR.SUBSTR` function introduced.
- `NORMALIZE` function introduced.

- `NTRIM` function introduced.
- `STRUNC` function introduced.

Universals

This part of the *Command Syntax Reference* discusses general topics pertinent to using command syntax. The topics are divided into five sections:

- Commands explains command syntax, including command specification, command order, and running commands in different modes. In this section, you will learn how to read syntax charts, which summarize command syntax in diagrams and provide an easy reference. Discussions of individual commands are found in an alphabetical reference in the next part of this manual.
- Files discusses different types of files used by the program. Terms frequently mentioned in this manual are defined. This section provides an overview of how files are handled.
- Variables and Variable Types and Formats contain important information about general rules and conventions regarding variables and variable definition.
- Transformations describes expressions that can be used in data transformation. Functions and operators are defined and illustrated. In this section, you will find a complete list of available functions and how to use them.

Commands

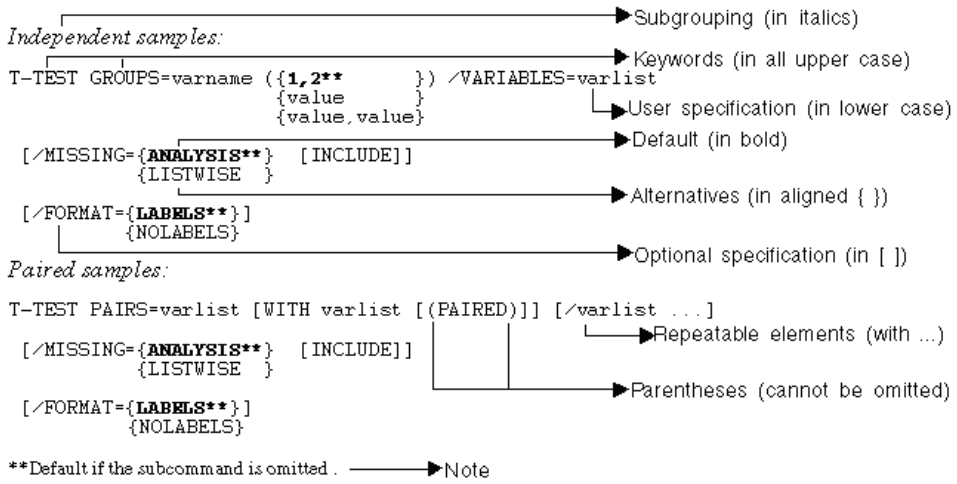
Commands are the instructions that you give the program to initiate an action. For the program to interpret your commands correctly, you must follow certain rules.

Syntax Diagrams

Each command described in this manual includes a syntax diagram that shows all of the subcommands, keywords, and specifications allowed for that command. By recognizing symbols and different type fonts, you can use the syntax diagram as a quick reference for any command.

- Lines of text in italics indicate limitation or operation mode of the command.
- Elements shown in upper case are keywords to identify commands, subcommands, functions, operators, and other specifications. In the sample syntax diagram below, `T-TEST` is the command and `GROUPS` is a subcommand.
- Elements in lower case describe specifications that you supply. For example, `varlist` indicates that you need to supply a list of variables.
- Elements in bold are defaults. There are two types of defaults. When the default is followed by **, as `ANALYSIS**` is in the sample syntax diagram below, the default (`ANALYSIS`) is in effect if the subcommand (`MISSING`) is not specified. If a default is not followed by **, it is in effect when the subcommand (or keyword) is specified by itself.

Figure 2-1
Syntax diagram



- Parentheses, apostrophes, and quotation marks are required where indicated.
- Unless otherwise noted, elements enclosed in square brackets (`[ ]`) are optional. For some commands, square brackets are part of the required syntax. The command description explains which specifications are required and which are optional.
- Braces (`{ }`) indicate a choice between elements. You can specify any one of the elements enclosed within the aligned braces.
- Ellipses indicate that you can repeat an element in the specification. The specification

  ```
  T-TEST PAIRS=varlist [WITH varlist [(PAIRED)]] [/varlist ...]
  ```

  means that you can specify multiple variable lists with optional `WITH` variables and the keyword `PAIRED` in parentheses.
- Most abbreviations are obvious; for example, `varname` stands for variable name and `varlist` stands for a variable list.
- The command terminator is not shown in the syntax diagram.

Command Specification

The following rules apply to all commands:

- Commands begin with a keyword that is the name of the command and often have additional specifications, such as subcommands and user specifications. Refer to the discussion of each command to see which subcommands and additional specifications are required.
- Commands and any command specifications can be entered in upper and lower case. Commands, subcommands, keywords, and variable names are translated to upper case before processing. All user specifications, including variable names, labels, and data values, preserve upper and lower case.
- Spaces can be added between specifications at any point where a single blank is allowed. In addition, lines can be broken at any point where a single blank is allowed. There are two exceptions: the `END DATA` command can have only one space between words, and string specifications on commands such as `TITLE`, `SUBTITLE`, `VARIABLE LABELS`, and `VALUE`

LABELS can be broken across two lines only by specifying a plus sign (+) between string segments. For more information, see String Values in Command Specifications on p. 35.

- Many command names and keywords can be abbreviated to the first three or more characters that can be resolved without ambiguity. For example, COMPUTE can be abbreviated to COMP but not COM because the latter does not adequately distinguish it from COMMENT. Some commands, however, require that all specifications be spelled out completely. This restriction is noted in the syntax chart for those commands.

Running Commands

You can run commands in either batch (production) or interactive mode. In batch mode, commands are read and acted upon as a batch, so the system knows that a command is complete when it encounters a new command. In interactive mode, commands are processed immediately, and you must use a command terminator to indicate when a command is complete.

Interactive Mode

The following rules apply to command specifications in interactive mode:

- Each command must start on a new line. Commands can begin in any column of a command line and continue for as many lines as needed. The exception is the END DATA command, which must begin in the first column of the first line after the end of data.
- Each command should end with a period as a command terminator. It is best to omit the terminator on BEGIN DATA, however, so that inline data are treated as one continuous specification.
- The command terminator must be the last nonblank character in a command.
- In the absence of a period as the command terminator, a blank line is interpreted as a command terminator.

Note: For compatibility with other modes of command execution (including command files run with INSERT or INCLUDE commands in an interactive session), each line of command syntax should not exceed 256 bytes.

Batch (Production) Mode

The following rules apply to command specifications in batch mode:

- All commands in the command file must begin in column 1. You can use plus (+) or minus (–) signs in the first column if you want to indent the command specification to make the command file more readable.
- If multiple lines are used for a command, column 1 of each continuation line must be blank.
- Command terminators are optional.
- A line cannot exceed 256 bytes; any additional characters are truncated.

The following is a sample command file that will run in either interactive or batch mode:

```
GET FILE=/MYFILES/BANK.SAV'
  /KEEP ID TIME SEX JOBCAT SALBEG SALNOW
```

```
  /RENAME SALNOW = SAL90.

DO IF TIME LT 82.
+  COMPUTE RATE=0.05.
ELSE.
+  COMPUTE RATE=0.04.
END IF.

COMPUTE SALNOW=(1+RATE)*SAL90.

EXAMINE VARIABLES=SALNOW BY SEX.
```

Subcommands

Many commands include additional specifications called **subcommands**.

- Subcommands begin with a keyword that is the name of the subcommand. Most subcommands include additional specifications.
- Some subcommands are followed by an equals sign before additional specifications. The equals sign is usually optional but is required where ambiguity is possible in the specification. To avoid ambiguity, it is best to use the equals signs as shown in the syntax diagrams in this manual.
- Most subcommands can be named in any order. However, some commands require a specific subcommand order. The description of each command includes a section on subcommand order.
- Subcommands are separated from each other by a slash. To avoid ambiguity, it is best to use the slashes as shown in the syntax diagrams in this manual.

Keywords

Keywords identify commands, subcommands, functions, operators, and other specifications.

- Keywords identifying logical operators (`AND`, `OR`, and `NOT`); relational operators (`EQ`, `GE`, `GT`, `LE`, `LT`, and `NE`); and `ALL`, `BY`, `TO`, and `WITH` are reserved words and cannot be used as variable names.

Values in Command Specifications

The following rules apply to values specified in commands:

- A single lowercase character in the syntax diagram, such as *n*, *w*, or *d*, indicates a user-specified value.
- The value can be an integer or a real number within a restricted range, as required by the specific command or subcommand. For exact restrictions, read the individual command description.
- A number specified as an argument to a subcommand can be entered with or without leading zeros.

String Values in Command Specifications

- Each string specified in a command should be enclosed in single or double quotes.
- To specify a single quote or apostrophe within a quoted string, either enclose the entire string in double quotes or double the single quote/apostrophe. Both of the following specifications are valid:

```
'Client''s Satisfaction'

"Client's Satisfaction"
```

- To specify double quotes within a string, use single quotes to enclose the string:

```
'Categories Labeled "UNSTANDARD" in the Report'
```

- String specifications can be broken across command lines by specifying each string segment within quotes and using a plus (+) sign to join segments. For example,

```
'One, Two'
```

  can be specified as

```
'One,'
+ ' Two'
```

  The plus sign can be specified on either the first or the second line of the broken string. Any blanks separating the two segments must be enclosed within one or the other string segment.
- Multiple blank spaces within quoted strings are preserved and can be significant. For example, “This string” and “This string” are treated as different values.

Delimiters

Delimiters are used to separate data values, keywords, arguments, and specifications.

- A blank is usually used to separate one specification from another, except when another delimiter serves the same purpose or when a comma is required.
- Commas are required to separate arguments to functions. Otherwise, blanks are generally valid substitutes for commas.
- Arithmetic operators (+, –, *, and /) serve as delimiters in expressions.
- Blanks can be used before and after operators or equals signs to improve readability, but commas cannot.
- Special delimiters include parentheses, apostrophes, quotation marks, the slash, and the equals sign. Blanks before and after special delimiters are optional.
- The slash is used primarily to separate subcommands and lists of variables. Although slashes are sometimes optional, it is best to enter them as shown in the syntax diagrams.
- The equals sign is used between a keyword and its specifications, as in `STATISTICS=MEAN`, and to show equivalence, as in `COMPUTE target variable=expression`. Equals signs following keywords are frequently optional but are sometimes required. In general, you should follow the format of the syntax charts and examples and always include equals signs wherever they are shown.

Command Order

Command order is more often than not a matter of common sense and follows this logical sequence: variable definition, data transformation, and statistical analysis. For example, you cannot label, transform, analyze, or use a variable in any way before it exists. The following general rules apply:

- Commands that define variables for a session (DATA LIST, GET, GET DATA, MATRIX DATA, etc.) must precede commands that assign labels or missing values to those variables; they must also precede transformation and procedure commands that use those variables.
- Transformation commands (IF, COUNT, COMPUTE, etc.) that are used to create and modify variables must precede commands that assign labels or missing values to those variables, and they must also precede the procedures that use those variables.
- Generally, the logical outcome of command processing determines command order. For example, a procedure that creates new variables in the active dataset must precede a procedure that uses those new variables.

In addition to observing the rules above, it is often important to distinguish between commands that cause the data to be read and those that do not, and between those that are stored pending execution with the next command that reads the data and those that take effect immediately without requiring that the data be read.

- Commands that cause the data to be read, as well as execute pending transformations, include all statistical procedures (e.g., CROSSTABS, FREQUENCIES, REGRESSION); some commands that save/write the contents of the active dataset (e.g., DATASET COPY, SAVE TRANSLATE, SAVE); AGGREGATE; AUTORECODE; EXECUTE; RANK; and SORT CASES.
- Commands that are stored, pending execution with the next command that reads the data, include transformation commands that modify or create new data values (e.g., COMPUTE, RECODE), commands that define conditional actions (e.g., DO IF, IF, SELECT IF), PRINT, WRITE, and XSAVE. For a comprehensive list of these commands, see Commands That Are Stored, Pending Execution on p. 39.
- Commands that take effect immediately without reading the data or executing pending commands include transformations that alter dictionary information without affecting the data values (e.g., MISSING VALUES, VALUE LABELS) and commands that don't require an active dataset (e.g., DISPLAY, HOST, INSERT, OMS, SET). In addition to taking effect immediately, these commands are also processed unconditionally. For example, when included within a DO IF structure, these commands run regardless of whether or not the condition is ever met. For a comprehensive list of these commands, see Commands That Take Effect Immediately on p. 37.

Example

```
DO IF expense = 0.
- COMPUTE profit=-99.
- MISSING VALUES expense (0).
ELSE.
- COMPUTE profit=income-expense.
END IF.
LIST VARIABLES=expense profit.
```

- COMPUTE precedes MISSING VALUES and is processed first; however, execution is delayed until the data are read.
- MISSING VALUES takes effect as soon as it is encountered, *even if the condition is never met* (i.e., even if there are no cases where expense=0).
- LIST causes the data to be read; thus, both COMPUTE and LIST are executed during the same data pass.
- Because MISSING VALUES is already in effect by this time, the first condition in the DO IF structure will never be met, because an *expense* value of 0 is considered missing and so the condition evaluates to missing when *expense* is 0.

Commands That Take Effect Immediately

These commands take effect immediately. They do not read the active dataset and do not execute pending transformations.

Files

SPSS reads, creates, and writes different types of files. This section provides an overview of these types and discusses concepts and rules that apply to all files.

Command File

A command file is a text file that contains syntax commands. You can type commands in a syntax window in an interactive session, use the Paste button in dialog boxes to paste generated commands into a syntax window, and/or use any text editor to create a command file. You can also edit a journal file to produce a command file. For more information, see Journal File on p. 40. The following is an example of a simple command file that contains both commands and inline data:

```
DATA LIST /ID 1-3 Gender 4 (A) Age 5-6 Opinion1 TO Opinion5 7-11.
BEGIN DATA
001F2621221
002M5611122
003F3422212
329M2121212
END DATA.
LIST.
```

- Case does not matter for commands but is significant for inline data. If you specified *f* for female and *m* for male in column 4 of the data line, the value of *Gender* would be *f* or *m* instead of *F* or *M* as it is now.
- Commands can be in upper or lower case. Uppercase characters are used for all commands throughout this manual only to distinguish them from other text.

Journal File

SPSS keeps a journal file to record all commands either run from a syntax window or generated from a dialog box during a session. You can retrieve this file with any text editor and review it to learn how the session went. You can also edit the file to build a new command file and use it in another run. An edited and tested journal file can be saved and used later for repeated tasks. The journal file also records any error or warning messages generated by commands. You can rerun these commands after making corrections and removing the messages.

The journal file is controlled by the File Locations tab of the Options dialog box, available from the Edit menu. You can turn journaling off and on, append or overwrite the journal file, and select the journal filename and location. By default, commands from subsequent sessions are appended to the journal, and the default journal filename is *spss.jnl*.

The following example is a journal file for a short session with a warning message.

Figure 2-2
Records from a journal file

```
DATA LIST /ID 1-3 Gender 4 (A) Age 5-6 Opinion1 TO Opinion5 7-11.
BEGIN DATA
001F2621221
002M5611122
003F3422212
004F45112L2
>Warning # 1102
>An invalid numeric field has been found.  The result has been set to the
>system-missing value.
END DATA.
LIST.
```

- The warning message, marked by the > symbol, tells you that an invalid numeric field has been found. Checking the last data line, you will notice that column 10 is *L*, which is probably a typographic error. You can correct the typo (for example, by changing the *L* to 1), delete the warning message, and submit the file again.

Data Files

A wide variety of data file formats can be read and written, including raw data files created by a data entry device or a text editor, formatted data files produced by a data management program, data files generated by other software packages, and SPSS-format data files.

Raw Data Files

Raw data files contain only data, either generated by a programming language or entered with a data entry device or a text editor. Raw data arranged in almost any format can be read, including raw matrix materials and nonprintable codes. User-entered data can be embedded within a command file as inline data (BEGIN DATA-END DATA) or saved as an external file. Nonprintable machine codes are usually stored in an external file.

Commands that read raw data files include:

- GET DATA
- DATA LIST
- MATRIX DATA

Complex and hierarchical raw data files can be read using commands such as:

- INPUT PROGRAM
- FILE TYPE
- REREAD
- REPEATING DATA

Data Files Created by Other Applications

You can read files from a variety of other software applications, including:

- Excel spreadsheets (GET DATA command).
- Database tables (GET DATA command).
- SPSS Dimensions data sources, including Quanvert, Quancept, and mrInterview (GET DATA command).
- Delimited (including tab-delimited and CSV) and fixed-format text data files (DATA LIST, GET DATA).
- dBase and Lotus files (GET TRANSLATE command).
- SAS datasets (GET SAS command).
- Stata data files (GET STATA command).

SPSS-Format Data Files

An SPSS-format data file is a file specifically formatted for use by SPSS, containing both data and the metadata (dictionary) that define the data.

- To save the active dataset in SPSS format, use SAVE or XSAVE. On most operating systems, the default extension of a saved SPSS-format data file is *.sav*. An SPSS-format data file can also be a matrix file created with the `MATRIX=OUT` subcommand on procedures that write matrices.
- To open an SPSS-format data file, use GET.

SPSS Data File Structure

The basic structure of an SPSS data file is similar to a database table:

- Rows (records) are cases. Each row represents a case or an observation. For example, each individual respondent to a questionnaire is a case.
- Columns (fields) are variables. Each column represents a variable or characteristic that is being measured. For example, each item on a questionnaire is a variable.

An SPSS data file also contains metadata that describes and defines the data contained in the file. This descriptive information is called the **dictionary**. The information contained in the dictionary includes:

- Variable names and descriptive variable labels (VARIABLE LABELS command).
- Descriptive values labels (VALUE LABELS command).
- Missing values definitions (MISSING VALUES command).
- Print and write formats (FORMATS command).

Use `DISPLAY DICTIONARY` to display the dictionary for the active dataset. For more information, see DISPLAY on p. 598.You can also use SYSFILE INFO to display dictionary information for any SPSS-format data file.

Long Variable Names

In some instances, data files with variable names longer than eight bytes require special consideration:

- If you save a data file in portable format (see EXPORT on p. 640), variable names that exceed eight bytes are converted to unique eight-character names. For example, *mylongrootname1*, *mylongrootname2*, and *mylongrootname3* would be converted to *mylongro*, *mylong_2*, and *mylong_3*, respectively.
- When using data files with variable names longer than eight bytes in version 10.x or 11.x, unique, eight-byte versions of variable names are used; however, the original variable names are preserved for use in release 12.0 or later. In releases prior to 10.0, the original long variable names are lost if you save the data file.
- Matrix data files (commonly created with the `MATRIX OUT` subcommand, available in some procedures) in which the *VARNAME_* variable is longer than an eight-byte string cannot be read by releases prior to 12.0.

Variables

The columns in an SPSS data file are **variables**. Variables are similar to fields in a database table.

- Variable names can be defined with numerous commands, including DATA LIST, GET DATA, NUMERIC, STRING, VECTOR, COMPUTE, and RECODE. They can be changed with the RENAME VARIABLES command.
- Optional variable attributes can include descriptive variable labels (VARIABLE LABELS command), value labels (VALUE LABELS command), and missing value definitions (MISSING VALUES command).

The following sections provide information on variable naming rules, syntax for referring to inclusive lists of variables (keywords `ALL` and `TO`), scratch (temporary) variables, and system variables.

Variable Names

Variable names are stored in the dictionary of an SPSS-format data file or active dataset. Observe the following rules when establishing variable names or referring to variables by their names on commands:

- Each variable name must be unique; duplication is not allowed.
- Variable names can be up to 64 bytes long, and the first character must be a letter or one of the characters @, #, or $. Subsequent characters can be any combination of letters, numbers, nonpunctuation characters, and a period (.). In code page mode, sixty-four bytes typically means 64 characters in single-byte languages (for example, English, French, German, Spanish, Italian, Hebrew, Russian, Greek, Arabic, and Thai) and 32 characters in double-byte languages (for example, Japanese, Chinese, and Korean). Many string characters that only take one byte in code page mode take two or more bytes in Unicode mode. For example, é is one byte in code page format but is two bytes in Unicode format; so *résumé* is six bytes in

a code page file and eight bytes in Unicode mode. For information on Unicode mode, see SET command, UNICODE subcommand.

Note: Letters include any nonpunctuation characters used in writing ordinary words in the languages supported in the platform's character set.

- Variable names cannot contain spaces.
- A # character in the first position of a variable name defines a scratch variable. You can only create scratch variables with command syntax. You cannot specify a # as the first character of a variable in dialog boxes that create new variables. For more information, see Scratch Variables on p. 46.
- A $ sign in the first position indicates that the variable is a system variable. For more information, see System Variables on p. 48. The $ sign is not allowed as the initial character of a user-defined variable.
- The period, the underscore, and the characters $, #, and @ can be used within variable names. For example, *A._$@#1* is a valid variable name.
- Variable names ending with a period should be avoided, since the period may be interpreted as a command terminator. You can only create variables that end with a period in command syntax. You cannot create variables that end with a period in dialog boxes that create new variables.
- Variable names ending in underscores should be avoided, since such names may conflict with names of variables automatically created by commands and procedures.
- Reserved keywords cannot be used as variable names. Reserved keywords are ALL, AND, BY, EQ, GE, GT, LE, LT, NE, NOT, OR, TO, and WITH.
- Variable names can be defined with any mixture of uppercase and lowercase characters, and case is preserved for display purposes.
- When long variable names need to wrap onto multiple lines in output, lines are broken at underscores, periods, and points where content changes from lower case to upper case.

Mixed Case Variable Names

Variable names can be defined with any mixture of upper- and lowercase characters, and case is preserved for display purposes.

- Variable names are stored and displayed exactly as specified on commands that read data or create new variables. For example, `compute NewVar = 1` creates a new variable that will be displayed as *NewVar* in the Data Editor and in output from any procedures that display variable names.
- Commands that refer to existing variable names are not case sensitive. For example, `FREQUENCIES VARIABLES = newvar`, `FREQUENCIES VARIABLES = NEWVAR`, and `FREQUENCIES VARIABLES = NewVar` are all functionally equivalent.
- In languages such as Japanese, where some characters exist in both narrow and wide forms, these characters are considered different and are displayed using the form in which they were entered.
- When long variable names need to wrap onto multiple lines in output, attempts are made to break lines at underscores, periods, and changes from lower to upper case.

You can use the RENAME VARIABLES command to change the case of any characters in a variable name.

Example

```
RENAME VARIABLES (newvariable = NewVariable).
```

- For the existing variable name specification, case is ignored. Any combination of upper and lower case will work.
- For the new variable name, case will be preserved as entered for display purposes.

For more information, see the RENAME VARIABLES command.

Long Variable Names

In some instances, data files with variable names longer than eight bytes require special consideration:

- If you save a data file in portable format (see EXPORT on p. 640), variable names that exceed eight bytes are converted to unique eight-character names. For example, *mylongrootname1*, *mylongrootname2*, and *mylongrootname3* would be converted to *mylongro*, *mylong_2*, and *mylong_3*, respectively.
- When using data files with variable names longer than eight bytes in version 10.x or 11.x, unique, eight-byte versions of variable names are used; however, the original variable names are preserved for use in release 12.0 or later. In releases prior to 10.0, the original long variable names are lost if you save the data file.
- Matrix data files (commonly created with the MATRIX OUT subcommand, available in some procedures) in which the *VARNAME_* variable is longer than an eight-byte string cannot be read by releases prior to 12.0.

Keyword TO

You can establish names for a set of variables or refer to any number of consecutive variables by specifying the beginning and the ending variables joined by the keyword TO.

To establish names for a set of variables with the keyword TO, use a character prefix with a numeric suffix.

- The prefix can be any valid name. Both the beginning and ending variables must use the same prefix.
- The numeric suffix can be any integer, but the first number must be smaller than the second. For example, ITEM1 TO ITEM5 establishes five variables named *ITEM1*, *ITEM2*, *ITEM3*, *ITEM4*, and *ITEM5*.
- Leading zeros used in numeric suffixes are included in the variable name. For example, V001 TO V100 establishes 100 variables—*V001*, *V002*, *V003*, ..., *V100*. V1 TO V100 establishes 100 variables—*V1*, *V2*, *V3*, ..., *V100*.

The keyword TO can also be used on procedures and other commands to refer to consecutive variables on the active dataset. For example, AVAR TO VARB refers to the variables *AVAR* and all subsequent variables up to and including *VARB*.

- In most cases, the TO specification uses the variable order on the active dataset. Use the DISPLAY command to see the order of variables on the active dataset.
- On some subcommands, the order in which variables are named on a previous subcommand, usually the VARIABLES subcommand, is used to determine which variables are consecutive and therefore are implied by the TO specification. This is noted in the description of individual commands.

Keyword ALL

The keyword ALL can be used in many commands to specify all of the variables in the active dataset. For example,

```
FREQUENCIES /VARIABLES = ALL.
```

or

```
OLAP CUBES income by ALL.
```

In the second example, a separate table will be created for every variable in the data file, including a table of *income* by *income*.

Scratch Variables

You can use **scratch variables** to facilitate operations in transformation blocks and input programs.

- To create a scratch variable, specify a variable name that begins with the # character—for example, *#ID*. Scratch variables can be either numeric or string.
- Scratch variables are initialized to 0 for numeric variables or blank for string variables.
- Scratch variables cannot be used in procedures and cannot be saved in a data file (but they can be written to an external text file with PRINT or WRITE).
- Scratch variables cannot be assigned missing values, variable labels, or value labels.
- Scratch variables can be created between procedures but are always discarded as the next procedure begins.
- Scratch variables are discarded once a TEMPORARY command is specified.
- The keyword TO cannot refer to scratch variables and permanent variables at the same time.
- Scratch variables cannot be specified on a WEIGHT command.
- Scratch variable cannot be specified on the LEAVE command.
- Scratch variables are not reinitialized when a new case is read. Their values are always carried across cases. (So using a scratch variable can be essentially equivalent to using the LEAVE command.)

Because scratch variables are discarded, they are often useful as loop index variables and as other variables that do not need to be retained at the end of a transformation block. For more information, see Indexing Clause on p. 974. Because scratch variables are not reinitialized for each case, they are also useful in loops that span cases in an input program. For more information, see Creating Data on p. 980.

Example

```
DATA LIST LIST (",") /Name (A15).
BEGIN DATA
Nick Lowe
Dave Edmunds
END DATA.
STRING LastName (A15).
COMPUTE #index=INDEX(Name, " ").
COMPUTE LastName=SUBSTR(Name, #index+1).
LIST.
```

Figure 2-3
Listing of case values

```
Name            LastName

Nick Lowe       Lowe
Dave Edmunds    Edmunds
```

- *#index* is a scratch variable that is set to the numeric position of the first occurrence of a blank space in *Name*.
- The scratch variable is then used in the second `COMPUTE` command to determine the starting position of *LastName* within *Name*.
- The default `LIST` command will list the values of all variables for all cases. It does not include *#index* because `LIST` is a procedure that reads the data, and all scratch variables are discarded at that point.

In this example, you could have obtained the same end result without the scratch variable, using:

```
COMPUTE LastName=SUBSTR(Name, INDEX(Name, " ")+1).
```

The use of a scratch variable here simply makes the code easier to read.

Example: Scratch variable initialization

```
DATA LIST FREE /Var1.
BEGIN DATA
2 2 2
END DATA.
COMPUTE Var2=Var1+Var2.
COMPUTE Var3=0.
COMPUTE Var3=Var1+Var3.
COMPUTE #ScratchVar=Var1+#ScratchVar.
COMPUTE Var4=#ScratchVar.
LIST.
```

Figure 2-4
Listing of case values

```
    Var1      Var2      Var3      Var4
```

```
2.00      .       2.00     2.00
2.00      .       2.00     4.00
2.00      .       2.00     6.00
```

- The new variable *Var2* is reinitialized to system-missing for each case, therefore `Var1+Var2` always results in system-missing.
- The new variable *Var3* is reset to 0 for each case (`COMPUTE Var3=0`), therefore `Var1+Var3` is always equivalent to `Var1+0`.
- *#ScratchVar* is initialized to 0 for the first case and is not reinitialized for subsequent cases; so `Var1+#ScratchVar` is equivalent to `Var1+0` for the first case, `Var1+2` for the second case, and `Var1+4` for the third case.
- *Var4* is set to the value of *#ScratchVar* in this example so that the value can be displayed in the case listing.

In this example, the commands:

```
COMPUTE #ScratchVar=Var1+#ScratchVar.
COMPUTE Var4=#ScratchVar.
```

are equivalent to:

```
COMPUTE Var4=Var1+Var4.
LEAVE Var4.
```

System Variables

System variables are special variables created during a working session to keep system-required information, such as the number of cases read by the system, the system-missing value, and the current date. System variables can be used in data transformations.

- The names of system variables begin with a dollar sign ($).
- You cannot modify a system variable or alter its print or write format. Except for these restrictions, you can use system variables anywhere that a normal variable is used in the transformation language.
- System variables are not available for procedures.

$CASENUM	*Current case sequence number.* For each case, *$CASENUM* is the number of cases read up to and including that case. The format is `F8.0`. The value of *$CASENUM* is not necessarily the row number in a Data Editor window (available in windowed environments), and the value changes if the file is sorted or new cases are inserted before the end of the file.
$SYSMIS	*System-missing value.* The system-missing value displays as a period (.) or whatever is used as the decimal point.
$JDATE	*Current date in number of days from October 14, 1582* (day 1 of the Gregorian calendar). The format is `F6.0`.
$DATE	*Current date in international date format with two-digit year.* The format is `A9` in the form dd-mmm-yy.
$DATE11	*Current date in international date format with four-digit year.* The format is `A11` in the form dd-mmm-yyyy.

$TIME	*Current date and time. $TIME* represents the number of seconds from midnight, October 14, 1582, to the date and time when the transformation command is executed. The format is F20. You can display this as a date in a number of different date formats. You can also use it in date and time functions.
$LENGTH	*The current page length.* The format is F11.0. For more information, see SET.
$WIDTH	*The current page width.* The format is F3.0. For more information, see SET.

Variable Types and Formats

There are two basic variable types:

- **String.** Also referred to alphanumeric. String values are stored as codes listed in the SPSS character set. For more information, see IMPORT/EXPORT Character Sets on p. 2017.
- **Numeric.** Numeric values are stored internally as double-precision floating-point numbers.

Variable formats determine how raw data is read into storage and how values are displayed and written. For example, all dates and times are stored internally as numeric values, but you can use date and time format specifications to both read and display date and time values in standard date and time formats. The following sections provide details on how formats are specified and how those formats affect how data are read, displayed, and written.

Input and Output Formats

Values are read according to their **input** format and displayed according to their **output** format. The input and output formats differ in several ways.

- The input format is either specified or implied on the DATA LIST, GET DATA, or other data definition commands. It is in effect only when cases are built in an active dataset.
- Output formats are automatically generated from input formats, with output formats expanded to include punctuation characters, such as decimal indicators, grouping symbols, and dollar signs. For example, an input format of DOLLAR7.2 will generate an output format of DOLLAR10.2 to accommodate the dollar sign, grouping symbol (comma), and decimal indicator (period).
- The formats (specified or default) on NUMERIC, STRING, COMPUTE, or other commands that create new variables are output formats. You must specify adequate widths to accommodate all punctuation characters.
- The output format is in effect during the entire working session (unless explicitly changed) and is saved in the dictionary of an SPSS-format data file.
- Output formats for numeric variables can be changed with FORMATS, PRINT FORMATS, and WRITE FORMATS.
- The width for string variables cannot be changed with command syntax. However, you can use STRING to declare a new variable with the desired format and then use COMPUTE to copy values from the existing string variable into the new variable.
- The format type cannot be changed from string to numeric, or vice versa, with command syntax. However, you can use RECODE to recode values from one variable into another variable of a different type.

String Variable Formats

- The values of string variables can contain numbers, letters, and special characters and can be up to 32,767 characters long.
- System-missing values cannot be generated for string variables, since any character is a legal string value.
- When a transformation command that creates or modifies a string variable yields a missing or undefined result, a null string is assigned. The variable displays as blanks and is not treated as missing.
- String formats are used to read and write string variables. The input values can be alphanumeric characters (A format) or the hexadecimal representation of alphanumeric characters (AHEX format).
- For fixed-format raw data, the width can be explicitly specified on commands such as DATA LIST and GET DATA or implied if column-style specifications are used. For freefield data, the default width is 1; if the input string may be longer, w must be explicitly specified. Input strings shorter than the specified width are right-padded with blanks.
- The output format for a string variable is always A. The width is determined by the input format or the format assigned on the STRING command.Once defined, the width of a string variable can only be changed with the ALTER TYPEcommand.

A Format (Standard Characters)

The A format is used to read standard characters. Characters can include letters, numbers, punctuation marks, blanks, and most other characters on your keyboard. Numbers entered as values for string variables cannot be used in calculations unless you convert them to numeric format with the NUMBER function. For more information, see String/Numeric Conversion Functions on p. 106.

Fixed data:

With fixed-format input data, any punctuation—including leading, trailing, and embedded blanks—within the column specifications is included in the string value. For example, a string value of

```
Mr. Ed
```

(with one embedded blank) is distinguished from a value of

```
Mr.  Ed
```

(with two embedded blanks). It is also distinguished from a string value of

```
MR. ED
```

(all upper case), and all three are treated as separate values. These can be important considerations for any procedures, transformations, or data selection commands involving string variables. Consider the following example:

```
DATA LIST FIXED /ALPHAVAR 1-10 (A).
BEGIN DATA
```

```
Mr. Ed
Mr. Ed
MR. ED
Mr.  Ed
 Mr. Ed
END DATA.
AUTORECODE ALPHAVAR /INTO NUMVAR.
LIST.
```

AUTORECODE recodes the values into consecutive integers. The following figure shows the recoded values.

Figure 2-5
Different string values illustrated

```
ALPHAVAR   NUMVAR

Mr. Ed         4
Mr. Ed         4
MR. ED         2
Mr.  Ed        3
 Mr. Ed        1
```

AHEX Format (Hexadecimal Characters)

The AHEX format is used to read the hexadecimal representation of standard characters. Each set of two hexadecimal characters represents one standard character. For codes used on different operating systems, see *IMPORT/EXPORT Character Sets* on p. 2017.

- The w specification refers to columns of the hexadecimal representation and must be an even number. Leading, trailing, and embedded blanks are not allowed, and only valid hexadecimal characters can be used in input values.
- For some operating systems (e.g., IBM CMS), letters in hexadecimal values must be upper case.
- The default output format for variables read with the AHEX input format is the A format. The default width is half the specified input width. For example, an input format of AHEX14 generates an output format of A7.
- Used as an output format, the AHEX format displays the printable characters in the hexadecimal characters specific to your system. The following commands run on a UNIX system—where A=41 (decimal 65), a=61 (decimal 97), and so on—produce the output shown below:

```
DATA LIST FIXED
   /A,B,C,D,E,F,G,H,I,J,K,L,M,N,O,P,Q,R,S,T,U,V,W,X,Y,Z 1-26 (A).
FORMATS ALL (AHEX2).
BEGIN DATA
ABCDEFGHIJKLMNOPQRSTUVWXYZ
abcdefghijklmnopqrstuvwxyz
END DATA.
LIST.
```

Figure 2-6
Display of hexadecimal representation of the character set with AHEX format

```
A  B  C  D  E  F  G  H  I  J  K  L  M  N  O  P  Q  R  S  T  U  V  W  X  Y  Z

41 42 43 44 45 46 47 48 49 4A 4B 4C 4D 4E 4F 50 51 52 53 54 55 56 57 58 59 5A
61 62 63 64 65 66 67 68 69 6A 6B 6C 6D 6E 6F 70 71 72 73 74 75 76 77 78 79 7A
```

Numeric Variable Formats

- By default, if no format is explicitly specified, commands that read raw data—such as DATA LIST and GET DATA—assume that variables are numeric with an F format type. The default width depends on whether the data are in fixed or freefield format. For a discussion of fixed data and freefield data, see DATA LIST on p. 501.
- Numeric variables created by COMPUTE, COUNT, or other commands that create numeric variables are assigned a format type of F8.2(or the default numeric format defined on SET FORMAT).
- If a data value exceeds its width specification, an attempt is made to display some value nevertheless. First, the decimals are rounded, then punctuation characters are taken out, then scientific notation is tried, and if there is still not enough space, asterisks (***) are producted, indicating that a value is present but cannot be displayed in the assigned width.
- The output format does not affect the value stored in the file. A numeric value is always stored in double precision.
- For default numeric (F) format and scientific notation (E) format, the decimal indicator of the input data from text data sources (read by commands such as DATA LIST and GET DATA) must match the SPSS locale decimal indicator (period or comma). Use SET DECIMAL to set the decimal indicator. Use SHOW DECIMAL to display the current decimal indicator.

F, N, and E Formats

The following table lists the formats most commonly used to read in and write out numeric data. Format names are followed by total width (w) and an optional number of decimal positions (d). For example, a format of F5.2 represents a numeric value with a total width of 5, including two decimal positions and a decimal indicator.

Table 2-1
Common numeric formats

Format type	Description	Sample format	Sample input	Output for fixed input		Output for freefield input	
				Format	Value	Format	Value
Fw.d	Standard numeric	F5.0	1234	F5.0	1234	F5.0	1234
			1.234		1*		1*
		F5.2	1234	F6.2	12.34	F6.2	1234.0
			1.234		1.23		1.23
Nw.d	Restricted numeric	N5.0	00123	F5.0	123	F5.0	123
			123		.†		123
		N5.2	12345	F6.2	123.45	F6.2	12345
			12.34		.†		.†
Ew.d	Scientific notation	E8.0	1234E3	E10.3	1.234E+06	E10.3	1.234E+06‡
			1234		1.234E+03		1.234E+03

* Only the display is truncated. The value is stored in full precision.

† System-missing value.

‡ Scientific notation is accepted in input data with F, COMMA, DOLLAR, DOT, and PCT formats. The same rules apply as specified below.

For fixed data:

- If a value has no coded decimal point but the input format specifies decimal positions, the rightmost positions are interpreted as implied decimal digits. For example, if the input F format specifies two decimal digits, the value 1234 is interpreted as 12.34; however, the value 123.4 is still interpreted as 123.4.
- With the N format, decimal places can only be implied. Only unsigned integers are allowed as input values. Values not padded with leading zeros to the specified width or those containing decimal points are assigned the system-missing value. This format is useful for reading and checking values that should be integers containing leading zeros.
- The E format reads all forms of scientific notation. If the sign is omitted, + is assumed. If the sign (+ or –) is specified before the exponent, the *E* or *D* can be omitted. A single space is permitted after the *E* or *D* and/or after the sign. If both the sign and the letter *E* or *D* are omitted, implied decimal places are assumed. For example, 1.234E3, 1.234+3, 1.234E+3, 1.234D3, 1.234D+3, 1.234E 3, and 1234 are all legitimate values. Only the last value can imply decimal places.
- E format input values can be up to 40 characters wide and include up to 15 decimal positions.
- The default output width (*w*) for the E format is either the specified input width or the number of specified decimal positions plus 7 (*d*+7), whichever is greater. The minimum width is 10 and the minimum decimal places are 3.

For freefield data:

- F format *w* and *d* specifications do not affect how data are read. They only determine the output formats (expanded, if necessary). 1234 is always read as 1234 in freefield data, but a specified F5.2 format will be expanded to F6.2 and the value will be displayed as 1234.0 (the last decimal place is rounded because of lack of space).
- When the N format is used for freefield data, input values with embedded decimal indicators are assigned the system-missing value, but integer input values without leading zeroes are treated as valid. For example, with an input format of N5.0, a value of 123 is treated the same as a value of 00123, but a value of 12.34 is assigned the system-missing value.
- The E format for freefield data follows the same rules as for fixed data except that no blank space is permitted in the value. Thus, 1.234E3 and 1.234+3 are allowed, but the value 1.234 3 will cause mistakes when the data are read.
- The default output E format and the width and decimal place limitations are the same as with fixed data.

N (Restricted Numeric) Output Format

N format input values are assigned an F output format. To display, print, and write N format values with leading zeroes, use the FORMATS command to specify N as the output format. For more information, see FORMATS on p. 694.

COMMA, DOT, DOLLAR, and PCT Formats

The numeric formats listed below read and write data with embedded punctuation characters and symbols, such as commas, dots, and dollar and percent signs. The input data may or may not contain such characters. The data values read in are stored as numbers but displayed using the appropriate formats.

- **DOLLAR.** Numeric values with a leading dollar sign, a comma used as the grouping separator, and a period used as the decimal indicator. For example, $1,234.56.
- **COMMA.** Numeric values with a comma used as the grouping separator and a period used as decimal indicator. For example, 1,234.56.
- **DOT.** Numeric values with a period used as the grouping separator and a comma used as the decimal indicator. For example, 1.234,56.
- **PCT.** Numeric values with a trailing percent sign. For example, 123.45%.

The input data values may or may not contain the punctuation characters allowed by the specified format, but the data values may not contain characters *not* allowed by the format. For example, with a DOLLAR input format, input values of 1234.56, 1,234.56, and $1,234.56 are all valid and stored internally as the same value—but with a COMMA input format, the input value with a leading dollar sign would be assigned the system-missing value.

```
DATA LIST LIST (" ") /dollarVar (DOLLAR9.2) commaVar (COMMA9.2)
  dotVar (DOT9.2) pctVar (PCT9.2).
BEGIN DATA
1234 1234 1234 1234
$1,234.00 1,234.00 1.234,00 1234.00%
END DATA.
LIST.
```

Figure 2-7
Output illustrating DOLLAR, COMMA, DOT, and PCT formats

```
    dollarVar     commaVar       dotVar      pctVar

    $1,234.00     1,234.00     1.234,00    1234.00%
    $1,234.00     1,234.00     1.234,00    1234.00%
```

Other formats that use punctuation characters and symbols are date and time formats and custom currency formats. For more information on date and time formats, see Date and Time Formats on p. 58. Custom currency formats are output formats only, and are defined with the SET command.

Binary and Hexadecimal Formats

Data can be read and written in formats used by a number of programming languages such as PL/I, COBOL, FORTRAN, and Assembler. The data can be binary, hexadecimal, or zoned decimal. Formats described in this section can be used both as input formats and output formats, but with fixed data only. The described formats are not available on all systems. Consult the*Base User's Guide* for your version for details.

The default output format for all formats described in this section is an equivalent F format, allowing the maximum number of columns for values with symbols and punctuation. To change the default, use FORMATS or WRITE FORMATS.

IBw.d (integer binary):

The IB format reads fields that contain fixed-point binary (integer) data. The data might be generated by COBOL using COMPUTATIONAL data items, by FORTRAN using INTEGER*2 or INTEGER*4, or by Assembler using fullword and halfword items. The general format is a signed binary number that is 16 or 32 bits in length.

The general syntax for the IB format is IBw.d, where w is the field width in bytes (omitted for column-style specifications) and d is the number of digits to the right of the decimal point. Since the width is expressed in bytes and the number of decimal positions is expressed in digits, *d* can be greater than *w*. For example, both of the following commands are valid:

```
DATA LIST FIXED /VAR1 (IB4.8).

DATA LIST FIXED /VAR1 1-4 (IB,8).
```

Widths of 2 and 4 represent standard 16-bit and 32-bit integers, respectively. Fields read with the IB format are treated as signed. For example, the one-byte binary value 11111111 would be read as –1.

PIBw.d (positive integer binary):

The PIB format is essentially the same as IB except that negative numbers are not allowed. This restriction allows one additional bit of magnitude. The same one-byte value 11111111 would be read as 255.

PIBHEXw (hexadecimal of PIB):

The PIBHEX format reads hexadecimal numbers as unsigned integers and writes positive integers as hexadecimal numbers. The general syntax for the PIBHEX format is PIBHEXw, where w indicates the total number of hexadecimal characters. The w specification must be an even number with a maximum of 16.

For input data, each hexadecimal number must consist of the exact number of characters. No signs, decimal points, or leading and trailing blanks are allowed. For some operating systems (such as IBM CMS), hexadecimal characters must be upper case. The following example illustrates the kind of data that the PIBHEX format can read:

```
DATA LIST FIXED
 /VAR1 1-4 (PIBHEX) VAR2 6-9 (PIBHEX) VAR3 11-14 (PIBHEX).
BEGIN DATA
0001 0002 0003
0004 0005 0006
0007 0008 0009
000A 000B 000C
000D 000E 000F
00F0 0B2C FFFF
END DATA.
LIST.
```

The values for *VAR1*, *VAR2*, and *VAR3* are listed in the figure below. The PIBHEX format can also be used to write decimal values as hexadecimal numbers, which may be useful for programmers.

Figure 2-8
Output displaying values read in PIBHEX format

```
 VAR1   VAR2   VAR3

    1      2      3
    4      5      6
    7      8      9
   10     11     12
   13     14     15
  240   2860  65535
```

Zw.d (zoned decimal):

The Z format reads data values that contain zoned decimal data. Such numbers may be generated by COBOL systems using DISPLAY data items, by PL/I systems using PICTURE data items, or by Assembler using zoned decimal data items.

In zoned decimal format, one digit is represented by one byte, generally hexadecimal F1 representing 1, F2 representing 2, and so on. The last byte, however, combines the sign for the number with the last digit. In the last byte, hexadecimal A, F, or C assigns +, and B, D, or E assigns –. For example, hexadecimal D1 represents 1 for the last digit and assigns the minus sign (–) to the number.

The general syntax of the Z format is Zw.d, where w is the total number of bytes (which is the same as columns) and d is the number of decimals. For input data, values can appear anywhere within the column specifications. Both leading and trailing blanks are allowed. Decimals can be implied by the input format specification or explicitly coded in the data. Explicitly coded decimals override the input format specifications.

The following example illustrates how the Z format reads zoned decimals in their printed forms on IBM mainframe and PC systems. The printed form for the sign zone (A to I for +1 to +9, and so on) may vary from system to system.

```
DATA LIST FIXED /VAR1 1-5 (Z) VAR2 7-11 (Z,2) VAR3 13-17 (Z)
 VAR4 19-23 (Z,2) VAR5 25-29 (Z) VAR6 31-35 (Z,2).
BEGIN DATA
1234A 1234A 1234B 1234B 1234C 1234C
1234D 1234D 1234E 1234E 1234F 1234F
1234G 1234G 1234H 1234H 1234I 1234I
1234J 1234J 1234K 1234K 1234L 1234L
1234M 1234M 1234N 1234N 1234O 1234O
1234P 1234P 1234Q 1234Q 1234R 1234R
1234{ 1234{ 1234} 1234} 1.23M 1.23M
END DATA.
LIST.
```

The values for *VAR1* to *VAR6* are listed in the following figure.

Figure 2-9
Output displaying values read in Z format

```
VAR1    VAR2   VAR3    VAR4   VAR5    VAR6

 12341  123.41  12342  123.42  12343  123.43
 12344  123.44  12345  123.45  12346  123.46
 12347  123.47  12348  123.48  12349  123.49
-12341 -123.41 -12342 -123.42 -12343 -123.43
-12344 -123.44 -12345 -123.45 -12346 -123.46
-12347 -123.47 -12348 -123.48 -12349 -123.49
 12340  123.40 -12340 -123.40     -1   -1.23
```

The default output format for the Z format is the equivalent F format, as shown in the figure. The default output width is based on the input width specification plus one column for the sign and one column for the implied decimal point (if specified). For example, an input format of Z4.0 generates an output format of F5.0, and an input format of Z4.2 generates an output format of F6.2.

Pw.d (packed decimal):

The P format is used to read fields with packed decimal numbers. Such numbers are generated by COBOL using COMPUTATIONAL–3 data items and by Assembler using packed decimal data items. The general format of a packed decimal field is two four-bit digits in each byte of the field except the last. The last byte contains a single digit in its four leftmost bits and a four-bit sign in its rightmost bits. If the last four bits are 1111 (hexadecimal F), the value is positive; if they are 1101 (hexadecimal D), the value is negative. One byte under the P format can represent numbers from –9 to 9.

The general syntax of the P format is Pw.d, where w is the number of bytes (not digits) and d is the number of digits to the right of the implied decimal point. The number of digits in a field is (2*w–1).

PKw.d (unsigned packed decimal):

The PK format is essentially the same as P except that there is no sign. That is, even the rightmost byte contains two digits, and negative data cannot be represented. One byte under the PK format can represent numbers from 0 to 99. The number of digits in a field is 2*w.

RBw (real binary):

The RB format is used to read data values that contain internal format floating-point numbers. Such numbers are generated by COBOL using COMPUTATIONAL–1 or COMPUTATIONAL–2 data items, by PL/I using FLOATING DECIMAL data items, by FORTRAN using REAL or REAL*8 data items, or by Assembler using floating-point data items.

The general syntax of the RB format is RBw, where w is the total number of bytes. The width specification must be an even number between 2 and 8. Normally, a width specification of 8 is used to read double-precision values, and a width of 4 is used to read single-precision values.

RBHEXw (hexadecimal of RB):

The RBHEX format interprets a series of hexadecimal characters as a number that represents a floating-point number. This representation is system-specific. If the field width is less than twice the width of a floating-point number, the value is right-padded with binary zeros. For some operating systems (for example, IBM CMS), letters in hexadecimal values must be upper case.

The general syntax of the RBHEX format is RBHEXw, where w indicates the total number of columns. The width must be an even number. The values are real (floating-point) numbers. Leading and trailing blanks are not allowed. Any data values shorter than the specified input width must be padded with leading zeros.

Date and Time Formats

Date and time formats are both input and output formats. Like numeric formats, each input format generates a default output format, automatically expanded (if necessary) to accommodate display width. Internally, all date and time format values are stored as a number of seconds: date formats (e.g., `DATE`, `ADATE`, `SDATE`, `DATETIME`) are stored as the number of seconds since October 14, 1582; time formats (`TIME`, `DTIME`) are stored as a number of seconds that represents a time interval (e.g., 10:00:00 is stored internally as 36000, which is 60 seconds x 60 minutes x 10 hours).

- All date and time formats have a minimum input width, and some have a different minimum output. Wherever the input minimum width is less than the output minimum, the width is expanded automatically when displaying or printing values. However, when you specify output formats, you must allow enough space for displaying the date and time in the format you choose.
- Input data shorter than the specified width are correctly evaluated as long as all the necessary elements are present. For example, with the `TIME` format, `1:2`, `01 2`, and `01:02` are all correctly evaluated even though the minimum width is 5. However, if only one element (hours or minutes) is present, you must use a time function to aggregate or convert the data. For more information, see Date and Time Functions on p. 93.
- If a date or time value cannot be completely displayed in the specified width, values are truncated in the output. For example, an input time value of 1:20:59 (1 hour, 20 minutes, 59 seconds) displayed with a width of 5 will generate an output value of 01:20, not 01:21. The truncation of output does not affect the numeric value stored in the working file.

The following table shows all available date and time formats, where *w* indicates the total number of columns and *d* (if present) indicates the number of decimal places for fractional seconds. The example shows the output format with the minimum width and default decimal positions (if applicable). The format allowed in the input data is much less restrictive. For more information, see Input Data Specification on p. 59.

Table 2-2
Date and time formats

Format type	Description	Min w		Max w	Max d	General form	Example
		In	Out				
DATEw	International date	9	9	40		dd-mmm-yy	28-OCT-90
		10	11			dd-mmm-yyyy	28-OCT-1990
ADATEw	American date	8	8	40		mm/dd/yy	10/28/90
		10	10			mm/dd/yyyy	10/28/1990
EDATEw	European date	8	8	40		dd.mm.yy	28.10.90
		10	10			dd.mm.yyyy	28.10.1990
JDATEw	Julian date	5	5	40		yyddd	90301
		7	7			yyyyddd	1990301
SDATEw	Sortable date*	8	8	40		yy/mm/dd	90/10/28
		10	10			yyyy/mm/dd	1990/10/28
QYRw	Quarter and year	4	6	40		q Q yy	4 Q 90
		6	8			q Q yyyy	4 Q 1990

Format type	Description	Min w		Max w	Max d	General form	Example
		In	Out				
MOYRw	Month and year	6	6	40		mmm yy	OCT 90
		8	8			mmm yyyy	OCT 1990
WKYRw	Week and year	6	8	40		ww WK yy	43 WK 90
		8	10			ww WK yyyy	43 WK 1990
WKDAYw	Day of the week	2	2	40		(name of the day)	SU
MONTHw	Month	3	3	40		(name of the month)	JAN
TIMEw	Time	5	5	40		hh:mm	01:02
TIMEw.d		10	10	40	16	hh:mm:ss.s	01:02:34.75
DTIMEw	Days and time	1	1	40		dd hh:mm	20 08:03
DTIMEw.d		13	13	40	16	dd hh:mm:ss.s	20 08:03:00
DATETIMEw	Date and time	17	17	40		dd-mmm-yyyy hh:mm	20-JUN-1990 08:03
DATETIMEw.d		22	22	40	16	dd-mmm-yyyy hh:mm:ss.s	20-JUN-1990 08:03:00

* All date and time formats produce sortable data. `SDATE`, a date format used in a number of Asian countries, can be sorted in its character form and is used as a sortable format by many programmers.

Input Data Specification

The following general rules apply to date and time input formats:

- The century value for two-digit years is defined by the *SET EPOCH* value. By default, the century range begins 69 years prior to the current year and ends 30 years after the current year. Whether all four digits or only two digits are displayed in output depends on the width specification on the format.
- Dashes, periods, commas, slashes, or blanks can be used as delimiters in the input values. For example, with the `DATE` format, the following input forms are all acceptable:

  ```
  28-OCT-90 28/10/1990 28.OCT.90 28 October, 1990
  ```

  The displayed values, however, will be the same: *28-OCT-90* or *28-OCT-1990*, depending on whether the specified width allows 11 characters in output.
- The `JDATE` format does not allow internal delimiters and requires leading zeros for day values of less than 100 and two-digit-year values of less than 10. For example, for January 1, 1990, the following two specifications are acceptable:

  ```
  90001 1990001
  ```

However, neither of the following is acceptable:

```
90 1 90/1
```

- Months can be represented in digits, Roman numerals, or three-character abbreviations, and they can be fully spelled out. For example, all of the following specifications are acceptable for October:

  ```
  10 X OCT October
  ```

- The quarter in QYR format is expressed as 1, 2, 3, or 4. It must be separated from the year by the letter *Q*. Blanks can be used as additional delimiters. For example, for the fourth quarter of 1990, all of the following specifications are acceptable:

  ```
  4Q90 4Q1990 4 Q 90 4 Q 1990
  ```

  On some operating systems, such as IBM CMS, *Q* must be upper case. The displayed output is *4 Q 90* or *4 Q 1990*, depending on whether the width specified allows all four digits of the year.

- The week in the WKYR format is expressed as a number from 1 to 53. Week 1 begins on January 1, week 2 on January 8, and so on. The value may be different from the number of the calendar week. The week and year must be separated by the string WK. Blanks can be used as additional delimiters. For example, for the 43rd week of 1990, all of the following specifications are acceptable:

  ```
  43WK90 43WK1990 43 WK 90 43 WK 1990
  ```

  On some operating systems, such as IBM CMS, WK must be upper case. The displayed output is *43 WK 90* or *43 WK 1990*, depending on whether the specified width allows enough space for all four digits of the year.

- In time specifications, colons can be used as delimiters between hours, minutes, and seconds. Hours and minutes are required, but seconds are optional. A period is required to separate seconds from fractional seconds. Hours can be of unlimited magnitude, but the maximum value for minutes is 59 and for seconds 59.999. . . .

- Data values can contain a sign (+ or –) in TIME and DTIME formats to represent time intervals before or after a point in time.

Example: DATE, ADATE, and JDATE

```
DATA LIST FIXED
 /VAR1 1-17 (DATE) VAR2 21-37 (ADATE) VAR3 41-47 (JDATE).
BEGIN DATA
28-10-90            10/28/90            90301
28.OCT.1990         X 28 1990           1990301
28 October, 2001    Oct.  28, 2001      2001301
END DATA.
LIST.
```

- Internally, all date format variables are stored as the number of seconds from 0 hours, 0 minutes, and 0 seconds of Oct. 14, 1582.

The LIST output from these commands is shown in the following figure.

Figure 2-10
Output illustrating DATE, ADATE, and JDATE formats

```
      VAR1              VAR2            VAR3
```

```
28-OCT-1990       10/28/1990        1990301
28-OCT-1990       10/28/1990        1990301
28-OCT-2001       10/28/2001        2001301
```

Example: QYR, MOYR, and WKYR

```
DATA LIST FIXED /VAR1 1-10 (QYR) VAR2 12-25 (MOYR) VAR3 28-37 (WKYR).
BEGIN DATA
4Q90       10/90           43WK90
4 Q 90     Oct-1990        43 WK 1990
4 Q 2001   October, 2001   43 WK 2001
END DATA.
LIST.
```

- Internally, the value of a QYR variable is stored as midnight of the first day of the first month of the specified quarter, the value of a MOYR variable is stored as midnight of the first day of the specified month, and the value of a WKYR format variable is stored as midnight of the first day of the specified week. Thus, *4Q90* and *10/90* are both equivalent to October 1, 1990, and *43WK90* is equivalent to October 22, 1990.

The LIST output from these commands is shown in the following figure.

Figure 2-11
Output illustrating QYR, MOYR, and WKYR formats

```
    VAR1       VAR2             VAR3

4 Q 1990   OCT 1990       43 WK 1990
4 Q 1990   OCT 1990       43 WK 1990
4 Q 2001   OCT 2001       43 WK 2001
```

Example: TIME

```
DATA LIST FIXED
 /VAR1 1-11 (TIME,2) VAR2 13-21 (TIME) VAR3 23-28 (TIME).
BEGIN DATA
1:2:34.75   1:2:34.75 1:2:34
END DATA.
LIST.
```

- TIME reads and writes time of the day or a time interval.
- Internally, the TIME values are stored as the number of seconds from midnight of the day or of the time interval.

The LIST output from these commands is shown in the following figure.

Figure 2-12
Output illustrating TIME format

```
       VAR1      VAR2   VAR3

 1:02:34.75   1:02:34   1:02
```

Example: WKDAY and MONTH

```
DATA LIST FIXED
 /VAR1 1-9 (WKDAY) VAR2 10-18 (WKDAY)
  VAR3 20-29 (MONTH) VAR4 30-32 (MONTH) VAR5 35-37 (MONTH).
BEGIN DATA
Sunday   Sunday    January   1    Jan
```

```
Monday   Monday    February  2    Feb
Tues     Tues      March     3    Mar
Wed      Wed       April     4    Apr
Th       Th        Oct       10   Oct
Fr       Fr        Nov       11   Nov
Sa       Sa        Dec       12   Dec
END DATA.
FORMATS VAR2 VAR5 (F2).
LIST.
```

- WKDAY reads and writes the day of the week; MONTH reads and writes the month of the year.
- Values for WKDAY are entered as strings but stored as numbers. They can be used in arithmetic operations but not in string functions.
- Values for MONTH can be entered either as strings or as numbers but are stored as numbers. They can be used in arithmetic operations but not in string functions.
- To display the values as numbers, assign an F format to the variable, as was done for *VAR2* and *VAR5* in the above example.

The LIST output from these commands is shown in the following figure.

Figure 2-13
Output illustrating WKDAY and MONTH formats

```
     VAR1 VAR2       VAR3 VAR4 VAR5

SUNDAY       1  JANUARY     JAN   1
MONDAY       2  FEBRUARY    FEB   2
TUESDAY      3  MARCH       MAR   3
WEDNESDAY    4  APRIL       APR   4
THURSDAY     5  OCTOBER     OCT  10
FRIDAY       6  NOVEMBER    NOV  11
SATURDAY     7  DECEMBER    DEC  12
```

Example: DTIME and DATETIME

```
DATA LIST FIXED /VAR1 1-14 (DTIME) VAR2 18-42 (DATETIME).
BEGIN DATA
20 8:3            20-6-90 8:3
20:8:03:46        20/JUN/1990 8:03:46
20 08 03 46.75    20 June, 2001 08 03 46.75
END DATA.
LIST.
```

- DTIME and DATETIME read and write time intervals.
- The decimal point explicitly coded in the input data for fractional seconds.
- The DTIME format allows a – or + sign in the data value to indicate a time interval before or after a point in time.
- Internally, values for a DTIME variable are stored as the number of seconds of the time interval, while those for a DATETIME variable are stored as the number of seconds from 0 hours, 0 minutes, and 0 seconds of Oct. 14, 1582.

The LIST output from these commands is shown in the following figure.

Figure 2-14
Output illustrating DTIME and DATETIME formats

```
          VAR1                      VAR2
```

```
20 08:03:00      20-JUN-1990 08:03:00
20 08:03:46      20-JUN-1990 08:03:46
20 08:03:46      20-JUN-2001 08:03:46
```

FORTRAN-like Input Format Specifications

You can use FORTRAN-like input format specifications to define formats for a set of variables, as in the following example:

```
DATA LIST FILE=HUBDATA RECORDS=3
      /MOHIRED, YRHIRED, DEPT1 TO DEPT4 (T12, 2F2.0, 4(1X,F1.0)).
```

- The specification `T12` in parentheses tabs to the 12th column. The first variable (*MOHIRED*) will be read beginning from column 12.
- The specification `2F2.0` assigns the format `F2.0` to two adjacent variables (*MOHIRED* and *YRHIRED*).
- The next four variables (*DEPT1* to *DEPT4*) are each assigned the format `F1.0`. The 4 in `4(1X,F1.0)` distributes the same format to four consecutive variables. `1X` skips one column before each variable. (The column-skipping specification placed within the parentheses is distributed to each variable.)

Transformation Expressions

Transformation expressions are used in commands such as `COMPUTE`, `IF`, `DO IF`, `LOOP IF`, and `SELECT IF`.

Release History

Release 13.0

- `APPLYMODEL` and `STRAPPLYMODEL` functions introduced.
- `DATEDIFF` and `DATESUM` functions introduced.

Release 14.0

- `REPLACE` function introduced.
- `VALUELABEL` function introduced.

Release 16.0

- `CHAR.INDEX` function introduced.
- `CHAR.LENGTH` function introduced.
- `CHAR.LPAD` function introduced.
- `CHAR.MBLEN` function introduced.
- `CHAR.RINDEX` function introduced.
- `CHAR.RPAD` function introduced.
- `CHAR.SUBSTR` function introduced.
- `NORMALIZE` function introduced.

- NTRIM function introduced.
- STRUNC function introduced.
- CUMHAZARD value introduced in APPLYMODEL and STRAPPLYMODEL functions.

Numeric Expressions

Numeric expressions can be used with the COMPUTE and IF commands and as part of a logical expression for commands such as IF, DO IF, LOOP IF, and SELECT IF. Arithmetic expressions can also appear in the index portion of a LOOP command, on the REPEATING DATA command, and on the PRINT SPACES command.

Arithmetic Operations

The following arithmetic operators are available:

+	*Addition*
−	*Subtraction*
*	*Multiplication*
/	*Division*
**	*Exponentiation*

- No two operators can appear consecutively.
- Arithmetic operators cannot be implied. For example, (VAR1)(VAR2) is not a legal specification; you must specify VAR1*VAR2.
- Arithmetic operators and parentheses serve as delimiters. To improve readability, blanks (not commas) can be inserted before and after an operator.
- To form complex expressions, you can use variables, constants, and functions with arithmetic operators.
- The order of execution is as follows: functions; exponentiation; multiplication, division, and unary –; and addition and subtraction.
- Operators at the same level are executed from left to right.
- To override the order of operation, use parentheses. Execution begins with the innermost set of parentheses and progresses out.

Numeric Constants

- Constants used in numeric expressions or as arguments to functions can be integer or noninteger, depending on the application or function.
- You can specify as many digits in a constant as needed as long as you understand the precision restrictions of your computer.
- Numeric constants can be signed (+ or –) but cannot contain any other special characters, such as the comma or dollar sign.

- Numeric constants can be expressed with scientific notation. Thus, the exponent for a constant in scientific notation is limited to two digits. The range of values allowed for exponents in scientific notation is from –99 to +99.

Complex Numeric Arguments

- Except where explicitly restricted, complex expressions can be formed by nesting functions and arithmetic operators as arguments to functions.
- The order of execution for complex numeric arguments is as follows: functions; exponentiation; multiplication, division, and unary –; and addition and subtraction.
- To control the order of execution in complex numeric arguments, use parentheses.

Arithmetic Operations with Date and Time Variables

Most date and time variables are stored internally as the number of seconds from a particular date or as a time interval and therefore can be used in arithmetic operations. Many operations involving dates and time can be accomplished with the extensive collection of date and time functions.

- A *date* is a floating-point number representing the number of seconds from midnight, October 14, 1582. Dates, which represent a particular point in time, are stored as the number of seconds to that date. For example, October 28, 2007, is stored as 13,412,908,800.
- A date includes the time of day, which is the time interval past midnight. When time of day is not given, it is taken as 00:00 and the date is an even multiple of 86,400 (the number of seconds in a day).
- A *time interval* is a floating-point number representing the number of seconds in a time period, for example, an hour, minute, or day. For example, the value representing 5.5 days is 475,200; the value representing the time interval 14:08:17 is 50,897.
- `QYR`, `MOYR`, and `WKYR` variables are stored as midnight of the first day of the respective quarter, month, and week of the year. Therefore, *1 Q 90*, *1/90*, and *1 WK 90* are all equivalents of January 1, 1990, 0:0:00.
- `WKDAY` variables are stored as 1 to 7 and `MONTH` variables as 1 to 12.

You can perform virtually any arithmetic operation with both date format and time format variables. Of course, not all of these operations are particularly useful. You can calculate the number of days between two dates by subtracting one date from the other—but adding two dates does not produce a very meaningful result.

By default, any new numeric variables that you compute are displayed in `F` format. In the case of calculations involving time and date variables, this means that the default output is expressed as a number of seconds. Use the `FORMATS` (or `PRINT FORMATS`) command to specify an appropriate format for the computed variable.

Example

```
DATA LIST FREE /Date1 Date2 (2ADATE10).
BEGIN DATA
6/20/2006 10/28/2006
END DATA.
COMPUTE DateDiff1=(Date2-Date1)/60/60/24.
```

```
COMPUTE DateDiff2=DATEDIFF(Date2,Date1, "days").
COMPUTE FutureDate1=Date2+(10*60*60*24).
COMPUTE FutureDate2=DATESUM(Date2, 10, "days").
FORMATS FutureDate1 FutureDate2 (ADATE10).
```

- The first two COMPUTE commands both calculate the number of days between two dates. In the first one, Date2-Date1 yields the number of seconds between the two dates, which is then converted to the number of days by dividing by number of seconds in a minute, number of minutes in an hour, and number of hours in a day. In the second one, the DATEDIFF function is used to obtain the equivalent result, but instead of an arithmetic formula to produce a result expressed in days, it simply includes the argument "days".
- The second pair of COMPUTE commands both calculate a date 10 days from *Date2*. In the first one, 10 days needs to be converted to the number of seconds in ten days before it can be added to *Date2*. In the second one, the "days" argument in the DATESUM function handles that conversion.
- The FORMATS command is used to display the results of the second two COMPUTE commands as dates, since the default format is F, which would display the results as the number of seconds since October 14, 1582.

For more information on date and time functions, see Date and Time Functions on p. 93.

Conditional Statements and Case Selection Based on Dates

To specify a date as a value in a conditional statement, use one of the data aggregation functions to express the date value. For example,

```
***this works***.
SELECT IF datevar >= date.mdy(3,1,2006).
***the following do not work***.
SELECT IF datevar >= 3/1/2006. /*this will select dates >= 0.0015.
SELECT IF datevar >= "3/1/2006" /*this will generate an error.
```

For more information, see Aggregation Functions on p. 93.

Domain Errors

Domain errors occur when numeric expressions are mathematically undefined or cannot be represented numerically on the computer for reasons other than missing data. Two common examples are division by 0 and the square root of a negative number. When there is a domain error, a warning is issued, and the system-missing value is assigned to the expression. For example, the command COMPUTE TESTVAR = TRUNC(SQRT(X/Y) * .5) returns system-missing if *X/Y* is negative or if *Y* is 0.

The following are domain errors in numeric expressions:

**	*A negative number to a noninteger power.*
/	*A divisor of 0.*
MOD	*A divisor of 0.*
SQRT	*A negative argument.*

EXP	*An argument that produces a result too large to be represented on the computer.*
LG10	*A negative or 0 argument.*
LN	*A negative or 0 argument.*
ARSIN	*An argument whose absolute value exceeds 1.*
NORMAL	*A negative or 0 argument.*
PROBIT	*A negative or 0 argument, or an argument 1 or greater.*

Numeric Functions

Numeric functions can be used in any numeric expression on `IF`, `SELECT IF`, `DO IF`, `ELSE IF`, `LOOP IF`, `END LOOP IF`, and `COMPUTE` commands. Numeric functions always return numbers (or the system-missing value whenever the result is indeterminate). The expression to be transformed by a function is called the *argument*. Most functions have a variable or a list of variables as arguments.

- In numeric functions with two or more arguments, each argument must be separated by a comma. Blanks alone cannot be used to separate variable names, expressions, or constants in transformation expressions.
- Arguments should be enclosed in parentheses, as in `TRUNC(INCOME)`, where the `TRUNC` function returns the integer portion of the variable *INCOME*.
- Multiple arguments should be separated by commas, as in `MEAN(Q1,Q2,Q3)`, where the `MEAN` function returns the mean of variables *Q1*, *Q2*, and *Q3*.

Example

```
COMPUTE Square_Root = SQRT(var4).
COMPUTE Remainder = MOD(var4, 3).
COMPUTE Average = MEAN.3(var1, var2, var3, var4).
COMPUTE Trunc_Mean = TRUNC(MEAN(var1 TO var4)).
```

- `SQRT(var4)` returns the square root of the value of *var4* for each case.
- `MOD(var4, 3)` returns the remainder (modulus) from dividing the value of *var4* by 3.
- `MEAN.3(var1, var2, var3, var4)` returns the mean of the four specified variables, provided that at least three of them have nonmissing values. The divisor for the calculation of the mean is the number of nonmissing values.
- `TRUNC(MEAN(var1 TO var4))` computes the mean of the values for the inclusive range of variables and then truncates the result. Since no minimum number of nonmissing values is specified for the function, a mean will be calculated (and truncated) as long as at least one of the variables has a nonmissing value for that case.

Arithmetic Functions

- All arithmetic functions except `MOD` have single arguments; `MOD` has two. The arguments to `MOD` must be separated by a comma.
- Arguments can be numeric expressions, as in `RND(A**2/B)`.

ABS. ABS(numexpr). Numeric. Returns the absolute value of numexpr, which must be numeric.

RND. RND(numexpr). Numeric. Returns the integer that results from rounding the absolute value of numexpr, which must be numeric, and then reaffixing the sign. Numbers ending in .5 exactly are rounded away from 0. For example, RND(-4.5) rounds to -5.

TRUNC. TRUNC(numexpr). Numeric. Returns the value of numexpr truncated to an integer (toward 0).

MOD. MOD(numexpr,modulus). Numeric. Returns the remainder when numexpr is divided by modulus. Both arguments must be numeric, and modulus must not be 0.

SQRT. SQRT(numexpr). Numeric. Returns the positive square root of numexpr, which must be numeric and not negative.

EXP. EXP(numexpr). Numeric. Returns e raised to the power numexpr, where e is the base of the natural logarithms and numexpr is numeric. Large values of numexpr may produce results that exceed the capacity of the machine.

LG10. LG10(numexpr). Numeric. Returns the base-10 logarithm of numexpr, which must be numeric and greater than 0.

LN. LN(numexpr). Numeric. Returns the base-e logarithm of numexpr, which must be numeric and greater than 0.

LNGAMMA. LNGAMMA(numexpr). Numeric. Returns the logarithm of the complete Gamma function of numexpr, which must be numeric and greater than 0.

ARSIN. ARSIN(numexpr). Numeric. Returns the inverse sine (arcsine), in radians, of numexpr, which must evaluate to a numeric value between -1 and +1.

ARTAN. ARTAN(numexpr). Numeric. Returns the inverse tangent (arctangent), in radians, of numexpr, which must be numeric.

SIN. SIN(radians). Numeric. Returns the sine of radians, which must be a numeric value, measured in radians.

COS. COS(radians). Numeric. Returns the cosine of radians, which must be a numeric value, measured in radians.

Statistical Functions

- Each argument to a statistical function (expression, variable name, or constant) must be separated by a comma.
- The *.n* suffix can be used with all statistical functions to specify the number of valid arguments. For example, `MEAN.2(A,B,C,D)` returns the mean of the valid values for variables *A*, *B*, *C*, and *D* only if at least two of the variables have valid values. The default for *n* is 2 for `SD`, `VARIANCE`, and `CFVAR` and 1 for other statistical functions. If the number specified exceeds the number of arguments in the function, the result is system-missing.
- The keyword `TO` can be used to refer to a set of variables in the argument list.

SUM. SUM(numexpr,numexpr[,..]). Numeric. Returns the sum of its arguments that have valid, nonmissing values. This function requires two or more arguments, which must be numeric. You can specify a minimum number of valid arguments for this function to be evaluated.

MEAN. MEAN(numexpr,numexpr[,..]). Numeric. Returns the arithmetic mean of its arguments that have valid, nonmissing values. This function requires two or more arguments, which must be numeric. You can specify a minimum number of valid arguments for this function to be evaluated.

SD. SD(numexpr,numexpr[,..]). Numeric. Returns the standard deviation of its arguments that have valid, nonmissing values. This function requires two or more arguments, which must be numeric. You can specify a minimum number of valid arguments for this function to be evaluated.

VARIANCE. VARIANCE(numexpr,numexpr[,..]). Numeric. Returns the variance of its arguments that have valid values. This function requires two or more arguments, which must be numeric. You can specify a minimum number of valid arguments for this function to be evaluated.

CFVAR. CFVAR(numexpr,numexpr[,...]). Numeric. Returns the coefficient of variation (the standard deviation divided by the mean) of its arguments that have valid values. This function requires two or more arguments, which must be numeric. You can specify a minimum number of valid arguments for this function to be evaluated.

MIN. MIN(value,value[,..]). Numeric or string. Returns the minimum value of its arguments that have valid, nonmissing values. This function requires two or more arguments. For numeric values, you can specify a minimum number of valid arguments for this function to be evaluated.

MAX. MAX(value,value[,..]). Numeric or string. Returns the maximum value of its arguments that have valid values. This function requires two or more arguments. For numeric values, you can specify a minimum number of valid arguments for this function to be evaluated.

Example

```
COMPUTE maxsum=MAX.2(SUM(var1 TO var3), SUM(var4 TO var6)).
```

- `MAX.2` will return the maximum of the two sums provided that both sums are nonmissing.
- The `.2` refers to the number of nonmissing arguments for the `MAX` function, which has only two arguments because each `SUM` function is considered a single argument.
- The new variable *maxsum* will be nonmissing if at least one variable specified for each `SUM` function is nonmissing.

Random Variable and Distribution Functions

Random variable and distribution function keywords are all of the form `prefix.suffix`, where the prefix specifies the function to be applied to the distribution and the suffix specifies the distribution.

- Random variable and distribution functions take both constants and variables for arguments.
- A function argument, if required, must come first and is denoted by *x* (quantile, which must fall in the range of values for the distribution) for cumulative distribution and probability density functions and *p* (probability) for inverse distribution functions.
- All random variable and distribution functions must specify distribution parameters as noted in their definitions.

- All arguments are real numbers.
- Restrictions to distribution parameters apply to all functions for that distribution. Restrictions for the function parameter *x* apply to that particular distribution function. The program issues a warning and returns system-missing when it encounters an out-of-range value for an argument.

The following are possible prefixes:

CDF *Cumulative distribution function.* A cumulative distribution function `CDF.d_spec(x,a,...)` returns a probability *p* that a variate with the specified distribution (`d_spec`) falls below *x* for continuous functions and at or below *x* for discrete functions.

IDF *Inverse distribution function.* Inverse distribution functions are not available for discrete distributions. An inverse distribution function `IDF.d_spec(p,a,...)` returns a value *x* such that `CDF.d_spec(x,a,...)`=*p* with the specified distribution (`d_spec`).

PDF *Probability density function.* A probability density function `PDF.d_spec(x,a,...)` returns the density of the specified distribution (`d_spec`) at *x* for continuous functions and the probability that a random variable with the specified distribution equals *x* for discrete functions.

RV *Random number generation function.* A random number generation function `RV.d_spec(a,...)` generates an independent observation with the specified distribution (`d_spec`).

NCDF *Noncentral cumulative distribution function.* A noncentral distribution function `NCDF.d_spec(x,a,b,...)` returns a probability *p* that a variate with the specified noncentral distribution falls below *x*. It is available only for beta, chi-square, *F*, and Student's *t*.

NPDF *Noncentral probability density function.* A noncentral probability density function `NCDF.d_spec(x,a,...)` returns the density of the specified distribution (`d_spec`) at *x*. It is available only for beta, chi-square, *F*, and Student's *t*.

SIG *Tail probability function.* A tail probability function `SIG.d_spec(x,a,...)` returns a probability *p* that a variate with the specified distribution (`d_spec`) is larger than *x*. The tail probability function is equal to 1 minus the cumulative distribution function.

The following are suffixes for continuous distributions:

BETA

Beta distribution. The beta distribution takes values in the range $0<x<1$ and has two shape parameters, α and β. Both α and β must be positive, and they have the property that the mean of the distribution is α/(α+β).

Common uses. The beta distribution is used in Bayesian analyses as a conjugate to the binomial distribution.

Functions. The `CDF`, `IDF`, `PDF`, `NCDF`, `NPDF`, and `RV` functions are available.

The beta distribution has PDF, CDF, and IDF

$$f(x;\alpha,\beta) = \frac{1}{\mathrm{B}(\alpha,\beta)} x^{\alpha-1}(1-x)^{\beta-1}$$

$$F(x;\alpha,\beta) = \mathrm{IB}(x;\alpha,\beta)$$

$$F^{-1}(p;\alpha,\beta) = \mathrm{IB}^{-1}(p;\alpha,\beta)$$

where $\mathrm{B}(a,b) = \int_0^1 x^{a-1}(1-x)^{b-1}dx$ is the beta function and
$\mathrm{IB}(x;a,b) = \int_0^x \frac{1}{\mathrm{B}(a,b)} t^{a-1}(1-t)^{b-1}dt$ is the incomplete beta function.

Relationship to other distributions.

- When $\alpha=\beta=1$, the beta(α,β) distribution is equivalent to the uniform(0,1) distribution.
- The beta(α,β) distribution is the distribution of $X/(X+Y)$ where X and Y are variables that have chi-square distributions with degrees of freedom parameters 2α and 2β, respectively.

Noncentral beta distribution. The noncentral beta distribution is a generalization of the beta distribution that takes values in the range $0<x<1$ and has an extra noncentrality parameter, λ, which must be greater than or equal to 0.

Functions.

The noncentral beta distribution has PDF, CDF, and IDF

$$f(x;\alpha,\beta,\lambda)=\sum_{j=0}^{\infty}\frac{1}{j!}\left(\frac{\lambda}{2}\right)^{j}e^{-\lambda/2}\frac{x^{\alpha+j-1}(1-x)^{\beta-1}}{\mathrm{B}(\alpha+j;\beta)}$$

$$F(x;\alpha,\beta,\lambda)=\sum_{j=0}^{\infty}\frac{1}{j!}\left(\frac{\lambda}{2}\right)^{j}e^{-\lambda/2}\mathrm{IB}(x;\alpha=j,\beta)$$

where $\mathrm{B}(a,b)=\int_0^1 x^{a-1}(1-x)^{b-1}dx$ is the beta function and $\mathrm{IB}(x;a,b)=\int_0^x \frac{1}{\mathrm{B}(a,b)}t^{a-1}(1-t)^{b-1}dt$ is the incomplete beta function.

Relationship to other distributions.

- When λ equals 0, this distribution reduces to the beta distribution.
- The noncentral beta(α,β,λ) distribution is the distribution of $X/(X+Y)$ where X is a variable that has a noncentral chi-square(2α,λ) distribution, and Y is a variable that has a central chi-square(2β) distribution.

BVNOR

Bivariate normal distribution. The bivariate normal distribution takes real values and has one correlation parameter, ρ, which must be between –1 and 1, inclusive.

Functions. The `CDF` and `PDF` functions are available and require two quantiles, *x1* and *x2*.

The bivariate normal distribution has PDF

$$f(x_1,x_2;\rho)=\frac{1}{2\pi\left(1-\rho^2\right)^{1/2}}\exp\left(\frac{-1}{2\left(1-\rho^2\right)}\left(x_1^2-2\rho x_1x_2+x_2^2\right)\right)$$

The CDF does not have a closed form and is computed by approximation.

Relationship to other distributions.

- Two variables with correlation ρ and marginal normal distributions with a mean of 0 and a standard deviation of 1 have a bivariate normal(ρ) distribution.

CAUCHY

Cauchy distribution. The Cauchy distribution takes real values and has a location parameter, θ, and a scale parameter, ς; ς must be positive. The Cauchy distribution is symmetric about the location parameter, but has such slowly decaying tails that the distribution does not have a computable mean.

Functions. The `CDF`, `IDF`, `PDF`, and `RV` functions are available.

The Cauchy distribution has PDF, CDF, and IDF

$$f(x;\theta,\varsigma) = \frac{1}{\pi\varsigma}\left(1 + \left(\frac{x-\theta}{\varsigma}\right)^2\right)^{-1}$$

$$F(x;\theta,\varsigma) = \frac{1}{2} + \frac{1}{\pi}\tan^{-1}\left(\frac{x-\theta}{\varsigma}\right)$$

$$F^{-1}(p;\theta,\varsigma) = \theta + \varsigma\tan\left(\pi(p-1/2)\right)$$

Relationship to other distributions.

- A "standardized" Cauchy variate, $(x-\theta)/\varsigma$, has a *t* distribution with 1 degree of freedom.

CHISQ

Chi-square distribution. The chi-square(ν) distribution takes values in the range x>=0 and has one degrees of freedom parameter, ν; it must be positive and has the property that the mean of the distribution is ν.

Functions. The `CDF`, `IDF`, `PDF`, `RV`, `NCDF`, `NPDF`, and `SIG` functions are available.

The chi-square distribution has PDF, CDF, and IDF

$$f(x;\nu) = \frac{1}{2^{\nu/2}\Gamma(\nu/2)}x^{(\nu/2)-1}e^{-x/2}$$

$$F(x;\nu) = \mathrm{IG}\left(\frac{x}{2};\frac{\nu}{2}\right)$$

$$F^{-1}(p;\nu) = 2IG^{-1}\left(p;\frac{\nu}{2}\right)$$

where $\Gamma(a) = \int_0^\infty x^{a-1}e^{-x}dx$ is the gamma function and
$\mathrm{IG}(x;a) = \int_0^x \frac{1}{\Gamma(a)}t^{a-1}e^{-t}dt$ is the incomplete gamma function.

Relationship to other distributions.

- The chi-square(*ν*) distribution is the distribution of the sum of squares of ν independent normal(0,1) random variates.
- The chi-square(*ν*) distribution is equivalent to the gamma(*ν*/2, 1/2) distribution.

Noncentral chi-square distribution. The noncentral chi-square distribution is a generalization of the chi-square distribution that takes values in the range x>=0 and has an extra noncentrality parameter, λ, which must be greater than or equal to 0.

Functions.

The noncentral chi-square distribution has PDF and CDF

$$f(x;\nu,\lambda)=\sum_{j=0}^{\infty}\frac{1}{j!}\left(\frac{\lambda}{2}\right)^{j}e^{-\lambda/2}\frac{x^{\nu/2+j-1}e^{-x/2}}{2^{\nu/2+j}\Gamma(\nu/2+j)}$$

$$F(x;\nu,\lambda)=\sum_{j=0}^{\infty}\frac{1}{j!}\left(\frac{\lambda}{2}\right)^{j}e^{-\lambda/2}\mathrm{IG}\left(\frac{x}{2};\frac{\nu}{2}+j\right)$$

where $\Gamma(a)=\int_0^{\infty}x^{a-1}e^{-x}dx$ is the gamma function and
$\mathrm{IG}(x;a)=\int_0^{x}\frac{1}{\Gamma(a)}t^{a-1}e^{-t}dt$ is the incomplete gamma function.

Relationship to other distributions.

- When λ equals 0, this distribution reduces to the chi-square distribution.
- The noncentral chi-square(ν,λ) distribution is the distribution of the sum of squares of ν independent normal(μ_i,1) random variates. Then $\lambda=\Sigma\mu_i^2$.

EXP

Exponential distribution. The exponential distribution takes values in the range x>=0 and has one scale parameter, β, which must be greater than 0 and has the property that the mean of the distribution is 1/β.

Common uses. In life testing, the scale parameter a represents the rate of decay.

Functions. The `CDF`, `IDF`, `PDF`, and `RV` functions are available.

The exponential distribution has PDF, CDF, and IDF

$$f(x;\beta)=\beta e^{-\beta x}$$

$$F(x;\beta)=1-e^{-\beta x}$$

$$F^{-1}(p;\beta)=-\tfrac{1}{\beta}\ln(1-p)$$

Relationship to other distributions.

- The exponential(β) distribution is equivalent to the gamma(1,β) distribution.

F

F *distribution.* The F distribution takes values in the range x>=0 and has two degrees of freedom parameters, ν1 and ν2, which are the "numerator" and "denominator" degrees of freedom, respectively. Both ν1 and ν2 must be positive.

Common uses. The *F* distribution is commonly used to test hypotheses under the Gaussian assumption.

Functions. The `CDF`, `IDF`, `IDF`, `RV`, `NCDF`, `NPDF`, and `SIG` functions are available.

The F distribution has PDF, CDF, and IDF

$$f(x;\nu_1,\nu_2) = \frac{1}{\mathrm{B}(\nu_1/2,\nu_2/2)}\left(\frac{\nu_1}{\nu_2}\right)^{\nu_1/2} x^{(\nu_1/2)-1}\left(1+\frac{\nu_1}{\nu_2}x\right)^{-(\nu_1+\nu_2)/2}$$

$$F(x;\nu_1,\nu_2) = \mathrm{IB}\left(\frac{\nu_1 x}{\nu_2+\nu_1 x};\frac{\nu_1}{2},\frac{\nu_2}{2}\right)$$

$$F^{-1}(p;\nu_1,\nu_2) = \frac{\nu_2}{\nu_1}\left(\frac{IB^{-1}(p;\nu_1/2,\,\nu_2/2)}{1-IB^{-1}(p;\nu_1/2,\,\nu_2/2)}\right)$$

where $\mathrm{B}(a,b) = \int_0^1 x^{a-1}(1-x)^{b-1}dx$ is the beta function and
$\mathrm{IB}(x;a,b) = \int_0^x \frac{1}{\mathrm{B}(a,b)}t^{a-1}(1-t)^{b-1}dt$ is the incomplete beta function.

Relationship to other distributions.

- The F(*v1*,*v2*) distribution is the distribution of (*X*/ν1)/(*Y*/ν2), where *X* and *Y* are independent chi-square random variates with *v1* and *v2* degrees of freedom, respectively.

Noncentral F distribution. The noncentral F distribution is a generalization of the F distribution that takes values in the range x>=0 and has an extra noncentrality parameter, λ, which must be greater than or equal to 0.

Functions.

The noncentral *F* distribution has PDF and CDF

$$f(x;\nu_1,b,\lambda) = \sum_{j=0}^{\infty}\frac{1}{j!}\left(\frac{\lambda}{2}\right)^j e^{-\lambda/2}\frac{(\nu_1/b)^{\nu_1/2+j}}{\mathrm{B}(\nu_1/2+j,b/2)}x^{\nu_1/2+j-1}\left(1+\frac{\nu_1}{b}x\right)^{-((\nu_1+b)/2+j)}$$

$$F(x;\nu_1,b,\lambda) = \sum_{j=0}^{\infty}\frac{1}{j!}\left(\frac{\lambda}{2}\right)^j e^{-\lambda/2}\mathrm{IB}\left(\frac{\nu_1 x}{b+\nu_1 x};\frac{\nu_1}{2}+j,\frac{b}{2}\right)$$

where $\mathrm{B}(a,b) = \int_0^1 x^{a-1}(1-x)^{b-1}dx$ is the beta function and
$\mathrm{IB}(x;a,b) = \int_0^x \frac{1}{\mathrm{B}(a,b)}t^{a-1}(1-t)^{b-1}dt$ is the incomplete beta function.

Relationship to other distributions.

- When λ equals 0, this distribution reduces to the *F* distribution.
- The noncentral *F* distribution is the distribution of (*X*/ν1)/(*Y*/ν2), where *X* and *Y* are independent variates with noncentral chi-square(*v1*, *λ*) and central chi-square(*v2*) distributions, respectively.

GAMMA

Gamma distribution. The gamma distribution takes values in the range x>=0 and has one shape parameter, α, and one scale parameter, β. Both parameters must be positive and have the property that the mean of the distribution is α/β.

Common uses. The gamma distribution is commonly used in queuing theory, inventory control, and precipitation processes.

Functions. The `CDF`, `IDF`, `PDF`, and `RV` functions are available.

The gamma distribution has PDF, CDF, and IDF

$$f(x;\alpha,\beta) = \frac{\beta^{\alpha}}{\Gamma(\alpha)} x^{\alpha-1} e^{-\beta x}$$

$$F(x;\alpha,\beta) = \mathrm{IG}(\beta x;\alpha)$$

$$F^{-1}(p;\alpha,\beta) = \frac{1}{\beta}\mathrm{IG}^{-1}(p;\alpha)$$

where $\Gamma(a) = \int_0^{\infty} x^{a-1} e^{-x} dx$ is the gamma function and $\mathrm{IG}(x;a) = \int_0^{x} \frac{1}{\Gamma(a)} t^{a-1} e^{-t} dt$ is the incomplete gamma function.

Relationship to other distributions.

- When α=1, the gamma(α,β) distribution reduces to the exponential(β) distribution.
- When β=1/2, the gamma(α,β) distribution reduces to the chi-square(2α) distribution.
- When α is an integer, the gamma distribution is also known as the Erlang distribution.

HALFNRM *Half-normal distribution.* The half-normal distribution takes values in the range x>=μ and has one location parameter, μ, and one scale parameter, σ. Parameter σ must be positive.

Functions. The `CDF`, `IDF`, `PDF`, and `RV` functions are available.

The half-normal distribution has PDF, CDF, and IDF

$$f(x;\mu,\sigma) = \phi\left(\frac{x-\mu}{\sigma}\right)/\sigma$$

$$F(x;\mu,\sigma) = 2\Phi\left(\frac{x-\mu}{\sigma}\right) - 1$$

$$F^{-1}(p;\mu,\sigma) = \mu + \sigma\Phi^{-1}\left(\frac{1+p}{2}\right)$$

Relationship to other distributions.

- If X has a normal(μ,σ) distribution, then $|X-\mu|$ has a half-normal(μ,σ) distribution.

IGAUSS *Inverse Gaussian distribution.* The inverse Gaussian, or Wald, distribution takes values in the range x>0 and has two parameters, μ and λ, both of which must be positive. The distribution has mean μ.

Common uses. The inverse Gaussian distribution is commonly used to test hypotheses for model parameter estimates.

Functions. The `CDF`, `IDF`, `PDF`, and `RV` functions are available.

The inverse Gaussian distribution has PDF and CDF

$$f\left(x;\mu,\lambda\right)=\left(\frac{\lambda}{2\pi x^3}\right)^{1/2}\exp\left(-\frac{\lambda(x-\mu)^2}{2\mu^2 x}\right)$$

$$F\left(x;\mu,\lambda\right)=\Phi\left(\sqrt{\frac{\lambda}{x}}\left(-1+\frac{x}{\mu}\right)\right)+e^{(2\lambda/\mu)}\Phi\left(-\sqrt{\frac{\lambda}{x}}\left(1+\frac{x}{\mu}\right)\right)$$

The IDF is computed by approximation.

LAPLACE *Laplace or double exponential distribution.* The Laplace distribution takes real values and has one location parameter, μ, and one scale parameter, β. Parameter β must be positive. The distribution is symmetric about μ and has exponentially decaying tails.

Functions. The `CDF`, `IDF`, `PDF`, and `RV` functions are available.

The Laplace distribution has PDF, CDF, and IDF

$$f(x;\mu,\beta)=\frac{1}{2b}e^{-|x-\mu|/\beta}$$

$$F(x;\mu,\beta)=\begin{cases}\frac{1}{2}e^{(x-\mu)/\beta} & x\leq\mu\\ 1-\frac{1}{2}e^{(\mu-x)/\beta} & x>\mu\end{cases}$$

$$F^{-1}(p;\mu,\beta)=\begin{cases}\mu+\beta\ln\left(2p\right) & 0\leq p\leq\frac{1}{2}\\ \mu-\beta\ln\left(2(1-p)\right) & \frac{1}{2}<p\leq 1\end{cases}$$

LOGISTIC *Logistic distribution.* The logistic distribution takes real values and has one location parameter, μ, and one scale parameter, ς. Parameter ς must be positive. The distribution is symmetric about μ and has longer tails than the normal distribution.

Common uses. The logistic distribution is used to model growth curves.

Functions. The `CDF`, `IDF`, `PDF`, and `RV` functions are available.

The logistic distribution has PDF, CDF, and IDF

$$f(x;\mu,\varsigma)=\frac{1}{\varsigma}e^{-(x-\mu)/\varsigma}\left(1+e^{-(x-\mu)/\varsigma}\right)^{-2}$$

$$F(x;\mu,\varsigma)=\frac{1}{1+e^{-(x-\mu)/\varsigma}}$$

$$F^{-1}(p;\mu,\varsigma)=\mu+\varsigma\ln\left(\frac{p}{1-p}\right)$$

LNORMAL *Lognormal distribution.* The lognormal distribution takes values in the range x>=0 and has two parameters, η and σ, both of which must be positive.

Common uses. Lognormal is used in the distribution of particle sizes in aggregates, flood flows, concentrations of air contaminants, and failure time.

Functions. The `CDF`, `IDF`, `PDF`, and `RV` functions are available.

The lognormal distribution has PDF, CDF, and IDF

$$f(x;\eta,\sigma) = \frac{1}{x\sigma\sqrt{2\pi}} e^{-(\ln(x/\eta))^2/(2\sigma^2)}$$

$$F(x;\eta,\sigma) = \Phi\left(\frac{1}{\sigma}\ln\left(\frac{x}{\eta}\right)\right)$$

$$F^{-1}(p;\eta,\sigma) = \eta e^{\sigma\Phi^{-1}(p)}$$

Relationship to other distributions.

- If X has a lognormal(η,σ) distribution, then ln(X) has a normal(ln(η),σ) distribution.

NORMAL

Normal distribution. The normal, or Gaussian, distribution takes real values and has one location parameter, μ, and one scale parameter, σ. Parameter σ must be positive. The distribution has mean μ and standard deviation σ.

Functions. The `CDF`, `IDF`, `PDF`, and `RV` functions are available.

The normal distribution has PDF, CDF, and IDF

$$f(x;\mu,\sigma) = \frac{1}{\sigma\sqrt{2\pi}} e^{-(x-\mu)^2/(2\sigma^2)}$$

$$F(x;\mu,\sigma) = \Phi\left(\frac{x-\mu}{\sigma}\right)$$

$$F^{-1}(p;\mu,\sigma) = \mu + \sigma\Phi^{-1}(p)$$

Relationship to other distributions.

- If X has a normal(μ,σ) distribution, then exp(X) has a normal(exp(μ),σ) distribution.

Three functions in releases earlier than 6.0 are special cases of the normal distribution functions: `CDFNORM(arg)=CDF.NORMAL(x,0,1)`, where `arg` is *x*; `PROBIT(arg)=IDF.NORMAL(p,0,1)`, where `arg` is *p*; and `NORMAL(arg)=RV.NORMAL(0,σ)`, where `arg` is σ.

PARETO

Pareto distribution. The Pareto distribution takes values in the range xmin<x and has a threshold parameter, xmin, and a shape parameter, α. Both parameters must be positive.

Common uses. Pareto is commonly used in economics as a model for a density function with a slowly decaying tail.

Functions. The `CDF`, `IDF`, `PDF`, and `RV` functions are available.

The Pareto distribution has PDF, CDF, and IDF

$$f(x; x_{\min}, \alpha) = \frac{\alpha}{x_{\min}} \left(\frac{x_{\min}}{x} \right)^{\alpha+1}$$

$$F(x; x_{\min}, \alpha) = 1 - \left(\frac{x_{\min}}{x} \right)^{\alpha}$$

$$F^{-1}(p; x_{\min}, \alpha) = x_{\min}(1-p)^{-1/\alpha}$$

SMOD *Studentized maximum modulus distribution.* The Studentized maximum modulus distribution takes values in the range x>0 and has a number of comparisons parameter, k*, and degrees of freedom parameter, ν, both of which must be greater than or equal to 1.

Common uses. The Studentized maximum modulus is commonly used in post hoc multiple comparisons for GLM and ANOVA.

Functions. The `CDF` and `IDF` functions are available, and are computed by approximation.

SRANGE *Studentized range distribution.* The Studentized range distribution takes values in the range x>0 and has a number of samples parameter, k, and degrees of freedom parameter, ν, both of which must be greater than or equal to 1.

Common uses. The Studentized range is commonly used in post hoc multiple comparisons for GLM and ANOVA.

Functions. The `CDF` and `IDF` functions are available, and are computed by approximation.

T *Student* t *distribution.* The Student t distribution takes real values and has one degrees of freedom parameter, ν, which must be positive. The Student t distribution is symmetric about 0.

Common uses. The major uses of the Student *t* distribution are to test hypotheses and construct confidence intervals for means of data.

Functions. The `CDF`, `IDF`, `PDF`, `RV`, `NCDF`, and `NPDF` functions are available.

The *t* distribution has PDF, CDF, and IDF

$$f(x;\nu) = \frac{1}{\sqrt{\nu}\mathrm{B}\left(\mathrm{v}/2,1/2\right)}\left(1+\frac{x^2}{\nu}\right)^{-(\nu+1)/2}$$

$$F(x;\nu) = \begin{cases} \frac{1}{2}\mathrm{IB}\left(\frac{\nu}{\nu+x^2};\frac{\nu}{2},\frac{1}{2}\right) & \mathrm{x} \le 0 \\ 1\text{-}\frac{1}{2}\mathrm{IB}\left(\frac{\nu}{\nu+x^2};\frac{\nu}{2},\frac{1}{2}\right) & x > 0 \end{cases}$$

$$F^{-1}(p;\nu) = \begin{cases} -\sqrt{\nu\left(1/\left(\mathrm{IB}^{-1}\left(2p;\frac{\nu}{2},\frac{1}{2}\right)\right)-1\right)} & 0 \le p \le \frac{1}{2} \\ \sqrt{\nu\left(1/\left(\mathrm{IB}^{-1}\left(2(1-p);\frac{\nu}{2},\frac{1}{2}\right)\right)-1\right)} & \frac{1}{2} < p \le 1 \end{cases}$$

where $\mathrm{B}(a,b) = \int_0^1 x^{a-1}(1-x)^{b-1}dx$ is the beta function and

$\mathrm{IB}(x;a,b) = \int_0^x \frac{1}{\mathrm{B}(a,b)} t^{a-1}(1-t)^{b-1}dt$ is the incomplete beta function.

Relationship to other distributions.

- The *t*(*v*) distribution is the distribution of *X*/*Y*, where *X* is a normal(0,1) variate and *Y* is a chi-square(*v*) variate divided by *v*.
- The square of a *t*(*v*) variate has an *F*(1,*v*) distribution.
- The *t*(*v*) distribution approaches the normal(0,1) distribution as *v* approaches infinity.

Noncentral t distribution. The noncentral t distribution is a generalization of the t distribution that takes real values and has an extra noncentrality parameter, λ, which must be greater than or equal to 0. When λ equals 0, this distribution reduces to the t distribution.

Functions.

The noncentral t distribution has PDF and CDF

$$f(x;\nu,\lambda)=\sum_{j=0}^{\infty}\frac{1}{j!}\left(\lambda\sqrt{2}\right)^{j}e^{-\lambda^2/2}\frac{\Gamma((\nu+j+1)/2)}{\Gamma(\nu/2)\Gamma(1/2)}\frac{x^j}{\nu^{(j+1)/2}}\left(1+\frac{x^2}{\nu}\right)^{-(\nu+j+1)/2}$$

$$F(x;\nu,\lambda)=\begin{cases}\frac{1}{2}\sum_{j=0}^{\infty}\frac{1}{j!}\left(-\lambda\sqrt{2}\right)^{j}e^{-\lambda^2/2}\frac{\Gamma((j+1)/2)}{\Gamma(1/2)}\mathrm{IB}\left(\frac{\nu}{\nu+x^2};\frac{\nu}{2},\frac{j+1}{2}\right) & x\le 0\\ 1-\frac{1}{2}\sum_{j=0}^{\infty}\frac{1}{j!}\left(\lambda\sqrt{2}\right)^{j}e^{-\lambda^2/2}\frac{\Gamma((j+1)/2)}{\Gamma(1/2)}\mathrm{IB}\left(\frac{\nu}{\nu+x^2};\frac{a}{2},\frac{j+1}{2}\right) & x>0\end{cases}$$

where $\mathrm{B}(a,b)=\int_0^1 x^{a-1}(1-x)^{b-1}dx$ is the beta function and

$\mathrm{IB}(x;a,b)=\int_0^x\frac{1}{\mathrm{B}(a,b)}t^{a-1}(1-t)^{b-1}dt$ is the incomplete beta function.

Relationship to other distributions.

- The noncentral $t(\nu,\lambda)$ distribution is the distribution of X/Y, where X is a normal(λ,1) variate and Y is a central chi-square(ν) variate divided by ν.

UNIFORM

Uniform distribution. The uniform distribution takes values in the range a<x<b and has a minimum value parameter, a, and a maximum value parameter, b.

Functions. The `CDF`, `IDF`, `PDF`, and `RV` functions are available.

The uniform distribution has PDF, CDF, and IDF

$f(x;a,b)=\frac{1}{b-a}$

$F(x;a,b)=\frac{x-a}{b-a}$

$F^{-1}(p;a,b)=a+(b-a)p$

The uniform random number function in releases earlier than 6.0 is a special case: `UNIFORM(arg)=RV.UNIFORM(0,b)`, where `arg` is parameter *b*. Among other uses, the uniform distribution commonly models the round-off error.

WEIBULL *Weibull distribution.* The Weibull distribution takes values in the range x>=0 and has one scale parameter, β, and one shape parameter, α, both of which must be positive.

Common uses. The Weibull distribution is commonly used in survival analysis.

Functions. The `CDF`, `IDF`, `PDF`, and `RV` functions are available.

The Weibull distribution has PDF, CDF, and IDF

$$f(x;\beta,\alpha) = \frac{\alpha}{\beta}\left(\frac{x}{\beta}\right)^{\alpha-1} e^{-(x/\beta)^{\alpha}}$$

$$F(x;\beta,\alpha) = 1 - e^{-(x/\beta)^{\alpha}}$$

$$F^{-1}(p;\beta,\alpha) = \beta(-\ln(1-p))^{1/\alpha}$$

Relationship to other distributions.

- A Weibull(β,1) distribution is equivalent to an exponential(β) distribution.

The following are suffixes for discrete distributions:

BERNOULLI *Bernoulli distribution.* The Bernoulli distribution takes values 0 or 1 and has one success probability parameter, θ, which must be between 0 and 1, inclusive.

Functions. The `CDF`, `PDF`, and `RV` functions are available.

The Bernoulli distribution has PDF and CDF

$$f(x;\theta) = \theta^{x}(1-\theta)^{1-x}$$

$$F(x;\theta) = \begin{cases} 1-\theta & x = 0 \\ 1 & x = 1 \end{cases}$$

Relationship to other distributions.

- The Bernoulli distribution is a special case of the binomial distribution and is used in simple success-failure experiments.

BINOM *Binomial distribution.* The binomial distribution takes integer values 0<=x<=n, representing the number of successes in n trials, and has one number of trials parameter, n, and one success probability parameter, θ. Parameter n must be a positive integer and parameter θ must be between 0 and 1, inclusive.

Common uses. The binomial distribution is used in independently replicated success-failure experiments.

Functions. The CDF, PDF, and RV functions are available.

The binomial distribution has PDF and CDF

$$f(x;n,\theta) = \binom{n}{x}\theta^x(1-\theta)^{n-x}$$

$$F(x;n,\theta) = \begin{cases} 1 - \mathrm{IB}(\theta; x+1, n-x) & x = 0,1,...,n-1 \\ 1 & x = n \end{cases}$$

where $\mathrm{IB}(x;a,b) = \int_0^x \frac{1}{\mathrm{B}(a,b)} t^{a-1}(1-t)^{b-1}dt$ is the incomplete beta function.

GEOM

Geometric distribution. The geometric distribution takes integer values x>=1, representing the number of trials needed (including the last trial) before a success is observed, and has one success probability parameter, θ, which must be between 0 and 1, inclusive.

Functions. The CDF, PDF, and RV functions are available.

The geometric distribution has PDF and CDF

$$f(x;\theta) = \theta(1-\theta)^{x-1}$$

$$F(x;\theta) = 1 - (1-\theta)^x$$

Relationship to other distributions.

- The geometric(θ) distribution is equivalent to the negative binomial (1,θ) distribution.

HYPER

Hypergeometric distribution. The hypergeometric distribution takes integer values in the range max(0, Np+n−N)<=x<=min(Np,n), and has three parameters, N, n, and Np, where N is the total number of objects in an urn model, n is the number of objects randomly drawn without replacement from the urn, Np is the number of objects with a given characteristic, and x is the number of objects with the given characteristic observed out of the withdrawn objects. All three parameters are positive integers, and both n and Np must be less than or equal to N.

Functions. The `CDF`, `PDF`, and `RV` functions are available.

The hypergeometric distribution has PDF and CDF

$$f(x; N, n, Np) = \frac{\binom{Np}{x}\binom{N-Np}{n-x}}{\binom{N}{n}}$$

$$F(x; N, n, Np) = \sum_{k=\max(0, n+Np-N)}^{x} \text{Prob}(X{=}k)$$

NEGBIN

Negative binomial distribution. The negative binomial distribution takes integer values in the range x>=r, where x is the number of trials needed (including the last trial) before r successes are observed, and has one threshold parameter, r, and one success probability parameter, θ. Parameter r must be a positive integer and parameter θ must be greater than 0 and less than or equal to 1.

Functions. The `CDF`, `PDF`, and `RV` functions are available.

The negative binomial distribution has PDF and CDF

$$f(x; r, \theta) = \binom{x-1}{r-1}\theta^r(1-\theta)^{x-r}$$

$$F(x; r, \theta) = \text{IB}(\theta; r, x-r+1)$$

where $\text{IB}(x; a, b) = \int_0^x \frac{1}{\text{B}(a, b)} t^{a-1}(1-t)^{b-1}dt$ is the incomplete beta function.

Relationship to other distributions.

- The negative binomial(1,θ) distribution is equivalent to the geometric(θ) distribution.

POISSON *Poisson distribution.* The Poisson distribution takes integer values in the range x>=0 and has one rate or mean parameter, λ. Parameter λ must be positive.

Common uses. The Poisson distribution is used in modeling the distribution of counts, such as traffic counts and insect counts.

Functions. The CDF, PDF, and RV functions are available.

The Poisson distribution has PDF and CDF

$$f(x;\lambda) = \frac{\lambda^x}{x!}e^{-\lambda}$$

$$F(x;\lambda) = 1 - \text{IG}(\lambda;x+1)$$

where $\text{IG}(x;a) = \int_0^x \frac{1}{\Gamma(a)} t^{a-1}e^{-t}dt$ is the incomplete gamma function.

Probability Density Functions

The following functions give the value of the density function with the specified distribution at the value *quant*, the first argument. Subsequent arguments are the parameters of the distribution. Note the period in each function name.

PDF.BERNOULLI. PDF.BERNOULLI(quant, prob). Numeric. Returns the probability that a value from the Bernoulli distribution, with the given probability parameter, will be equal to quant.

PDF.BETA. PDF.BETA(quant, shape1, shape2). Numeric. Returns the probability density of the beta distribution, with the given shape parameters, at quant.

PDF.BINOM. PDF.BINOM(quant, n, prob). Numeric. Returns the probability that the number of successes in n trials, with probability prob of success in each, will be equal to quant. When n is 1, this is the same as PDF.BERNOULLI.

PDF.BVNOR. PDF.BVNOR(quant1, quant2, corr). Numeric. Returns the probability density of the standard bivariate normal distribution, with the given correlation parameter, at quant1, quant2.

PDF.CAUCHY. PDF.CAUCHY(quant, loc, scale). Numeric. Returns the probability density of the Cauchy distribution, with the given location and scale parameters, at quant.

PDF.CHISQ. PDF.CHISQ(quant, df). Numeric. Returns the probability density of the chi-square distribution, with df degrees of freedom, at quant.

PDF.EXP. PDF.EXP(quant, shape). Numeric. Returns the probability density of the exponential distribution, with the given shape parameter, at quant.

PDF.F. PDF.F(quant, df1, df2). Numeric. Returns the probability density of the F distribution, with degrees of freedom df1 and df2, at quant.

PDF.GAMMA. PDF.GAMMA(quant, shape, scale). Numeric. Returns the probability density of the gamma distribution, with the given shape and scale parameters, at quant.

PDF.GEOM. PDF.GEOM(quant, prob). Numeric. Returns the probability that the number of trials to obtain a success, when the probability of success is given by prob, will be equal to quant.

PDF.HALFNRM. PDF.HALFNRM(quant, mean, stddev). Numeric. Returns the probability density of the half normal distribution, with specified mean and standard deviation, at quant.

PDF.HYPER. PDF.HYPER(quant, total, sample, hits). Numeric. Returns the probability that the number of objects with a specified characteristic, when sample objects are randomly selected from a universe of size total in which hits have the specified characteristic, will be equal to quant.

PDF.IGAUSS. PDF.IGAUSS(quant, loc, scale). Numeric. Returns the probability density of the inverse Gaussian distribution, with the given location and scale parameters, at quant.

PDF.LAPLACE. PDF.LAPLACE(quant, mean, scale). Numeric. Returns the probability density of the Laplace distribution, with the specified mean and scale parameters, at quant.

PDF.LOGISTIC. PDF.LOGISTIC(quant, mean, scale). Numeric. Returns the probability density of the logistic distribution, with the specified mean and scale parameters, at quant.

PDF.LNORMAL. PDF.LNORMAL(quant, a, b). Numeric. Returns the probability density of the log-normal distribution, with the specified parameters, at quant.

PDF.NEGBIN. PDF.NEGBIN(quant, thresh, prob). Numeric. Returns the probability that the number of trials to obtain a success, when the threshold parameter is thresh and the probability of success is given by prob, will be equal to quant.

PDF.NORMAL. PDF.NORMAL(quant, mean, stddev). Numeric. Returns the probability density of the normal distribution, with specified mean and standard deviation, at quant.

PDF.PARETO. PDF.PARETO(quant, threshold, shape). Numeric. Returns the probability density of the Pareto distribution, with the specified threshold and shape parameters, at quant.

PDF.POISSON. PDF.POISSON(quant, mean). Numeric. Returns the probability that a value from the Poisson distribution, with the specified mean or rate parameter, will be equal to quant.

PDF.T. PDF.T(quant, df). Numeric. Returns the probability density of Student's t distribution, with the specified degrees of freedom df, at quant.

PDF.UNIFORM. PDF.UNIFORM(quant, min, max). Numeric. Returns the probability density of the uniform distribution, with the specified minimum and maximum, at quant.

PDF.WEIBULL. PDF.WEIBULL(quant, a, b). Numeric. Returns the probability density of the Weibull distribution, with the specified parameters, at quant.

NPDF.BETA. NPDF.BETA(quant, shape1, shape2, nc). Numeric. Returns the probability density of the noncentral beta distribution, with the given shape and noncentrality parameters, at quant.

NPDF.CHISQ. NPDF.CHISQ(quant, df, nc). Numeric. Returns the probability density of the noncentral chi-square distribution, with df degrees of freedom and the specified noncentrality parameter, at quant.

NPDF.F. NPDF.F(quant, df1, df2, nc). Numeric. Returns the probability density of the noncentral F distribution, with degrees of freedom df1 and df2 and noncentrality nc, at quant.

NPDF.T. NPDF.T(quant, df, nc). Numeric. Returns the probability density of the noncentral Student's t distribution, with the specified degrees of freedom df and noncentrality nc, at quant.

Tail Probability Functions

The following functions give the probability that a random variable with the specified distribution will be greater than *quant*, the first argument. Subsequent arguments are the parameters of the distribution. Note the period in each function name.

SIG.CHISQ. SIG.CHISQ(quant, df). Numeric. Returns the cumulative probability that a value from the chi-square distribution, with df degrees of freedom, will be greater than quant

SIG.F. These significance values should not be used to test hypotheses about the F values in this table. Cluster analysis specifically attempts to maximize between-group variance, and the significance values reported here do not reflect this.

Cumulative Distribution Functions

The following functions give the probability that a random variable with the specified distribution will be less than *quant*, the first argument. Subsequent arguments are the parameters of the distribution. Note the period in each function name.

CDF.BERNOULLI. CDF.BERNOULLI(quant, prob). Numeric. Returns the cumulative probability that a value from the Bernoulli distribution, with the given probability parameter, will be less than or equal to quant.

CDF.BETA. CDF.BETA(quant, shape1, shape2). Numeric. Returns the cumulative probability that a value from the Beta distribution, with the given shape parameters, will be less than quant.

CDF.BINOM. CDF.BINOM(quant, n, prob). Numeric. Returns the cumulative probability that the number of successes in n trials, with probability prob of success in each, will be less than or equal to quant. When n is 1, this is the same as CDF.BERNOULLI.

CDF.BVNOR. CDF.BVNOR(quant1, quant2, corr). Numeric. Returns the cumulative probability that a value from the standard bivariate normal distribution, with the given correlation parameter, will be less than quant1 and quant2.

CDF.CAUCHY. CDF.CAUCHY(quant, loc, scale). Numeric. Returns the cumulative probability that a value from the Cauchy distribution, with the given location and scale parameters, will be less than quant.

CDF.CHISQ. CDF.CHISQ(quant, df). Numeric. Returns the cumulative probability that a value from the chi-square distribution, with df degrees of freedom, will be less than quant.

CDF.EXP. CDF.EXP(quant, scale). Numeric. Returns the cumulative probability that a value from the exponential distribution, with the given scale parameter, will be less than quant.

CDF.F. CDF.F(quant, df1, df2). Numeric. Returns the cumulative probability that a value from the F distribution, with degrees of freedom df1 and df2, will be less than quant.

CDF.GAMMA. CDF.GAMMA(quant, shape, scale). Numeric. Returns the cumulative probability that a value from the Gamma distribution, with the given shape and scale parameters, will be less than quant.

CDF.GEOM. CDF.GEOM(quant, prob). Numeric. Returns the cumulative probability that the number of trials to obtain a success, when the probability of success is given by prob, will be less than or equal to quant.

CDF.HALFNRM. CDF.HALFNRM(quant, mean, stddev). Numeric. Returns the cumulative probability that a value from the half normal distribution, with specified mean and standard deviation, will be less than quant.

CDF.HYPER. CDF.HYPER(quant, total, sample, hits). Numeric. Returns the cumulative probability that the number of objects with a specified characteristic, when sample objects are randomly selected from a universe of size total in which hits have the specified characteristic, will be less than or equal to quant.

CDF.IGAUSS. CDF.IGAUSS(quant, loc, scale). Numeric. Returns the cumulative probability that a value from the inverse Gaussian distribution, with the given location and scale parameters, will be less than quant.

CDF.LAPLACE. CDF.LAPLACE(quant, mean, scale). Numeric. Returns the cumulative probability that a value from the Laplace distribution, with the specified mean and scale parameters, will be less than quant.

CDF.LOGISTIC. CDF.LOGISTIC(quant, mean, scale). Numeric. Returns the cumulative probability that a value from the logistic distribution, with the specified mean and scale parameters, will be less than quant.

CDF.LNORMAL. CDF.LNORMAL(quant, a, b). Numeric. Returns the cumulative probability that a value from the log-normal distribution, with the specified parameters, will be less than quant.

CDF.NEGBIN. CDF.NEGBIN(quant, thresh, prob). Numeric. Returns the cumulative probability that the number of trials to obtain a success, when the threshold parameter is thresh and the probability of success is given by prob, will be less than or equal to quant.

CDFNORM. CDFNORM(zvalue). Numeric. Returns the probability that a random variable with mean 0 and standard deviation 1 would be less than zvalue, which must be numeric.

CDF.NORMAL. CDF.NORMAL(quant, mean, stddev). Numeric. Returns the cumulative probability that a value from the normal distribution, with specified mean and standard deviation, will be less than quant.

CDF.PARETO. CDF.PARETO(quant, threshold, shape). Numeric. Returns the cumulative probability that a value from the Pareto distribution, with the specified threshold and shape parameters, will be less than quant.

CDF.POISSON. CDF.POISSON(quant, mean). Numeric. Returns the cumulative probability that a value from the Poisson distribution, with the specified mean or rate parameter, will be less than or equal to quant.

CDF.SMOD. CDF.SMOD(quant, a, b). Numeric. Returns the cumulative probability that a value from the Studentized maximum modulus, with the specified parameters, will be less than quant.

CDF.SRANGE. CDF.SRANGE(quant, a, b). Numeric. Returns the cumulative probability that a value from the Studentized range statistic, with the specified parameters, will be less than quant.

CDF.T. CDF.T(quant, df). Numeric. Returns the cumulative probability that a value from Student's t distribution, with the specified degrees of freedom df, will be less than quant.

CDF.UNIFORM. CDF.UNIFORM(quant, min, max). Numeric. Returns the cumulative probability that a value from the uniform distribution, with the specified minimum and maximum, will be less than quant.

CDF.WEIBULL. CDF.WEIBULL(quant, a, b). Numeric. Returns the cumulative probability that a value from the Weibull distribution, with the specified parameters, will be less than quant.

NCDF.BETA. NCDF.BETA(quant, shape1, shape2, nc). Numeric. Returns the cumulative probability that a value from the noncentral Beta distribution, with the given shape and noncentrality parameters, will be less than quant.

NCDF.CHISQ. NCDF.CHISQ(quant, df, nc). Numeric. Returns the cumulative probability that a value from the noncentral chi-square distribution, with df degrees of freedom and the specified noncentrality parameter, will be less than quant.

NCDF.F. NCDF.F(quant, df1, df2, nc). Numeric. Returns the cumulative probability that a value from the noncentral F distribution, with degrees of freedom df1 and df2, and noncentrality nc, will be less than quant.

NCDF.T. NCDF.T(quant, df, nc). Numeric. Returns the cumulative probability that a value from the noncentral Student's t distribution, with the specified degrees of freedom df and noncentrality nc, will be less than quant.

Inverse Distribution Functions

The following functions give the value in a specified distribution having a cumulative probability equal to *prob*, the first argument. Subsequent arguments are the parameters of the distribution. Note the period in each function name.

IDF.BETA. IDF.BETA(prob, shape1, shape2). Numeric. Returns the value from the Beta distribution, with the given shape parameters, for which the cumulative probability is prob.

IDF.CAUCHY. IDF.CAUCHY(prob, loc, scale). Numeric. Returns the value from the Cauchy distribution, with the given location and scale parameters, for which the cumulative probability is prob.

IDF.CHISQ. IDF.CHISQ(prob, df). Numeric. Returns the value from the chi-square distribution, with the specified degrees of freedom df, for which the cumulative probability is prob. For example, the chi-square value that is significant at the 0.05 level with 3 degrees of freedom is IDF.CHISQ(0.95,3).

IDF.EXP. IDF.EXP(p, scale). Numeric. Returns the value of an exponentially decaying variable, with rate of decay scale, for which the cumulative probability is p.

IDF.F. IDF.F(prob, df1, df2). Numeric. Returns the value from the F distribution, with the specified degrees of freedom, for which the cumulative probability is prob. For example, the F value that is significant at the 0.05 level with 3 and 100 degrees of freedom is IDF.F(0.95,3,100).

IDF.GAMMA. IDF.GAMMA(prob, shape, scale). Numeric. Returns the value from the Gamma distribution, with the specified shape and scale parameters, for which the cumulative probability is prob.

IDF.HALFNRM. IDF.HALFNRM(prob, mean, stddev). Numeric. Returns the value from the half normal distribution, with the specified mean and standard deviation, for which the cumulative probability is prob.

IDF.IGAUSS. IDF.IGAUSS(prob, loc, scale). Numeric. Returns the value from the inverse Gaussian distribution, with the given location and scale parameters, for which the cumulative probability is prob.

IDF.LAPLACE. IDF.LAPLACE(prob, mean, scale). Numeric. Returns the value from the Laplace distribution, with the specified mean and scale parameters, for which the cumulative probability is prob.

IDF.LOGISTIC. IDF.LOGISTIC(prob, mean, scale). Numeric. Returns the value from the logistic distribution, with specified mean and scale parameters, for which the cumulative probability is prob.

IDF.LNORMAL. IDF.LNORMAL(prob, a, b). Numeric. Returns the value from the log-normal distribution, with specified parameters, for which the cumulative probability is prob.

IDF.NORMAL. IDF.NORMAL(prob, mean, stddev). Numeric. Returns the value from the normal distribution, with specified mean and standard deviation, for which the cumulative probability is prob.

IDF.PARETO. IDF.PARETO(prob, threshold, shape). Numeric. Returns the value from the Pareto distribution, with specified threshold and scale parameters, for which the cumulative probability is prob.

IDF.SMOD. IDF.SMOD(prob, a, b). Numeric. Returns the value from the Studentized maximum modulus, with the specified parameters, for which the cumulative probability is prob.

IDF.SRANGE. IDF.SRANGE(prob, a, b). Numeric. Returns the value from the Studentized range statistic, with the specified parameters, for which the cumulative probability is prob.

IDF.T. IDF.T(prob, df). Numeric. Returns the value from Student's t distribution, with specified degrees of freedom df, for which the cumulative probability is prob.

IDF.UNIFORM. IDF.UNIFORM(prob, min, max). Numeric. Returns the value from the uniform distribution between min and max for which the cumulative probability is prob.

IDF.WEIBULL. IDF.WEIBULL(prob, a, b). Numeric. Returns the value from the Weibull distribution, with specified parameters, for which the cumulative probability is prob.

PROBIT. PROBIT(prob). Numeric. Returns the value in a standard normal distribution having a cumulative probability equal to prob. The argument prob is a probability greater than 0 and less than 1.

Random Variable Functions

The following functions give a random variate from a specified distribution. The arguments are the parameters of the distribution. You can repeat the sequence of pseudorandom numbers by setting a seed in the Preferences dialog box before each sequence. Note the period in each function name.

NORMAL. NORMAL(stddev). Numeric. Returns a normally distributed pseudorandom number from a distribution with mean 0 and standard deviation stddev, which must be a positive number. You can repeat the sequence of pseudorandom numbers by setting a seed in the Random Number Seed dialog box before each sequence.

RV.BERNOULLI. RV.BERNOULLI(prob). Numeric. Returns a random value from a Bernoulli distribution with the specified probability parameter prob.

RV.BETA. RV.BETA(shape1, shape2). Numeric. Returns a random value from a Beta distribution with specified shape parameters.

RV.BINOM. RV.BINOM(n, prob). Numeric. Returns a random value from a binomial distribution with specified number of trials and probability parameter.

RV.CAUCHY. RV.CAUCHY(loc, scale). Numeric. Returns a random value from a Cauchy distribution with specified location and scale parameters.

RV.CHISQ. RV.CHISQ(df). Numeric. Returns a random value from a chi-square distribution with specified degrees of freedom df.

RV.EXP. RV.EXP(scale). Numeric. Returns a random value from an exponential distribution with specified scale parameter.

RV.F. RV.F(df1, df2). Numeric. Returns a random value from an F distribution with specified degrees of freedom, df1 and df2.

RV.GAMMA. RV.GAMMA(shape, scale). Numeric. Returns a random value from a Gamma distribution with specified shape and scale parameters.

RV.GEOM. RV.GEOM(prob). Numeric. Returns a random value from a geometric distribution with specified probability parameter.

RV.HALFNRM. RV.HALFNRM(mean, stddev). Numeric. Returns a random value from a half normal distribution with the specified mean and standard deviation.

RV.HYPER. RV.HYPER(total, sample, hits). Numeric. Returns a random value from a hypergeometric distribution with specified parameters.

RV.IGAUSS. RV.IGAUSS(loc, scale). Numeric. Returns a random value from an inverse Gaussian distribution with the specified location and scale parameters.

RV.LAPLACE. RV.LAPLACE(mean, scale). Numeric. Returns a random value from a Laplace distribution with specified mean and scale parameters.

RV.LOGISTIC. RV.LOGISTIC(mean, scale). Numeric. Returns a random value from a logistic distribution with specified mean and scale parameters.

RV.LNORMAL. RV.LNORMAL(a, b). Numeric. Returns a random value from a log-normal distribution with specified parameters.

RV.NEGBIN. RV.NEGBIN(threshold, prob). Numeric. Returns a random value from a negative binomial distribution with specified threshold and probability parameters.

RV.NORMAL. RV.NORMAL(mean, stddev). Numeric. Returns a random value from a normal distribution with specified mean and standard deviation.

RV.PARETO. RV.PARETO(threshold, shape). Numeric. Returns a random value from a Pareto distribution with specified threshold and shape parameters.

RV.POISSON. RV.POISSON(mean). Numeric. Returns a random value from a Poisson distribution with specified mean/rate parameter.

RV.T. RV.T(df). Numeric. Returns a random value from a Student's t distribution with specified degrees of freedom df.

RV.UNIFORM. RV.UNIFORM(min, max). Numeric. Returns a random value from a uniform distribution with specified minimum and maximum. See also the UNIFORM function.

WEIBULL. RV.WEIBULL(a, b). Numeric. Returns a random value from a Weibull distribution with specified parameters.

UNIFORM. UNIFORM(max). Numeric. Returns a uniformly distributed pseudorandom number between 0 and the argument max, which must be numeric (but can be negative). You can repeat the sequence of pseudorandom numbers by setting the same Random Number Seed (available in the Transform menu) before each sequence.

Date and Time Functions

Date and time functions provide aggregation, conversion, and extraction routines for dates and time intervals. Each function transforms an expression consisting of one or more arguments. Arguments can be complex expressions, variable names, or constants. Date and time expressions and variables are legitimate arguments.

Aggregation Functions

Aggregation functions generate date and time intervals from values that were not read by date and time input formats.

- All aggregation functions begin with `DATE` or `TIME`, depending on whether a date or a time interval is requested. This is followed by a subfunction that corresponds to the type of values found in the data.
- The subfunctions are separated from the function by a period (.) and are followed by an argument list specified in parentheses.
- The arguments to the `DATE` and `TIME` functions must be separated by commas and must resolve to integer values.
- Functions that contain a day argument—for example, `DATE.DMY(d,m,y)`—check the validity of the argument. The value for day must be an integer between 1 and 31. If an invalid value is encountered, a warning is displayed and the value is set to system-missing. However, if the day value is invalid for a particular month—for example, 31 in September, April, June, and November or 29 through 31 for February in nonleap years—the resulting date is placed in the next month. For example `DATE.DMY(31, 9, 2006)` returns the date value for October 1, 2006.

DATE.DMY. DATE.DMY(day,month,year). Numeric. Returns a date value corresponding to the indicated day, month, and year. The arguments must resolve to integers, with day between 1 and 31, month between 1 and 13, and year a four-digit integer greater than 1582. To display the result as a date, assign a date format to the result variable.

DATE.MDY. DATE.MDY(month,day,year). Numeric. Returns a date value corresponding to the indicated month, day, and year. The arguments must resolve to integers, with day between 1 and 31, month between 1 and 13, and year a four-digit integer greater than 1582. To display the result as a date, assign a date format to the result variable.

DATE.MOYR. DATE.MOYR(month,year). Numeric. Returns a date value corresponding to the indicated month and year. The arguments must resolve to integers, with month between 1 and 13, and year a four-digit integer greater than 1582. To display the result as a date, assign a date format to the result variable.

DATE.QYR. DATE.QYR(quarter,year). Numeric. Returns a date value corresponding to the indicated quarter and year. The arguments must resolve to integers, with quarter between 1 and 4, and year a four-digit integer greater than 1582. To display the result as a date, assign a date format to the result variable.

DATE.WKYR. DATE.WKYR(weeknum,year). Numeric. Returns a date value corresponding to the indicated weeknum and year. The arguments must resolve to integers, with weeknum between 1 and 52, and year a four-digit integer greater than 1582. To display the result as a date, assign a date format to the result variable.

DATE.YRDAY. DATE.YRDAY(year,daynum). Numeric. Returns a date value corresponding to the indicated year and daynum. The arguments must resolve to integers, with daynum between 1 and 366 and with year being a four-digit integer greater than 1582. To display the result as a date, assign a date format to the result variable.

TIME.DAYS. TIME.DAYS(days). Numeric. Returns a time interval corresponding to the indicated number of days. The argument must be numeric. To display the result as a time, assign a time format to the result variable.

TIME.HMS. TIME.HMS(hours,minutes,seconds). Numeric . Returns a time interval corresponding to the indicated number of hours, minutes, and seconds. Hours must resolve to an integer, and minutes must resolve to an integer less than 60. Seconds can contain decimals but must resolve to a number less than 60. All arguments must resolve to either all positive or all negative values. To display the result as a time, assign a time format to the result variable.

Example

```
DATA LIST FREE
  /Year Month Day Hour Minute Second Days.
BEGIN DATA
2006 10 28 23 54 30 1.5
END DATA.
COMPUTE Date1=DATE.DMY(Day, Month, Year).
COMPUTE Date2=DATE.MDY(Month, Day, Year).
COMPUTE MonthYear=DATE.MOYR(Month, Year).
COMPUTE Time=TIME.HMS(Hour, Minute, Second).
COMPUTE Duration=TIME.DAYS(Days).
LIST VARIABLES=Date1 to Duration.
FORMATS
  Date1 (DATE11) Date2 (ADATE10) MonthYear (MOYR8)
  Time (TIME8) Duration (Time8).
LIST VARIABLES=Date1 to Duration.

***LIST Results Before Applying Formats***
       Date1        Date2    MonthYear     Time Duration
 13381372800  13381372800  13379040000    86070   129600

***LIST Results After Applying Formats***
      Date1      Date2 MonthYear     Time Duration
28-OCT-2006 10/28/2006  OCT 2006 23:54:30 36:00:00
```

- Since dates and times are stored internally as a number of seconds, prior to applying the appropriate date or time formats, all the computed values are displayed as numbers that indicate the respective number of seconds.
- The internal values for *Date1* and *Date2* are exactly the same. The only difference between `DATE.DMY` and `DATE.MDY` is the order of the arguments.

Date and Time Conversion Functions

The conversion functions convert time intervals from one unit of time to another. Time intervals are stored as the number of seconds in the interval; the conversion functions provide a means for calculating more appropriate units, for example, converting seconds to days.

Each conversion function consists of the CTIME function followed by a period (.), the target time unit, and an argument. The argument can consist of expressions, variable names, or constants. The argument must already be a time interval. For more information, see Aggregation Functions on p. 93. Time conversions produce noninteger results with a default format of F8.2.

Since time and dates are stored internally as seconds, a function that converts to seconds is not necessary.

CTIME.DAYS. CTIME.DAYS(timevalue). Numeric. Returns the number of days, including fractional days, in timevalue, which is a number of seconds, a time expression, or a time format variable.

CTIME.HOURS. CTIME.HOURS(timevalue). Numeric. Returns the number of hours, including fractional hours, in timevalue, which is a number of seconds, a time expression, or a time format variable.

CTIME.MINUTES. CTIME.MINUTES(timevalue). Numeric. Returns the number of minutes, including fractional minutes, in timevalue, which is a number of seconds, a time expression, or a time format variable.

CTIME.SECONDS. CTIME.SECONDS(timevalue). Numeric. Returns the number of seconds, including fractional seconds, in timevalue, which is a number, a time expression, or a time format variable.

Example

```
DATA LIST FREE (",")
  /StartDate (ADATE12) EndDate (ADATE12)
  StartDateTime(DATETIME20) EndDateTime(DATETIME20)
  StartTime (TIME10) EndTime (TIME10).
BEGIN DATA
3/01/2003, 4/10/2003
01-MAR-2003 12:00, 02-MAR-2003 12:00
09:30, 10:15
END DATA.
COMPUTE days = CTIME.DAYS(EndDate-StartDate).
COMPUTE hours = CTIME.HOURS(EndDateTime-StartDateTime).
COMPUTE minutes = CTIME.MINUTES(EndTime-StartTime).
```

- CTIME.DAYS calculates the difference between *EndDate* and *StartDate* in days—in this example, 40 days.
- CTIME.HOURS calculates the difference between *EndDateTime* and *StartDateTime* in hours—in this example, 24 hours.
- CTIME.MINUTES calculates the difference between *EndTime* and *StartTime* in minutes—in this example, 45 minutes.

YRMODA Function

YRMODA(arg list) *Convert year, month, and day to a day number.* The number returned is the number of days since October 14, 1582 (day 0 of the Gregorian calendar).

- Arguments for `YRMODA` can be variables, constants, or any other type of numeric expression but must yield integers.
- Year, month, and day must be specified in that order.
- The first argument can be any year between 0 and 99, or between 1582 to 47516.
- If the first argument yields a number between 00 and 99, 1900 through 1999 is assumed.
- The month can range from 1 through 13. Month 13 with day 0 yields the last day of the year. For example, `YRMODA(1990,13,0)` produces the day number for December 31, 1990. Month 13 with any other day yields the day of the first month of the coming year—for example, `YRMODA(1990,13,1)` produces the day number for January 1, 1991.
- The day can range from 0 through 31. Day 0 is the last day of the previous month regardless of whether it is 28, 29, 30, or 31. For example, `YRMODA(1990,3,0)` yields 148791.00, the day number for February 28, 1990.
- The function returns the system-missing value if any of the three arguments is missing or if the arguments do not form a valid date *after* October 14, 1582.
- Since `YRMODA` yields the number of days instead of seconds, you can not display it in date format unless you convert it to the number of seconds.

Extraction Functions

The extraction functions extract subfields from dates or time intervals, targeting the day or a time from a date value. This permits you to classify events by day of the week, season, shift, and so forth.

Each extraction function begins with `XDATE`, followed by a period, the subfunction name (what you want to extract), and an argument.

XDATE.DATE. XDATE.DATE(datevalue). Numeric. Returns the date portion from a numeric value that represents a date. The argument can be a number, a date format variable, or an expression that resolves to a date. To display the result as a date, apply a date format to the variable.

XDATE.HOUR. XDATE.HOUR(datetime). Numeric. Returns the hour (an integer between 0 and 23) from a value that represents a time or a datetime. The argument can be a number, a time or datetime variable or an expression that resolves to a time or datetime value.

XDATE.JDAY. XDATE.JDAY(datevalue). Numeric. Returns the day of the year (an integer between 1 and 366) from a numeric value that represents a date. The argument can be a number, a date format variable, or an expression that resolves to a date.

XDATE.MDAY. XDATE.MDAY(datevalue). Numeric. Returns the day of the month (an integer between 1 and 31) from a numeric value that represents a date. The argument can be a number, a date format variable, or an expression that resolves to a date.

XDATE.MINUTE. XDATE.MINUTE(datetime). Numeric. Returns the minute (an integer between 0 and 59) from a value that represents a time or a datetime. The argument can be a number, a time or datetime variable, or an expression that resolves to a time or datetime value.

XDATE.MONTH. XDATE.MONTH(datevalue). Numeric. Returns the month (an integer between 1 and 12) from a numeric value that represents a date. The argument can be a number, a date format variable, or an expression that resolves to a date.

XDATE.QUARTER. XDATE.QUARTER(datevalue). Numeric. Returns the quarter of the year (an integer between 1 and 4) from a numeric value that represents a date. The argument can be a number, a date format variable, or an expression that resolves to a date.

XDATE.SECOND. XDATE.SECOND(datetime). Numeric. Returns the second (a number between 0 and 60) from a value that represents a time or a datetime. The argument can be a number, a time or datetime variable or an expression that resolves to a time or datetime value.

XDATE.TDAY. XDATE.TDAY(timevalue). Numeric. Returns the number of whole days (as an integer) from a numeric value that represents a time interval. The argument can be a number, a time format variable, or an expression that resolves to a time interval.

XDATE.TIME. XDATE.TIME(datetime). Numeric. Returns the time portion from a value that represents a time or a datetime. The argument can be a number, a time or datetime variable or an expression that resolves to a time or datetime value. To display the result as a time, apply a time format to the variable.

XDATE.WEEK. XDATE.WEEK(datevalue). Numeric. Returns the week number (an integer between 1 and 53) from a numeric value that represents a date. The argument can be a number, a date format variable, or an expression that resolves to a date.

XDATE.WKDAY. XDATE.WKDAY(datevalue). Numeric. Returns the day-of-week number (an integer between 1, Sunday, and 7, Saturday) from a numeric value that represents a date. The argument can be a number, a date format variable, or an expression that resolves to a date.

XDATE.YEAR. XDATE.YEAR(datevalue). Numeric. Returns the year (as a four-digit integer) from a numeric value that represents a date. The argument can be a number, a date format variable, or an expression that resolves to a date.

Example

```
DATA LIST FREE (",")
  /StartDateTime (datetime25).
BEGIN DATA
29-OCT-2003 11:23:02
1 January 1998 1:45:01
21/6/2000 2:55:13
END DATA.
COMPUTE dateonly=XDATE.DATE(StartDateTime).
FORMATS dateonly(ADATE10).
COMPUTE hour=XDATE.HOUR(StartDateTime).
COMPUTE DayofWeek=XDATE.WKDAY(StartDateTime).
COMPUTE WeekofYear=XDATE.WEEK(StartDateTime).
COMPUTE quarter=XDATE.QUARTER(StartDateTime).
```

- The date portion extracted with `XDATE.DATE` returns a date expressed in seconds; so, `FORMATS` is used to display the date in a readable date format.

- Day of the week is an integer between 1 (Sunday) and 7 (Saturday).
- Week of the year is an integer between 1 and 53 (January 1–7 = 1).

Date Differences

The DATEDIFF function calculates the difference between two date values and returns an integer (with any fraction component truncated) in the specified date/time units. The general form of the expression is

```
DATEDIFF(datetime2, datetime1, "unit").
```

where *datetime2* and *datetime1* are both date or time format variables (or numeric values that represent valid date/time values), and "unit" is one of the following string literal values, enclosed in quotes:

- Years
- Quarters
- Months
- Weeks
- Days
- Hours
- Minutes
- Seconds

Example

```
DATA LIST FREE /date1 date2 (2ADATE10).
BEGIN DATA
1/1/2004 2/1/2005
1/1/2004 2/15/2005
1/30/2004 1/29/2005
END DATA.
COMPUTE years=DATEDIFF(date2, date1, "years").
```

- The result will be the integer portion of the number of years between the two dates, with any fractional component truncated.
- One "year" is defined as the same month and day, one year before or after the second date argument.
- For the first two cases, the result is 1, since in both cases the number of years is greater than or equal to 1 and less than 2.
- For the third case, the result is 0, since the difference is one day short of a year based on the definition of year.

Example

```
DATA LIST FREE /date1 date2 (2ADATE10).
BEGIN DATA
1/1/2004 2/1/2004
1/1/2004 2/15/2004
```

```
1/30/2004 2/1/2004
END DATA.
COMPUTE months=DATEDIFF(date2, date1, "months").
```

- The result will be the integer portion of the number of months between the two dates, with any fractional component truncated.
- One "month" is defined as the same day of the month, one calendar month before or after the second date argument.
- For the first two cases, the result will be 1, since both February 1 and February 15, 2004, are greater than or equal to one month and less than two months after January 1, 2004.
- For the third case, the result will be 0. By definition, *any* date in February 2004 will be less than one month after January 30, 2004, resulting in a value of 0.

Date Increments

The `DATESUM` function calculates a date or time value a specified number of units from a given date or time value. The general form of the function is:

```
DATESUM(datevar, value, "unit", "method").
```

- `datevar` is a date/time format variable (or a numeric value that represents a valid date/time value).
- `value` is a positive or negative number. For variable-length units (years, quarters, months), fractional values are truncated to integers.
- `"unit"` is one of the following string literal values enclosed in quotes: years, quarters, months, weeks, days, hours, minutes, seconds.
- `"method"` is an optional specification for variable-length units (years, quarters, months) enclosed in quotes. The method can be `"rollover"` or `"closest"`. The **rollover** method advances excess days into the next month. The **closest** method uses the closest legitimate date within the month. This is the default.

Example

```
DATA LIST FREE /datevar1 (ADATE10).
BEGIN DATA
2/28/2004
2/29/2004
END DATA.
COMPUTE rollover_year=DATESUM(datevar1, 1, "years", "rollover").
COMPUTE closest_year=DATESUM(datevar1, 1, "years", "closest").
COMPUTE fraction_year=DATESUM(datevar1, 1.5, "years").
FORMATS rollover_year closest_year fraction_year (ADATE10).
SUMMARIZE
 /TABLES=datevar1 rollover_year closest_year fraction_year
 /FORMAT=VALIDLIST NOCASENUM
 /CELLS=NONE.
```

Figure 2-15
Results of rollover and closest year calculations

	datevar1	rollover_year	closest_year	fraction_year
1	02/28/2004	02/28/2005	02/28/2005	08/28/2005
2	02/29/2004	03/01/2005	02/28/2005	08/29/2005
3	02/28/2004	02/28/2005	02/28/2005	08/28/2005
4	02/29/2004	03/01/2005	02/28/2005	08/29/2005

- The rollover and closest methods yield the same result when incrementing February 28, 2004, by one year: February 28, 2005.
- Using the rollover method, incrementing February 29, 2004, by one year returns a value of March 1, 2005. Since there is no February 29, 2005, the excess day is rolled over to the next month.
- Using the closest method, incrementing February 29, 2004, by one year returns a value of February 28, 2005, which is the closest day in the same month of the following year.
- The results for *fraction_year* are exactly the same as for *closest_year* because the closest method is used by default, and the value parameter of 1.5 is truncated to 1 for variable-length units.
- All three `COMPUTE` commands create new variables that display values in the default F format, which for a date value is a large integer. The `FORMATS` command specifies the `ADATE` format for the new variables.

Example

```
DATA LIST FREE /datevar1 (ADATE10).
BEGIN DATA
01/31/2003
01/31/2004
03/31/2004
05/31/2004
END DATA.
COMPUTE rollover_month=DATESUM(datevar1, 1, "months", "rollover").
COMPUTE closest_month=DATESUM(datevar1, 1, "months", "closest").
COMPUTE previous_month_rollover =
  DATESUM(datevar1, -1, "months", "rollover").
COMPUTE previous_month_closest =
  DATESUM(datevar1, -1, "months", "closest").
FORMATS rollover_month closest_month
  previous_month_rollover previous_month_closest (ADATE10).
SUMMARIZE
  /TABLES=datevar1 rollover_month closest_month
   previous_month_rollover previous_month_closest
  /FORMAT=VALIDLIST NOCASENUM
  /CELLS=NONE.
```

Figure 2-16
Results of month calculations

	datevar1	rollover_month	closest_month	previous_ month_rollover	previous_ month_closest
1	01/31/2003	03/03/2003	02/28/2003	12/31/2002	12/31/2002
2	01/31/2004	03/02/2004	02/29/2004	12/31/2003	12/31/2003
3	03/31/2004	05/01/2004	04/30/2004	03/02/2004	02/29/2004
4	05/31/2004	07/01/2004	06/30/2004	05/01/2004	04/30/2004

- Using the rollover method, incrementing by one month from January 31 yields a date in March, since February has a maximum of 29 days; and incrementing one month from March 31 and May 31 yields May 1 and July 1, respectively, since April and June each have only 30 days.
- Using the closest method, incrementing by one month from the last day of any month will always yield the last day of the next month.
- Using the rollover method, decrementing by one month (by specifying a negative value parameter) from the last day of a month may sometimes yield unexpected results, since the excess days are rolled back to the original month. For example, one month prior to March 31 yields March 3 for nonleap years and March 2 for leap years.
- Using the closest method, decrementing by one month from the last day of the month will always yield the last day of the previous month.

String Expressions

Expressions involving string variables can be used on `COMPUTE` and `IF` commands and in logical expressions on commands such as `IF`, `DO IF`, `LOOP IF`, and `SELECT IF`.

- A string expression can be a constant enclosed in quotes (for example, `'IL'`), a string function, or a string variable. For more information, see String Functions on p. 101.
- An expression must return a string if the target variable is a string.
- The string returned by a string expression does not have to be the same length as the target variable; no warning messages are issued if the lengths are not the same. If the target variable produced by a `COMPUTE` command is shorter, the result is right-trimmed. If the target variable is longer, the result is right-padded.

String Functions

- The target variable for each string function must be a string and *must have already been declared* (see `STRING`).
- Multiple arguments in a list must be separated by commas.
- When two strings are compared, the case in which they are entered is significant. The `LOWER` and `UPCASE` functions are useful for making comparisons of strings regardless of case.
- String functions that include a byte position or count argument or return a byte position or count may return different results in Unicode mode than in code page mode. For example, é is one byte in code page mode but is two bytes in Unicode mode; so *résumé* is six bytes in code page mode and eight bytes in Unicode mode.
- In Unicode mode, trailing blanks are always removed from the values of string variables in string functions unless explicitly preserved with the `NTRIM` function.
- In code page mode, trailing blanks are always preserved in the values of string variables unless explicitly removed with the `RTRIM` function.

For more information on Unicode mode, see UNICODE Subcommand.

CHAR.INDEX. CHAR.INDEX(haystack, needle[, divisor]). Numeric. Returns a number indicating the character position of the first occurrence of needle in haystack. The optional third argument, divisor, is a number of characters used to divide needle into separate strings. Each substring is

used for searching and the function returns the first occurrence of any of the substrings. For example, CHAR.INDEX(var1, 'abcd') will return the value of the starting position of the complete string "abcd" in the string variable var1; CHAR.INDEX(var1, 'abcd', 1) will return the value of the position of the first occurrence of any of the values in the string; and CHAR.INDEX(var1, 'abcd', 2) will return the value of the first occurrence of either "ab" or "cd". Divisor must be a positive integer and must divide evenly into the length of needle. Returns 0 if needle does not occur within haystack.

CHAR.LENGTH. CHAR.LENGTH(strexpr). Numeric. Returns the length of strexpr in characters, with any trailing blanks removed.

CHAR.LPAD. CHAR.LPAD(strexpr1,length[,strexpr2]). String. Left-pads strexpr1 to make its length the value specified by length using as many complete copies as will fit of strexpr2 as the padding string. The value of length represents the number of characters and must be a positive integer. If the optional argument strexpr2 is omitted, the value is padded with blank spaces.

CHAR.MBLEN. CHAR.MBLEN(strexpr,pos). Numeric. Returns the number of bytes in the character at character position pos of strexpr.

CHAR.RINDEX. CHAR.RINDEX(haystack,needle[,divisor]). Numeric. Returns an integer that indicates the starting character position of the last occurrence of the string needle in the string haystack. The optional third argument, divisor, is the number of characters used to divide needle into separate strings. For example, CHAR.RINDEX(var1, 'abcd') will return the starting position of the last occurrence of the entire string "abcd" in the variable var1; CHAR.RINDEX(var1, 'abcd', 1) will return the value of the position of the last occurrence of any of the values in the string; and CHAR.RINDEX(var1, 'abcd', 2) will return the value of the starting position of the last occurrence of either "ab" or "cd". Divisor must be a positive integer and must divide evenly into the length of needle. If needle is not found, the value 0 is returned.

CHAR.RPAD. CHAR.RPAD(strexpr1,length[,strexpr2]). String. Right-pads strexpr1 with strexpr2 to extend it to the length given by length using as many complete copies as will fit of strexpr2 as the padding string. The value of length represents the number of characters and must be a positive integer. The optional third argument strexpr2 is a quoted string or an expression that resolves to a string. If strepxr2 is omitted, the value is padded with blanks.

CHAR.SUBSTR. CHAR.SUBSTR(strexpr,pos[,length]). String. Returns the substring beginning at character position pos of strexpr. The optional third argument represents the number of characters in the substring. If the optional argument length is omitted, returns the substring beginning at character position pos of strexpr and running to the end of strexpr. For example CHAR.SUBSTR('abcd', 2) returns 'bcd' and CHAR.SUBSTR('abcd', 2, 2) returns 'bc'.

CONCAT. CONCAT(strexpr,strexpr[,..]). String. Returns a string that is the concatenation of all its arguments, which must evaluate to strings. This function requires two or more arguments. In code page mode, if strexpr is a string variable, use RTRIM if you only want the actual string value without the right-padding to the defined variable width. For example, CONCAT(RTRIM(stringvar1), RTRIM(stringvar2)).

LENGTH. LENGTH(strexpr). Numeric. Returns the length of strexpr in bytes, which must be a string expression. For string variables, in Unicode mode this is the number of bytes in each value, excluding trailing blanks, but in code page mode this is the defined variable length, including

trailing blanks. To get the length (in bytes) without trailing blanks in code page mode, use LENGTH(RTRIM(strexpr)).

LOWER. LOWER(strexpr). String. Returns strexpr with uppercase letters changed to lowercase and other characters unchanged. The argument can be a string variable or a value. For example, LOWER(name1) returns charles if the value of name1 is Charles.

LTRIM. LTRIM(strexpr[,char]). String. Returns strexpr with any leading instances of char removed. If char is not specified, leading blanks are removed. Char must resolve to a single character.

MAX. MAX(value,value[,..]). Numeric or string. Returns the maximum value of its arguments that have valid values. This function requires two or more arguments. For numeric values, you can specify a minimum number of valid arguments for this function to be evaluated.

MIN. MIN(value,value[,..]). Numeric or string. Returns the minimum value of its arguments that have valid, nonmissing values. This function requires two or more arguments. For numeric values, you can specify a minimum number of valid arguments for this function to be evaluated.

MBLEN.BYTE. MBLEN.BYTE(strexpr,pos). Numeric. Returns the number of bytes in the character at byte position pos of strexpr.

NORMALIZE. NORMALIZE(strexp). String. Returns the normalized version of strexp. In Unicode mode, it returns Unicode NFC. In code page mode, it has no effect and returns strexp unmodified. The length of the result may be different from the length of the input.

NTRIM. NTRIM(varname). Returns the value of varname, without removing trailing blanks. The value of varname must be a variable name; it cannot be an expression.

REPLACE. REPLACE(a1, a2, a3[, a4]). String. In a1, instances of a2 are replaced with a3. The optional argument a4 specifies the number of occurrences to replace; if a4 is omitted, all occurrences are replaced. Arguments a1, a2, and a3 must resolve to string values (literal strings enclosed in quotes or string variables), and the optional argument a4 must resolve to a non-negative integer. For example, REPLACE("abcabc", "a", "x") returns a value of "xbcxbc" and REPLACE("abcabc", "a", "x", 1) returns a value of "xbcabc".

RTRIM. RTRIM(strexpr[,char]). String. Trims trailing instances of char within strexpr. The optional second argument char is a single quoted character or an expression that yields a single character. If char is omitted, trailing blanks are trimmed.

STRUNC. STRUNC(strexp, length). String. Returns strexp truncated to length (in bytes) and then trimmed of any trailing blanks. Truncation removes any fragment of a character that would be truncated.

UPCASE. UPCASE(strexpr). String. Returns strexpr with lowercase letters changed to uppercase and other characters unchanged.

Deprecated String Functions

The following functions provide functionality similar to the newer `CHAR` functions, but they operate at the byte level rather than the character level. For example, the `INDEX` function returns the byte position of *needle* within *haystack*, whereas `CHAR.INDEX` returns the character position. These functions are supported primarily for compatibility with previous releases.

INDEX. INDEX(haystack,needle[,divisor]). Numeric. Returns a number that indicates the byte position of the first occurrence of needle in haystack. The optional third argument, divisor, is a number of bytes used to divide needle into separate strings. Each substring is used for searching and the function returns the first occurrence of any of the substrings. Divisor must be a positive integer and must divide evenly into the length of needle. Returns 0 if needle does not occur within haystack.

LPAD. LPAD(strexpr1,length[,strexpr2]). String. Left-pads strexpr1 to make its length the value specified by length using as many complete copies as will fit of strexpr2 as the padding string. The value of length represents the number of bytes and must be a positive integer. If the optional argument strexpr2 is omitted, the value is padded with blank spaces.

RINDEX. RINDEX(haystack,needle[,divisor]). Numeric. Returns an integer that indicates the starting byte position of the last occurrence of the string needle in the string haystack. The optional third argument, divisor, is the number of bytes used to divide needle into separate strings. Divisor must be a positive integer and must divide evenly into the length of needle. If needle is not found, the value 0 is returned.

RPAD. RPAD(strexpr1,length[,strexpr2]). String. Right-pads strexpr1 with strexpr2 to extend it to the length given by length using as many complete copies as will fit of strexpr2 as the padding string. The value of length represents the number of bytes and must be a positive integer. The optional third argument strexpr2 is a quoted string or an expression that resolves to a string. If strepxr2 is omitted, the value is padded with blanks.

SUBSTR. SUBSTR(strexpr,pos[,length]). String. Returns the substring beginning at byte position pos of strexpr. The optional third argument represents the number of bytes in the substring. If the optional argument length is omitted, returns the substring beginning at byte position pos of strexpr and running to the end of strexpr. When used on the left side of an equals sign, the substring is replaced by the string specified on the right side of the equals sign. The rest of the original string remains intact. For example, `SUBSTR(ALPHA6,3,1)='*'` changes the third character of all values for *ALPHA6* to *. If the replacement string is longer or shorter than the substring, the replacement is truncated or padded with blanks on the right to an equal length.

Example

```
STRING stringVar1 stringVar2 stringVar3 (A22).
COMPUTE stringVar1='  Does this'.
COMPUTE stringVar2='ting work?'.
COMPUTE stringVar3=
  CONCAT(RTRIM(LTRIM(stringVar1)), " ",
  REPLACE(stringVar2, "ting", "thing")).
```

- The `CONCAT` function concatenates the values of *stringVar1* and *stringVar2*, inserting a space as a literal string (`" "`) between them.
- The `RTRIM` function strips off trailing blanks from *stringVar1*. In code page mode, this is necessary to eliminate excessive space between the two concatenated string values because in code page mode all string variable values are automatically right-padded to the defined width of the string variables. In Unicode mode, this has no effect because trailing blanks are automatically removed from string variable values in Unicode mode.

- The LTRIM function removes the leading spaces from the beginning of the value of *stringVar1*.
- The REPLACE function replaces the misspelled "ting" with "thing" in *stringVar2*.

The final result is a string value of *"Does this thing work?"*

Example

This example extracts the numeric components from a string telephone number into three numeric variables.

```
DATA LIST FREE (",") /telephone (A16).
BEGIN DATA
111-222-3333
222 - 333 - 4444
333-444-5555
444 - 555-6666
555-666-0707
END DATA.
STRING #telstr(A16).
COMPUTE #telstr = telephone.
VECTOR tel(3,f4).
LOOP #i = 1 to 2.
- COMPUTE #dash = CHAR.INDEX(#telstr,"-").
- COMPUTE tel(#i) = NUMBER(CHAR.SUBSTR(#telstr,1,#dash-1),f10).
- COMPUTE #telstr = CHAR.SUBSTR(#telstr,#dash+1).
END LOOP.
COMPUTE tel(3) = NUMBER(#telstr,f10).
EXECUTE.
FORMATS tel1 tel2 (N3) tel3 (N4).
```

- A temporary (scratch) string variable, *#telstr*, is declared and set to the value of the original string telephone number.
- The VECTOR command creates three numeric variables—*tel1, tel2,* and *tel3*—and creates a vector containing those variables.
- The LOOP structure iterates twice to produce the values for *tel1* and *tel2*.
- COMPUTE #dash = CHAR.INDEX(#telstr,"-") creates another temporary variable, *#dash*, that contains the position of the first dash in the string value.
- On the first iteration, COMPUTE tel(#i) = NUMBER(CHAR.SUBSTR(#telstr,1,#dash-1),f10) extracts everything prior to the first dash, converts it to a number, and sets *tel1* to that value.
- COMPUTE #telstr = CHAR.SUBSTR(#telstr,#dash+1) then sets *#telstr* to the remaining portion of the string value after the first dash.
- On the second iteration, COMPUTE #dash... sets *#dash* to the position of the "first" dash in the modified value of *#telstr*. Since the area code and the original first dash have been removed from *#telstr*, this is the position of the dash between the exchange and the number.
- COMPUTE tel(#)... sets *tel2* to the numeric value of everything up to the "first" dash in the modified version of *#telstr*, which is everything after the first dash and before the second dash in the original string value.

- `COMPUTE #telstr...` then sets *#telstr* to the remaining segment of the string value—everything after the "first" dash in the modified value, which is everything after the second dash in the original value.
- After the two loop iterations are complete, `COMPUTE tel(3) = NUMBER(#telstr,f10)` sets *tel3* to the numeric value of the final segment of the original string value.

String/Numeric Conversion Functions

NUMBER. NUMBER(strexpr,format). Numeric. Returns the value of the string expression strexpr as a number. The second argument, format, is the numeric format used to read strexpr. For example, NUMBER(stringDate,DATE11) converts strings containing dates of the general format dd-mmm-yyyy to a numeric number of seconds that represent that date. (To display the value as a date, use the FORMATS or PRINT FORMATS command.) If the string cannot be read using the format, this function returns system-missing.

STRING. STRING(numexpr,format). String. Returns the string that results when numexpr is converted to a string according to format. STRING(-1.5,F5.2) returns the string value '-1.50'. The second argument format must be a format for writing a numeric value.

Example

```
DATA LIST FREE /tel1 tel2 tel3.
BEGIN DATA
123 456 0708
END DATA.
STRING telephone (A12).
COMPUTE telephone=
  CONCAT(STRING(tel1,N3), "-", STRING(tel2, N3), "-", STRING(tel3, N4)).
```

- A new string variable, *telephone*, is declared to contain the computed string value.
- The three numeric variables are converted to strings and concatenated with dashes between the values.
- The numeric values are converted using N format to preserve any leading zeros.

LAG Function

LAG. LAG(variable[, n]). Numeric or string. The value of variable in the previous case or n cases before. The optional second argument, n, must be a positive integer; the default is 1. For example, prev4=LAG(gnp,4) returns the value of gnp for the fourth case before the current one. The first four cases have system-missing values for prev4.

- The result is of the same type (numeric or string) as the variable specified as the first argument.
- The first *n* cases for string variables are set to blanks. For example, if `PREV2=LAG (LNAME,2)` is specified, blanks will be assigned to the first two cases for *PREV2*.
- When `LAG` is used with commands that select cases (for example, `SELECT IF` and `SAMPLE`), `LAG` counts cases *after* case selection, even if specified before these commands. For more information, see Command Order on p. 36.

Note: In a series of transformation commands without any intervening EXECUTE commands or other commands that read the data, lag functions are calculated after all other transformations, regardless of command order. For example,

```
COMPUTE lagvar=LAG(var1).
COMPUTE var1=var1*2.
```

and

```
COMPUTE lagvar=LAG(var1).
EXECUTE.
COMPUTE var1=var1*2.
```

yield very different results for the value of *lagvar*, since the former uses the transformed value of *var1* while the latter uses the original value.

VALUELABEL Function

VALUELABEL. VALUELABEL(varname). String. Returns the value label for the value of variable or an empty string if there is no label for the value. The value of varname must be a variable name; it cannot be an expression.

Example

```
STRING labelvar (A120).
COMPUTE labelvar=VALUELABEL(var1).
DO REPEAT varlist=var2, var3, var4
         /newvars=labelvar2, labelvar3, labelvar4.
- STRING newvars(A120).
- COMPUTE newvars=VALUELABEL(varlist).
END REPEAT.
```

Logical Expressions

Logical expressions can appear on the IF, SELECT IF, DO IF, ELSE IF, LOOP IF, and END LOOP IF commands. A logical expression is evaluated as true or false, or as missing if it is indeterminate. A logical expression returns 1 if the expression is true, 0 if it is false, or system-missing if it is missing. Thus, logical expressions can be any expressions that yield this three-value logic.

- The simplest logical expression is a logical variable. A logical variable is any numeric variable that has the values 1, 0, or system-missing. Logical variables cannot be strings.
- Logical expressions can be simple logical variables or relations, or they can be complex logical tests involving variables, constants, functions, relational operators, logical operators, and parentheses to control the order of evaluation.
- On an IF command, a logical expression that is true causes the assignment expression to be executed. A logical expression that returns missing has the same effect as one that is false—that is, the assignment expression is not executed and the value of the target variable is not altered.

- On a DO IF command, a logical expression that is true causes the execution of the commands immediately following the DO IF, up to the next ELSE IF, ELSE, or END IF. If it is false, the next ELSE IF or ELSE command is evaluated. If the logical expression returns missing for each of these, the entire structure is skipped.
- On a SELECT IF command, a logical expression that is true causes the case to be selected. A logical expression that returns missing has the same effect as one that is false—that is, the case is not selected.
- On a LOOP IF command, a logical expression that is true causes looping to begin (or continue). A logical expression that returns missing has the same effect as one that is false—that is, the structure is skipped.
- On an END LOOP IF command, a logical expression that is false returns control to the LOOP command for that structure, and looping continues. If it is true, looping stops and the structure is terminated. A logical expression that returns a missing value has the same effect as one that is true—that is, the structure is terminated.

Example

```
DATA LIST FREE (",") /a.
BEGIN DATA
1, , 1 , ,
END DATA.
COMPUTE b=a.
* The following does NOT work since the second condition
  is never evaluated.
DO IF a=1.
COMPUTE a1=1.
ELSE IF MISSING(a).
COMPUTE a1=2.
END IF.
* On the other hand the following works.
DO IF MISSING(b).
COMPUTE b1=2.
ELSE IF b=1.
COMPUTE b1=1.
END IF.
```

- The first DO IF will never yield a value of 2 for *a1* because if *a* is missing, then DO IF a=1 evaluates as missing and control passes immediately to END IF. So *a1* will either be 1 or missing.
- In the second DO IF, however, we take care of the missing condition first; so if the value of *b* is missing, DO IF MISSING(b) evaluates as true and *b1* is set to 2; otherwise, *b1* is set to 1.

String Variables in Logical Expressions

String variables, like numeric variables, can be tested in logical expressions.

- String variables must be declared before they can be used in a string expression.
- String variables cannot be compared to numeric variables.
- If strings of different lengths are compared, the shorter string is right-padded with blanks to equal the length of the longer string.

- The magnitude of strings can be compared using LT, GT, and so on, but the outcome depends on the sorting sequence of the computer. Use with caution.
- User-missing string values are treated the same as nonmissing string values when evaluating string variables in logical expressions. In other words, all string variable values are treated as valid, nonmissing values in logical expressions.

Relational Operators

A relation is a logical expression that compares two values using a *relational operator*. In the command

```
IF (X EQ 0) Y=1
```

the variable *X* and 0 are expressions that yield the values to be compared by the EQ relational operator. The following are the relational operators:

Symbol	Definition
EQ or =	Equal to
NE or ~= or ¬ = or <>	Not equal to
LT or <	Less than
LE or <=	Less than or equal to
GT or >	Greater than
GE or >=	Greater than or equal to

- The expressions in a relation can be variables, constants, or more complicated arithmetic expressions.
- Blanks (not commas) must be used to separate the relational operator from the expressions. To make the command more readable, use extra blanks or parentheses.
- For string values, "less than" and "greater than" results can vary by locale even for the same set of characters, since the national collating sequence is used. Language order, not ASCII order, determines where certain characters fall in the sequence.

NOT Logical Operator

The NOT logical operator reverses the true/false outcome of the expression that immediately follows.

- The NOT operator affects only the expression that immediately follows, unless a more complex logical expression is enclosed in parentheses.
- You can substitute ~ or ¬ for NOT as a logical operator.
- NOT can be used to check whether a numeric variable has the value 0, 1, or any other value. For example, all scratch variables are initialized to 0. Therefore, NOT (#ID) returns false or missing when *#ID* has been assigned a value other than 0.

AND and OR Logical Operators

Two or more relations can be logically joined using the logical operators AND and OR. Logical operators combine relations according to the following rules:

- The ampersand (&) symbol is a valid substitute for the logical operator AND. The vertical bar (|) is a valid substitute for the logical operator OR.
- Only one logical operator can be used to combine two relations. However, multiple relations can be combined into a complex logical expression.
- Regardless of the number of relations and logical operators used to build a logical expression, the result is either true, false, or indeterminate because of missing values.
- Operators or expressions cannot be implied. For example, `X EQ 1 OR 2` is illegal; you must specify `X EQ 1 OR X EQ 2`.
- The ANY and RANGE functions can be used to simplify complex expressions.

AND	*Both relations must be true for the complex expression to be true.*
OR	*If either relation is true, the complex expression is true.*

The following table lists the outcomes for AND and OR combinations.

Table 2-3
Logical outcomes

Expression	Outcome	Expression	Outcome
true AND true	= true	true OR true	= true
true AND false	= false	true OR false	= true
false AND false	= false	false OR false	= false
true AND missing	= missing	true OR missing	= true*
missing AND missing	= missing	missing OR missing	= missing
false AND missing	= false*	false OR missing	= missing

* Expressions where the outcome can be evaluated with incomplete information. For more information, see Missing Values in Logical Expressions on p. 116.

Example

```
DATA LIST FREE /var1 var2 var3.
BEGIN DATA
1 1 1
1 2 1
1 2 3
4 2 4
END DATA.
SELECT IF var1 = 4 OR ((var2 > var1) AND (var1 <> var3)).
```

- Any case that meets the first condition—`var1 = 4`—will be selected, which in this example is only the last case.

- Any case that meets the second condition will also be selected. In this example, only the third case meets this condition, which contains two criteria: *var2* is greater than *var1* and *var1* is not equal to *var3*.

Order of Evaluation

- When arithmetic operators and functions are used in a logical expression, the order of operations is functions and arithmetic operations first, then relational operators, and then logical operators.
- When more than one logical operator is used, NOT is evaluated first, then AND, and then OR.
- To change the order of evaluation, use parentheses.

Logical Functions

- Each argument to a logical function (expression, variable name, or constant) must be separated by a comma.
- The target variable for a logical function must be numeric.
- The functions RANGE and ANY can be useful shortcuts to more complicated specifications on the IF, DO IF, and other conditional commands. For example, for non-missing values, the command

  ```
  SELECT IF ANY(REGION,"NW","NE","SE").
  ```

  is equivalent to

  ```
  SELECT IF (REGION EQ "NW" OR REGION EQ "NE" OR REGION EQ "SE").
  ```

RANGE. RANGE(test,lo,hi[,lo,hi,..]). Logical. Returns 1 or true if test is within any of the inclusive range(s) defined by the pairs lo, hi. Arguments must be all numeric or all strings of the same length, and each of the lo, hi pairs must be ordered with lo <= hi. Note: For string values, results can vary by locale even for the same set of characters, since the national collating sequence is used. Language order, not ASCII order, determines where certain characters fall in the sequence.

ANY. ANY(test,value[,value,...]). Logical. Returns 1 or true if the value of test matches any of the subsequent values; returns 0 or false otherwise. This function requires two or more arguments. For example, ANY(var1, 1, 3, 5) returns 1 if the value of var1 is 1, 3, or 5 and 0 for other values. ANY can also be used to scan a list of variables or expressions for a value. For example, ANY(1, var1, var2, var3) returns 1 if any of the three specified variables has a value of 1 and 0 if all three variables have values other than 1.

See Treatment of Missing Values in Arguments for information on how missing values are handled by the ANY and RANGE functions.

Scoring Expressions (SPSS Server)

Scoring functions are available only if you have access to SPSS Server.

Scoring expressions apply model XML from an external file to the active dataset and generate predicted values, predicted probabilities, and other values based on that model.

- Scoring expressions must be preceded by a MODEL HANDLE command that identifies the external XML model file and optionally does variable mapping.
- Scoring expressions require two arguments: the first identifies the model, and the second identifies the scoring function. An optional third argument allows users to obtain the probability (for each case) associated with a selected category, in the case of a categorical target variable.
- Procedures that can generate model XML include REGRESSION, DISCRIMINANT, and TWOSTEP CLUSTER, plus some procedures available in some add-on options. See the MODEL HANDLE command for more information.
- Prior to applying scoring functions to a set of data, a data validation analysis is performed. The analysis includes checking that data are of the correct type as well as checking that the data values are in the set of allowed values defined in the model. For example, for categorical variables, a value that is neither a valid category nor defined as user-missing would be treated as an invalid value. Values that are found to be invalid are treated as system-missing.

The following scoring expressions are available:

ApplyModel. ApplyModel(handle, "function", category). Numeric. Applies a particular scoring function to the input case data using the model specified by handle and where "function" is one of the following string literal values enclosed in quotes: predict, stddev, probability, confidence, nodeid, cumhazard. The model handle is the name associated with the external XML file, as defined on the MODEL HANDLE command. The optional category is only valid if the function is "probability", and must have the same data type as the target variable. It specifies that the probability should be calculated for a specific category. ApplyModel returns system-missing if a value can not be computed. String values must be enclosed in quotes. For example, `ApplyModel(name1, 'probability', 'reject')`, where `name1` is the model's handle name and `'reject'` is a valid category for a target variable that is a string.

StrApplyModel. StrApplyModel(handle, "function", category). String. Applies a particular scoring function to the input case data using the model specified by handle and where "function" is one of the following string literal values enclosed in quotes: predict, stddev, probability, confidence, nodeid, cumhazard. The model handle is the name associated with the external XML file, as defined on the MODEL HANDLE command. The optional category is only valid if the function is "probability", and must have the same data type as the target variable. It specifies that the probability should be calculated for a specific category. StrApplyModel returns a blank string if a value cannot be computed.

The following scoring functions are available:

PREDICT	*Returns the predicted value of the target variable.*
STDDEV	*Standard deviation.*
PROBABILITY	*Probability associated with a particular category of a target variable.* Applies only to categorical variables. In the absence of the optional third parameter, *category*, this is the probability that the predicted category is the correct one for the target variable. If a particular category is specified, then this is the probability that the specified category is the correct one for the target variable.
CONFIDENCE	*A probability measure associated with the predicted value of a categorical target variable.* Applies only to categorical variables.

NODEID *The terminal node number.* Applies only to tree models.

CUMHAZARD *Cumulative hazard value.* Applies only to Cox regression models.

The following table lists the set of scoring functions available for each type of model that supports scoring. The function type denoted as `PROBABILITY (category)` refers to specification of a particular category (the optional third parameter) for the `PROBABILITY` function.

Table 2-4
Supported functions by model type

Model type	Supported functions
Tree (categorical target)	`PREDICT`, `PROBABILITY`, `PROBABILITY (category)`, `CONFIDENCE`, `NODEID`
Tree (scale target)	`PREDICT`, `NODEID`
Boosted Tree (C5.0)	`PREDICT`, `CONFIDENCE`
Linear Regression	`PREDICT`, `STDDEV`
Binary Logistic Regression	`PREDICT`, `PROBABILITY`, `PROBABILITY (category)`, `CONFIDENCE`
Conditional Logistic Regression	`PREDICT`
Multinomial Logistic Regression	`PREDICT`, `PROBABILITY`, `PROBABILITY (category)`, `CONFIDENCE`
General Linear Model	`PREDICT`, `STDDEV`
Discriminant	`PREDICT`, `PROBABILITY`
TwoStep Cluster	`PREDICT`
K-Means Cluster	`PREDICT`, `CONFIDENCE`
Kohonen	`PREDICT`
Neural Net (categorical target)	`PREDICT`, `PROBABILITY`, `PROBABILITY (category)`, `CONFIDENCE`
Neural Net (scale target)	`PREDICT`
Naive Bayes	`PREDICT`, `PROBABILITY`, `PROBABILITY (category)`, `CONFIDENCE`
Anomaly Detection	`PREDICT`
Ruleset	`PREDICT`, `CONFIDENCE`
Generalized Linear Model (categorical target)	`PREDICT`, `PROBABILITY`, `PROBABILITY (category)`, `CONFIDENCE`
Generalized Linear Model (scale target)	`PREDICT`, `STDDEV`
Ordinal Multinomial Regression	`PREDICT`, `PROBABILITY`, `PROBABILITY (category)`, `CONFIDENCE`
Cox Regression	`PREDICT`, `CUMHAZARD`

- For the Binary Logistic Regression, Multinomial Logistic Regression, and Naive Bayes models, the value returned by the `CONFIDENCE` function is identical to that returned by the `PROBABILITY` function.
- For the K-Means model, the value returned by the `CONFIDENCE` function is the least distance.
- For tree and ruleset models, the confidence can be interpreted as an adjusted probability of the predicted category and is always less than the value given by `PROBABILITY`. For these models, the confidence value is more reliable than the value given by `PROBABILITY`.

- For neural network models, the confidence provides a measure of whether the predicted category is much more likely than the second-best predicted category.
- For Ordinal Multinomial Regression and Generalized Linear Model, the PROBABILITY function is supported when the target variable is binary.

Missing Values

Functions and simple arithmetic expressions treat missing values in different ways. In the expression

```
(var1+var2+var3)/3
```

the result is missing if a case has a missing value for any of the three variables.

In the expression

```
MEAN(var1, var2, var3)
```

the result is missing only if the case has missing values for all three variables.

For statistical functions, you can specify the minimum number of arguments that must have nonmissing values. To do so, type a period and the minimum number after the function name, as in:

```
MEAN.2(var1, var2, var3)
```

The following sections contain more information on the treatment of missing values in functions and transformation expressions, including special missing value functions.

Treatment of Missing Values in Arguments

If the logic of an expression is indeterminate because of missing values, the expression returns a missing value and the command is not executed. The following table summarizes how missing values are handled in arguments to various functions.

Table 2-5
Missing values in arguments

Function	Returns system-missing if
MOD (x1,x2)	x1 is missing, or x2 is missing and x1 is not 0.
MAX.n (x1,x2,...xk) MEAN.n (x1,x2,...xk) MIN.n (x1,x2,...x1) SUM.n (x1,x2,...xk)	Fewer than *n* arguments are valid; the default *n* is 1.
CFVAR.n (x1,x2,...xk) SD.n (x1,x2,...xk) VARIANCE.n (x1,x2,...xk)	Fewer than *n* arguments are valid; the default *n* is 2.

Function	Returns system-missing if
LPAD(x1,x2,x3) LTRIM(x1,x2) RTRIM(x1,x2) RPAD(x1,x2,x3)	x1 or x2 is illegal or missing.
SUBSTR(x1,x2,x3)	x2 or x3 is illegal or missing.
NUMBER(x,format) STRING(x,format)	The conversion is invalid.
INDEX(x1,x2,x3) RINDEX(x1,x2,x3)	x3 is invalid or missing.
LAG (x,n)	x is missing *n* cases previously (and always for the first *n* cases); the default *n* is 1.
ANY (x,x1,x2,...xk)	For numeric values, if x is missing or all the remaining arguments are missing, the result is system-missing. For string values, user-missing value are treated as valid values, and the result is never missing.
RANGE (x,x1,x2,...xk1,xk2)	For numeric values, the result is system-missing if: ■ x is missing, or ■ all the ranges defined by the remaining arguments are missing, or ■ any range has a starting value that is higher than the ending value. A numeric range is missing if either of the arguments that define the range is missing. This includes ranges for which one of the arguments is equal to the value of the first argument in the expression. For example: RANGE(x, x1, x2) is missing if any of the arguments is missing, even if x1 or x2 is equal to x. For string values, user-missing values are treated as valid values, and the result is only missing if any range has a starting value that is higher than the ending value.
VALUE (x)	x is system-missing.
MISSING (x) NMISS (x1,x2,...xk) NVALID (x1,x2,...xk) SYSMIS (x)	Never.

- Any function that is not listed in this table returns the system-missing value when the argument is missing.
- The system-missing value is a displayed as a period (.) for numeric variables.
- String variables do not have system-missing values. An invalid string expression nested within a complex transformation yields a null string, which is passed to the next level of operation and treated as missing. However, an invalid string expression that is not nested is displayed as a blank string and is *not* treated as missing.

Missing Values in Numeric Expressions

- Most numeric expressions receive the system-missing value when any one of the values in the expression is missing.
- Some arithmetic operations involving 0 can be evaluated even when the variables have missing values. These operations are:

Expression	Result
`0 * missing`	0
`0 / missing`	0
`MOD(0,missing)`	0

- The *.n* suffix can be used with the statistical functions SUM, MEAN, MIN, MAX, SD, VARIANCE, and CFVAR to specify the number of valid arguments that you consider acceptable. The default of *n* is 2 for SD, VARIANCE, and CFVAR, and 1 for other statistical functions. For example,

```
COMPUTE FACTOR = SUM.2(SCORE1 TO SCORE3).
```

computes the variable *FACTOR* only if a case has valid information for at least two scores. *FACTOR* is assigned the system-missing value if a case has valid values for fewer than two scores. If the number specified exceeds the number of arguments in the function, the result is system-missing.

Missing Values in String Expressions

- If the numeric argument (which can be an expression) for the functions LPAD and RPAD is illegal or missing, the result is a null string. If the padding or trimming is the only operation, the string is then padded to its entire length with blanks. If the operation is nested, the null string is passed to the next nested level.
- If a numeric argument to SUBSTR is illegal or missing, the result is a null string. If SUBSTR is the only operation, the string is blank. If the operation is nested, the null string is passed to the next nested level.
- If a numeric argument to INDEX or RINDEX is illegal or missing, the result is system-missing.

Missing Values in Logical Expressions

In a simple relation, the logic is indeterminate if the expression on either side of the relational operator is missing. When two or more relations are joined by logical operators AND and OR, a missing value is always returned if all of the relations in the expression are missing. However, if any one of the relations can be determined, SPSS tries to return true or false according to the logical outcomes. For more information, see AND and OR Logical Operators on p. 110.

- When two relations are joined with the AND operator, the logical expression can never be true if one of the relations is indeterminate. The expression can, however, be false.
- When two relations are joined with the OR operator, the logical expression can never be false if one relation returns missing. The expression, however, can be true.

Missing Value Functions

- Each argument to a missing-value function (expression, variable name, or constant) must be separated by a comma.
- With the exception of the MISSING function, only numeric values can be used as arguments in missing-value functions.
- The keyword TO can be used to refer to a set of variables in the argument list for functions NMISS and NVALID.
- The functions MISSING and SYSMIS are logical functions and can be useful shortcuts to more complicated specifications on the IF, DO IF, and other conditional commands.

VALUE. VALUE(variable). Numeric or string. Returns the value of variable, ignoring user missing-value definitions for variable, which must be a variable name or a vector reference to a variable name.

MISSING. MISSING(variable). Logical. Returns 1 or true if variable has a system- or user-missing value. The argument should be a variable name in the active dataset.

SYSMIS. SYSMIS(numvar). Logical. Returns 1 or true if the value of numvar is system-missing. The argument numvar must be the name of a numeric variable in the active dataset.

NMISS. NMISS(variable[,..]). Numeric. Returns a count of the arguments that have system- and user-missing values. This function requires one or more arguments, which should be variable names in the active dataset.

NVALID. NVALID(variable[,..]). Numeric. Returns a count of the arguments that have valid, nonmissing values. This function requires one or more arguments, which should be variable names in the active dataset.

2SLS

2SLS is available in the Regression Models option.

```
2SLS [EQUATION=]dependent variable WITH predictor variable
 [/[EQUATION=]dependent variable...]
  /INSTRUMENTS=varlist
 [/ENDOGENOUS=varlist]
 [/{CONSTANT**}
   {NOCONSTANT}
 [/PRINT=COV]
 [/SAVE = [PRED] [RESID]]
 [/APPLY[='model name']]
```

**Default if the subcommand or keyword is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
2SLS VAR01 WITH VAR02 VAR03
  /INSTRUMENTS VAR03 LAGVAR01.
```

Overview

2SLS performs two-stage least-squares regression to produce consistent estimates of parameters when one or more predictor variables might be correlated with the disturbance. This situation typically occurs when your model consists of a system of simultaneous equations wherein endogenous variables are specified as predictors in one or more of the equations. The two-stage least-squares technique uses instrumental variables to produce regressors that are not contemporaneously correlated with the disturbance. Parameters of a single equation or a set of simultaneous equations can be estimated.

Options

New Variables. You can change NEWVAR settings on the TSET command prior to 2SLS to evaluate the regression statistics without saving the values of predicted and residual variables, or you can save the new values to replace the values that were saved earlier, or you can save the new values without erasing values that were saved earlier (see the TSET command). You can also use the SAVE subcommand on 2SLS to override the NONE or the default CURRENT settings on NEWVAR.

Covariance Matrix. You can obtain the covariance matrix of the parameter estimates in addition to all of the other output by specifying PRINT=DETAILED on the TSET command prior to 2SLS. You can also use the PRINT subcommand to obtain the covariance matrix, regardless of the setting on PRINT.

Basic Specification

The basic specification is at least one EQUATION subcommand and one INSTRUMENTS subcommand.

- For each specified equation, 2SLS estimates and displays the regression analysis-of-variance table, regression standard error, mean of the residuals, parameter estimates, standard errors of the parameter estimates, standardized parameter estimates, *t* statistic significance tests and probability levels for the parameter estimates, tolerance of the variables, and correlation matrix of the parameter estimates.
- If the setting on NEWVAR is either ALL or the default CURRENT, two new variables containing the predicted and residual values are automatically created for each equation. The variables are labeled and added to the active dataset.

Subcommand Order

- Subcommands can be specified in any order.

Syntax Rules

- The INSTRUMENTS subcommand must specify at least as many variables as are specified after WITH on the longest EQUATION subcommand.
- If a subcommand is specified more than once, the effect is cumulative (except for the APPLY subcommand, which executes only the last occurrence).

Operations

- 2SLS cannot produce forecasts beyond the length of any regressor series.
- 2SLS honors the WEIGHT command.
- 2SLS uses listwise deletion of missing data. Whenever a variable is missing a value for a particular observation, that observation will not be used in any of the computations.

EQUATION Subcommand

EQUATION specifies the structural equations for the model and is required. The actual keyword EQUATION is optional.

- An equation specifies a single dependent variable, followed by keyword WITH and one or more predictor variables.
- You can specify more than one equation. Multiple equations are separated by slashes.

Example

```
2SLS EQUATION=Y1 WITH X1 X2
```

```
  /INSTRUMENTS=X1 LAGX2 X3.
```

- In this example, *Y1* is the dependent variable, and *X1* and *X2* are the predictors. The instruments that are used to predict the *X2* values are *X1*, *LAGX2*, and *X3*.

INSTRUMENTS Subcommand

INSTRUMENTS specifies the instrumental variables. These variables are used to compute predicted values for the endogenous variables in the first stage of 2SLS.

- At least one INSTRUMENTS subcommand must be specified.
- If more than one INSTRUMENTS subcommand is specified, the effect is cumulative. All variables that are named on INSTRUMENTS subcommands are used as instruments to predict all the endogenous variables.
- Any variable in the active dataset can be named as an instrument.
- Instrumental variables can be specified on the EQUATION subcommand, but this specification is not required.
- The INSTRUMENTS subcommand must name at least as many variables as are specified after WITH on the longest EQUATION subcommand.
- If all the predictor variables are listed as the only INSTRUMENTS, the results are the same as results from ordinary least-squares regression.

Example

```
2SLS DEMAND WITH PRICE, INCOME
  /PRICE WITH DEMAND, RAINFALL, LAGPRICE
  /INSTRUMENTS=INCOME, RAINFALL, LAGPRICE.
```

- The endogenous variables are PRICE and DEMAND.
- The instruments to be used to compute predicted values for the endogenous variables are INCOME, RAINFALL, and LAGPRICE.

ENDOGENOUS Subcommand

All variables that are not specified on the INSTRUMENTS subcommand are used as endogenous variables by 2SLS. The ENDOGENOUS subcommand simply allows you to document what these variables are.

- Computations are not affected by specifications on the ENDOGENOUS subcommand.

Example

```
2SLS Y1 WITH X1 X2 X3
  /INSTRUMENTS=X2 X4 LAGY1
  /ENDOGENOUS=Y1 X1 X3.
```

- In this example, the ENDOGENOUS subcommand is specified to document the endogenous variables.

CONSTANT and NOCONSTANT Subcommands

Specify CONSTANT or NOCONSTANT to indicate whether a constant term should be estimated in the regression equation. The specification of either subcommand overrides the CONSTANT setting on the TSET command for the current procedure.

- CONSTANT is the default and specifies that the constant term is used as an instrument.
- NOCONSTANT eliminates the constant term.

SAVE Subcommand

SAVE saves the values of predicted and residual variables that are generated during the current session to the end of the active dataset. The default names *FIT_n* and *ERR_n* will be generated, where *n* increments each time variables are saved for an equation. SAVE overrides the NONE or the default CURRENT setting on NEWVAR for the current procedure.

PRED *Save the predicted value.* The new variable is named *FIT_n*, where *n* increments each time a predicted or residual variable is saved for an equation.

RESSID *Save the residual value.* The new variable is named *ERR_n*, where *n* increments each time a predicted or residual variable is saved for an equation.

PRINT Subcommand

PRINT can be used to produce an additional covariance matrix for each equation. The only specification on this subcommand is keyword COV. The PRINT subcommand overrides the PRINT setting on the TSET command for the current procedure.

APPLY Subcommand

APPLY allows you to use a previously defined 2SLS model without having to repeat the specifications.

- The only specification on APPLY is the name of a previous model. If a model name is not specified, the model that was specified on the previous 2SLS command is used.
- To change the series that are used with the model, enter new series names before or after the APPLY subcommand.
- To change one or more model specifications, specify the subcommands of only those portions that you want to change after the APPLY subcommand.
- If no series are specified on the command, the series that were originally specified with the model that is being reapplied are used.

Example

```
2SLS Y1 WITH X1 X2 / X1 WITH Y1 X2
  /INSTRUMENTS=X2 X3.
2SLS APPLY
  /INSTRUMENTS=X2 X3 LAGX1.
```

- In this example, the first command requests `2SLS` using *X2* and *X3* as instruments.
- The second command specifies the same equations but changes the instruments to *X2*, *X3*, and *LAGX1*.

ACF

```
ACF VARIABLES= series names

 [/DIFF={1}]
        {n}

 [/SDIFF={1}]
         {n}

 [/PERIOD=n]

 [/{NOLOG**}]
   {LN     }

 [/SEASONAL]

 [/MXAUTO={16**}]
          {n   }

 [/SERROR={IND**}]
          {MA   }

 [/PACF]

 [/APPLY [='model name']]
```

**Default if the subcommand is omitted and there is no corresponding specification on the TSET command.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
ACF TICKETS.
```

Overview

ACF displays and plots the sample autocorrelation function of one or more time series. You can also display and plot the autocorrelations of transformed series by requesting natural log and differencing transformations within the procedure.

Options

Modifying the Series. You can request a natural log transformation of the series using the LN subcommand and seasonal and nonseasonal differencing to any degree using the SDIFF and DIFF subcommands. With seasonal differencing, you can specify the periodicity on the PERIOD subcommand.

Statistical Output. With the MXAUTO subcommand, you can specify the number of lags for which you want autocorrelations to be displayed and plotted, overriding the maximum specified on TSET. You can also display and plot values at periodic lags only using the SEASONAL

subcommand. In addition to autocorrelations, you can display and plot partial autocorrelations using the PACF subcommand.

Method of Calculating Standard Errors. You can specify one of two methods of calculating the standard errors for the autocorrelations on the SERROR subcommand.

Basic Specification

The basic specification is one or more series names.

- For each series specified, ACF automatically displays the autocorrelation value, standard error, Box-Ljung statistic, and probability for each lag.
- ACF plots the autocorrelations and marks the bounds of two standard errors on the plot. By default, ACF displays and plots autocorrelations for up to 16 lags or the number of lags specified on TSET.
- If a method has not been specified on TSET, the default method of calculating the standard error (IND) assumes that the process is white noise.

Subcommand Order

- Subcommands can be specified in any order.

Syntax Rules

- VARIABLES can be specified only once.
- Other subcommands can be specified more than once, but only the last specification of each one is executed.

Operations

- Subcommand specifications apply to all series named on the ACF command.
- If the LN subcommand is specified, any differencing requested on that ACF command is done on the log-transformed series.
- Confidence limits are displayed in the plot, marking the bounds of two standard errors at each lag.

Limitations

- A maximum of one VARIABLES subcommand. There is no limit on the number of series named on the list.

Example

```
ACF VARIABLES = TICKETS
  /LN
  /DIFF=1
  /SDIFF=1
  /PER=12
  /MXAUTO=50.
```

- This example produces a plot of the autocorrelation function for the series *TICKETS* after a natural log transformation, differencing, and seasonal differencing have been applied. Along with the plot, the autocorrelation value, standard error, Box-Ljung statistic, and probability are displayed for each lag.
- LN transforms the data using the natural logarithm (base *e*) of the series.
- DIFF differences the series once.
- SDIFF and PERIOD apply one degree of seasonal differencing with a period of 12.
- MXAUTO specifies that the maximum number of lags for which output is to be produced is 50.

VARIABLES Subcommand

VARIABLES specifies the series names and is the only required subcommand.

DIFF Subcommand

DIFF specifies the degree of differencing used to convert a nonstationary series to a stationary one with a constant mean and variance before the autocorrelations are computed.

- You can specify 0 or any positive integer on DIFF.
- If DIFF is specified without a value, the default is 1.
- The number of values used in the calculations decreases by 1 for each degree−1 of differencing.

Example

```
ACF VARIABLES = SALES
  /DIFF=1.
```

- In this example, the series *SALES* will be differenced once before the autocorrelations are computed and plotted.

SDIFF Subcommand

If the series exhibits a seasonal or periodic pattern, you can use the SDIFF subcommand to seasonally difference the series before obtaining autocorrelations.

- The specification on SDIFF indicates the degree of seasonal differencing and can be 0 or any positive integer.
- If SDIFF is specified without a value, the degree of seasonal differencing defaults to 1.
- The number of seasons used in the calculations decreases by 1 for each degree of seasonal differencing.
- The length of the period used by SDIFF is specified on the PERIOD subcommand. If the PERIOD subcommand is not specified, the periodicity established on the TSET or DATE command is used (see the PERIOD subcommand).

PERIOD Subcommand

PERIOD indicates the length of the period to be used by the SDIFF or SEASONAL subcommands.

- The specification on PERIOD indicates how many observations are in one period or season and can be any positive integer greater than 1.
- The PERIOD subcommand is ignored if it is used without the SDIFF or SEASONAL subcommands.
- If PERIOD is not specified, the periodicity established on TSET PERIOD is in effect. If TSET PERIOD is not specified, the periodicity established on the DATE command is used. If periodicity was not established anywhere, the SDIFF and SEASONAL subcommands will not be executed.

Example

```
ACF VARIABLES = SALES
  /SDIFF=1M
  /PERIOD=12.
```

- This command applies one degree of seasonal differencing with a periodicity (season) of 12 to the series *SALES* before autocorrelations are computed.

LN and NOLOG Subcommands

LN transforms the data using the natural logarithm (base *e*) of the series and is used to remove varying amplitude over time. NOLOG indicates that the data should not be log transformed. NOLOG is the default.

- If you specify LN on an ACF command, any differencing requested on that command will be done on the log-transformed series.
- There are no additional specifications on LN or NOLOG.
- Only the last LN or NOLOG subcommand on an ACF command is executed.
- If a natural log transformation is requested when there are values in the series that are less than or equal to zero, the ACF will not be produced for that series because nonpositive values cannot be log transformed.
- NOLOG is generally used with an APPLY subcommand to turn off a previous LN specification.

Example

```
ACF VARIABLES = SALES
  /LN.
```

- This command transforms the series *SALES* using the natural log transformation and then computes and plots autocorrelations.

SEASONAL Subcommand

Use the SEASONAL subcommand to focus attention on the seasonal component by displaying and plotting autocorrelations at periodic lags only.

- There are no additional specifications on SEASONAL.
- If SEASONAL is specified, values are displayed and plotted at the periodic lags indicated on the PERIOD subcommand. If PERIOD is not specified, the periodicity established on the TSET or DATE command is used (see the PERIOD subcommand).
- If SEASONAL is not specified, autocorrelations for all lags up to the maximum are displayed and plotted.

Example

```
ACF VARIABLES = SALES
  /SEASONAL
  /PERIOD=12.
```

- In this example, autocorrelations are displayed only at every 12th lag.

MXAUTO Subcommand

MXAUTO specifies the maximum number of lags for a series.

- The specification on MXAUTO must be a positive integer.
- If MXAUTO is not specified, the default number of lags is the value set on TSET MXAUTO. If TSET MXAUTO is not specified, the default is 16.
- The value on MXAUTO overrides the value set on TSET MXAUTO.

Example

```
ACF VARIABLES = SALES
  /MXAUTO=14.
```

- This command sets the maximum number of autocorrelations to be displayed for the series *SALES* to 14.

SERROR Subcommand

SERROR specifies the method of calculating the standard errors for the autocorrelations.

- You must specify either the keyword IND or MA on SERROR.
- The method specified on SERROR overrides the method specified on the TSET ACFSE command.
- If SERROR is not specified, the method indicated on TSET ACFSE is used. If TSET ACFSE is not specified, the default is IND.

IND *Independence model.* The method of calculating the standard errors assumes that the underlying process is white noise.

MA *MA model.* The method of calculating the standard errors is based on Bartlett's approximation. With this method, appropriate where the true MA order of the process is k–1, standard errors grow at increased lags (Pankratz, 1983).

Example

```
ACF VARIABLES = SALES
  /SERROR=MA.
```

- In this example, the standard errors of the autocorrelations are computed using the MA method.

PACF Subcommand

Use the PACF subcommand to display and plot sample partial autocorrelations as well as autocorrelations for each series named on the ACF command.

- There are no additional specifications on PACF.
- PACF also displays the standard errors of the partial autocorrelations and indicates the bounds of two standard errors on the plot.
- With the exception of SERROR, all other subcommands specified on that ACF command apply to both the partial autocorrelations and the autocorrelations.

Example

```
ACF VARIABLES = SALES
  /DIFFERENCE=1
  /PACF.
```

- This command requests both autocorrelations and partial autocorrelations for the series *SALES* after it has been differenced once.

APPLY Subcommand

APPLY allows you to use a previously defined ACF model without having to repeat the specifications.

- The only specification on APPLY is the name of a previous model in quotation marks. If a model name is not specified, the model specified on the previous ACF command is used.
- To change one or more model specifications, specify the subcommands of only those portions you want to change after the APPLY subcommand.
- If no series are specified on the ACF command, the series that were originally specified with the model being reapplied are used.
- To change the series used with the model, enter new series names before or after the APPLY subcommand.

Example

```
ACF VARIABLES = TICKETS
  /LN
  /DIFF=1
  /SDIFF=1
  /PERIOD=12
  /MXAUTO=50.
ACF VARIABLES = ROUNDTRP
  /APPLY.
ACF APPLY
```

```
  /NOLOG.
ACF APPLY 'MOD_2'
  /PERIOD=6.
```

- The first command requests a maximum of 50 autocorrelations for the series *TICKETS* after a natural log transformation, differencing, and one degree of seasonal differencing with a periodicity of 12 have been applied. This model is assigned the default name *MOD_1*.
- The second command displays and plots the autocorrelation function for the series *ROUNDTRP* using the same model that was used for the series *TICKETS*. This model is assigned the name *MOD_2*.
- The third command requests another autocorrelation function of the series *ROUNDTRP* using the same model but without the natural log transformation. Note that when `APPLY` is the first specification after the `ACF` command, the slash (/) before it is not necessary. This model is assigned the name *MOD_3*.
- The fourth command reapplies *MOD_2*, autocorrelations for the series *ROUNDTRP* with the natural log and differencing specifications, but this time with a periodicity of 6. This model is assigned the name *MOD_4*. It differs from *MOD_2* only in the periodicity.

ADD DOCUMENT

```
ADD DOCUMENT
  'text'
  'text'.
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Example

```
ADD DOCUMENT
  "This data file is a 10% random sample from the"
  "master data file. It's seed value is 13254689.".
```

Overview

ADD DOCUMENT saves a block of text of any length in an SPSS-format data file. The result is equivalent to the DOCUMENT command. The documentation can be displayed with the DISPLAY DOCUMENT command.

When GET retrieves a data file, or APPLY DICTIONARY is used to apply documents from another data file, or ADD FILES, MATCH FILES, or UPDATE is used to combine data files, all documents from each specified file are copied into the working file. DROP DOCUMENTS can be used to drop those documents from the working file.

Basic Specification

The basic specification is ADD DOCUMENT followed by one or more optional lines of quoted text. The text is stored in the file dictionary when the data file is saved in SPSS format.

Syntax Rules

- Each line must be enclosed in single or double quotation marks, following the standard rules for quoted strings.
- Each line can be up to 80 bytes long (typically 80 characters in single-byte languages), including the command name but not including the quotation marks used to enclose the text. If any line exceeds 80 bytes, an error will result and the command will not be executed.
- The text can be entered on as many lines as needed.
- Multiple ADD DOCUMENT commands can be specified for the same data file.

Operations

- The text from each ADD DOCUMENT command is appended to the end of the list of documentation, followed by the date in parentheses.
- An ADD DOCUMENT command with no quoted text string appends a date in parentheses to the documentation.

- DISPLAY DOCUMENTS will display all documentation for the data file specified on the ADD DOCUMENT and/or DOCUMENT commands. Documentation is displayed exactly as entered; each line of the ADD DOCUMENT command is displayed as a separate line, and there is no line wrapping.
- DROP DOCUMENTS deletes all documentation created by both ADD DOCUMENT and DOCUMENT.

Example

If the command name and the quoted text string are specified on the same line, the command name counts toward the 80-byte line limit, so it's a good idea to put the command name on a separate line, as in:

```
ADD DOCUMENT
  "This is some text that describes this file.".
```

Example

To insert blank lines between blocks of text, enter a null string, as in:

```
ADD DOCUMENT
  "This is some text that describes this file."
  ""
  "This is some more text preceded by a blank line.".
```

ADD FILES

```
ADD FILES FILE={'savfile'|'dataset'}
               {*                  }

 [/RENAME=(old varnames=new varnames)...]

 [/IN=varname]

 /FILE=... [/RENAME=...] [/IN=...]

 [/BY varlist]

 [/MAP]

 [/KEEP={ALL**  }] [/DROP=varlist]
        {varlist}

 [/FIRST=varname]  [/LAST=varname]
```

**Default if the subcommand is omitted.

Example

```
ADD FILES FILE="/data/school1.sav" /FILE="/data/school2.sav".
```

Overview

ADD FILES combines cases from 2 up to 50 SPSS-format data files by concatenating or interleaving cases. When cases are **concatenated**, all cases from one file are added to the end of all cases from another file. When cases are **interleaved**, cases in the resulting file are ordered according to the values of one or more key variables.

The files specified on ADD FILES can be external SPSS-format data files, the active dataset, or previously defined datasets. The combined file becomes the new active dataset.

In general, ADD FILES is used to combine files containing the same variables but different cases. To combine files containing the same cases but different variables, use MATCH FILES. To update existing SPSS-format data files, use UPDATE.

Options

Variable Selection. You can specify which variables from each input file are included in the new active dataset using the DROP and KEEP subcommands.

Variable Names. You can rename variables in each input file before combining the files using the RENAME subcommand. This permits you to combine variables that are the same but whose names differ in different input files or to separate variables that are different but have the same name.

Variable Flag. You can create a variable that indicates whether a case came from a particular input file using IN. When interleaving cases, you can use the FIRST or LAST subcommands to create a variable that flags the first or last case of a group of cases with the same value for the key variable.

Variable Map. You can request a map showing all variables in the new active dataset, their order, and the input files from which they came using the MAP subcommand.

Basic Specification

- The basic specification is two or more FILE subcommands, each of which specifies a file to be combined. If cases are to be interleaved, the BY subcommand specifying the key variables is also required.
- All variables from all input files are included in the new active dataset unless DROP or KEEP is specified.

Subcommand Order

- RENAME and IN must immediately follow the FILE subcommand to which they apply.
- BY, FIRST, and LAST must follow all FILE subcommands and their associated RENAME and IN subcommands.

Syntax Rules

- RENAME can be repeated after each FILE subcommand. RENAME applies only to variables in the file named on the FILE subcommand immediately preceding it.
- BY can be specified only once. However, multiple key variables can be specified on BY. When BY is used, all files must be sorted in ascending order by the key variables (see SORT CASES).
- FIRST and LAST can be used only when files are interleaved (when BY is used).
- MAP can be repeated as often as desired.

Operations

- ADD FILES reads all input files named on FILE and builds a new active dataset that replaces any active dataset created earlier in the session. ADD FILES is executed when the data are read by one of the procedure commands or the EXECUTE, SAVE, or SORT CASES commands.
- The resulting file contains complete dictionary information from the input files, including variable names, labels, print and write formats, and missing-value indicators. It also contains the documents from each input file. See DROP DOCUMENTS for information on deleting documents.
- Variables are copied in order from the first file specified, then from the second file specified, and so on. Variables that are not contained in all files receive the system-missing value for cases that do not have values for those variables.
- If the same variable name exists in more than one file but the format type (numeric or string) does not match, the command is not executed.
- If a numeric variable has the same name but different formats (for example, F8.0 and F8.2) in different input files, the format of the variable in the first-named file is used.
- If a string variable has the same name but different formats (for example, A24 and A16) in different input files, the command is not executed.
- If the active dataset is named as an input file, any N and SAMPLE commands that have been specified are applied to the active dataset before the files are combined.
- If only one of the files is weighted, the program turns weighting off when combining cases from the two files. To weight the cases, use the WEIGHT command again.

Limitations

- A maximum of 50 files can be combined on one ADD FILES command.
- The TEMPORARY command cannot be in effect if the active dataset is used as an input file.

Examples

```
ADD FILES FILE="/data/school1.sav"
         /FILE="/data/school2.sav".
```

- ADD FILES concatenates cases from the SPSS-format data files *school1.sav* and *school2.sav*. All cases from *school1.sav* precede all cases from *school2.sav* in the resulting file.

```
SORT CASES BY LOCATN DEPT.
ADD FILES  FILE="/data/source.sav" /FILE=* /BY LOCATN DEPT
 /KEEP AVGHOUR AVGRAISE LOCATN DEPT SEX HOURLY RAISE /MAP.
SAVE OUTFILE="/data/prsnnl.sav".
```

- SORT CASES sorts cases in the active dataset in ascending order of their values for *LOCATN* and *DEPT*.
- ADD FILES combines two files: the SPSS-format data file *source.sav* and the sorted active dataset. The file *source.sav* must also be sorted by *LOCATN* and *DEPT*.
- BY indicates that the keys for interleaving cases are *LOCATN* and *DEPT*, the same variables used on SORT CASES.
- KEEP specifies the variables to be retained in the resulting file.
- MAP produces a list of variables in the resulting file and the two input files.
- SAVE saves the resulting file as a new SPSS-format data file named *prsnnl.sav*.

FILE Subcommand

FILE identifies the files to be combined. A separate FILE subcommand must be used for each input file.

- An asterisk may be specified on FILE to indicate the active dataset.
- Dataset names instead of file names can be used to refer to currently open datasets.
- The order in which files are named determines the order of cases in the resulting file.

Example

```
GET DATA /TYPE=XLS  /FILE='/temp/excelfile1.xls'.
DATASET NAME exceldata1.
GET DATA /TYPE=XLS  /FILE='/temp/excelfile2.xls'.
ADD FILES FILE='exceldata1'
         /FILE=*
         /FILE='/temp/mydata.sav'.
```

RENAME Subcommand

RENAME renames variables in input files *before* they are processed by ADD FILES. RENAME follows the FILE subcommand that specifies the file containing the variables to be renamed.

- RENAME applies only to the FILE subcommand immediately preceding it. To rename variables from more than one input file, enter a RENAME subcommand after each FILE subcommand that specifies a file with variables to be renamed.
- Specifications for RENAME consist of a left parenthesis, a list of old variable names, an equals sign, a list of new variable names, and a right parenthesis. The two variable lists must name or imply the same number of variables. If only one variable is renamed, the parentheses are optional.
- More than one such specification can be entered on a single RENAME subcommand, each enclosed in parentheses.
- The TO keyword can be used to refer to consecutive variables in the file and to generate new variable names.
- RENAME takes effect immediately. KEEP and DROP subcommands entered prior to RENAME must use the old names, while those entered after RENAME must use the new names.
- All specifications within a single set of parentheses take effect simultaneously. For example, the specification RENAME (A,B = B,A) swaps the names of the two variables.
- Variables cannot be renamed to scratch variables.
- Input data files are not changed on disk; only the copy of the file being combined is affected.

Example

```
ADD FILES FILE="/data/clients.sav" /RENAME=(TEL_NO, ID_NO = PHONE, ID)
 /FILE="/data/master.sav" /BY ID.
```

- ADD FILES adds new client cases from the file *clients.sav* to existing client cases in the file *master.sav*.
- Two variables on *clients.sav* are renamed prior to the match. *TEL_NO* is renamed *PHONE* to match the name used for phone numbers in the master file. *ID_NO* is renamed *ID* so that it will have the same name as the identification variable in the master file and can be used on the BY subcommand.
- The BY subcommand orders the resulting file according to client ID number.

BY Subcommand

BY specifies one or more key variables that determine the order of cases in the resulting file. When BY is specified, cases from the input files are interleaved according to their values for the key variables.

- BY must follow the FILE subcommands and any associated RENAME and IN subcommands.
- The key variables specified on BY must be present and have the same names in all input files.
- Key variables can be string or numeric.
- All input files must be sorted in ascending order of the key variables. If necessary, use SORT CASES before ADD FILES.
- Cases in the resulting file are ordered by the values of the key variables. All cases from the first file with the first value for the key variable are first, followed by all cases from the second file with the same value, followed by all cases from the third file with the same value, and

so forth. These cases are followed by all cases from the first file with the next value for the key variable, and so on.

- Cases with system-missing values are first in the resulting file. User-missing values are interleaved with other values.

DROP and KEEP Subcommands

DROP and KEEP are used to include only a subset of variables in the resulting file. DROP specifies a set of variables to exclude and KEEP specifies a set of variables to retain.

- DROP and KEEP do not affect the input files on disk.
- DROP and KEEP must follow all FILE and RENAME subcommands.
- DROP and KEEP must specify one or more variables. If RENAME is used to rename variables, specify the new names on DROP and KEEP.
- DROP and KEEP take effect immediately. If a variable specified on DROP or KEEP does not exist in the input files, was dropped by a previous DROP subcommand, or was not retained by a previous KEEP subcommand, the program displays an error message and does not execute the ADD FILES command.
- DROP cannot be used with variables created by the IN, FIRST, or LAST subcommands.
- KEEP can be used to change the order of variables in the resulting file. With KEEP, variables are kept in the order in which they are listed on the subcommand. If a variable is named more than once on KEEP, only the first mention of the variable is in effect; all subsequent references to that variable name are ignored.
- The keyword ALL can be specified on KEEP. ALL must be the last specification on KEEP, and it refers to all variables not previously named on that subcommand. It is useful when you want to arrange the first few variables in a specific order.

Example

```
ADD FILES FILE="/data/particle.sav" /RENAME=(PARTIC=pollute1)
 /FILE="/data/gas.sav" /RENAME=(OZONE TO SULFUR=pollut2 TO pollute4)
 /KEEP=pollute1 pollute2 pollute3 pollute4.
```

- The renamed variables are retained in the resulting file. KEEP is specified after all the FILE and RENAME subcommands, and it refers to the variables by their new names.

IN Subcommand

IN creates a new variable in the resulting file that indicates whether a case came from the input file named on the preceding FILE subcommand. IN applies only to the file specified on the immediately preceding FILE subcommand.

- IN has only one specification, the name of the flag variable.
- The variable created by IN has the value 1 for every case that came from the associated input file and the value 0 for every case that came from a different input file.

- Variables created by IN are automatically attached to the end of the resulting file and cannot be dropped. If FIRST or LAST are used, the variable created by IN precedes the variables created by FIRST or LAST.

Example

```
ADD FILES  FILE="/data/week10.sav" /FILE="/data/week11.sav"
  /IN=INWEEK11 /BY=EMPID.
```

- IN creates the variable *INWEEK11*, which has the value 1 for all cases in the resulting file that came from the input file *week11.sav* and the value 0 for those cases that were not in the file *week11.sav*.

Example

```
ADD FILES  FILE="/data/week10.sav" /FILE="/data/week11.sav"
  /IN=INWEEK11 /BY=EMPID.
IF  (NOT INWEEK11) SALARY1=0.
```

- The variable created by IN is used to screen partially missing cases for subsequent analyses.
- Since IN variables have either the value 1 or 0, they can be used as logical expressions, where 1 = true and 0 = false. The IF command sets the variable *SALARY1* equal to 0 for all cases that came from the file *INWEEK11*.

FIRST and LAST Subcommands

FIRST and LAST create logical variables that flag the first or last case of a group of cases with the same value on the BY variables. FIRST and LAST must follow all FILE subcommands and their associated RENAME and IN subcommands.

- FIRST and LAST have only one specification, the name of the flag variable.
- FIRST creates a variable with the value 1 for the first case of each group and the value 0 for all other cases.
- LAST creates a variable with the value 1 for the last case of each group and the value 0 for all other cases.
- Variables created by FIRST and LAST are automatically attached to the end of the resulting file and cannot be dropped.

Example

```
ADD FILES  FILE="/data/school1.sav" /FILE="/data/school2.sav"
 /BY=GRADE /FIRST=HISCORE.
```

- The variable *HISCORE* contains the value 1 for the first case in each grade in the resulting file and the value 0 for all other cases.

MAP Subcommand

MAP produces a list of the variables included in the new active dataset and the file or files from which they came. Variables are listed in the order in which they exist in the resulting file. MAP has no specifications and must follow after all FILE and RENAME subcommands.

- Multiple MAP subcommands can be used. Each MAP subcommand shows the current status of the active dataset and reflects only the subcommands that precede the MAP subcommand.
- To obtain a map of the active dataset in its final state, specify MAP last.
- If a variable is renamed, its original and new names are listed. Variables created by IN, FIRST, and LAST are not included in the map, since they are automatically attached to the end of the file and cannot be dropped.

Adding Cases from Different Data Sources

You can add cases from any data source that SPSS can read by defining dataset names for each data source that you read (DATASET NAME command) and then using ADD FILES to add the cases from each file. The following example merges the contents of three text data files, but it could just as easily merge the contents of a text data file, and Excel spreadsheet, and a database table.

Example

```
DATA LIST FILE="/data/gasdata1.txt"
  /1 OZONE 10-12 CO 20-22 SULFUR 30-32.
DATASET NAME gasdata1.
DATA LIST FILE="/data/gasdata2.txt"
  /1 OZONE 10-12 CO 20-22 SULFUR 30-32.
DATASET NAME gasdata2.
DATA LIST FILE="/data/gasdata3.txt"
  /1 OZONE 10-12 CO 20-22 SULFUR 30-32.
DATASET NAME gasdata3.
ADD FILES FILE='gasdata1'
  /FILE='gasdata2'
  /FILE='gasdata3'.
SAVE OUTFILE='/data/combined_data.sav'.
```

ADD VALUE LABELS

```
ADD VALUE LABELS varlist value 'label' value 'label'...[/varlist...]
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Example

```
ADD VALUE LABELS JOBGRADE 'P' 'Parttime Employee'
                          'C' 'Customer Support'.
```

Overview

`ADD VALUE LABELS` adds or alters value labels without affecting other value labels already defined for that variable. In contrast, `VALUE LABELS` adds or alters value labels but deletes all existing value labels for that variable when it does so.

Basic Specification

The basic specification is a variable name and individual values with associated labels.

Syntax Rules

- Labels can be assigned to values of any previously defined variable. It is not necessary to enter value labels for all of a variable's values.
- Each value label must be enclosed in single or double quotes.
- To specify a single quote or apostrophe within a quoted string, either enclose the entire string in double quotes or double the single quote/apostrophe.
- Value labels can contain any characters, including blanks.
- The same labels can be assigned to the same values of different variables by specifying a list of variable names. For string variables, the variables on the list must have the same defined width (for example, `A8`).
- Multiple sets of variable names and value labels can be specified on one `ADD VALUE LABELS` command as long as each set is separated from the previous one by a slash.
- To continue a label from one command line to the next, specify a plus sign (+) before the continuation of the label and enclose each segment of the label, including the blank between them, in single or double quotes.

Operations

- Unlike most transformations, `ADD VALUE LABELS` takes effect as soon as it is encountered in the command sequence. Thus, special attention should be paid to its position among commands.
- The added value labels are stored in the active dataset dictionary.

- ADD VALUE LABELS can be used for variables that have no previously assigned value labels.
- Adding labels to some values does not affect labels previously assigned to other values.

Limitations

- Value labels cannot exceed 120 bytes.

Examples

Adding Value Labels

```
ADD VALUE LABELS V1 TO V3 1 'Officials & Managers'
                          6 'Service Workers'
                /V4 'N' 'New Employee'.
```

- Labels are assigned to the values 1 and 6 of the variables between and including *V1* and *V3* in the active dataset.
- Following the required slash, a label for the value *N* for the variable *V4* is specified. *N* is a string value and must be enclosed in single or double quotes.
- If labels already exist for these values, they are changed in the dictionary. If labels do not exist for these values, new labels are added to the dictionary.
- Existing labels for other values for these variables are not affected.

Specifying a Label on Multiple Lines

```
ADD VALUE LABELS OFFICE88 1 "EMPLOYEE'S OFFICE ASSIGNMENT PRIOR"
   + " TO 1988".
```

- The label for the value 1 for *OFFICE88* is specified on two command lines. The plus sign concatenates the two string segments, and a blank is included at the beginning of the second string in order to maintain correct spacing in the label.

Value Labels for String Variables

- For string variables, the values and the labels must be enclosed in single or double quotes.
- If a specified value is longer than the defined width of the variable, the program displays a warning and truncates the value. The added label will be associated with the truncated value.
- If a specified value is shorter than the defined width of the variable, the program adds blanks to right-pad the value without warning. The added label will be associated with the padded value.
- If a single set of labels is to be assigned to a list of string variables, the variables must have the same defined width (for example, A8).

Example

```
ADD VALUE LABELS  STATE 'TEX' 'TEXAS' 'TEN' 'TENNESSEE'
                        'MIN' 'MINNESOTA'.
```

- ADD VALUE LABELS assigns labels to three values of the variable *STATE*. Each value and each label is specified in quotes.

- Assuming that the variable *STATE* is defined as three characters wide, the labels *TEXAS*, *TENNESSEE*, and *MINNESOTA* will be appropriately associated with the values *TEX*, *TEN*, and *MIN*. However, if *STATE* was defined as two characters wide, the program would truncate the specified values to two characters and would not be able to associate the labels correctly. Both *TEX* and *TEN* would be truncated to *TE* and would first be assigned the label *TEXAS*, which would then be changed to *TENNESSEE* by the second specification.

Example

```
ADD VALUE LABELS STATE REGION "U" "UNKNOWN".
```

- The label *UNKNOWN* is assigned to the value *U* for both *STATE* and *REGION*.
- *STATE* and *REGION* must have the same defined width. If they do not, a separate specification must be made for each, as in the following:

```
ADD VALUE LABELS STATE "U" "UNKNOWN" / REGION "U" "UNKNOWN".
```

AGGREGATE

```
AGGREGATE [OUTFILE={'savfile'|'dataset'}]
                   {*      } [MODE={REPLACE     }] [OVERWRITE={NO }]
                                   {ADDVARIABLES}              {YES}

 [/MISSING=COLUMNWISE] [/DOCUMENT]

 [/PRESORTED] /BREAK=varlist[({A})][varlist...]
                              {D}

 /aggvar['label'] aggvar['label']...=function(arguments)

 [/aggvar ...]
```

Available functions:

SUM	Sum	MEAN	Mean
SD	Standard deviation	MAX	Maximum
MIN	Minimum	PGT	% of cases greater than value
PLT	% of cases less than value	PIN	% of cases between values
POUT	% of cases not in range	FGT	Fraction greater than value
FLT	Fraction less than value	FIN	Fraction between values
FOUT	Fraction not in range	N	Weighted number of cases
NU	Unweighted number of cases	NMISS	Weighted number of missing cases
NUMISS	Unweighted number of missing cases	FIRST	First nonmissing value
LAST	Last nonmissing value	MEDIAN	Median

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Release History

Release 13.0

- MODE keyword introduced.
- OVERWRITE keyword introduced.

Example

```
AGGREGATE
  /OUTFILE='/temp/temp.sav'
  /BREAK=gender
  /age_mean=MEAN(age).
```

Overview

AGGREGATE aggregates groups of cases in the active dataset into single cases and creates a new aggregated file or creates new variables in the active dataset that contain aggregated data. The values of one or more variables in the active dataset define the case groups. These variables are called **break variables**. A set of cases with identical values for each break variable is called a **break group**. Aggregate functions are applied to **source variables** in the active dataset to create new aggregated variables that have one value for each break group.

Options

Data. You can create new variables in the active dataset that contain aggregated data, replace the active dataset with aggregated results, or create a new SPSS-format data file that contains the aggregated results.

Documentary Text. You can copy documentary text from the original file into the aggregated file using the DOCUMENT subcommand. By default, documentary text is dropped.

Aggregated Variables. You can create aggregated variables using any of 19 aggregate functions. The functions SUM, MEAN, and SD can aggregate only numeric variables. All other functions can use both numeric and string variables.

Labels and Formats. You can specify variable labels for the aggregated variables. Variables created with the functions MAX, MIN, FIRST, and LAST assume the formats and value labels of their source variables. All other variables assume the default formats described under Aggregate Functions on p. 147.

Basic Specification

The basic specification is BREAK and at least one aggregate function and source variable. OUTFILE specifies a name for the aggregated file. BREAK names the case grouping (break) variables. The aggregate function creates a new aggregated variable.

Subcommand Order

- If specified, OUTFILE must be specified first.
- If specified, DOCUMENT and PRESORTED must precede BREAK. No other subcommand can be specified between these two subcommands.
- MISSING, if specified, must immediately follow OUTFILE.
- The aggregate functions must be specified last.

Operations

- When replacing the active dataset or creating a new data file, the aggregated file contains the break variables plus the variables created by the aggregate functions.
- AGGREGATE excludes cases with missing values from all aggregate calculations except those involving the functions N, NU, NMISS, and NUMISS.
- Unless otherwise specified, AGGREGATE sorts cases in the aggregated file in ascending order of the values of the grouping variables.

- If PRESORTED is specified, a new aggregate case is created each time a different value or combination of values is encountered on variables named on the BREAK subcommand.
- AGGREGATE ignores split-file processing. To achieve the same effect, name the variable or variables used to split the file as break variables before any other break variables. AGGREGATE produces one file, but the aggregated cases are in the same order as the split files.

Example

```
AGGREGATE
  /OUTFILE='/temp/temp.sav'
  /BREAK=gender marital
  /age_mean=MEAN(age)
  /age_median=MEDIAN(age)
  /income_median=MEDIAN(income).
```

- AGGREGATE creates a new SPSS-format data file, *temp.sav*, that contains two break variables (*gender* and *marital*) and all of the new aggregate variables.
- BREAK specifies *gender* and *marital* as the break variables. In the aggregated file, cases are sorted in ascending order of *gender* and in ascending order of *marital* within *gender*. The active dataset remains unsorted.
- Three aggregated variables are created: *age_mean* contains the mean age for each group defined by the two break variables; *age_median* contains the median age; and *income_median* contains the median income.

OUTFILE Subcommand

OUTFILE specifies the handling of the aggregated results. It must be the first subcommand on the AGGREGATE command.

- OUTFILE='file specification' saves the aggregated data to a new file, leaving the active dataset unaffected. The file contains the new aggregated variables and the break variables that define the aggregated cases.
- A defined dataset name can be used for the file specification, saving the aggregated data to a dataset in the current session. The dataset must be defined before being used in the AGGREGATE command. For more information, see DATASET DECLARE on p. 530.
- OUTFILE=* with no additional keywords on the OUTFILE subcommand will replace the active dataset with the aggregated results.
- OUTFILE=* MODE=ADDVARIABLES appends the new variables with the aggregated data to the active dataset (instead of replacing the active dataset with the aggregated data).
- OUTFILE=* MODE=ADDVARIABLES OVERWRITE=YES overwrites variables in the active dataset if those variable names are the same as the aggregate variable names specified on the AGGREGATE command.
- MODE and OVERWRITE can be used only with OUTFILE=*; they are invalid with OUTFILE='file specification'.
- Omission of the OUTFILE subcommand is equivalent to OUTFILE=* MODE=ADDVARIABLES.

Example

```
AGGREGATE
  /OUTFILE=* MODE=ADDVARIABLES
  /BREAK=region
  /sales_mean = MEAN(var1)
  /sales_median = MEDIAN(var1)
  /sales_sum = SUM(var1).
```

- The aggregated variables are appended to the end of the active data file. No existing cases or variables are deleted.
- For each case, the new aggregated variable values represent the mean, median, and total (sum) sales values for its region.

Creating a New Aggregated Data File versus Appending Aggregated Variables

When you create a new aggregated data file with `OUTFILE='file specification'` or `OUTFILE=* MODE=REPLACE`, the new file contains:

- The break variables from the original data file and the new aggregate variables defined by the aggregate functions. Original variables other than the break variables are not retained.
- One case for each group defined by the break variables. If there is one break variable with two values, the new data file will contain only two cases.

When you append aggregate variables to the active dataset with `OUTFILE=* MODE=ADDVARIABLES`, the modified data file contains:

- All of the original variables plus all of the new variables defined by the aggregate functions, with the aggregate variables appended to the end of the file.
- The same number of cases as the original data file. The data file itself is not aggregated. Each case with the same value(s) of the break variable(s) receives the same values for the new aggregate variables. For example, if *gender* is the only break variable, all males would receive the same value for a new aggregate variable that represents the average age.

Example

```
DATA LIST FREE /age (F2) gender (F2).
BEGIN DATA
25 1
35 1
20 2
30 2
60 2
END DATA.
*create new file with aggregated results.
AGGREGATE
  /OUTFILE='/temp/temp.sav'
  /BREAK=gender
  /age_mean=MEAN(age)
  /groupSize=N.
*append aggregated variables to active dataset.
AGGREGATE
  /OUTFILE=* MODE=ADDVARIABLES
  /BREAK=gender
  /age_mean=MEAN(age)
```

```
  /groupSize=N.
```

Figure 8-1
New aggregated data file

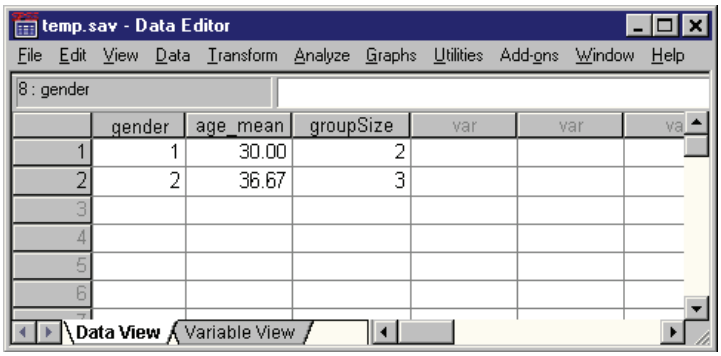

Figure 8-2
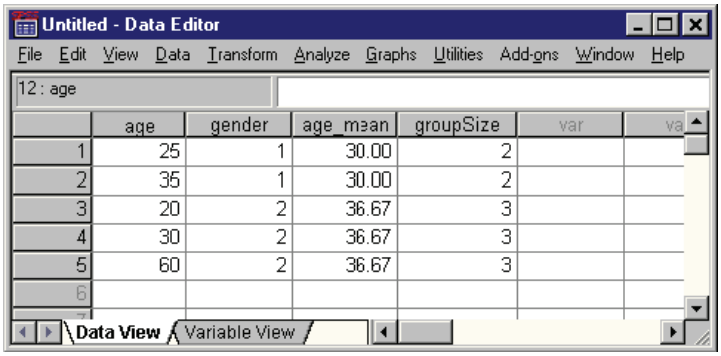
Aggregate variables appended to active dataset



BREAK Subcommand

BREAK lists the grouping variables, also called break variables. Each unique combination of values of the break variables defines one break group.

- The variables named on BREAK can be any combination of variables in the active dataset.
- Unless PRESORTED is specified, aggregated variables are appended to the active dataset (OUTFILE=* MODE=ADDVARIABLES), AGGREGATE sorts cases after aggregating. By default, cases are sorted in ascending order of the values of the break variables. AGGREGATE sorts first on the first break variable, then on the second break variable within the groups created by the first, and so on.
- Sort order can be controlled by specifying an A (for ascending) or D (for descending) in parentheses after any break variables.
- The designations A and D apply to all preceding undesignated variables.
- The subcommand PRESORTED overrides all sorting specifications, and no sorting is performed with OUTFILE=* MODE=ADDVARIABLES.

```
AGGREGATE
  /OUTFILE=*  MODE=ADDVARIABLES
  /BREAK=region
```

```
  /sales_mean = MEAN(var1)
  /sales_median = MEDIAN(var1)
  /sales_sum = SUM(var1).
```

For each case, the new aggregated variable values represent the mean, median, and total (sum) sales values for its region.

DOCUMENT Subcommand

DOCUMENT copies documentation from the original file into the aggregated file.

- DOCUMENT must appear after OUTFILE but before BREAK.
- By default, documents from the original data file are not retained with the aggregated data file when creating a new aggregated data file with either OUTFILE='file specification' or OUTFILE=* MODE=REPLACE. The DOCUMENT subcommand retains the original data file documents.
- Appending variables with OUTFILE=* MODE=ADDVARIABLES has no effect on data file documents, and the DOCUMENT subcommand is ignored. If the data file previously had documents, they are retained.

PRESORTED Subcommand

If the data are already sorted in order by the break variables, you can reduce run time and memory requirements by using the PRESORTED subcommand.

- If specified, PRESORTED must precede BREAK. The only specification is the keyword PRESORTED. PRESORTED has no additional specifications.
- When PRESORTED is specified, the program forms an aggregate case out of each group of *adjacent* cases with the same values for the break variables.
- When PRESORTED is specified, if AGGREGATE is appending new variables to the active dataset rather than writing a new file or replacing the active dataset, the cases must be sorted in ascending order by the BREAK variables.

Example

```
AGGREGATE OUTFILE='/temp/temp.sav'
 /PRESORTED
 /BREAK=gender marital
 /mean_age=MEAN(age).
```

Aggregate Functions

An aggregated variable is created by applying an aggregate function to a variable in the active dataset. The variable in the active dataset is called the **source** variable, and the new aggregated variable is the **target** variable.

- The aggregate functions must be specified last on AGGREGATE.

- The simplest specification is a target variable list, followed by an equals sign, a function name, and a list of source variables.
- The number of target variables named must match the number of source variables.
- When several aggregate variables are defined at once, the first-named target variable is based on the first-named source variable, the second-named target is based on the second-named source, and so on.
- Only the functions MAX, MIN, FIRST, and LAST copy complete dictionary information from the source variable. For all other functions, new variables do not have labels and are assigned default dictionary print and write formats. The default format for a variable depends on the function used to create it (see the list of available functions below).
- You can provide a variable label for a new variable by specifying the label in single or double quotes immediately following the new variable name. Value labels cannot be assigned in AGGREGATE.
- To change formats or add value labels to an active dataset created by AGGREGATE, use the PRINT FORMATS, WRITE FORMATS, FORMATS, or VALUE LABELS command. If the aggregate file is written to disk, first retrieve the file using GET, specify the new labels and formats, and resave the file.

The following is a list of available functions:

SUM(varlist)	*Sum across cases.* Default formats are F8.2.
MEAN(varlist)	*Mean across cases.* Default formats are F8.2.
MEDIAN(varlist)	*Median across cases.* Default formats are F8.2.
SD(varlist)	*Standard deviation across cases.* Default formats are F8.2.
MAX(varlist)	*Maximum value across cases.* Complete dictionary information is copied from the source variables to the target variables.
MIN(varlist)	*Minimum value across cases.* Complete dictionary information is copied from the source variables to the target variables.
PGT(varlist,value)	*Percentage of cases greater than the specified value.* Default formats are F5.1.
PLT(varlist,value)	*Percentage of cases less than the specified value.* Default formats are F5.1.
PIN(varlist,value1,value2)	*Percentage of cases between value1 and value2, inclusive.* Default formats are F5.1.
POUT(varlist,value1,value2)	*Percentage of cases not between value1 and value2.* Cases where the source variable equals *value1* or *value2* are not counted. Default formats are F5.1.
FGT(varlist,value)	*Fraction of cases greater than the specified value.* Default formats are F5.3.
FLT(varlist,value)	*Fraction of cases less than the specified value.* Default formats are F5.3.
FIN(varlist,value1,value2)	*Fraction of cases between value1 and value2, inclusive.* Default formats are F5.3.
FOUT(varlist,value1,value2)	*Fraction of cases not between value1 and value2.* Cases where the source variable equals *value1* or *value2* are not counted. Default formats are F5.3.
N(varlist)	*Weighted number of cases in break group.* Default formats are F7.0 for unweighted files and F8.2 for weighted files.

NU(varlist)	*Unweighted number of cases in break group.* Default formats are F7.0.
NMISS(varlist)	*Weighted number of missing cases.* Default formats are F7.0 for unweighted files and F8.2 for weighted files.
NUMISS(varlist)	*Unweighted number of missing cases.* Default formats are F7.0.
FIRST(varlist)	*First nonmissing observed value in break group.* Complete dictionary information is copied from the source variables to the target variables.
LAST(varlist)	*Last nonmissing observed value in break group.* Complete dictionary information is copied from the source variables to the target variables.

- The functions SUM, MEAN, and SD can be applied only to numeric source variables. All other functions can use short and long string variables as well as numeric ones.
- The N and NU functions do not require arguments. Without arguments, they return the number of weighted and unweighted valid cases in a break group. If you supply a variable list, they return the number of weighted and unweighted valid cases for the variables specified.
- For several functions, the argument includes values as well as a source variable designation. Either blanks or commas can be used to separate the components of an argument list.
- For PIN, POUT, FIN, and FOUT, the first value should be less than or equal to the second. If the first is greater, AGGREGATE automatically reverses them and prints a warning message. If the two values are equal, PIN and FIN calculate the percentages and fractions of values equal to the argument. POUT and FOUT calculate the percentages and fractions of values not equal to the argument.
- String values specified in an argument should be enclosed in quotes. They are evaluated in alphabetical order.

Using the MEAN Function

```
AGGREGATE OUTFILE='AGGEMP.SAV' /BREAK=LOCATN
 /AVGSAL 'Average Salary' AVGRAISE = MEAN(SALARY RAISE).
```

- AGGREGATE defines two aggregate variables, *AVGSAL* and *AVGRAISE*.
- *AVGSAL* is the mean of *SALARY* for each break group, and *AVGRAISE* is the mean of *RAISE*.
- The label *Average Salary* is assigned to *AVGSAL*.

Using the PLT Function

```
AGGREGATE OUTFILE=* /BREAK=DEPT
 /LOWVAC,LOWSICK = PLT (VACDAY SICKDAY,10).
```

- AGGREGATE creates two aggregated variables: *LOWVAC* and *LOWSICK*. *LOWVAC* is the percentage of cases with values less than 10 for *VACDAY*, and *LOWSICK* is the percentage of cases with values less than 10 for *SICKDAY*.

Using the FIN Function

```
AGGREGATE OUTFILE='GROUPS.SAV' /BREAK=OCCGROUP
 /COLLEGE = FIN(EDUC,13,16).
```

- AGGREGATE creates the variable *COLLEGE*, which is the fraction of cases with 13 to 16 years of education (variable *EDUC*).

Using the PIN Function

```
AGGREGATE OUTFILE=* /BREAK=CLASS
 /LOCAL = PIN(STATE,'IL','IO').
```

- AGGREGATE creates the variable *LOCAL*, which is the percentage of cases in each break group whose two-letter state code represents Illinois, Indiana, or Iowa. (The abbreviation for Indiana, IN, is between IL and IO in an alphabetical sort sequence.)

MISSING Subcommand

By default, AGGREGATE uses all nonmissing values of the source variable to calculate aggregated variables. An aggregated variable will have a missing value only if the source variable is missing for every case in the break group. You can alter the default missing-value treatment by using the MISSING subcommand. You can also specify the inclusion of user-missing values on any function.

- MISSING must immediately follow OUTFILE.
- COLUMNWISE is the only specification available for MISSING.
- If COLUMNWISE is specified, the value of an aggregated variable is missing for a break group if the source variable is missing for any case in the group.
- COLUMNWISE does not affect the calculation of the N, NU, NMISS, or NUMISS functions.
- COLUMNWISE does not apply to break variables. If a break variable has a missing value, cases in that group are processed and the break variable is saved in the file with the missing value. Use SELECT IF if you want to eliminate cases with missing values for the break variables.

Including Missing Values

You can force a function to include user-missing values in its calculations by specifying a period after the function name.

- AGGREGATE ignores periods used with the functions N, NU, NMISS, and NUMISS if these functions have no arguments.
- User-missing values are treated as valid when these four functions are followed by a period and have a variable as an argument. NMISS.(AGE) treats user-missing values as valid and thus gives the number of cases for which *AGE* has the system-missing value only.

The effect of specifying a period with N, NU, NMISS, and NUMISS is illustrated by the following:

```
N = N. = N(AGE) + NMISS(AGE) = N.(AGE) + NMISS.(AGE)

NU = NU. = NU(AGE) + NUMISS(AGE) = NU.(AGE) + NUMISS.(AGE)
```

- The function N (the same as N. with no argument) yields a value for each break group that equals the number of cases with valid values (N(AGE)) plus the number of cases with user- or system-missing values (NMISS(AGE)).

- This in turn equals the number of cases with either valid or user-missing values (`N.(AGE)`) plus the number with system-missing values (`NMISS.(AGE)`).
- The same identities hold for the `NU`, `NMISS`, and `NUMISS` functions.

Default Treatment of Missing Values

```
AGGREGATE OUTFILE='AGGEMP.SAV' /MISSING=COLUMNWISE /BREAK=LOCATN
 /AVGSAL = MEAN(SALARY).
```

- *AVGSAL* is missing for an aggregated case if *SALARY* is missing for any case in the break group.

Including User-Missing Values

```
AGGREGATE OUTFILE=* /BREAK=DEPT
 /LOVAC = PLT.(VACDAY,10).
```

- *LOVAC* is the percentage of cases within each break group with values less than 10 for *VACDAY*, even if some of those values are defined as user missing.

Aggregated Values that Retain Missing-Value Status

```
AGGREGATE OUTFILE='CLASS.SAV' /BREAK=GRADE
  /FIRSTAGE = FIRST.(AGE).
```

- The first value of *AGE* in each break group is assigned to the variable *FIRSTAGE*.
- If the first value of *AGE* in a break group is user missing, that value will be assigned to *FIRSTAGE*. However, the value will retain its missing-value status, since variables created with `FIRST` take dictionary information from their source variables.

Comparing Missing-Value Treatments

The table below demonstrates the effects of specifying the `MISSING` subcommand and a period after the function name. Each entry in the table is the number of cases used to compute the specified function for the variable *EDUC*, which has 10 nonmissing cases, 5 user-missing cases, and 2 system-missing cases for the group. Note that columnwise treatment produces the same results as the default for every function except the `MEAN` function.

Table 8-1
Default versus columnwise missing-value treatments

Function	Default	Columnwise
`N`	17	17
`N.`	17	17
`N(EDUC)`	10	10
`N.(EDUC)`	15	15
`MEAN(EDUC)`	10	0
`MEAN.(EDUC)`	15	0

Function	Default	Columnwise
NMISS(EDUC)	7	7
NMISS.(EDUC)	2	2

AIM

```

```

* Default if the keyword is omitted.

** Default if the subcommand or keyword is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
AIM TSC_1
  /CATEGORICAL type
  /CONTINUOUS price engine_s horsepow wheelbas width length
              curb_wgt fuel_cap mpg
  /PLOT CLUSTER.
```

Overview

AIM provides graphical output to show the relative importance of categorical and scale variables to the formation of clusters of cases as indicated by the grouping variable.

Basic Specification

The basic specification is a grouping variable, a CATEGORICAL or CONTINUOUS subcommand, and a PLOT subcommand.

Subcommand Order

- The grouping variable must be specified first.
- Subcommands can be specified in any order.

Syntax Rules

- All subcommands should be specified only once. If a subcommand is repeated, only the last specification will be used.

Limitations

The WEIGHT variable, if specified, is ignored by this procedure.

Grouping Variable

- The grouping variable must be the first specification after the procedure name.
- The grouping variable can be of any type (numeric or string).

Example

```
AIM clu_id
  /CONTINUOUS age work salary.
```

- This is a typical example where *CLU_ID* is the cluster membership saved from a clustering procedure (say TwoStep Cluster) where *AGE*, *WORK*, and *SALARY* are the variables used to find the clusters.

CATEGORICAL Subcommand

Variables that are specified in this subcommand are treated as categorical variables, regardless of their defined measurement level.

- There is no restriction on the types of variables that can be specified on this subcommand.
- The grouping variable cannot be specified on this subcommand.

CONTINUOUS Subcommand

Variables that are specified in this subcommand are treated as scale variables, regardless of their defined measurement level.

- Variables specified on this subcommand must be numeric.
- The grouping variable cannot be specified on this subcommand.

CRITERIA Subcommand

The CRITERIA subcommand offers the following options in producing graphs.

ADJUST = BONFERRONI | NONE

Adjust the confidence level for simultaneous confidence intervals or the tolerance level for simultaneous tests. BONFERRONI uses Bonferroni adjustments. This is the default. NONE specifies that no adjustments should be applied.

CI = number *Confidence Interval.* This option controls the confidence level. Specify a value greater than 0 and less than 100. The default value is 95.

HIDENOTSIG = NO | YES

Hide groups or variables that are determined to be not significant. `YES` specifies that all confidence intervals and all test results should be shown. This is the default. `NO` specifies that only the significant confidence intervals and test results should be shown.

SHOWREFLINE = NO | YES

Display reference lines that are the critical values or the tolerance levels in tests. `YES` specifies that the appropriate reference lines should be shown. This is the default. `NO` specifies that reference lines should not be shown.

MISSING Subcommand

The `MISSING` subcommand specifies the way to handle cases with user-missing values.

- A case is never used if it contains system-missing values in the grouping variable, categorical variable list, or the continuous variable list.
- If this subcommand is not specified, the default is `EXCLUDE`.

EXCLUDE *Exclude both user-missing and system-missing values.* This is the default.

INCLUDE *User-missing values are treated as valid.* Only system-missing values are not included in the analysis.

PLOT Subcommand

The `PLOT` subcommand specifies which graphs to produce.

CATEGORY *Within Cluster Percentages.* This option displays a clustered bar chart for each categorical variable. The bars represent percentages of categories in each cluster. The cluster marginal count is used as the base for the percentages.

CLUSTER (TYPE=BAR | PIE)

Cluster frequency charts. Displays a bar or pie chart, depending upon the option selected, representing the frequency of each level of the grouping variable.

ERRORBAR *Error Bar.* This option displays an error bar by group ID for each continuous variable.

IMPORTANCE (X=GROUP | VARIABLE Y=TEST | PVALUE)

Attribute Importance. This option displays a bar chart that shows the relative importance of the attributes/variables. The specified options further control the display.

`X = GROUP` causes values of the grouping variable to be displayed on the *x* axis. A separate chart is produced for each variable. `X = VARIABLE` causes variable names to be displayed on the *x* axis. A separate chart is produced for each value of the grouping variable.

`Y = TEST` causes test statistics to be displayed on the *y* axis. Student's *t* statistics are displayed for scale variables, and chi-square statistics are displayed for categorical variables. `Y = PVALUE` causes *p*-value-related measures to be displayed on the *y* axis. Specifically, $-\log_{10}$(pvalue) is shown so that in both cases larger values indicate "more significant" results.

Example: Importance Charts by Group

```
AIM clu_id
  /CONTINUOUS age work salary
  /CATEGORICAL minority
  /PLOT CATEGORY CLUSTER (TYPE = PIE) IMPORTANCE (X=GROUP Y=TEST).
```

- A frequency pie chart is requested.
- Student's *t* statistics are plotted against the group ID for each scale variable, and chi-square statistics are plotted against the group ID for each categorical variable.

Example: Importance Charts by Variable

```
AIM clu_id
  /CONTINUOUS age work salary
  /CATEGORICAL minority
  /CRITERIA HIDENOTSIG=YES CI=95 ADJUST=NONE
  /PLOT CATEGORY CLUSTER (TYPE = BAR)
              IMPORTANCE (X = VARIABLE, Y = PVALUE).
```

- A frequency bar chart is requested.
- –log10(pvalue) values are plotted against variables, both scale and categorical, for each level of the grouping variable.
- In addition, bars are not shown if their *p* values exceed 0.05.

ALTER TYPE

```
ALTER TYPE varlist([input format = ] {output format    }) [varlist...]
                                     {AMIN [+ [n[%]]   }
                                     {AHEXMIN [+ [n[%]]}
  [/PRINT [{ALTEREDTYPES*] [ALTEREDVALUES]}]
          {NONE                          }
```

* Default if subcommand omitted.

Release History

Release 16.0

- Command introduced.

Example

```
ALTER TYPE StringDate1 to StringDate4 (Date11).
ALTER TYPE ALL (A=AMIN).
```

Overview

`ALTER TYPE` can be used to change the fundamental type (string or numeric) or format of variables, including changing the defined width of string variables.

Options

- You can use the `TO` keyword to specify a list of variables or the `ALL` keyword to specify all variables in the active dataset.
- The optional input format specification restricts the type modification to only variables in the list that match the input format. If the input format doesn't include a width specification, all variables that match the basic format are included. An input format specification without a width specification includes all variables that match the basic format, regardless of defined width.
- `AMIN` or `AHEXMIN` can be used as the output format specification to change the defined width of a string variable to the minimum width necessary to display all observed values of that variable without truncation.
- `AMIN + n` or `AHEXMIN + n` sets the width of string variables to the minimum necessary width plus *n* bytes.
- `AMIN + n%` or `AHEXMIN + n%` sets the width of string variables to the minimum necessary width plus *n* percent of that width. The result is rounded to an integer.

Basic Specification

The basic specification is the name of a variable in the active dataset followed by an output format specification enclosed in parentheses, as in:

```
ALTER TYPE StringVar (A4).
```

Syntax Rules

- All variables specified or implied in the variable list(s) must exist in the active dataset.
- Each variable list must be followed by a format specification enclosed in parentheses.
- Format specifications must be valid SPSS formats. For information on valid format specifications, see Variable Types and Formats.
- If specified, the optional input format must be followed by an equals sign and then the output format.
- If a variable is included in more than one variable list on the same `ALTER TYPE` command, only the format specification associated with the last instance of the variable name will be applied. (If you want to "chain" multiple modifications for the same variable, use multiple `ALTER TYPE` commands.)

Operations

- If the command does not include any `AMIN` or `AHEXMIN` format specifications and does not include `ALTEREDVALUES` on the `PRINT` subcommand, the command takes effect immediately. It does not read the active dataset or execute pending transformations.
- If the command includes one or more `AMIN` or `AHEXMIN` format specifications or includes `ALTEREDVALUES` on the `PRINT` subcommand, the command reads the active dataset and causes execution of any pending transformations.
- Converting a numeric variable to string will result in truncated values if the numeric value cannot be represented in the specified string width.
- Converting a string variable to numeric will result in a system-missing value if the string contains characters that would be invalid for the specified numeric format.

Examples

```
DATA LIST FREE
  /Numvar1 (F2) Numvar2 (F1)
  StringVar1 (A20) StringVar2 (A30)
  StringDate1 (A11) StringDate2 (A10) StringDate3 (A10).
BEGIN DATA
1 23 a234 b2345 28-Oct-2007 10/28/2007 10/29/2008
END DATA.
ALTER TYPE Numvar1 (F5.2) Numvar2 (F3).
ALTER TYPE
   StringDate1 to StringDate3 (A11 = DATE11).
ALTER TYPE
   StringDate1 to StringDate3 (A10 = ADATE10).
ALTER TYPE ALL (A=AMIN).
```

- The first `ALTER TYPE` command changes the formats of *Numvar1* and *Numvar2* from `F2` and `F1` to `F5.2` and `F3`.

- The next ALTER TYPE command converts all string variables between *StringDate1* and *StringDate3* (in file order) with a defined string width of 11 to the numeric date format DATE11 (dd-mmm-yyyy). The only variable that meets these criteria is *StringDate1*; so that is the only variable converted.
- The third ALTER TYPE command converts all string variables between *StringDate1* and *StringDate3* with a defined string width of 10 to the numeric date format ADATE11 (mm/dd/yyyy). In this example, this conversion is applied to *StringDate2* and *StringDate3*.
- The last ALTER TYPE command changes the defined width of all remaining string variables to the minimum width necessary for each variable to avoid truncation of any values. In this example, *StringVar1* changes from A20 to A4 and *StringVar2* changes from A30 to A5. This command reads the data and executes any pending transformation commands.

PRINT Subcommand

The optional PRINT subcommand controls the display of information about the variables modified by the ALTER TYPE command. The following options are available:

ALTEREDTYPES. *Display a list of variables for which the formats were changed and the old and new formats.* This is the default.

ALTEREDVALUES. *Display a report of values that were changed if the fundamental type (string or numeric) was changed or the defined string width was changed.* This report is limited to the first 25 values that were changed for each variable.

NONE. *Don't display any summary information.* This is an alternative to ALTEREDTYPES and/or ALTEREDVALUES and cannot be used in combination with them.

ALSCAL

```

```

**Default if the subcommand or keyword is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
ALSCAL VARIABLES=ATLANTA TO TAMPA.
```

ALSCAL was originally designed and programmed by Forrest W. Young, Yoshio Takane, and Rostyslaw J. Lewyckyj of the Psychometric Laboratory, University of North Carolina.

Overview

ALSCAL uses an alternating least-squares algorithm to perform multidimensional scaling (MDS) and multidimensional unfolding (MDU). You can select one of the five models to obtain stimulus coordinates and/or weights in multidimensional space.

Options

Data Input. You can read inline data matrices, including all types of two- or three-way data, such as a single matrix or a matrix for each of several subjects, using the INPUT subcommand. You can read square (symmetrical or asymmetrical) or rectangular matrices of proximities with the SHAPE subcommand and proximity matrices created by PROXIMITIES and CLUSTER with the MATRIX subcommand. You can also read a file of coordinates and/or weights to provide initial or fixed values for the scaling process with the FILE subcommand.

Methodological Assumptions. You can specify data as matrix-conditional, row-conditional, or unconditional on the CONDITION subcommand. You can treat data as nonmetric (nominal or ordinal) or as metric (interval or ratio) using the LEVEL subcommand. You can also use LEVEL to identify ordinal-level proximity data as measures of similarity or dissimilarity, and you can specify tied observations as untied (continuous) or leave them tied (discrete).

Model Selection. You can specify the most commonly used multidimensional scaling models by selecting the correct combination of ALSCAL subcommands, keywords, and criteria. In addition to the default Euclidean distance model, the MODEL subcommand offers the individual differences (weighted) Euclidean distance model (INDSCAL), the asymmetric Euclidean distance model (ASCAL), the asymmetric individual differences Euclidean distance model (AINDS), and the generalized Euclidean metric individual differences model (GEMSCAL).

Output. You can produce output that includes raw and scaled input data, missing-value patterns, normalized data with means, squared data with additive constants, each subject's scalar product and individual weight space, plots of linear or nonlinear fit, and plots of the data transformations using the PRINT and PLOT subcommands.

Basic Specification

The basic specification is VARIABLES followed by a variable list. By default, ALSCAL produces a two-dimensional nonmetric Euclidean multidimensional scaling solution. Input is assumed to be one or more square symmetric matrices with data elements that are dissimilarities at the ordinal level of measurement. Ties are not untied, and conditionality is by subject. Values less than 0 are treated as missing. The default output includes the improvement in Young's S-stress for successive iterations, two measures of fit for each input matrix (Kruskal's stress and the squared correlation, RSQ), and the derived configurations for each of the dimensions.

Subcommand Order

Subcommands can be named in any order.

Operations

- ALSCAL calculates the number of input matrices by dividing the total number of observations in the dataset by the number of rows in each matrix. All matrices must contain the same number of rows. This number is determined by the settings on SHAPE and INPUT (if used). For square matrix data, the number of rows in the matrix equals the number of variables. For rectangular matrix data, it equals the number of rows specified or implied. For additional information, see the INPUT and SHAPE subcommands below.
- ALSCAL ignores user-missing specifications in all variables in the configuration/weights file. For more information, see FILE Subcommand on p. 165. The system-missing value is converted to 0.
- With split-file data, ALSCAL reads initial or fixed configurations from the configuration/weights file for each split-file group. For more information, see FILE Subcommand on p. 165. If there is only one initial configuration in the file, ALSCAL rereads these initial or fixed values for successive split-file groups.
- By default, ALSCAL estimates upper and lower bounds on missing values in the active dataset in order to compute the initial configuration. To prevent this, specify CRITERIA=NOULB. Missing values are always ignored during the iterative process.

Limitations

- A maximum of 100 variables on the VARIABLES subcommand.
- A maximum of six dimensions can be scaled.
- ALSCAL does not recognize data weights created by the WEIGHT command.
- ALSCAL analyses can include no more than 32,767 values in each of the input matrices. Large analyses may require significant computing time.

Example

```
* Air distances among U.S. cities.
* Data are from Johnson and Wichern (1982), page 563.
DATA LIST
 /ATLANTA BOSTON CINCNATI COLUMBUS DALLAS INDNPLIS
   LITTROCK LOSANGEL MEMPHIS STLOUIS SPOKANE TAMPA 1-60.
BEGIN DATA
   0
1068    0

 467 1379  928  985 1077  975  912 2480  779 1016 2821   0
END DATA.
```

```
ALSCAL VARIABLES=ATLANTA TO TAMPA
 /PLOT.
```

- By default, ALSCAL assumes a symmetric matrix of dissimilarities for ordinal-level variables. Only values below the diagonal are used. The upper triangle can be left blank. The 12 cities form the rows and columns of the matrix.
- The result is a classical MDS analysis that reproduces a map of the United States when the output is rotated to a north-south by east-west orientation.

VARIABLES Subcommand

VARIABLES identifies the columns in the proximity matrix or matrices that ALSCAL reads.

- VARIABLES is required and can name only numeric variables.
- Each matrix must have at least four rows and four columns.

INPUT Subcommand

ALSCAL reads data row by row, with each case in the active dataset representing a single row in the data matrix. (VARIABLES specifies the columns.) Use INPUT when reading rectangular data matrices to specify how many rows are in each matrix.

- The specification on INPUT is ROWS. If INPUT is not specified or is specified without ROWS, the default is ROWS(ALL). ALSCAL assumes that each case in the active dataset represents one row of a single input matrix and that the result is a square matrix.
- You can specify the number of rows (*n*) in each matrix in parentheses after the keyword ROWS. The number of matrices equals the number of observations divided by the number specified.
- The number specified on ROWS must be at least 4 and must divide evenly into the total number of rows in the data.
- With split-file data, *n* refers to the number of cases in each split-file group. All split-file groups must have the same number of rows.

Example

```
ALSCAL VARIABLES=V1 to V7 /INPUT=ROWS(8).
```

- INPUT indicates that there are eight rows per matrix, with each case in the active dataset representing one row.
- The total number of cases must be divisible by 8.

SHAPE Subcommand

Use SHAPE to specify the structure of the input data matrix or matrices.

- You can specify one of the three keywords listed below.

- Both SYMMETRIC and ASYMMETRIC refer to square matrix data.

SYMMETRIC	*Symmetric data matrix or matrices.* For a symmetric matrix, ALSCAL looks only at the values below the diagonal. Values on and above the diagonal can be omitted. This is the default.
ASYMMETRIC	*Asymmetric data matrix or matrices.* The corresponding values in the upper and lower triangles are not all equal. The diagonal is ignored.
RECTANGULAR	*Rectangular data matrix or matrices.* The rows and columns represent different sets of items.

Example

```
ALSCAL VAR=V1 TO V8 /SHAPE=RECTANGULAR.
```

- ALSCAL performs a classical MDU analysis, treating the rows and columns as separate sets of items.

LEVEL Subcommand

LEVEL identifies the level of measurement for the values in the data matrix or matrices. You can specify one of the keywords defined below.

ORDINAL	*Ordinal-level data.* This specification is the default. It treats the data as ordinal, using Kruskal's least-squares monotonic transformation (Kruskal, 1964). The analysis is nonmetric. By default, the data are treated as discrete dissimilarities. Ties in the data remain tied throughout the analysis. To change the default, specify UNTIE and/or SIMILAR in parentheses. UNTIE treats the data as continuous and resolves ties in an optimal fashion; SIMILAR treats the data as similarities. UNTIE and SIMILAR cannot be used with the other levels of measurement.
INTERVAL(n)	*Interval-level data.* This specification produces a metric analysis of the data using classical regression techniques. You can specify any integer from 1 to 4 in parentheses for the degree of polynomial transformation to be fit to the data. The default is 1.
RATIO(n)	*Ratio-level data.* This specification produces a metric analysis. You can specify an integer from 1 to 4 in parentheses for the degree of polynomial transformation. The default is 1.
NOMINAL	*Nominal-level data.* This specification treats the data as nominal by using a least-squares categorical transformation (Takane, Young, and de Leeuw, 1977). This option produces a nonmetric analysis of nominal data. It is useful when there are few observed categories, when there are many observations in each category, and when the order of the categories is not known.

Example

```
ALSCAL VAR=ATLANTA TO TAMPA /LEVEL=INTERVAL(2).
```

- This example identifies the distances between U.S. cities as interval-level data. The 2 in parentheses indicates a polynomial transformation with linear and quadratic terms.

CONDITION Subcommand

CONDITION specifies which numbers in a dataset are comparable.

MATRIX	*Only numbers within each matrix are comparable.* If each matrix represents a different subject, this specification makes comparisons conditional by subject. This is the default.
ROW	*Only numbers within the same row are comparable.* This specification is appropriate only for asymmetric or rectangular data. They cannot be used when ASCAL or AINDS is specified on MODEL.
UNCONDITIONAL	*All numbers are comparable.* Comparisons can be made among any values in the input matrix or matrices.

Example

```
ALSCAL VAR=V1 TO V8 /SHAPE=RECTANGULAR /CONDITION=ROW.
```

- ALSCAL performs a Euclidean MDU analysis conditional on comparisons within rows.

FILE Subcommand

ALSCAL can read proximity data from the active dataset or, with the MATRIX subcommand, from a matrix data file created by PROXIMITIES or CLUSTER. The FILE subcommand reads a file containing additional data—an initial or fixed configuration for the coordinates of the stimuli and/or weights for the matrices being scaled. This file can be created with the OUTFILE subcommand on ALSCAL or with an input program (created with the INPUT PROGRAM command).

- The minimum specification is the file that contains the configurations and/or weights.
- FILE can include additional specifications that define the structure of the configuration/weights file.
- The variables in the configuration/weights file that correspond to successive ALSCAL dimensions must have the names *DIM1*, *DIM2*, ..., *DIMr*, where *r* is the maximum number of ALSCAL dimensions. The file must also contain the short string variable *TYPE_* to identify the types of values in all rows.
- Values for the variable *TYPE_* can be CONFIG, ROWCONF, COLCONF, SUBJWGHT, and STIMWGHT, in that order. Each value can be truncated to the first three letters. Stimulus coordinate values are specified as CONFIG; row stimulus coordinates, as ROWCONF; column stimulus coordinates, as COLCONF; and subject and stimulus weights, as SUBJWGHT and STIMWGHT, respectively. ALSCAL accepts CONFIG and ROWCONF interchangeably.
- ALSCAL skips unneeded types as long as they appear in the file in their proper order. Generalized weights (GEM) and flattened subject weights (FLA) cannot be initialized or fixed and will always be skipped. (These weights can be generated by ALSCAL but cannot be used as input.)

The following list summarizes the optional specifications that can be used on FILE to define the structure of the configuration/weights file:

- Each specification can be further identified with the option INITIAL or FIXED in parentheses.

- INITIAL is the default. INITIAL indicates that the external configuration or weights are to be used as initial coordinates and are to be modified during each iteration.
- FIXED forces ALSCAL to use the externally defined structure without modification to calculate the best values for all unfixed portions of the structure.

CONFIG *Read stimulus configuration.* The configuration/weights file contains initial stimulus coordinates. Input of this type is appropriate when SHAPE=SYMMETRIC or SHAPE= ASYMMETRIC, or when the number of variables in a matrix equals the number of variables on the ALSCAL command. The value of the *TYPE_* variable must be either CON or ROW for all stimulus coordinates for the configuration.

ROWCONF *Read row stimulus configuration.* The configuration/weights file contains initial row stimulus coordinates. This specification is appropriate if SHAPE= RECTANGULAR and if the number of ROWCONF rows in the matrix equals the number of rows specified on the INPUT subcommand (or, if INPUT is omitted, the number of cases in the active dataset). The value of *TYPE_* must be either ROW or CON for the set of coordinates for each row.

COLCONF *Read column stimulus configuration.* The configuration/weights file contains initial column stimulus coordinates. This kind of file can be used only if SHAPE= RECTANGULAR and if the number of COLCONF rows in the matrix equals the number of variables on the ALSCAL command. The value of *TYPE_* must be COL for the set of coordinates for each column.

SUBJWGHT *Read subject (matrix) weights.* The configuration/weights file contains subject weights. The number of observations in a subject-weights matrix must equal the number of matrices in the proximity file. Subject weights can be used only if the model is INDSCAL, AINDS, or GEMSCAL. The value of *TYPE_* for each set of weights must be SUB.

STIMWGHT *Read stimulus weights.* The configuration/weights file contains stimulus weights. The number of observations in the configuration/weights file must equal the number of matrices in the proximity file. Stimulus weights can be used only if the model is AINDS or ASCAL. The value of *TYPE_* for each set of weights must be STI.

If the optional specifications for the configuration/weights file are not specified on FILE, ALSCAL sequentially reads the *TYPE_* values appropriate to the model and shape according to the defaults in the table below.

Example

```
ALSCAL VAR=V1 TO V8 /FILE=ONE CON(FIXED) STI(INITIAL).
```

- ALSCAL reads the configuration/weights file *ONE*.
- The stimulus coordinates are read as fixed values, and the stimulus weights are read as initial values.

Table 11-1
Default specifications for the FILE subcommand

Shape	Model	Default specifications
SYMMETRIC	EUCLID	CONFIG (or ROWCONF)
	INDSCAL	CONFIG (or ROWCONF) SUBJWGHT
	GEMSCAL	CONFIG (or ROWCONF) SUBJWGHT
ASYMMETRIC	EUCLID	CONFIG (or ROWCONF)

Shape	Model	Default specifications
	INDSCAL	CONFIG (or ROWCONF) SUBJWGHT
	GEMSCAL	CONFIG (or ROWCONF) SUBJWGHT
	ASCAL	CONFIG (or ROWCONF) STIMWGHT
	AINDS	CONFIG (or ROWCONF) SUBJWGHT STIMWGHT
RECTANGULAR	EUCLID	ROWCONF (or CONFIG) COLCONF
	INDSCAL	ROWCONF (or CONFIG) COLCONF SUBJWGHT
	GEMSCAL	ROWCONF (or CONFIG) COLCONF SUBJWGHT

MODEL Subcommand

MODEL (alias METHOD) defines the scaling model for the analysis. The only specification is MODEL (or METHOD) and any one of the five scaling and unfolding model types. EUCLID is the default.

EUCLID *Euclidean distance model.* This model can be used with any type of proximity matrix and is the default.

INDSCAL *Individual differences (weighted) Euclidean distance model.* ALSCAL scales the data using the weighted individual differences Euclidean distance model (Carroll and Chang, 1970). This type of analysis can be specified only if the analysis involves more than one data matrix and more than one dimension is specified on CRITERIA.

ASCAL *Asymmetric Euclidean distance model.* This model (Young, 1975) can be used only if SHAPE=ASYMMETRIC and more than one dimension is requested on CRITERIA.

AINDS *Asymmetric individual differences Euclidean distance model.* This option combines Young's asymmetric Euclidean model (Young et al., 1975) with the individual differences model (Carroll et al., 1970). This model can be used only when SHAPE=ASYMMETRIC, the analysis involves more than one data matrix, and more than one dimension is specified on CRITERIA.

GEMSCAL *Generalized Euclidean metric individual differences model.* The number of directions for this model is set with the DIRECTIONS option on CRITERIA. The number of directions specified can be equal to but cannot exceed the group space dimensionality. By default, the number of directions equals the number of dimensions in the solution.

Example

```
ALSCAL VARIABLES = V1 TO V6
 /SHAPE = ASYMMETRIC
 /CONDITION = ROW
 /MODEL = GEMSCAL
 /CRITERIA = DIM(4) DIRECTIONS(4).
```

- In this example, the number of directions in the GEMSCAL model is set to 4.

CRITERIA Subcommand

Use CRITERIA to control features of the scaling model and to set convergence criteria for the solution. You can specify one or more of the following:

CONVERGE(n) *Stop iterations if the change in S-stress is less than* n. S-stress is a goodness-of-fit index. By default, *n*=0.001. To increase the precision of a solution, specify a smaller value, for example, 0.0001. To obtain a less precise solution (perhaps to reduce computing time), specify a larger value, for example, 0.05. Negative values are not allowed. If *n*=0, the algorithm will iterate 30 times unless a value is specified with the ITER option.

ITER(n) *Set the maximum number of iterations to* n. The default value is 30. A higher value will give a more precise solution but will take longer to compute.

STRESSMIN(n) *Set the minimum stress value to* n. By default, ALSCAL stops iterating when the value of S-stress is 0.005 or less. STRESSMIN can be assigned any value from 0 to 1.

NEGATIVE *Allow negative weights in individual differences models.* By default, ALSCAL does not permit the weights to be negative. Weighted models include INDSCAL, ASCAL, AINDS, and GEMSCAL. The NEGATIVE option is ignored if the model is EUCLID.

CUTOFF(n) *Set the cutoff value for treating distances as missing to* n. By default, ALSCAL treats all negative similarities (or dissimilarities) as missing and 0 and positive similarities as nonmissing (*n*=0). Changing the CUTOFF value causes ALSCAL to treat similarities greater than or equal to that value as nonmissing. User- and system-missing values are considered missing regardless of the CUTOFF specification.

NOULB *Do not estimate upper and lower bounds on missing values.* By default, ALSCAL estimates the upper and lower bounds on missing values in order to compute the initial configuration. This specification has no effect during the iterative process, when missing values are ignored.

DIMENS(min[,max]) *Set the minimum and maximum number of dimensions in the scaling solution.* By default, ALSCAL calculates a solution with two dimensions. To obtain solutions for more than two dimensions, specify the minimum and the maximum number of dimensions in parentheses after DIMENS. The minimum and maximum can be integers between 2 and 6. A single value represents both the minimum and the maximum. For example, DIMENS(3) is equivalent to DIMENS(3,3). The minimum number of dimensions can be set to 1 only if MODEL=EUCLID.

DIRECTIONS(n) *Set the number of principal directions in the generalized Euclidean model to* n. This option has no effect for models other than GEMSCAL. The number of principal directions can be any positive integer between 1 and the number of dimensions specified on the DIMENS option. By default, the number of directions equals the number of dimensions.

TIESTORE(n) *Set the amount of storage needed for ties to* n. This option estimates the amount of storage needed to deal with ties in ordinal data. By default, the amount of storage is set to 1000 or the number of cells in a matrix, whichever is smaller. Should this be insufficient, ALSCAL terminates and displays a message that more space is needed.

CONSTRAIN *Constrain multidimensional unfolding solution.* This option can be used to keep the initial constraints throughout the analysis.

PRINT Subcommand

PRINT requests output not available by default. You can specify the following:

DATA *Display input data.* The display includes both the initial data and the scaled data for each subject according to the structure specified on SHAPE.

HEADER *Display a header page.* The header includes the model, output, algorithmic, and data options in effect for the analysis.

- Data options listed by PRINT=HEADER include the number of rows and columns, number of matrices, measurement level, shape of the data matrix, type of data (similarity or dissimilarity), whether ties are tied or untied, conditionality, and data cutoff value.
- Model options listed by PRINT=HEADER are the type of model specified (EUCLID, INDSCAL, ASCAL, AINDS, or GEMSCAL), minimum and maximum dimensionality, and whether or not negative weights are permitted.
- Output options listed by PRINT=HEADER indicate whether the output includes the header page and input data, whether ALSCAL plotted configurations and transformations, whether an output dataset was created, and whether initial stimulus coordinates, initial column stimulus coordinates, initial subject weights, and initial stimulus weights were computed.
- Algorithmic options listed by PRINT=HEADER include the maximum number of iterations permitted, the convergence criterion, the maximum S-stress value, whether or not missing data are estimated by upper and lower bounds, and the amount of storage allotted for ties in ordinal data.

Example

```
ALSCAL VAR=ATLANTA TO TAMPA /PRINT=DATA.
```

- In addition to scaled data, ALSCAL will display initial data.

PLOT Subcommand

PLOT controls the display of plots. The minimum specification is simply PLOT to produce the defaults.

DEFAULT *Default plots.* Default plots include plots of stimulus coordinates, matrix weights (if the model is INDSCAL, AINDS, or GEMSCAL), and stimulus weights (if the model is AINDS or ASCAL). The default also includes a scatterplot of the linear fit between the data and the model and, for certain types of data, scatterplots of the nonlinear fit and the data transformation.

ALL *Transformation plots in addition to the default plots.* A separate plot is produced for each subject if CONDITION=MATRIX and a separate plot for each row if CONDITION=ROW. For interval and ratio data, PLOT=ALL has the same effect as PLOT=DEFAULT. This option can generate voluminous output, particularly when CONDITION=ROW.

Example

```
ALSCAL VAR=V1 TO V8 /INPUT=ROWS(8) /PLOT=ALL.
```

- This command produces all of the default plots. It also produces a separate plot for each subject's data transformation and a plot of *V1* through *V8* in a two-dimensional space for each subject.

OUTFILE Subcommand

OUTFILE saves coordinate and weight matrices to an SPSS data file. The only specification is a name for the output file.

- The output data file has an alphanumeric (short string) variable named *TYPE_* that identifies the kind of values in each row, a numeric variable named *DIMENS* that specifies the number of dimensions, a numeric variable named *MATNUM* that indicates the subject (matrix) to which each set of coordinates corresponds, and variables named *DIM1*, *DIM2*, ..., *DIMn* that correspond to the *n* dimensions in the model.
- The values of any split-file variables are also included in the output file.
- The file created by OUTFILE can be used by subsequent ALSCAL commands as initial data.

The following are the types of configurations and weights that can be included in the output file:

CONFIG	*Stimulus configuration coordinates*.
ROWCONF	*Row stimulus configuration coordinates*.
COLCONF	*Column stimulus configuration coordinates*.
SUBJWGHT	*Subject (matrix) weights*.
FLATWGHT	*Flattened subject (matrix) weights*.
GEMWGHT	*Generalized weights*.
STIMWGHT	*Stimulus weights*.

Only the first three characters of each identifier are written to the variable *TYPE_* in the file. For example, CONFIG becomes CON. The structure of the file is determined by the SHAPE and MODEL subcommands, as shown in the following table.

Table 11-2
Types of configurations and/or weights in output files

Shape	Model	TYPE_
SYMMETRIC	EUCLID	CON
	INDSCAL	CON SUB FLA
	GEMSCAL	CON SUB FLA GEM
ASYMMETRIC	EUCLID	CON

Shape	Model	TYPE_
	INDSCAL	CON SUB FLA
	GEMSCAL	CON SUB FLA GEM
	ASCAL	CON STI
	AINDS	CON SUB FLA STI
RECTANGULAR	EUCLID	ROW COL
	INDSCAL	ROW COL SUB FLA
	GEMSCAL	ROW COL SUB FLA GEM

Example

```
ALSCAL VAR=ATLANTA TO TAMPA /OUTFILE=ONE.
```

- OUTFILE creates the configuration/weights file *ONE* from the example of air distances between cities.

MATRIX Subcommand

MATRIX reads matrix data files. It can read a matrix written by either PROXIMITIES or CLUSTER.

- Generally, data read by ALSCAL are already in matrix form. If the matrix materials are in the active dataset, you do not need to use MATRIX to read them. Simply use the VARIABLES subcommand to indicate the variables (or columns) to be used. However, if the matrix materials are not in the active dataset, MATRIX must be used to specify the matrix data file that contains the matrix.
- The proximity matrices that ALSCAL reads have *ROWTYPE_* values of PROX. No additional statistics should be included with these matrix materials.
- ALSCAL ignores unrecognized *ROWTYPE_* values in the matrix file. In addition, it ignores variables present in the matrix file that are not specified on the VARIABLES subcommand in ALSCAL. The order of rows and columns in the matrix is unimportant.
- Since ALSCAL does not support case labeling, it ignores values for the *ID* variable (if present) in a CLUSTER or PROXIMITIES matrix.

- If split-file processing was in effect when the matrix was written, the same split file must be in effect when ALSCAL reads that matrix.
- The specification on MATRIX is the keyword IN and the matrix file in parentheses.
- MATRIX=IN cannot be used unless a active dataset has already been defined. To read an existing matrix data file at the beginning of a session, first use GET to retrieve the matrix file and then specify IN(*) on MATRIX.

IN (filename) *Read a matrix data file.* If the matrix data file is the active dataset, specify an asterisk in parentheses (*). If the matrix data file is another file, specify the filename in parentheses. A matrix file read from an external file does not replace the active dataset.

Example

```
PROXIMITIES V1 TO V8 /ID=NAMEVAR /MATRIX=OUT(*).
ALSCAL VAR=CASE1 TO CASE10 /MATRIX=IN(*).
```

- PROXIMITIES uses *V1* through *V8* in the active dataset to generate a matrix file of Euclidean distances between each pair of cases based on the eight variables. The number of rows and columns in the resulting matrix equals the number of cases. MATRIX=OUT then replaces the active dataset with this new matrix data file.
- MATRIX=IN on ALSCAL reads the matrix data file, which is the new active dataset. In this instance, MATRIX is optional because the matrix materials are in the active dataset.
- If there were 10 cases in the original active dataset, ALSCAL performs a multidimensional scaling analysis in two dimensions on *CASE1* through *CASE10*.

Example

```
GET FILE PROXMTX.
ALSCAL VAR=CASE1 TO CASE10 /MATRIX=IN(*).
```

- GET retrieves the matrix data file *PROXMTX*.
- MATRIX=IN specifies an asterisk because the active dataset is the matrix. MATRIX is optional, however, since the matrix materials are in the active dataset.

Example

```
GET FILE PRSNNL.
FREQUENCIES VARIABLE=AGE.
ALSCAL VAR=CASE1 TO CASE10 /MATRIX=IN(PROXMTX).
```

- This example performs a frequencies analysis on the file *PRSNNL* and then uses a different file containing matrix data for ALSCAL. The file is an existing matrix data file.
- MATRIX=IN is required because the matrix data file, *PROXMTX*, is not the active dataset. *PROXMTX* does not replace *PRSNNL* as the active dataset.

Specification of Analyses

The following tables summarize the analyses that can be performed for the major types of proximity matrices that you can use with ALSCAL, list the specifications needed to produce these analyses for nonmetric models, and list the specifications for metric models. You can include additional specifications to control the precision of your analysis with CRITERIA.

Table 11-3
Models for types of matrix input

Matrix mode	Matrix form	Model class	Single matrix	Replications of single matrix	Two or more individual matrices
Object by object	Symmetric	Multidimensional scaling	CMDS Classical multidimensional scaling	RMDS Replicated multidimensional scaling	WMDS(INDSCAL) Weighted multidimensional scaling
	Asymmetric single process	Multidimensional scaling	CMDS(row conditional) Classical row conditional multidimensional scaling	RMDS(row conditional) Replicated row conditional multi dimensional scaling	WMDS(row conditional) Weighted row conditional multidimensional scaling

                    {'savfile'|'dataset'}             {'savfile'|'dataset'}
```

**Default if the subcommand or keyword is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
ANACOR TABLE=MENTAL(1,4) BY SES(1,6).
```

Overview

ANACOR performs correspondence analysis, which is an isotropic graphical representation of the relationships between the rows and columns of a two-way table.

Options

Number of Dimensions. You can specify how many dimensions ANACOR should compute.

Method of Normalization. You can specify one of five different methods for normalizing the row and column scores.

Computation of Variances and Correlations. You can request computation of variances and correlations for singular values, row scores, or column scores.

Data Input. You can analyze the usual individual casewise data or aggregated data from table cells.

Display Output. You can control which statistics are displayed and plotted. You can also control how many value-label characters are used on the plots.

Writing Matrices. You can write matrix data files containing row and column scores and variances for use in further analyses.

Basic Specification

- The basic specification is ANACOR and the TABLE subcommand. By default, ANACOR computes a two-dimensional solution, displays the TABLE, SCORES, and CONTRIBUTIONS statistics, and plots the row scores and column scores of the first two dimensions.

Subcommand Order

- Subcommands can appear in any order.

Operations

- If a subcommand is specified more than once, only the last occurrence is executed.

Limitations

- If the data within table cells contains negative values. ANACOR treats those values as 0.

Example

```
ANACOR TABLE=MENTAL(1,4) BY SES(1,6)
 /PRINT=SCORES CONTRIBUTIONS
 /PLOT=ROWS COLUMNS.
```

- Two variables, *MENTAL* and *SES*, are specified on the TABLE subcommand. *MENTAL* has values ranging from 1 to 4, and *SES* has values ranging from 1 to 6.
- The row and column scores and the contribution of each row and column to the inertia of each dimension are displayed.
- Two plots are produced. The first one plots the first two dimensions of row scores, and the second one plots the first two dimensions of column scores.

TABLE Subcommand

TABLE specifies the row and column variables, along with their value ranges for individual casewise data. For table data, TABLE specifies the keyword ALL and the number of rows and columns.

- The TABLE subcommand is required.

Casewise Data

- Each variable is followed by a value range in parentheses. The value range consists of the variable's minimum value, a comma, and the variable's maximum value.
- Values outside of the specified range are not included in the analysis.

- Values do not have to be sequential. Empty categories receive scores of 0 and do not affect the rest of the computations.

Example

```
DATA LIST FREE/VAR1 VAR2.
BEGIN DATA
3 1
6 1
3 1
4 2
4 2
6 3
6 3
6 3
3 2
4 2
6 3
END DATA.
ANACOR TABLE=VAR1(3,6) BY VAR2(1,3).
```

- `DATA LIST` defines two variables, *VAR1* and *VAR2*.
- *VAR1* has three levels, coded 3, 4, and 6, while *VAR2* also has three levels, coded 1, 2, and 3.
- Because a range of (3,6) is specified for *VAR1*, `ANACOR` defines four categories, coded 3, 4, 5, and 6. The empty category, 5, for which there is no data, receives zeros for all statistics but does not affect the analysis.

Table Data

- The cells of a table can be read and analyzed directly by using the keyword `ALL` after `TABLE`.
- The columns of the input table must be specified as variables on the `DATA LIST` command. Only columns are defined, not rows.
- `ALL` is followed by the number of rows in the table, a comma, and the number of columns in the table, all enclosed in parentheses.
- If you want to analyze only a subset of the table, the specified number of rows and columns can be smaller than the actual number of rows and columns.
- The variables (columns of the table) are treated as the column categories, and the cases (rows of the table) are treated as the row categories.
- Rows cannot be labeled when you specify `TABLE=ALL`. If labels in your output are important, use the `WEIGHT` command method to enter your data (see Analyzing Aggregated Data on p. 183).

Example

```
DATA LIST /COL01 TO COL07 1-21.
BEGIN DATA
 50 19 26  8 18  6  2
 16 40 34 18 31  8  3
 12 35 65 66123 23 21
 11 20 58110223 64 32
 14 36114185714258189
  0  6 19 40179143 71
END DATA.
```

```
ANACOR TABLE=ALL(6,7).
```

- DATA LIST defines the seven columns of the table as the variables.
- The TABLE=ALL specification indicates that the data are the cells of a table. The (6,7) specification indicates that there are six rows and seven columns.

DIMENSION Subcommand

DIMENSION specifies the number of dimensions you want ANACOR to compute.

- If you do not specify the DIMENSION subcommand, ANACOR computes two dimensions.
- DIMENSION is followed by an integer indicating the number of dimensions.
- In general, you should choose as few dimensions as needed to explain most of the variation. The minimum number of dimensions that can be specified is 1. The maximum number of dimensions that can be specified is equal to the number of levels of the variable with the least number of levels, minus 1. For example, in a table where one variable has five levels and the other has four levels, the maximum number of dimensions that can be specified is (4 – 1), or 3. Empty categories (categories with no data, all zeros, or all missing data) are not counted toward the number of levels of a variable.
- If more than the maximum allowed number of dimensions is specified, ANACOR reduces the number of dimensions to the maximum.

NORMALIZATION Subcommand

The NORMALIZATION subcommand specifies one of five methods for normalizing the row and column scores. Only the scores and variances are affected; contributions and profiles are not changed.

The following keywords are available:

CANONICAL *For each dimension, rows are the weighted average of columns divided by the matching singular value, and columns are the weighted average of rows divided by the matching singular value*. This is the default if the NORMALIZATION subcommand is not specified. DEFAULT is an alias for CANONICAL. Use this normalization method if you are primarily interested in differences or similarities between variables.

PRINCIPAL *Distances between row points and column points are approximations of chi-square distances*. The distances represent the distance between the row or column and its corresponding average row or column profile. Use this normalization method if you want to examine both differences between categories of the row variable and differences between categories of the column variable (but not differences between variables).

RPRINCIPAL *Distances between row points are approximations of chi-square distances*. This method maximizes distances between row points. This is useful when you are primarily interested in differences or similarities between categories of the row variable.

CPRINCIPAL *Distances between column points are approximations of chi-square distances*. This method maximizes distances between column points. This is useful when you are primarily interested in differences or similarities between categories of the column variable.

The fifth method has no keyword. Instead, any value in the range –2 to +2 is specified after NORMALIZATION. A value of 1 is equal to the RPRINCIPAL method, a value of 0 is equal to CANONICAL, and a value of –1 is equal to the CPRINCIPAL method. The inertia is spread over both row and column scores. This method is useful for interpreting joint plots.

VARIANCES Subcommand

Use VARIANCES to display variances and correlations for the singular values, the row scores, and/or the column scores. If VARIANCES is not specified, variances and correlations are not included in the output.

The following keywords are available:

SINGULAR	*Variances and correlations of the singular values*.
ROWS	*Variances and correlations of the row scores*.
COLUMNS	*Variances and correlations of the column scores*.

PRINT Subcommand

Use PRINT to control which correspondence statistics are displayed. If PRINT is not specified, displayed statistics include the numbers of rows and columns, all nontrivial singular values, proportions of inertia, and the cumulative proportion of inertia that is accounted for.

The following keywords are available:

TABLE	*A crosstabulation of the input variables showing row and column marginals*.
PROFILES	*The row and column profiles*. PRINT=PROFILES is analogous to the CELLS=ROW COLUMN subcommand in CROSSTABS.
SCORES	*The marginal proportions and scores of each row and column*.
CONTRIBUTIONS	*The contribution of each row and column to the inertia of each dimension, and the proportion of distance to the origin that is accounted for in each dimension*.
PERMUTATION	*The original table permuted according to the scores of the rows and columns for each dimension*.
NONE	*No output other than the singular values*.
DEFAULT	*TABLE, SCORES, and CONTRIBUTIONS.* These statistics are displayed if you omit the PRINT subcommand.

PLOT Subcommand

Use PLOT to produce plots of the row scores, column scores, and row and column scores, as well as to produce plots of transformations of the row scores and transformations of the column scores. If PLOT is not specified, plots are produced for the row scores in the first two dimensions and the column scores in the first two dimensions.

The following keywords are available:

TRROWS	*Plot of transformations of the row category values into row scores*.
TRCOLUMNS	*Plot of transformations of the column category values into column scores*.
ROWS	*Plot of row scores*.
COLUMNS	*Plot of column scores*.
JOINT	*A combined plot of the row and column scores*. This plot is not available when NORMALIZATION=PRINCIPAL.
NONE	*No plots*.
DEFAULT	*ROWS and COLUMNS*.

- The keywords ROWS, COLUMNS, JOINT, and DEFAULT can be followed by an integer value in parentheses to indicate how many characters of the value label are to be used on the plot. The value can range from 1 to 20; the default is 3. Spaces between words count as characters.
- TRROWS and TRCOLUMNS plots use the full value labels up to 20 characters.
- If a label is missing for any value, the actual values are used for all values of that variable.
- Value labels should be unique.
- The first letter of a label on a plot marks the place of the actual coordinate. Be careful that multiple-word labels are not interpreted as multiple points on a plot.

In addition to the plot keywords, the following keyword can be specified:

NDIM	*Dimension pairs to be plotted*. NDIM is followed by a pair of values in parentheses. If NDIM is not specified, plots are produced for dimension 1 by dimension 2.

- The first value indicates the dimension that is plotted against all higher dimensions. This value can be any integer from 1 to the number of dimensions minus 1.
- The second value indicates the highest dimension to be used in plotting the dimension pairs. This value can be any integer from 2 to the number of dimensions.
- Keyword ALL can be used instead of the first value to indicate that all dimensions are paired with higher dimensions.
- Keyword MAX can be used instead of the second value to indicate that plots should be produced up to, and including, the highest dimension fit by the procedure.

Example

```
ANACOR TABLE=MENTAL(1,4) BY SES(1,6)
 /PLOT NDIM(1,3) JOINT(5).
```

- The NDIM(1,3) specification indicates that plots should be produced for two dimension pairs—dimension 1 versus dimension 2 and dimension 1 versus dimension 3.
- JOINT requests combined plots of row and column scores. The (5) specification indicates that the first five characters of the value labels are to be used on the plots.

Example

```
ANACOR TABLE=MENTAL(1,4) BY SES(1,6)
 /PLOT NDIM(ALL,3) JOINT(5).
```

- This plot is the same as above except for the ALL specification following NDIM, which indicates that all possible pairs up to the second value should be plotted. Therefore, JOINT plots will be produced for dimension 1 versus dimension 2, dimension 2 versus dimension 3, and dimension 1 versus dimension 3.

MATRIX Subcommand

Use MATRIX to write row and column scores and variances to matrix data files.

MATRIX is followed by keyword OUT, an equals sign, and one or both of the following keywords:

SCORE ('file'|'dataset')	*Write row and column scores to a matrix data file.*
VARIANCE ('file'|'dataset')	*Write variances to a matrix data file.*

- You can specify the file with either an asterisk (*), to replace the active dataset , a quoted file specification or a previously declared dataset name (DATASET DECLARE command), enclosed in parentheses.
- If you specify both SCORE and VARIANCE on the same MATRIX subcommand, you must specify two different files.

The variables in the SCORE matrix data file and their values are:

ROWTYPE_	*String variable containing the value ROW for all rows and COLUMN for all columns.*
LEVEL	*String variable containing the values (or value labels, if present) of each original variable.*
VARNAME_	*String variable containing the original variable names.*
DIM1...DIMn	*Numeric variables containing the row and column scores for each dimension.* Each variable is labeled *DIMn*, where *n* represents the dimension number.

The variables in the VARIANCE matrix data file and their values are:

ROWTYPE_	*String variable containing the value COV for all cases in the file.*
SCORE	*String variable containing the values SINGULAR, ROW, and COLUMN.*
LEVEL	*String variable containing the system-missing value for SINGULAR and the sequential row or column number for ROW and COLUMN.*
VARNAME_	*String variable containing the dimension number.*
DIM1...DIMn	*Numeric variables containing the covariances for each dimension.* Each variable is labeled *DIMn*, where *n* represents the dimension number.

Analyzing Aggregated Data

To analyze aggregated data, such as data from a crosstabulation where cell counts are available but the original raw data are not, you can use the TABLE=ALL option or the WEIGHT command before ANACOR.

Example

To analyze a 3×3 table, such as the table that is shown below, you could use these commands:

```
DATA LIST FREE/ BIRTHORD ANXIETY COUNT.
BEGIN DATA
1 1 48
1 2 27
1 3 22
2 1 33
2 2 20
2 3 39
3 1 29
3 2 42
3 3 47
END DATA.
WEIGHT BY COUNT.
ANACOR TABLE=BIRTHORD (1,3) BY ANXIETY (1,3).
```

- The WEIGHT command weights each case by the value of *COUNT*, as if there are 48 subjects with *BIRTHORD*=1 and *ANXIETY*=1, 27 subjects with *BIRTHORD*=1 and *ANXIETY*=2, and so on.
- ANACOR can then be used to analyze the data.
- If any table cell value equals 0, the WEIGHT command issues a warning, but the ANACOR analysis is done correctly.
- The table cell values (the WEIGHT values) cannot be negative. WEIGHT changes system-missing values and negative values to 0.
- For large aggregated tables, you can use the TABLE=ALL option or the transformation language to enter the table "as is."

Table 12-1
3 x 3 table

		Anxiety		
		High	**Med**	**Low**
Birth order	First	48	27	22
	Second	33	20	39
	Other	29	42	47

ANOVA

```
ANOVA VARIABLES= varlist BY varlist(min,max)...varlist(min,max)
 [WITH varlist] [/VARIABLES=...]

 [/COVARIATES={FIRST**}]
              {WITH   }
              {AFTER  }

 [/MAXORDERS={ALL** }]
             {n     }
             {NONE  }

 [/METHOD={UNIQUE**    }]
          {EXPERIMENTAL}
          {HIERARCHICAL}

 [/MISSING={EXCLUDE**}]
           {INCLUDE  }
```

**Default if the subcommand is omitted.

†REG (table of regression coefficients) is displayed only if the design is relevant.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
ANOVA VARIABLES=PRESTIGE BY REGION(1,9) SEX,RACE(1,2)
 /MAXORDERS=2
 /STATISTICS=MEAN.
```

Overview

ANOVA performs analysis of variance for factorial designs. The default is the full factorial model if there are five or fewer factors. Analysis of variance tests the hypothesis that the group means of the dependent variable are equal. The dependent variable is interval-level, and one or more categorical variables define the groups. These categorical variables are termed **factors**. ANOVA also allows you to include continuous explanatory variables, termed **covariates**. Other procedures that perform analysis of variance are ONEWAY, SUMMARIZE, and GLM. To perform a comparison of two means, use TTEST.

Options

Specifying Covariates. You can introduce covariates into the model using the WITH keyword on the VARIABLES subcommand.

Order of Entry of Covariates. By default, covariates are processed before main effects for factors. You can process covariates with or after main effects for factors using the COVARIATES subcommand.

Suppressing Interaction Effects. You can suppress the effects of various orders of interaction using the MAXORDERS subcommand.

Methods for Decomposing Sums of Squares. By default, the regression approach (keyword UNIQUE) is used. You can request the classic experimental or hierarchical approach using the METHOD subcommand.

Statistical Display. Using the STATISTICS subcommand, you can request means and counts for each dependent variable for groups defined by each factor and each combination of factors up to the fifth level. You also can request unstandardized regression coefficients for covariates and multiple classification analysis (MCA) results, which include the MCA table, the Factor Summary table, and the Model Goodness of Fit table. The MCA table shows **treatment effects** as deviations from the grand mean and includes a listing of unadjusted category effects for each factor, category effects adjusted for other factors, and category effects adjusted for all factors and covariates. The Factor Summary table displays eta and beta values. The Goodness of Fit table shows R and R^2 for each model.

Basic Specification

- The basic specification is a single VARIABLES subcommand with an analysis list. The minimum analysis list specifies a list of dependent variables, the keyword BY, a list of factor variables, and the minimum and maximum integer values of the factors in parentheses.
- By default, the model includes all interaction terms up to five-way interactions. The sums of squares are decomposed using the regression approach, in which all effects are assessed simultaneously, with each effect adjusted for all other effects in the model. A case that has a missing value for any variable in an analysis list is omitted from the analysis.

Subcommand Order

- The subcommands can be named in any order.

Operations

A separate analysis of variance is performed for each dependent variable in an analysis list, using the same factors and covariates.

Limitations

- A maximum of 5 analysis lists.
- A maximum of 5 dependent variables per analysis list.
- A maximum of 10 factor variables per analysis list.
- A maximum of 10 covariates per analysis list.
- A maximum of 5 interaction levels.
- A maximum of 25 value labels per variable displayed in the MCA table.
- The combined number of categories for all factors in an analysis list plus the number of covariates must be less than the sample size.

Examples

```
ANOVA VARIABLES=PRESTIGE BY REGION(1,9) SEX, RACE(1,2)
 /MAXORDERS=2
 /STATISTICS=MEAN.
```

- VARIABLES specifies a three-way analysis of variance—*PRESTIGE* by *REGION*, *SEX*, and *RACE*.
- The variables *SEX* and *RACE* each have two categories, with values 1 and 2 included in the analysis. *REGION* has nine categories, valued 1 through 9.
- MAXORDERS examines interaction effects up to and including the second order. All three-way interaction terms are pooled into the error sum of squares.
- STATISTICS requests a table of means of *PRESTIGE* within the combined categories of *REGION*, *SEX*, and *RACE*.

Example: Specifying Multiple Analyses

```
ANOVA VARIABLES=PRESTIGE BY REGION(1,9) SEX,RACE(1,2)
  /RINCOME BY SEX,RACE(1,2).
```

- ANOVA specifies a three-way analysis of variance of *PRESTIGE* by *REGION*, *SEX*, and *RACE*, and a two-way analysis of variance of *RINCOME* by *SEX* and *RACE*.

VARIABLES Subcommand

VARIABLES specifies the analysis list.

- More than one design can be specified on the same ANOVA command by separating the analysis lists with a slash.
- Variables named before the keyword BY are dependent variables. Value ranges are not specified for dependent variables.
- Variables named after BY are factor (independent) variables.
- Every factor variable must have a value range indicating its minimum and maximum values. The values must be separated by a space or a comma and enclosed in parentheses.
- Factor variables must have integer values. Non-integer values for factors are truncated.
- Cases with values outside the range specified for a factor are excluded from the analysis.
- If two or more factors have the same value range, you can specify the value range once following the last factor to which it applies. You can specify a single range that encompasses the ranges of all factors on the list. For example, if you have two factors, one with values 1 and 2 and the other with values 1 through 4, you can specify the range for both as 1,4. However, this may reduce performance and cause memory problems if the specified range is larger than some of the actual ranges.
- Variables named after the keyword WITH are covariates.
- Each analysis list can include only one BY and one WITH keyword.

COVARIATES Subcommand

COVARIATES specifies the order for assessing blocks of covariates and factor main effects.

- The order of entry is irrelevant when METHOD=UNIQUE.

FIRST	*Process covariates before factor main effects.* This is the default.
WITH	*Process covariates concurrently with factor main effects.*
AFTER	*Process covariates after factor main effects.*

MAXORDERS Subcommand

MAXORDERS suppresses the effects of various orders of interaction.

ALL	*Examine all interaction effects up to and including the fifth order.* This is the default.
n	*Examine all interaction effects up to and including the* n*th order.* For example, MAXORDERS=3 examines all interaction effects up to and including the third order. All higher-order interaction sums of squares are pooled into the error term.
NONE	*Delete all interaction terms from the model.* All interaction sums of squares are pooled into the error sum of squares. Only main and covariate effects appear in the ANOVA table.

METHOD Subcommand

METHOD controls the method for decomposing sums of squares.

UNIQUE	*Regression approach*. UNIQUE overrides any keywords on the COVARIATES subcommand. All effects are assessed simultaneously for their partial contribution. The MCA and MEAN specifications on the STATISTICS subcommand are not available with the regression approach. This is the default if METHOD is omitted.
EXPERIMENTAL	*Classic experimental approach.* Covariates, main effects, and ascending orders of interaction are assessed separately in that order.
HIERARCHICAL	*Hierarchical approach.*

Regression Approach

All effects are assessed simultaneously, with each effect adjusted for all other effects in the model. This is the default when the METHOD subcommand is omitted. Since MCA tables cannot be produced when the regression approach is used, specifying MCA or ALL on STATISTICS with the default method triggers a warning.

Some restrictions apply to the use of the regression approach:

- The lowest specified categories of all the independent variables must have a marginal frequency of at least 1, since the lowest specified category is used as the reference category. If this rule is violated, no ANOVA table is produced and a message identifying the first offending variable is displayed.
- Given an *n*-way crosstabulation of the independent variables, there must be no empty cells defined by the lowest specified category of any of the independent variables. If this restriction is violated, one or more levels of interaction effects are suppressed and a warning message is issued. However, this constraint does not apply to categories defined for an independent variable but not occurring in the data. For example, given two independent variables, each with categories of 1, 2, and 4, the (1,1), (1,2), (1,4), (2,1), and (4,1) cells must not be empty. The (1,3) and (3,1) cells will be empty but the restriction on empty cells will not be violated. The (2,2), (2,4), (4,2), and (4,4) cells may be empty, although the degrees of freedom will be reduced accordingly.

To comply with these restrictions, specify precisely the lowest non-empty category of each independent variable. Specifying a value range of (0,9) for a variable that actually has values of 1 through 9 results in an error, and no ANOVA table is produced.

Classic Experimental Approach

Each type of effect is assessed separately in the following order (unless `WITH` or `AFTER` is specified on the `COVARIATES` subcommand):

- Effects of covariates
- Main effects of factors
- Two-way interaction effects
- Three-way interaction effects
- Four-way interaction effects
- Five-way interaction effects

The effects within each type are adjusted for all other effects of that type and also for the effects of all prior types. (See Table 13-1 on p. 189.)

Hierarchical Approach

The hierarchical approach differs from the classic experimental approach only in the way it handles covariate and factor main effects. In the hierarchical approach, factor main effects and covariate effects are assessed hierarchically—factor main effects are adjusted only for the factor main effects already assessed, and covariate effects are adjusted only for the covariates already assessed. (See Table 13-1 on p. 189.) The order in which factors are listed on the `ANOVA` command determines the order in which they are assessed.

Example

The following analysis list specifies three factor variables named *A*, *B*, and *C*:

```
ANOVA VARIABLES=Y BY A,B,C(0,3).
```

The following table summarizes the three methods for decomposing sums of squares for this example.

- With the default *regression* approach, each factor or interaction is assessed with all other factors and interactions held constant.
- With the *classic experimental* approach, each main effect is assessed with the two other main effects held constant, and two-way interactions are assessed with all main effects and other two-way interactions held constant. The three-way interaction is assessed with all main effects and two-way interactions held constant.
- With the *hierarchical* approach, the factor main effects A, B, and C are assessed with all prior main effects held constant. The order in which the factors and covariates are listed on the ANOVA command determines the order in which they are assessed in the hierarchical analysis. The interaction effects are assessed the same way as in the experimental approach.

Table 13-1
Terms adjusted for under each option

Effect	Regression (UNIQUE)	Experimental	Hierarchical
A	All others	B,C	None
B	All others	A,C	A
C	All others	A,B	A,B
AB	All others	A,B,C,AC,BC	A,B,C,AC,BC
AC	All others	A,B,C,AB,BC	A,B,C,AB,BC
BC	All others	A,B,C,AB,AC	A,B,C,AB,AC
ABC	All others	A,B,C,AB,AC,BC	A,B,C,AB,AC,BC

Summary of Analysis Methods

The following table describes the results obtained with various combinations of methods for controlling the entry of covariates and decomposing the sums of squares.

Table 13-2
Combinations of COVARIATES and METHOD subcommands

Method	Assessments between types of effects	Assessments within the same type of effect
METHOD=UNIQUE	**Covariates**, **Factors**, and **Interactions** simultaneously	**Covariates**: adjust for factors, interactions, and all other covariates **Factors**: adjust for covariates, interactions, and all other factors **Interactions**: adjust for covariates, factors, and all other interactions

Method	Assessments between types of effects	Assessments within the same type of effect
METHOD=EXPERIMENTAL	**Covariates** then **Factors** then **Interactions**	**Covariates:** adjust for all other covariates **Factors:** adjust for covariates and all other factors **Interactions**: adjust for covariates, factors, and all other interactions of the same and lower orders
METHOD=HIERARCHICAL	**Covariates** then **Factors** then **Interactions**	**Covariates**: adjust for covariates that are preceding in the list **Factors**: adjust for covariates and factors preceding in the list **Interactions**: adjust for covariates, factors, and all other interactions of the same and lower orders
COVARIATES=WITH and METHOD=EXPERIMENTAL	**Factors** and **Covariates** concurrently then **Interactions**	**Covariates**: adjust for factors and all other covariates **Factors**: adjust for covariates and all other factors **Interactions**: adjust for covariates, factors, and all other interactions of the same and lower orders
COVARIATES=WITH and METHOD=HIERARCHICAL	**Factors** and **Covariates** concurrently then **Interactions**	**Factors**: adjust only for preceding factors **Covariates**: adjust for factors and preceding covariates **Interactions**: adjust for covariates, factors, and all other interactions of the same and lower orders
COVARIATES=AFTER and METHOD=EXPERIMENTAL	**Factors** then **Covariates** then **Interactions**	**Factors**: adjust for all other factors **Covariates**: adjust for factors and all other covariates **Interactions**: adjust for covariates, factors, and all other interactions of the same and lower orders
COVARIATES=AFTER and METHOD=HIERARCHICAL	**Factors** then **Covariates** then **Interactions**	**Factors**: adjust only for preceding factors **Covariates**: adjust factors and preceding covariates **Interactions**: adjust for covariates, factors, and all other interactions of the same and lower orders

STATISTICS Subcommand

STATISTICS requests additional statistics. STATISTICS can be specified by itself or with one or more keywords.

- If you specify STATISTICS without keywords, ANOVA calculates MEAN and REG (each defined below).
- If you specify a keyword or keywords on the STATISTICS subcommand, ANOVA calculates only the additional statistics you request.

MEAN	*Means and counts table.* This statistic is not available when METHOD is omitted or when METHOD=UNIQUE. See "Cell Means" below.
REG	*Unstandardized regression coefficients.* Displays unstandardized regression coefficients for the covariates. For more information, see Regression Coefficients for the Covariates on p. 191.
MCA	*Multiple classification analysis.* The MCA, the Factor Summary, and the Goodness of Fit tables are not produced when METHOD is omitted or when METHOD=UNIQUE. For more information, see Multiple Classification Analysis on p. 191.
ALL	*Means and counts table, unstandardized regression coefficients, and multiple classification analysis.*
NONE	*No additional statistics.* ANOVA calculates only the statistics needed for analysis of variance. This is the default if the STATISTICS subcommand is omitted.

Cell Means

STATISTICS=MEAN displays the Cell Means table.

- This statistic is not available with METHOD=UNIQUE.
- The Cell Means table shows the means and counts of each dependent variable for each cell defined by the factors and combinations of factors. Dependent variables and factors appear in their order on the VARIABLES subcommand.
- If MAXORDERS is used to suppress higher-order interactions, cell means corresponding to suppressed interaction terms are not displayed.
- The means displayed are the observed means in each cell, and they are produced only for dependent variables, not for covariates.

Regression Coefficients for the Covariates

STATISTICS=REG requests the unstandardized regression coefficients for the covariates.

- The regression coefficients are computed at the point where the covariates are entered into the equation. Thus, their values depend on the type of design specified by the COVARIATES or METHOD subcommand.
- The coefficients are displayed in the ANOVA table.

Multiple Classification Analysis

STATISTICS=MCA displays the MCA, the Factor Summary, and the Model Goodness of Fit tables.

- The MCA table presents counts, predicted means, and deviations of predicted means from the grand mean for each level of each factor. The predicted and deviation means each appear in up to three forms: unadjusted, adjusted for other factors, and adjusted for other factors and covariates.

- The Factor Summary table displays the correlation ratio (eta) with the unadjusted deviations (the square of eta indicates the proportion of variance explained by all categories of the factor), a partial beta equivalent to the standardized partial regression coefficient that would be obtained by assigning the unadjusted deviations to each factor category and regressing the dependent variable on the resulting variables, and the parallel partial betas from a regression that includes covariates in addition to the factors.
- The Model Goodness of Fit table shows R and R^2 for each model.
- The tables cannot be produced if `METHOD` is omitted or if `METHOD=UNIQUE`. When produced, the MCA table does not display the values adjusted for factors if `COVARIATES` is omitted, if `COVARIATES=FIRST`, or if `COVARIATES=WITH` and `METHOD=EXPERIMENTAL`. A full MCA table is produced only if `METHOD=HIERARCHICAL` or if `METHOD=EXPERIMENTAL` and `COVARIATES=AFTER`.

MISSING Subcommand

By default, a case that has a missing value for any variable named in the analysis list is deleted for all analyses specified by that list. Use `MISSING` to include cases with user-missing data.

EXCLUDE *Exclude cases with missing data.* This is the default.

INCLUDE *Include cases with user-defined missing data.*

Release History

Release 14.0

- `ATTRIBUTES` keyword introduced on `FILEINFO` and `VARINFO` subcommands.

Example

```
APPLY DICTIONARY FROM = 'lastmonth.sav'.
```

Overview

APPLY DICTIONARY can apply variable and file-based dictionary information from an external SPSS-format data file or open dataset to the current active dataset. Variable-based dictionary information in the current active dataset can be applied to other variables in the current active dataset.

- The applied variable information includes variable and value labels, missing-value flags, alignments, variable print and write formats, measurement levels, and widths.
- The applied file information includes variable and multiple response sets, documents, file label, and weight.
- APPLY DICTIONARY can apply information selectively to variables and can apply selective file-based dictionary information.
- Individual variable attributes can be applied to individual and multiple variables of the same type (strings of the same character length or numeric).
- APPLY DICTIONARY can add new variables but cannot remove variables, change data, or change a variable's name or type.
- Undefined (empty) attributes in the source dataset do not overwrite defined attributes in the active dataset.

Basic Specification

The basic specification is the FROM subcommand and the name of an SPSS-format data file or open dataset. The file specification should be enclosed in quotation marks.

Subcommand Order

The subcommands can be specified in any order.

Syntax Rules

- The file containing the dictionary information to be applied (the **source file**) must be an SPSS-format data file, the active dataset, or a defined dataset.
- The file to which the dictionary information is applied (the **target file**) must be the active dataset. You cannot specify another file.
- If a subcommand is issued more than once, APPLY DICTIONARY will ignore all but the last instance of the subcommand.
- Equals signs displayed in the syntax chart and in the examples presented here are required elements; they are not optional.

Matching Variable Type

APPLY DICTIONARY considers two variables to have a matching variable type if:

- Both variables are numeric. This includes all numeric, currency, and date formats.
- Both variables are string (alphanumeric).

FROM Subcommand

FROM specifies an SPSS-format data file, an open dataset or the active dataset as the source file whose dictionary information is to be applied to the active dataset.

- FROM is required.
- Only one SPSS-format data file or open dataset(including the active dataset) can be specified on FROM.
- The file specification should be enclosed in quotation marks.
- The active dataset can be specified in the FROM subcommand by using an asterisk (*) as the value. File-based dictionary information (FILEINFO subcommand) is ignored when the active dataset is used as the source file.

Example

```
APPLY DICTIONARY FROM "lastmonth.sav".
```

- This will apply variable information from *lastmonth.sav* to matching variables in the active dataset.
- The default variable information applied from the source file includes variable labels, value labels, missing values, level of measurement, alignment, column width (for Data Editor display), and print and write formats.
- If weighting is on in the source dataset and a matching weight variable exists in the active (target) dataset, weighting by that variable is turned on in the active dataset. No other file information (documents, file label, multiple response sets) from the source file is applied to the active dataset.

NEWVARS Subcommand

NEWVARS is required to create new variables in the active (target) dataset.

Example

```
APPLY DICTIONARY FROM “lastmonth.sav”
  /NEWVARS.
```

- For a new, blank active dataset, all variables with all of their variable definition attributes are copied from the source dataset, creating a new dataset with an identical set of variables (but no data values).
- For an active dataset that contains any variables, variable definition attributes from the source dataset are applied to the matching variables in the active (target) dataset. If the source dataset contains any variables that are not present in the active dataset (determined by variable name), these variables are created in the active dataset.

SOURCE and TARGET Subcommands

The SOURCE subcommand is used to specify variables in the source file from which to apply variable definition attributes. The TARGET subcommand is used to specify variables in the active dataset to which to apply variable definition attributes.

- All variables specified in the SOURCE subcommand must exist in the source file.
- If the TARGET subcommand is specified without the SOURCE subcommand, all variables specified must exist in the source file.
- If the NEWVARS subcommand is specified, variables that are specified in the SOURCE subcommand that exist in the source file but not in the target file will be created in the target file as new variables using the variable definition attributes (variable and value labels, missing values, etc.) from the source variable.
- For variables with matching name and type, variable definition attributes from the source variable are applied to the matching target variable.
- If both SOURCE and TARGET are specified, the SOURCE subcommand can specify only one variable. Variable definition attributes from that single variable in the SOURCE subcommand are applied to all variables of the matching type. When applying the attributes of one variable to many variables, all variables specified in the SOURCE and TARGET subcommands must be of the same type.
- For variables with matching names but different types, only variable labels are applied to the target variables.

Table 14-1
Variable mapping for SOURCE and TARGET subcommands

SOURCE subcommand	TARGET subcommand	Variable mapping
none	none	Variable definition attributes from the source dataset are applied to matching variables in the active (target) dataset. New variables may be created if the NEWVARS subcommand is specified.
many	none	Variable definition attributes for the specified variables are copied from the source dataset to the matching variables in the active (target) dataset. All specified variables must exist in the source dataset. New variables may be created if the NEWVARS subcommand is specified.
none	many	Variable definition attributes for the specified variables are copied from the source dataset to the matching variables in the active (target) dataset. All specified variables must exist in the source dataset. New variables may be created if the NEWVARS subcommand is specified.
one	many	Variable definition attributes for the specified variable in the source dataset are applied to all specified variables in the active (target) dataset that have a matching type. New variables may be created if the NEWVARS subcommand is specified.
many	many	Invalid. Command not executed.

Example

```
APPLY DICTIONARY from *
  /SOURCE VARIABLES = var1
  /TARGET VARIABLES = var2 var3 var4
```

```
  /NEWVARS.
```

- Variable definition attributes for *var1* in the active dataset are copied to *var2*, *var3*, and *var4* in the same dataset if they have a matching type.
- Any variables specified in the TARGET subcommand that do not already exist are created, using the variable definition attributes of the variable specified in the SOURCE subcommand.

Example

```
APPLY DICTIONARY from "lastmonth.sav"
  /SOURCE VARIABLES = var1, var2, var3.
```

- Variable definition attributes from the specified variables in the source dataset are applied to the matching variables in the active dataset.
- For variables with matching names but different types, only variable labels from the source variable are copied to the target variable.
- In the absence of a NEWVARS subcommand, no new variables will be created.

FILEINFO Subcommand

FILEINFO applies global file definition attributes from the source dataset to the active (target) dataset.

- File definition attributes in the active dataset that are undefined in the source dataset are not affected.
- This subcommand is ignored if the source dataset is the active dataset.
- This subcommand is ignored if no keywords are specified.
- For keywords that contain an associated value, the equals sign between the keyword and the value is required—for example, DOCUMENTS = MERGE.

ATTRIBUTES *Applies file attributes defined by the* DATAFILE ATTRIBUTE *command*. You can REPLACE or MERGE file attributes.

DOCUMENTS *Applies documents (defined with the* DOCUMENTS *command) from the source dataset to the active (target) dataset.* You can REPLACE or MERGE documents.

DOCUMENTS = REPLACE replaces any documents in the active dataset, deleting preexisting documents in the file. This is the default if DOCUMENTS is specified without a value.

DOCUMENTS = MERGE merges documents from the source and active datasets. Unique documents in the source file that don't exist in the active dataset are added to the active dataset. All documents are then sorted by date.

FILELABEL *Replaces the file label (defined with the* FILE LABEL *command)*.

MRSETS *Applies multiple response set definitions from the source dataset to the active dataset.* (Note that multiple response sets are currently used only by the TABLES add-on module.) Multiple response sets in the source dataset that contain variables that don't exist in the active dataset are ignored unless those variables are created by the same APPLY DICTIONARY command. You can REPLACE or MERGE multiple response sets.

MRSETS = REPLACE deletes any existing multiple response sets in the active dataset, replacing them with multiple response sets from the source dataset.

MRSETS = MERGE adds multiple response sets from the source dataset to the collection of multiple response sets in the active dataset. If a set with the same name exists in both files, the existing set in the active dataset is unchanged.

VARSETS *Applies variable set definitions from the source dataset to the active dataset.* Variable sets are used to control the list of variables that are displayed in dialog boxes. Variable sets are defined by selecting Define Sets from the Utilities menu. Sets in the source data file that contain variables that don't exist in the active dataset are ignored unless those variables are created by the same APPLY DICTIONARY command. You can REPLACE or MERGE variable sets.

VARSETS = REPLACE deletes any existing variable sets in the active dataset, replacing them with variable sets from the source dataset.

VARSETS = MERGE adds variable sets from the source dataset to the collection of variable sets in the active dataset. If a set with the same name exists in both files, the existing set in the active dataset is unchanged.

WEIGHT *Weights cases by the variable specified in the source file if there's a matching variable in the target file*. This is the default if the subcommand is omitted.

ALL *Applies all file information from the source dataset to the active dataset*. Documents, multiple response sets, and variable sets are merged, not replaced. File definition attributes in the active dataset that are undefined in the source data file are not affected.

Example

```
APPLY DICTIONARY FROM "lastmonth.sav"
  /FILEINFO DOCUMENTS = REPLACE MRSETS = MERGE.
```

- Documents in the source dataset replace documents in the active dataset unless there are no defined documents in the source dataset.
- Multiple response sets from the source dataset are added to the collection of defined multiple response sets in the active dataset. Sets in the source dataset that contain variables that don't exist in the active dataset are ignored. If the same set name exists in both datasets, the set in the active dataset remains unchanged.

VARINFO Subcommand

VARINFO applies variable definition attributes from the source dataset to the matching variables in the active dataset. With the exception of VALLABELS, all keywords replace the variable definition attributes in the active dataset with the attributes from the matching variables in the source dataset.

ALIGNMENT *Applies variable alignment for Data Editor display.* This setting affects alignment (left, right, center) only in the Data View display of the Data Editor.

ATTRIBUTES *Applies file attributes defined by the* VARIABLE ATTRIBUTE *command*. You can REPLACE or MERGE variable attributes.

FORMATS *Applies variable print and write formats*. This is the same variable definition attribute that can be defined with the FORMATS command. This setting is primarily applicable only to numeric variables. For string variables, this affects only the formats if the source or target variable is AHEX format and the other is A format.

LEVEL *Applies variable measurement level (nominal, ordinal, scale)*. This is the same variable definition attribute that can be defined with the VARIABLE LEVEL command.

MISSING *Applies variable missing value definitions*. Any existing defined missing values in the matching variables in the active dataset are deleted. This is the same variable definition attribute that can be defined with the `MISSING VALUES` command. Missing values definitions are not applied to string variables if the source variable contains missing values of a longer width than the defined width of the target variable.

VALLABELS *Applies value label definitions*. Value labels are not applied to string variables if the source variable contains defined value labels for values longer than the defined width of the target variable. You can `REPLACE` or `MERGE` value labels.

`VALLABELS = REPLACE` replaces any defined value labels from variable in the active dataset with the value labels from the matching variable in the source dataset.

`VALLABELS = MERGE` merges defined value labels for matching variables. If the same value has a defined value label in both the source and active datasets, the value label in the active dataset is unchanged.

WIDTH *Display column width in the Data Editor.* This affects only column width in Data View in the Data Editor. It has no affect on the defined width of the variable.

Example

```
APPLY DICTIONARY from "lastmonth.sav"
  /VARINFO LEVEL MISSING VALLABELS = MERGE.
```

- The level of measurement and defined missing values from the source dataset are applied to the matching variables in the active (target) dataset. Any existing missing values definitions for those variables in the active dataset are deleted.
- Value labels for matching variables in the two datasets are merged. If the same value has a defined value label in both the source and active datasets, the value label in the active dataset is unchanged.

AUTORECODE

```
AUTORECODE VARIABLES=varlist
 /INTO new varlist
 [/BLANK={VALID**}
         {MISSING}
 [/GROUP]
 [/APPLY TEMPLATE='filespec']
 [/SAVE TEMPLATE='filespec']
 [/DESCENDING]
 [/PRINT]
```

**Default if the subcommand omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Release History

Release 13.0

- BLANK subcommand introduced.
- GROUP subcommand introduced.
- APPLY TEMPLATE and SAVE TEMPLATE subcommands introduced.

Example

```
AUTORECODE VARIABLES=Company /INTO Rcompany.
```

Overview

AUTORECODE recodes the values of string and numeric variables to consecutive integers and puts the recoded values into a new variable called a **target variable**. The value labels or values of the original variable are used as value labels for the target variable. AUTORECODE is useful for creating numeric independent (grouping) variables from string variables for procedures such as ONEWAY and DISCRIMINANT. AUTORECODE can also recode the values of factor variables to consecutive integers, which may be required by some procedures and which reduces the amount of workspace needed by some statistical procedures.

Basic Specification

The basic specification is VARIABLES and INTO. VARIABLES specifies the variables to be recoded. INTO provides names for the target variables that store the new values. VARIABLES and INTO must name or imply the same number of variables.

Subcommand Order

- VARIABLES must be specified first.
- INTO must immediately follow VARIABLES.
- All other subcommands can be specified in any order.

Syntax Rules

- A variable cannot be recoded into itself. More generally, target variable names cannot duplicate any variable names already in the working file.
- If the GROUP or APPLY TEMPLATE subcommand is specified, all variables on the VARIABLES subcommand must be the same type (numeric or string).
- If APPLY TEMPLATE is specified, all variables on the VARIABLES subcommand must be the same type (numeric or string) as the type defined in the template.
- File specifications on the APPLY TEMPLATE and SAVE TEMPLATE subcommands follow the normal conventions for file specifications. Enclosing file specifications in quotation marks is recommended.

Operations

- The values of each variable to be recoded are sorted and then assigned numeric values. By default, the values are assigned in ascending order: 1 is assigned to the lowest nonmissing value of the original variable; 2, to the second-lowest nonmissing value; and so on, for each value of the original variable.
- Values of the original variables are unchanged.
- Missing values are recoded into values higher than any nonmissing values, with their order preserved. For example, if the original variable has 10 nonmissing values, the first missing value is recoded as 11 and retains its user-missing status. System-missing values remain system-missing. (See the GROUP, APPLY TEMPLATE, and SAVE TEMPLATE subcommands for additional rules for user-missing values.)
- AUTORECODE does not sort the cases in the working file. As a result, the consecutive numbers assigned to the target variables may not be in order in the file.
- Target variables are assigned the same variable labels as the original source variables. To change the variable labels, use the VARIABLE LABELS command after AUTORECODE.
- Value labels are automatically generated for each value of the target variables. If the original value had a label, that label is used for the corresponding new value. If the original value did not have a label, the old value itself is used as the value label for the new value. The defined print format of the old value is used to create the new value label.
- AUTORECODE ignores SPLIT FILE specifications. However, any SELECT IF specifications are in effect for AUTORECODE.

Example

```
DATA LIST / COMPANY 1-21 (A) SALES 24-28.
BEGIN DATA
CATFOOD JOY            10000
OLD FASHIONED CATFOOD  11200
```

```
 . . .
PRIME CATFOOD          10900
CHOICE CATFOOD         14600
END DATA.

AUTORECODE VARIABLES=COMPANY /INTO=RCOMPANY /PRINT.

TABLES TABLE = SALES BY RCOMPANY
  /TTITLE='CATFOOD SALES BY COMPANY'.
```

- AUTORECODE recodes *COMPANY* into a numeric variable *RCOMPANY*. Values of *RCOMPANY* are consecutive integers beginning with 1 and ending with the number of different values entered for *COMPANY*. The values of *COMPANY* are used as value labels for *RCOMPANY*'s numeric values. The *PRINT* subcommand displays a table of the original and recoded values.

VARIABLES Subcommand

VARIABLES specifies the variables to be recoded. VARIABLES is required and must be specified first. The actual keyword VARIABLES is optional.

- Values from the specified variables are recoded and stored in the target variables listed on INTO. Values of the original variables are unchanged.

INTO Subcommand

INTO provides names for the target variables that store the new values. INTO is required and must immediately follow VARIABLES.

- The number of target variables named or implied on INTO must equal the number of source variables listed on VARIABLES.

Example

```
AUTORECODE VARIABLES=V1 V2 V3 /INTO=NEWV1 TO NEWV3 /PRINT.
```

- AUTORECODE stores the recoded values of *V1*, *V2*, and *V3* into target variables named *NEWV1*, *NEWV2*, and *NEWV3*.

BLANK Subcommand

The BLANK subcommand specifies how to autorecode blank string values.

- BLANK is followed by an equals sign (=) and the keyword VALID or MISSING.
- The BLANK subcommand applies only to string variables (both short and long strings). System-missing numeric values remain system-missing in the new, autorecoded variable(s).

- The BLANK subcommand has no effect if there are no string variables specified on the VARIABLES subcommand.

VALID	*Blank string values are treated as valid, nonmissing values and are autorecoded into nonmissing values.* This is the default.
MISSING	*Blank string values are autorecoded into a user-missing value higher than the highest nonmissing value*.

Example

```
DATA LIST /stringVar (A1).
BEGIN DATA
a
b

c
d
END DATA.
AUTORECODE
  VARIABLES=stringVar  /INTO NumericVar
  /BLANK=MISSING.
```

- The values *a*, *b*, *c*, and *d* are autorecoded into the numeric values 1 through 4.
- The blank value is autorecoded to 5, and 5 is defined as user-missing.

GROUP Subcommand

The subcommand GROUP allows you to specify that a single autorecoding scheme should be generated for all the specified variables, yielding consistent coding for all of the variables.

- The GROUP subcommand has no additional keywords or specifications. By default, variables are not grouped for autorecoding.
- All variables must be the same type (numeric or string).
- All observed values for all specified variables are used to create a sorted order of values to recode into sequential integers.
- String variables can be of any length and can be of unequal length.
- User-missing values for the target variables are based on the first variable in the original variable list with defined user-missing values. All other values from other original variables, except for system-missing, are treated as valid.
- If only one variable is specified on the VARIABLES subcommand, the GROUP subcommand is ignored.
- If GROUP and APPLY TEMPLATE are used on the same AUTORECODE command, value mappings from the template are applied first. All remaining values are recoded into values higher than the last value in the template, with user-missing values (based on the first variable in the list with defined user-missing values) recoded into values higher than the last valid value. See the APPLY TEMPLATE subcommand for more information.

Example

```
DATA LIST FREE /var1 (a1) var2 (a1).
BEGIN DATA
a d
b e
c f
END DATA.
MISSING VALUES var1 ("c") var2 ("f").
AUTORECODE VARIABLES=var1 var2
  /INTO newvar1 newvar2
  /GROUP.
```

- A single autorecoding scheme is created and applied to both new variables.
- The user-missing value `"c"` from *var1* is autorecoded into a user-missing value.
- The user-missing value `"f"` from *var2* is autorecoded into a valid value.

Table 15-1
Original and recoded values

Original value	Autorecoded value
a	1
b	2
c	6 (user-missing)
d	3
e	4
f	5

SAVE TEMPLATE Subcommand

The `SAVE TEMPLATE` subcommand allows you to save the autorecode scheme used by the current `AUTORECODE` command to an external template file, which you can then use when autorecoding other variables using the `APPLY TEMPLATE` subcommand.

- `SAVE TEMPLATE` is followed by an equals sign (=) and a quoted file specification. The default file extension for autorecode templates is *.sat*.
- The template contains information that maps the original nonmissing values to the recoded values.
- Only information for nonmissing values is saved in the template. User-missing value information is not retained.
- If more than one variable is specified on the `VARIABLES` subcommand, the first variable specified is used for the template, unless `GROUP` or `APPLY TEMPLATE` is also specified, in which case a common autorecoding scheme for all variables is saved in the template.

Example

```
DATA LIST FREE /var1 (a1) var2 (a1).
BEGIN DATA
a d
b e
c f
```

```
END DATA.
MISSING VALUES var1 ("c") var2 ("f").
AUTORECODE VARIABLES=var1 var2
  /INTO newvar1 newvar2
  /SAVE TEMPLATE='/temp/var1_template.sat'.
```

- The saved template contains an autorecode scheme that maps the string values of "a" and "b" from *var1* to the numeric values 1 and 2, respectively.
- The template contains no information for the value of "c" for *var1* because it is defined as user-missing.
- The template contains no information for values associated with *var2* because the GROUP subcommand was not specified.

Template File Format

An autorecode template file is actually an SPSS-format data file that contains two variables: *Source_* contains the original, unrecoded valid values, and *Target_* contains the corresponding recoded values. Together these two variables provide a mapping of original and recoded values.

You can therefore, theoretically, build your own custom template files, or simply include the two mapping variables in an existing data file—but this type of use has not been tested.

APPLY TEMPLATE Subcommand

The APPLY TEMPLATE subcommand allows you to apply a previously saved autorecode template to the variables in the current AUTORECODE command, appending any additional values found in the variables to the end of the scheme, preserving the relationship between the original and autorecode values stored in the saved scheme.

- APPLY TEMPLATE is followed by an equals sign (=) and a quoted file specification.
- All variables on the VARIABLES subcommand must be the same type (numeric or string), and that type must match the type defined in the template.
- Templates do not contain any information on user-missing values. User-missing values for the target variables are based on the first variable in the original variable list with defined user-missing values. All other values from other original variables, except for system-missing, are treated as valid.
- Value mappings from the template are applied first. All remaining values are recoded into values higher than the last value in the template, with user-missing values (based on the first variable in the list with defined user-missing values) recoded into values higher than the last valid value.
- If multiple variables are specified on the VARIABLES subcommand, APPLY TEMPLATE generates a grouped recoding scheme, with or without an explicit GROUP subcommand.

Example

```
DATA LIST FREE /var1 (a1).
BEGIN DATA
a b d
```

```
END DATA.
AUTORECODE VARIABLES=var1
  /INTO newvar1
  /SAVE TEMPLATE='/temp/var1_template.sat'.
DATA LIST FREE /var2 (a1).
BEGIN DATA
a b c
END DATA.
AUTORECODE VARIABLES=var2
  /INTO newvar2
  /APPLY TEMPLATE='/temp/var1_template.sat'.
```

- The template file *var1_template.sat* maps the string values a, b, and d to the numeric values 1, 2, and 3, respectively.
- When the template is applied to the variable *var2* with the string values a, b, and c, the autorecoded values for *newvar2* are 1, 2, and 4, respectively. The string value "c" is autorecoded to 4 because the template maps 3 to the string value "d".
- The data dictionary contains defined value labels for all four values—the three from the template and the one new value read from the file.

Table 15-2
Defined value labels for newvar2

Value	Label
1	a
2	b
3	d
4	c

Interaction between APPLY TEMPLATE and SAVE TEMPLATE

- If APPLY TEMPLATE and SAVE TEMPLATE are both used in the same AUTORECODE command, APPLY TEMPLATE is always processed first, regardless of subcommand order, and the autorecode scheme saved by SAVE TEMPLATE is the union of the original template plus any appended value definitions.
- APPLY TEMPLATE and SAVE TEMPLATE can specify the same file, resulting in the template being updated to include any newly appended value definitions.

Example

```
AUTORECODE VARIABLES=products
 /INTO productCodes
 /APPLY TEMPLATE='/mydir/product_codes.sat'
 /SAVE TEMPLATE='/mydir/product_codes.sat.
```

- The autorecode scheme in the template file is applied for autorecoding *products* into *productCodes*.
- Any data values for *products* not defined in the template are autorecoded into values higher than the highest value in the original template.

- Any user-missing values for *products* are autorecoded into values higher than the highest nonmissing autorecoded value.
- The template saved is the autorecode scheme used to autorecode *product*—the original autorecode scheme plus any additional values in *product* that were appended to the scheme.

PRINT Subcommand

PRINT displays a correspondence table of the original values of the source variables and the new values of the target variables. The new value labels are also displayed.

- The only specification is the keyword PRINT. There are no additional specifications.

DESCENDING Subcommand

By default, values for the source variable are recoded in ascending order (from lowest to highest). DESCENDING assigns the values to new variables in descending order (from highest to lowest). The largest value is assigned 1, the second-largest, 2, and so on.

- The only specification is the keyword DESCENDING. There are no additional specifications.

BEGIN DATA-END DATA

```
BEGIN DATA
data records
END DATA
```

Example

```
BEGIN DATA
1  3424  274 ABU DHABI 2
2 39932   86 AMSTERDAM 4
3  8889  232 ATHENS
4  3424  294 BOGOTA    3
END DATA.
```

Overview

BEGIN DATA and END DATA are used when data are entered within the command sequence (inline data). BEGIN DATA and END DATA are also used for inline matrix data. BEGIN DATA signals the beginning of data lines and END DATA signals the end of data lines.

Basic Specification

The basic specification is BEGIN DATA, the data lines, and END DATA. BEGIN DATA must be specified by itself on the line that immediately precedes the first data line. END DATA is specified by itself on the line that immediately follows the last data line.

Syntax Rules

- BEGIN DATA, the data, and END DATA must precede the first procedure.
- The command terminator after BEGIN DATA is optional. It is best to leave it out so that the program will treat inline data as one continuous specification.
- END DATA must always begin in column 1. It must be spelled out in full and can have only one space between the words END and DATA. Procedures and additional transformations can follow the END DATA command.
- Data lines must *not* have a command terminator. For inline data formats, see DATA LIST.
- Inline data records are limited to a maximum of 80 columns. (On some systems, the maximum may be fewer than 80 columns.) If data records exceed 80 columns, they must be stored in an external file that is specified on the FILE subcommand of the DATA LIST (or similar) command.

Operations

- When the program encounters BEGIN DATA, it begins to read and process data on the next input line. All preceding transformation commands are processed as the working file is built.
- The program continues to evaluate input lines as data until it encounters END DATA, at which point it begins evaluating input lines as commands.

- No other commands are recognized between BEGIN DATA and END DATA.
- The INCLUDE command can specify a file that contains BEGIN DATA, data lines, and END DATA . The data in such a file are treated as inline data. Thus, the FILE subcommand should be omitted from the DATA LIST (or similar) command.
- When running the program from prompts, the prompt DATA> appears immediately after BEGIN DATA is specified. After END DATA is specified, the command line prompt returns.

Examples

```
DATA LIST /XVAR 1 YVAR ZVAR 3-12 CVAR 14-22(A) JVAR 24.
BEGIN DATA
1  3424  274 ABU DHABI 2
2 39932   86 AMSTERDAM 4
3  8889  232 ATHENS
4  3424  294 BOGOTA    3
5 11323  332 HONG KONG 3
6   323  232 MANILA    1
7  3234  899 CHICAGO   4
8 78998 2344 VIENNA    3
9  8870  983 ZURICH    5
END DATA.
MEANS XVAR BY JVAR.
```

- DATA LIST defines the names and column locations of the variables. The FILE subcommand is omitted because the data are inline.
- There are nine cases in the inline data. Each line of data completes a case.
- END DATA signals the end of data lines. It begins in column 1 and has only a single space between END and DATA.

BEGIN GPL-END GPL

```
BEGIN GPL
  gpl specification
END GPL
```

Release History

Release 14.0

- Command introduced.

Example

```
GGRAPH
  /GRAPHDATASET NAME="graphdataset" VARIABLES=jobcat COUNT()
  /GRAPHSPEC SOURCE=INLINE.
BEGIN GPL
  SOURCE: s=userSource(id("graphdataset"))
  DATA: jobcat=col(source(s), name("jobcat"), unit.category())
  DATA: count=col(source(s), name("COUNT"))
  GUIDE: axis(dim(1), label("Employment Category"))
  GUIDE: axis(dim(2), label("Count"))
  ELEMENT: interval(position(jobcat*count))
END GPL.
```

Overview

BEGIN GPL and END GPL are used when Graphics Production Language (GPL) code is entered within the command sequence (inline graph specification). BEGIN GPL and END GPL must follow a GGRAPH command, without any blank lines between BEGIN GPL and the command terminator line for GGRAPH. Only comments are allowed between BEGIN GPL and the command terminator line for GGRAPH. BEGIN GPL must be at the start of the line on which it appears, with no preceding spaces. BEGIN GPL signals the beginning of GPL code, and END GPL signals the end of GPL code.

For more information about GGRAPH, see GGRAPH on p. 781.See the *GPL Reference Guide* on the manuals CD for more details about GPL. The examples in the GPL documentation may look different compared to the syntax pasted from the Chart Builder. The main difference is when aggregation occurs. See Working with the GPL on p. 791 for information about the differences. See Examples on p. 794 for examples with GPL that is similar to the pasted syntax.

Syntax Rules

- Within a GPL block, only GPL statements are allowed.
- Strings in GPL are enclosed in quotation marks. You cannot use single quotes (apostrophes).
- With the SPSS Batch Facility (available only with SPSS Server), use the -i switch when submitting command files that contain GPL blocks.

Scope and Limitations

- GPL blocks cannot be nested within GPL blocks.
- GPL blocks cannot be contained within `DEFINE-!ENDDEFINE` macro definitions.
- GPL blocks can be contained in command syntax files run via the `INSERT` command, with the default `SYNTAX=INTERACTIVE` setting.
- GPL blocks cannot be contained within command syntax files run via the `INCLUDE` command.

BEGIN PROGRAM-END PROGRAM

BEGIN PROGRAM-END PROGRAM is available in the Programmability Extension. It is not available in SPSS Statistical Services for SQL Server 2005.

```
BEGIN PROGRAM [programming language name].
programming language-specific statements
END PROGRAM.
```

Release History

Release 14.0

- Command introduced.

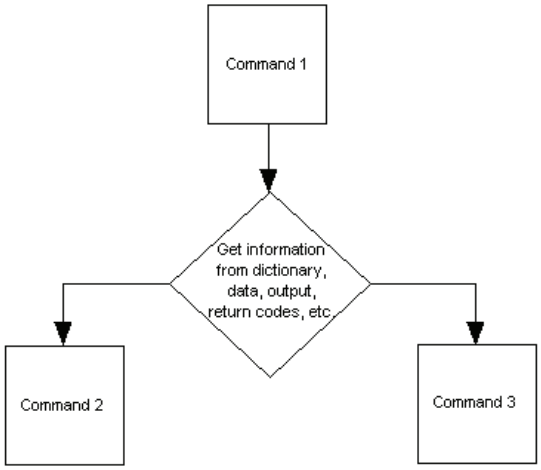
Overview

BEGIN PROGRAM-END PROGRAM provides the ability to integrate the capabilities of external programming languages with SPSS. One of the major benefits of these program blocks is the ability to add **jobwise** flow control to the command stream. Outside of program blocks, SPSS can execute **casewise** conditional actions, based on criteria that evaluate each case, but jobwise flow control, such as running different procedures for different variables based on data type or level of measurement or determining which procedure to run next based on the results of the last procedure is much more difficult. Program blocks make jobwise flow control much easier to accomplish. With program blocks, you can control the commands that are run based on many criteria, including:

- Dictionary information (e.g., data type, measurement level, variable names)
- Data conditions
- Output values
- Error codes (that indicate if a command ran successfully or not)

You can also read data from the active dataset to perform additional computations, update the active dataset with results, create new datasets, and create custom pivot table output.

Figure 18-1
Jobwise Flow Control



Operations

- `BEGIN PROGRAM` signals the beginning of a set of code instructions controlled by an external programming language.
- After `BEGIN PROGRAM` is executed, other commands do not execute until `END PROGRAM` is encountered.

Syntax Rules

- Within a program block, only statements recognized by the specified programming language are allowed.
- Command syntax generated within a program block must follow **interactive** syntax rules. For more information, see Running Commands on p. 33.
- Within a program block, each line should not exceed 251 bytes (although syntax generated by those lines can be longer).
- With the SPSS Batch Facility (available only with SPSS Server), use the -i switch when submitting command files that contain program blocks. All command syntax (not just the program blocks) in the file must adhere to interactive syntax rules.

Within a program block, the programming language is in control, and the syntax rules for that programming language apply. Command syntax generated from within program blocks must always follow interactive syntax rules. For most practical purposes this means command strings you build in a programming block must contain a period (.) at the end of each command.

Scope and Limitations

- Programmatic variables created in a program block cannot be used outside of program blocks.
- Program blocks cannot be contained within `DEFINE-!ENDDEFINE` macro definitions.

- Program blocks can be contained in command syntax files run via the `INSERT` command, with the default `SYNTAX=INTERACTIVE` setting.
- Program blocks cannot be contained within command syntax files run via the `INCLUDE` command.

Using External Programming Languages

Use of the Programmability Extension requires an integration plug-in for an external language. An integration plug-in for the Python programming language is available from the installation CD. For Windows, the Python programming language is also available from the installation CD. An integration plug-in for the R programming language is available from SPSS Developer Central at *http://www.spss.com/devcentral*. Documentation for installed plug-ins is available from */help/programmability* in the directory where SPSS is installed.

BREAK

```
BREAK
```

This command does not read the active dataset. It is stored, pending execution with the next command that reads the dataset. For more information, see Command Order on p. 36.

Overview

BREAK controls looping that cannot be fully controlled with IF clauses. Generally, BREAK is used within a DO IF–END IF structure. The expression on the DO IF command specifies the condition in which BREAK is executed.

Basic Specification

- The only specification is the keyword BREAK. There are no additional specifications.
- BREAK must be specified within a loop structure. Otherwise, an error results.

Operations

- A BREAK command inside a loop structure but not inside a DO IF–END IF structure terminates the first iteration of the loop for all cases, since no conditions for BREAK are specified.
- A BREAK command within an inner loop terminates only iterations in that structure, not in any outer loop structures.

Examples

```
VECTOR          #X(10).
LOOP            #I = 1 TO #NREC.
+  DATA LIST       NOTABLE/ #X1 TO #X10 1-20.
+  LOOP            #J = 1 TO 10.
+     DO IF           SYSMIS(#X(#J)).
+        BREAK.
+     END IF.
+     COMPUTE         X = #X(#J).
+     END CASE.
+  END LOOP.
END LOOP.
```

- The inner loop terminates when there is a system-missing value for any of the variables *#X1* to *#X10*.
- The outer loop continues until all records are read.

CACHE

```
CACHE.
```

This command does not read the active dataset. It is stored, pending execution with the next command that reads the dataset. For more information, see Command Order on p. 36.

Although the virtual active file can vastly reduce the amount of temporary disk space required, the absence of a temporary copy of the "active" file means that the original data source has to be reread for each procedure. For data tables read from a database source, this means that the SQL query that reads the information from the database must be reexecuted for any command or procedure that needs to read the data. Since virtually all statistical analysis procedures and charting procedures need to read the data, the SQL query is reexecuted for each procedure that you run, which can result in a significant increase in processing time if you run a large number of procedures.

If you have sufficient disk space on the computer performing the analysis (either your local computer or a remote server), you can eliminate multiple SQL queries and improve processing time by creating a data cache of the active file with the CACHE command. The CACHE command copies all of the data to a temporary disk file the next time the data are passed to run a procedure. If you want the cache written immediately, use the EXECUTE command after the CACHE command.

- The only specification is the command name CACHE.
- A cache file will not be written during a procedure that uses temporary variables.
- A cache file will not be written if the data are already in a temporary disk file and that file has not been modified since it was written.

Example

```
CACHE.
TEMPORARY.
RECODE alcohol(0 thru .04 = 'sober') (.04 thru .08 = 'tipsy')
  (else = 'drunk') into state.
FREQUENCIES var=state.
GRAPH...
```

No cache file will be written during the FREQUENCIES procedure. It will be written during the GRAPH procedure.

CASEPLOT

```
CASEPLOT VARIABLES=varlist

 [/DIFF={1}]
        {n}

 [/SDIFF={1}]
         {n}

 [/PERIOD=n]

 [/{NOLOG**}]
   {LN     }

 [/ID=varname]

 [/MARK={varname           }]
        {date specification}

 [/SPLIT {UNIFORM**}]
         {SCALE    }

 [/APPLY [='model name']]
```

For plots with one variable:

```
 [/FORMAT=[{NOFILL**}]  [{NOREFERENCE**     }]]
           {LEFT    }    {REFERENCE[(value)]}
```

For plots with multiple variables:

```
 [/FORMAT={NOJOIN**}]
          {JOIN    }
          {HILO    }
```

**Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Release History

Release 14.0

- For plots with one variable, new option to specify a value with the REFERENCE keyword on the FORMAT subcommand.

Example

```
CASEPLOT VARIABLES = TICKETS
  /LN
  /DIFF
  /SDIFF
  /PERIOD=12
  /FORMAT=REFERENCE
  /MARK=Y 55 M 6.
```

Overview

CASEPLOT produces a plot of one or more time series or sequence variables. You can request natural log and differencing transformations to produce plots of transformed variables. Several plot formats are available.

Options

Modifying the Variables. You can request a natural log transformation of the variable using the LN subcommand and seasonal and nonseasonal differencing to any degree using the SDIFF and DIFF subcommands. With seasonal differencing, you can also specify the periodicity on the PERIOD subcommand.

Plot Format. With the FORMAT subcommand, you can fill in the area on one side of the plotted values on plots with one variable. You can also plot a reference line indicating the variable mean. For plots with two or more variables, you can specify whether you want to join the values for each case with a horizontal line. With the ID subcommand, you can label the vertical axis with the values of a specified variable. You can mark the onset of an intervention variable on the plot with the MARK subcommand.

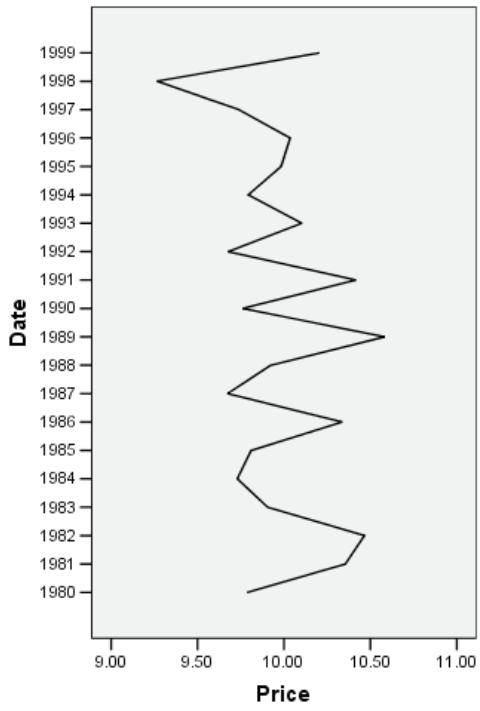
Split-File Processing. You can control how to plot data that have been divided into subgroups by a SPLIT FILE command using the SPLIT subcommand.

Basic Specification

The basic specification is one or more variable names.

- If the DATE command has been specified, the vertical axis is labeled with the *DATE_* variable at periodic intervals. Otherwise, sequence numbers are used. The horizontal axis is labeled with the value scale determined by the plotted variables.

Figure 21-1
CASEPLOT with DATE variable



Subcommand Order

- Subcommands can be specified in any order.

Syntax Rules

- `VARIABLES` can be specified only once.
- Other subcommands can be specified more than once, but only the last specification of each one is executed.

Operations

- Subcommand specifications apply to all variables named on the `CASEPLOT` command.
- If the `LN` subcommand is specified, any differencing requested on that `CASEPLOT` command is done on the log-transformed variables.
- Split-file information is displayed as part of the subtitle, and transformation information is displayed as part of the footnote.

Limitations

- A maximum of one `VARIABLES` subcommand. There is no limit on the number of variables named on the list.

Examples

```
CASEPLOT VARIABLES = TICKETS
  /LN
  /DIFF
  /SDIFF
  /PERIOD=12
  /FORMAT=REFERENCE
  /MARK=Y 55 M 6.
```

- This example produces a plot of *TICKETS* after a natural log transformation, differencing, and seasonal differencing have been applied.
- LN transforms the data using the natural logarithm (base *e*) of the variable.
- DIFF differences the variable once.
- SDIFF and PERIOD apply one degree of seasonal differencing with a periodicity of 12.
- FORMAT=REFERENCE adds a reference line at the variable mean.
- MARK provides a marker on the plot at June, 1955. The marker is displayed as a horizontal reference line.

VARIABLES Subcommand

VARIABLES specifies the names of the variables to be plotted and is the only required subcommand.

DIFF Subcommand

DIFF specifies the degree of differencing used to convert a nonstationary variable to a stationary one with a constant mean and variance before plotting.

- You can specify any positive integer on DIFF.
- If DIFF is specified without a value, the default is 1.
- The number of values displayed decreases by 1 for each degree of differencing.

Example

```
CASEPLOT VARIABLES = TICKETS
  /DIFF=2.
```

- In this example, TICKETS is differenced twice before plotting.

SDIFF Subcommand

If the variable exhibits a seasonal or periodic pattern, you can use the SDIFF subcommand to seasonally difference a variable before plotting.

- The specification on SDIFF indicates the degree of seasonal differencing and can be any positive integer.
- If SDIFF is specified without a value, the degree of seasonal differencing defaults to 1.

- The number of seasons displayed decreases by 1 for each degree of seasonal differencing.
- The length of the period used by SDIFF is specified on the PERIOD subcommand. If the PERIOD subcommand is not specified, the periodicity established on the TSET or DATE command is used (see the PERIOD subcommand below).

PERIOD Subcommand

PERIOD indicates the length of the period to be used by the SDIFF subcommand.

- The specification on PERIOD indicates how many observations are in one period or season and can be any positive integer.
- PERIOD is ignored if it is used without the SDIFF subcommand.
- If PERIOD is not specified, the periodicity established on TSET PERIOD is in effect. If TSET PERIOD is not specified either, the periodicity established on the DATE command is used. If periodicity is not established anywhere, the SDIFF subcommand will not be executed.

Example

```
CASEPLOT VARIABLES = TICKETS
  /SDIFF=1
  /PERIOD=12.
```

- This command applies one degree of seasonal differencing with 12 observations per season to *TICKETS* before plotting.

LN and NOLOG Subcommands

LN transforms the data using the natural logarithm (base *e*) of the variable and is used to remove varying amplitude over time. NOLOG indicates that the data should not be log transformed. NOLOG is the default.

- If you specify LN on CASEPLOT, any differencing requested on that command will be done on the log-transformed variable.
- There are no additional specifications on LN or NOLOG.
- Only the last LN or NOLOG subcommand on a CASEPLOT command is executed.
- If a natural log transformation is requested, any value less than or equal to zero is set to system-missing.
- NOLOG is generally used with an APPLY subcommand to turn off a previous LN specification.

Example

```
CASEPLOT VARIABLES = TICKETS
  /LN.
```

- In this example, *TICKETS* is transformed using the natural logarithm before plotting.

ID Subcommand

ID names a variable whose values will be used as the left-axis labels.

- The only specification on ID is a variable name. If you have a variable named *ID* in your active dataset, the equals sign after the subcommand is required.
- ID overrides the specification on TSET ID.
- If ID or TSET ID is not specified, the left vertical axis is labeled with the *DATE_* variable created by the DATE command. If the *DATE_* variable has not been created, the observation or sequence number is used as the label.

Example

```
CASEPLOT VARIABLES = VARA
  /ID=VARB.
```

- In this example, the values of the variable *VARB* will be used to label the left axis of the plot of *VARA*.

FORMAT Subcommand

FORMAT controls the plot format.

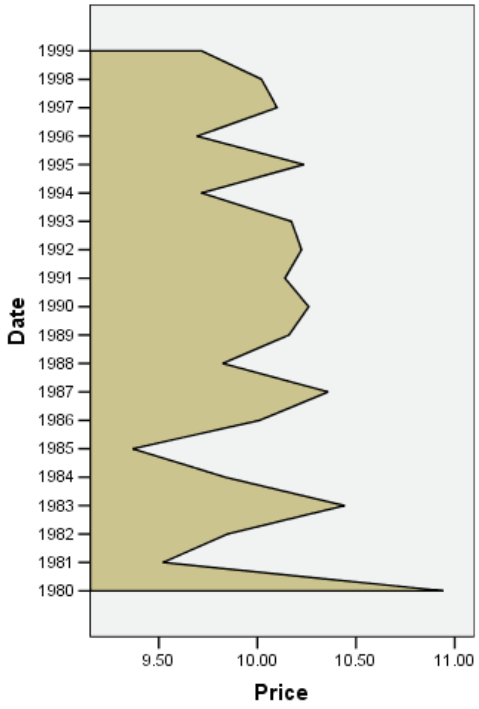
- The specification on FORMAT is one of the keywords listed below.
- The keywords NOFILL, LEFT, NOREFERENCE, and REFERENCE apply to plots with one variable. NOFILL and LEFT are alternatives and indicate how the plot is filled. NOREFERENCE and REFERENCE are alternatives and specify whether a reference line is displayed. One keyword *from each set* can be specified. NOFILL and NOREFERENCE are the defaults.
- The keywords JOIN, NOJOIN, and HILO apply to plots with multiple variables and are alternatives. NOJOIN is the default. Only one keyword can be specified on a FORMAT subcommand for plots with two variables.

The following formats are available for plots of one variable:

NOFILL *Plot only the values for the variable with no fill.* NOFILL produces a plot with no fill to the left or right of the plotted values. This is the default format when one variable is specified.

LEFT *Plot the values for the variable and fill in the area to the left.* If the plotted variable has missing or negative values, the keyword LEFT is ignored and the default NOFILL is used instead.

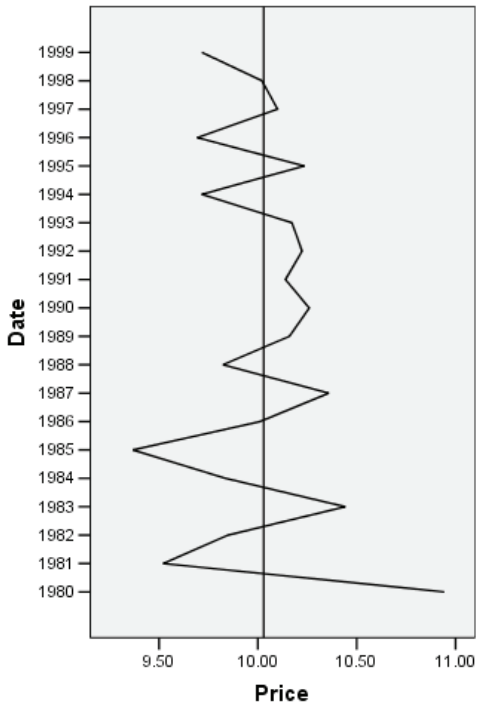
Figure 21-2
FORMAT=LEFT



NOREFERENCE *Do not plot a reference line.* This is the default when one variable is specified.

REFERENCE(value) *Plot a reference line at the specified value or at the variable mean if no value is specified.* A fill chart is displayed as an area chart with a reference line and a non-fill chart is displayed as a line chart with a reference line.

Figure 21-3
FORMAT=REFERENCE



The following formats are available for plots of multiple variables:

NOJOIN *Plot the values of each variable named.* Different colors or line patterns are used for multiple variables. Multiple occurrences of the same value for a single observation are plotted using a dollar sign ($). This is the default format for plots of multiple variables.

JOIN *Plot the values of each variable and join the values for each case.* Values are plotted as described for `NOJOIN`, and the values for each case are joined together by a line.

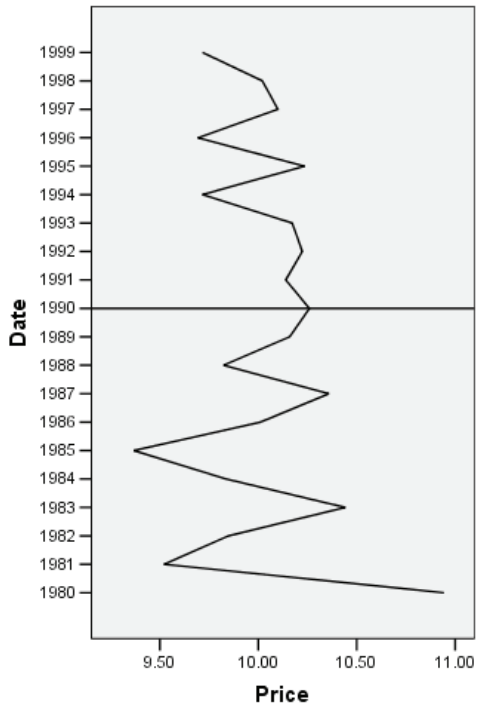
HILO *Plot the highest and lowest values across variables for each case and join the two values together.* The high and low values are plotted as a pair of vertical bars and are joined with a dashed line. `HILO` is ignored if more than three variables are specified, and the default `NOJOIN` is used instead.

MARK Subcommand

Use `MARK` to indicate the onset of an intervention variable.

- The onset date is indicated by a horizontal reference line.
- The specification on `MARK` can be either a variable name or an onset date if the *DATE_* variable exists.
- If a variable is named, the reference line indicates where the values of that variable change.
- A date specification follows the same format as the `DATE` command—that is, a keyword followed by a value. For example, the specification for June, 1955, is `Y 1955 M 6` (or `Y 55 M 6` if only the last two digits of the year are used on `DATE`).

Figure 21-4
MARK Y=1990



SPLIT Subcommand

SPLIT specifies how to plot data that have been divided into subgroups by a SPLIT FILE command. The specification on SPLIT is either SCALE or UNIFORM.

- If FORMAT=REFERENCE is specified when SPLIT=SCALE, the reference line is placed at the mean of the subgroup. If FORMAT=REFERENCE is specified when SPLIT=UNIFORM, the reference line is placed at the overall mean.

UNIFORM	*Uniform scale.* The horizontal axis is scaled according to the values of the entire dataset. This is the default if SPLIT is not specified.
SCALE	*Individual scale.* The horizontal axis is scaled according to the values of each individual subgroup.

Example

```
SPLIT FILE BY REGION.
CASEPLOT VARIABLES = TICKETS / SPLIT=SCALE.
```

- This example produces one plot for each *REGION* subgroup.
- The horizontal axis for each plot is scaled according to the values of *TICKETS* for each particular region.

APPLY Subcommand

APPLY allows you to produce a caseplot using previously defined specifications without having to repeat the CASEPLOT subcommands.

- The only specification on APPLY is the name of a previous model in quotes. If a model name is not specified, the specifications from the previous CASEPLOT command are used.
- If no variables are specified, the variables that were specified for the original plot are used.
- To change one or more plot specifications, specify the subcommands of only those portions you want to change after the APPLY subcommand.
- To plot different variables, enter new variable names before or after the APPLY subcommand.

Example

```
CASEPLOT VARIABLES = TICKETS
  /LN
  /DIFF=1
  /SDIFF=1
  /PER=12.
CASEPLOT VARIABLES = ROUNDTRP
  /APPLY.
CASEPLOT APPLY
  /NOLOG.
```

- The first command produces a plot of *TICKETS* after a natural log transformation, differencing, and seasonal differencing.
- The second command plots *ROUNDTRP* using the same transformations specified for *TICKETS*.
- The third command produces a plot of *ROUNDTRP* but this time without any natural log transformation. The variable is still differenced once and seasonally differenced with a periodicity of 12.

CASESTOVARS

```
CASESTOVARS

[/ID = varlist]

[/FIXED = varlist]

[/AUTOFIX = {YES**}]
            {NO   }

[/VIND [ROOT = rootname]]

[/COUNT = new variable ["label"]]

[/RENAME varname=rootname varname=rootname ...]

[/SEPARATOR = {"."     }]
              {"string"}]

[/INDEX = varlist]

[/GROUPBY = {VARIABLE**}]
            {INDEX     }]

[/DROP = varlist]
```

**Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
CASESTOVARS /ID idvar /INDEX var1.
```

Overview

A **variable** contains information that you want to analyze, such as a measurement or a test score. A **case** is an observation, such as an individual or an institution.

In a **simple data file**, each variable is a single **column** in your data, and each case is a single **row** in your data. So, if you were recording the score on a test for all students in a class, the scores would appear in only one column and there would be only one row for each student.

Complex data files store data in more than one column or row. For example, in a complex data file, information about a case could be stored in more than one row. So, if you were recording monthly test scores for all students in a class, there would be multiple rows for each student—one for each month.

CASESTOVARS restructures complex data that has multiple rows for a case. You can use it to restructure data in which repeated measurements of a single case were recorded in multiple rows (row groups) into a new data file in which each case appears as separate variables (variable groups) in a single row. It replaces the active dataset.

Options

Automatic Classification of Fixed Variables. The values of **fixed variables** do not vary within a row group. You can use the AUTOFIX subcommand to let the procedure determine which variables are fixed and which variables are to become variable groups in the new data file.

Naming New Variables. You can use the RENAME, SEPARATOR, and INDEX subcommands to control the names for the new variables.

Ordering New Variables. You can use the GROUPBY subcommand to specify how to order the new variables in the new data file.

Creating Indicator Variables. You can use the VIND subcommand to create indicator variables. An **indicator variable** indicates the presence or absence of a value for a case. An indicator variable has the value of 1 if the case has a value; otherwise, it is 0.

Creating a Count Variable. You can use the COUNT subcommand to create a count variable that contains the number of rows in the original data that were used to create a row in the new data file.

Variable Selection. You can use the DROP subcommand to specify which variables from the original data file are dropped from the new data file.

Basic Specification

The basic specification is simply the command keyword.

- If split-file processing is in effect, the basic specification creates a row in the new data file for each combination of values of the SPLIT FILE variables. If split-file processing is not in effect, the basic specification results in a new data file with one row.
- Because the basic specification can create quite a few new columns in the new data file, the use of an ID subcommand to identify groups of cases is recommended.

Subcommand Order

Subcommands can be specified in any order.

Syntax Rules

Each subcommand can be specified only once.

Operations

- **Original row order.** CASESTOVARS assumes that the original data are sorted by SPLIT and ID variables.
- **Identifying row groups in the original file.** A **row group** consists of rows in the original data that share the same values of variables listed on the ID subcommand. Row groups are consolidated into a single row in the new data file. Each time a new combination of ID values is encountered, a new row is created.

- **Split-file processing and row groups.** If split-file processing is in effect, the split variables are automatically used to identify row groups (they are treated as though they appeared first on the ID subcommand). Split-file processing remains in effect in the new data file unless a variable that is used to split the file is named on the DROP subcommand.
- **New variable groups.** A **variable group** is a group of related columns in the new data file that is created from a variable in the original data. Each variable group contains a variable for each index value or combination of index values encountered.
- **Candidate variables.** A variable in the original data is a candidate to become a variable group in the new data file if it is not used on the SPLIT command or the ID, FIXED, or DROP subcommands and its values vary within the row group. Variables named on the SPLIT, ID, and FIXED subcommands are assumed to not vary within the row group and are simply copied into the new data file.
- **New variable names.** The names of the variables in a new group are constructed by the procedure. It uses the rootname specified on the RENAME subcommand and the string named on the SEPARATOR subcommand.
- **New variable formats.** With the exception of names and labels, the dictionary information for all of the new variables in a group (for example, value labels and format) is taken from the variable in the original data.
- **New variable order.** New variables are created in the order specified by the GROUPBY subcommand.
- **Weighted files.** The WEIGHT command does not affect the results of CASESTOVARS. If the original data are weighted, the new data file will be weighted unless the variable that is used as the weight is dropped from the new data file.
- **Selected cases.** The FILTER and USE commands do not affect the results of CASESTOVARS. It processes all cases.

Limitations

The TEMPORARY command cannot be in effect when CASESTOVARS is executed.

Examples

The following is the LIST output for a data file in which repeated measurements for the same case are stored on separate rows in a single variable.

The commands:

```
SPLIT FILE BY insure.
CASESTOVARS
    /ID=caseid
    /INDEX=month.
```

create a new variable group for *bps* and a new group for *bpd*. The LIST output for the new active dataset is as follows:

- The row groups in the original data are identified by *insure* and *caseid*.
- There are four row groups—one for each combination of the values in *insure* and *caseid*.

- The command creates four rows in the new data file, one for each row group.
- The candidate variables from the original file are *bps* and *bpd*. They vary within the row group, so they will become variable groups in the new data file.
- The command creates two new variable groups—one for *bps* and one for *bpd*.
- Each variable group contains three new variables—one for each unique value of the index variable *month*.

ID Subcommand

The `ID` subcommand specifies variables that identify the rows from the original data that should be grouped together in the new data file.

- If the `ID` subcommand is omitted, only `SPLIT FILE` variables (if any) will be used to group rows in the original data and to identify rows in the new data file.
- `CASESTOVARS` expects the data to be sorted by `SPLIT FILE` variables and then by `ID` variables. If split-file processing is in effect, the original data should be sorted on the split variables in the order given on the `SPLIT FILE` command and then on the `ID` variables in the order in which they appear in the `ID` subcommand.
- A variable may appear on both the `SPLIT FILE` command and the `ID` subcommand.
- Variables listed on the `SPLIT FILE` command and on the `ID` subcommand are copied into the new data file with their original values and dictionary information unless they are dropped with the `DROP` subcommand.
- Variables listed on the `ID` subcommand may not appear on the `FIXED` or `INDEX` subcommands.
- Rows in the original data for which any `ID` variable has the system-missing value or is blank are not included in the new data file, and a warning message is displayed.
- `ID` variables are not candidates to become a variable group in the new data file.

INDEX Subcommand

In the original data, a variable appears in a single column. In the new data file, that variable will appear in multiple new columns. The `INDEX` subcommand names the variables in the original data that should be used to create the new columns. `INDEX` variables are also used to name the new columns.

Optionally, with the `GROUPBY` subcommand, `INDEX` variables can be used to determine the order of the new columns, and, with the `VIND` subcommand, `INDEX` variables can be used to create indicator variables.

- String variables can be used as index variables. They cannot contain blank values for rows in the original data that qualify for inclusion in the new data file.
- Numeric variables can be used as index variables. They must contain only non-negative integer values and cannot have system-missing or blank values.
- Within each row group in the original file, each row must have a different combination of values of the index variables.

- If the INDEX subcommand is not used, the index starts with 1 within each row group and increments each time a new value is encountered in the original variable.
- Variables listed on the INDEX subcommand may not appear on the ID, FIXED, or DROP subcommands.
- Index variables are not are not candidates to become a variable group in the new data file.

VIND Subcommand

The VIND subcommand creates indicator variables in the new data file. An indicator variable indicates the presence or absence of a value for a case. An indicator variable has the value of 1 if the case has a value; otherwise, it is 0.

- One new indicator variable is created for each unique value of the variables specified on the INDEX subcommand.
- If the INDEX subcommand is not used, an indicator variable is created each time a new value is encountered within a row group.
- An optional rootname can be specified after the ROOT keyword on the subcommand. The default rootname is *ind*.
- The format for the new indicator variables is F1.0.

Example

If the original variables are:

```
insure     caseid     month     bps     bpd
```

and the data are as shown in the first example, the commands:

```
SPLIT FILE BY insure.
CASESTOVARS
    /ID=caseid
    /INDEX=month
    /VIND
    /DROP=caseid bpd.
```

create a new file with the following data:

- The command created three new indicator variables—one for each unique value of the index variable *month*.

COUNT Subcommand

CASESTOVARS consolidates row groups in the original data into a single row in the new data file. The COUNT subcommand creates a new variable that contains the number of rows in the original data that were used to generate the row in the new data file.

- One new variable is named on the COUNT subcommand. It must have a unique name.

- The label for the new variable is optional and, if specified, must be delimited by single or double quotes.
- The format of the new count variable is F4.0.

Example

If the original data are as shown in the first example, the commands:

```
SPLIT FILE BY insure.
CASESTOVARS
    /ID=caseid
    /COUNT=countvar
    /DROP=insure month bpd.
```

create a new file with the following data:

- The command created a count variable, *countvar*, which contains the number of rows in the original data that were used to generate the current row.

FIXED Subcommand

The FIXED subcommand names the variables that should be copied from the original data to the new data file.

- CASESTOVARS assumes that variables named on the FIXED subcommand do not vary within row groups in the original data. If they vary, a warning message is generated and the command is executed.
- Fixed variables appear as a single column in the new data file. Their values are simply copied to the new file.
- The AUTOFIX subcommand can automatically determine which variables in the original data are fixed. By default, the AUTOFIX subcommand overrides the FIXED subcommand.

AUTOFIX Subcommand

The AUTOFIX subcommand evaluates candidate variables and classifies them as either fixed or as the source of a variable group.

- A **candidate variable** is a variable in the original data that does not appear on the SPLIT command or on the ID, INDEX, and DROP subcommands.

- An original variable that does not vary within the row group is classified as a **fixed variable** and is copied into a single variable in the new data file.
- An original variable that does vary within the row group is classified as the **source of a variable group**. It becomes a variable group in the new data file.

YES *Evaluate and automatically classify all candidate variables.* The procedure automatically evaluates and classifies all candidate variables. This is the default. If there is a FIXED subcommand, the procedure displays a warning message for each misclassified variable and automatically corrects the error. Otherwise, no warning messages are displayed. This option overrides the FIXED subcommand.

NO *Evaluate all candidate variables and issue warnings.* The procedure evaluates all candidate variables and determines if they are fixed. If a variable is listed on the FIXED subcommand but it is not actually fixed (that is, it varies within the row group), a warning message is displayed and the command is not executed. If a variable is not listed on the FIXED subcommand but it is actually fixed (that is, it does not vary within the row group), a warning message is displayed and the command is executed. The variable is classified as the source of a variable group and becomes a variable group in the new data file.

RENAME Subcommand

CASESTOVARS creates variable groups with new variables. The first part of the new variable name is either derived from the name of the original variable or is the rootname specified on the RENAME subcommand.

- The specification is the original variable name followed by a rootname.
- The named variable cannot be a SPLIT FILE variable and cannot appear on the ID, FIXED, INDEX, or DROP subcommands.
- A variable can be renamed only once.
- Only one RENAME subcommand can be used, but it can contain multiple specifications.

SEPARATOR Subcommand

CASESTOVARS creates variable groups that contain new variables. There are two parts to the name of a new variable—a rootname and an index. The parts are separated by a string. The separator string is specified on the SEPARATOR subcommand.

- If a separator is not specified, the default is a period.
- A separator can contain multiple characters.
- The separator must be delimited by single or double quotes.
- You can suppress the separator by specifying /SEPARATOR="".

GROUPBY Subcommand

The GROUPBY subcommand controls the order of the new variables in the new data file.

VARIABLE	*Group new variables by original variable.* The procedure groups all variables created from an original variable together. This is the default.
INDEX	*Group new variables by index variable.* The procedure groups variables according to the index variables.

Example

If the original variables are:

```
insure     caseid     month     bps     bpd
```

and the data are as shown in the first example, the commands:

```
SPLIT FILE BY insure.
CASESTOVARS
    /ID=caseid
    /INDEX=month
    /GROUPBY=VARIABLE.
```

create a new data file with the following variable order:

- Variables are grouped by variable group—*bps* and *bpd*.

Example

Using the same original data, the commands:

```
SPLIT FILE BY insure.
CASESTOVARS
    /ID=insure caseid
    /INDEX=month
    /GROUPBY=INDEX.
```

create a new data file with the following variable order:

- Variables are grouped by values of the index variable *month—1*, *2*, and *3*.

DROP Subcommand

The DROP subcommand specifies the subset of variables to exclude from the new data file.

- You can drop variables that appear on the ID list.
- Variables listed on the DROP subcommand may not appear on the FIXED or INDEX subcommand.
- Dropped variables are not candidates to become a variable group in the new data file.
- You cannot drop all variables. The new data file is required to have at least one variable.

CATPCA

CATPCA is available in the Categories option.

```
CATPCA VARIABLES = varlist

 /ANALYSIS varlist
      [[(WEIGHT={1**}] [LEVEL={SPORD**}] [DEGREE={2}] [INKNOT={2}]]
                {n  }                    {n}          {n}
                                 {SPNOM  }  [DEGREE={2}] [INKNOT={2}]
                                                {n}          {n}
                                 {ORDI   }
                                 {NOMI   }
                                 {MNOM   }
                                 {NUME   }

 [/DISCRETIZATION = [varlist[([{GROUPING   }] [{NCAT={7}  }] [DISTR={NORMAL }])]]]
                                                  {n}             {UNIFORM}
                                  {EQINTV={n} }
                                  {RANKING    }
                                  {MULTIPLYING}

 [/MISSING = [varlist [([{PASSIVE**}] [{MODEIMPU}])]]]
                                      {EXTRACAT}
                           {ACTIVE   }   {MODEIMPU}
                                      {EXTRACAT}
                                      {LISTWISE}

 [/SUPPLEMENTARY = [OBJECT(varlist)] [VARIABLE(varlist)]]

 [/CONFIGURATION = [{INITIAL}] (file)]
                    {FIXED  }

 [/DIMENSION = {2**}]
               {n  }

 [/NORMALIZATION = {VPRINCIPAL**}]
                   {OPRINCIPAL  }
                   {SYMMETRICAL }
                   {INDEPENDENT }
                   {n           }

 [/MAXITER = {100**}]
             {n    }

 [/CRITITER = {.00001**}]
              {value   }

 [/PRINT = [DESCRIP**[(varlist)]] [VAF] [LOADING**][QUANT[(varlist)]][HISTORY]

          [RESID(varlist[({1})])[(n)]]
                         {n}
          [PROJCENTR(varname, varlist)[(n)]] [NONE]]
          [NDIM(value,value)]

 [/SAVE = [TRDATA[({TRA     }[(n)])]] [OBJECT[({OBSCO   }[(n)])]] ]
                   {rootname}                  {rootname}
          [APPROX[({APP     })]]
                   {rootname}
```

```
[/OUTFILE = [TRDATA[('savfile'|'dataset')]] [DISCRDATA[('savfile'|'dataset')]]
            [OBJECT[('savfile'|'dataset')]] [APPROX[('savfile'|'dataset')]]].
```

** Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Release History

Release 13.0

- NDIM keyword introduced on PLOT subcommand.
- The maximum label length on the PLOT subcommand is increased to 64 for variable names, 255 for variable labels, and 60 for value labels (previous value was 20).

Overview

CATPCA performs principal components analysis on a set of variables. The variables can be given mixed optimal scaling levels, and the relationships among observed variables are not assumed to be linear.

In CATPCA, dimensions correspond to components (that is, an analysis with two dimensions results in two components), and object scores correspond to component scores.

Options

Optimal Scaling Level. You can specify the optimal scaling level at which you want to analyze each variable (levels include spline ordinal, spline nominal, ordinal, nominal, multiple nominal, or numerical).

Discretization. You can use the DISCRETIZATION subcommand to discretize fractional-value variables or to recode categorical variables.

Missing Data. You can use the MISSING subcommand to specify the treatment of missing data on a per-variable basis.

Supplementary Objects and Variables. You can specify objects and variables that you want to treat as supplementary to the analysis and then fit them into the solution.

Read Configuration. CATPCA can read a configuration from a file through the CONFIGURATION subcommand. This information can be used as the starting point for your analysis or as a fixed solution in which to fit variables.

Number of Dimensions. You can specify how many dimensions (components) CATPCA should compute.

Normalization. You can specify one of five different options for normalizing the objects and variables.

Algorithm Tuning. You can use the MAXITER and CRITITER subcommands to control the values of algorithm-tuning parameters.

Optional Output. You can request optional output through the PRINT subcommand.

Optional Plots. You can request a plot of object points, transformation plots per variable, and plots of category points per variable or a joint plot of category points for specified variables. Other plot options include residuals plots, a biplot, a triplot, component loadings plot, and a plot of projected centroids.

Writing Discretized Data, Transformed Data, Object (Component) Scores, and Approximations. You can write the discretized data, transformed data, object scores, and approximations to external files for use in further analyses.

Saving Transformed Data, Object (Component) Scores, and Approximations. You can save the transformed variables, object scores, and approximations to the working data file.

Basic Specification

The basic specification is the CATPCA command with the VARIABLES and ANALYSIS subcommands.

Syntax Rules

- The VARIABLES and ANALYSIS subcommands must always appear.
- All subcommands can be specified in any order.
- Variables that are specified in the ANALYSIS subcommand must be found in the VARIABLES subcommand.
- Variables that are specified in the SUPPLEMENTARY subcommand must be found in the ANALYSIS subcommand.

Operations

- If a subcommand is repeated, it causes a syntax error, and the procedure terminates.

Limitations

- CATPCA operates on category indicator variables. The category indicators should be positive integers. You can use the DISCRETIZATION subcommand to convert fractional-value variables and string variables into positive integers.
- In addition to system-missing values and user-defined missing values, category indicator values that are less than 1 are treated by CATPCA as missing. If one of the values of a categorical variable has been coded 0 or a negative value and you want to treat it as a valid category, use the COMPUTE command to add a constant to the values of that variable such that the lowest value will be 1 (see the COMPUTE command or the *Base User's Guide* for more information about COMPUTE). You can also use the RANKING option of the DISCRETIZATION subcommand for this purpose, except for variables that you want to treat as numeric, because the characteristic of equal intervals in the data will not be maintained.
- There must be at least three valid cases.
- Split-file has no implications for CATPCA.

Example

```
CATPCA VARIABLES = TEST1 TEST2 TEST3 TO TEST6 TEST7 TEST8
  /ANALYSIS = TEST1 TO TEST2(WEIGHT=2 LEVEL=ORDI)
              TEST3 TO TEST5(LEVEL=SPORD INKNOT=3)
              TEST6 TEST7(LEVEL=SPORD DEGREE=3)
              TEST8(LEVEL=NUME)
  /DISCRETIZATION = TEST1(GROUPING NCAT=5 DISTR=UNIFORM)
              TEST6(GROUPING) TEST8(MULTIPLYING)
  /MISSING = TEST5(ACTIVE) TEST6(ACTIVE EXTRACAT) TEST8(LISTWISE)
  /SUPPLEMENTARY = OBJECT(1 3) VARIABLE(TEST1)
  /CONFIGURATION = ('iniconf.sav')
  /DIMENSION = 2
  /NORMALIZATION = VPRINCIPAL
  /MAXITER = 150
  /CRITITER = .000001
  /PRINT =  DESCRIP LOADING CORR QUANT(TEST1 TO TEST3) OBJECT
  /PLOT = TRANS(TEST2 TO TEST5) OBJECT(TEST2 TEST3)
  /SAVE = TRDATA OBJECT
  /OUTFILE = TRDATA('/data/trans.sav') OBJECT('/data/obs.sav').
```

- VARIABLES defines variables. The keyword TO refers to the order of the variables in the working data file.
- The ANALYSIS subcommand defines variables that are used in the analysis. *TEST1* and *TEST2* have a weight of 2. For the other variables, WEIGHT is not specified; thus, they have the default weight value of 1. The optimal scaling level for *TEST1* and *TEST2* is ordinal. The optimal scaling level for *TEST3* to *TEST7* is spline ordinal. The optimal scaling level for *TEST8* is numerical. The keyword TO refers to the order of the variables in the VARIABLES subcommand. The splines for *TEST3* to *TEST5* have degree 2 (default because unspecified) and 3 interior knots. The splines for *TEST6* and *TEST7* have degree 3 and 2 interior knots (default because unspecified).
- DISCRETIZATION specifies that *TEST6* and *TEST8*, which are fractional-value variables, are discretized: *TEST6* by recoding into 7 categories with a normal distribution (default because unspecified) and *TEST8* by "multiplying." *TEST1*, which is a categorical variable, is recoded into 5 categories with a close-to-uniform distribution.
- MISSING specifies that objects with missing values on *TEST5* and *TEST6* are included in the analysis; missing values on *TEST5* are replaced with the mode (default if not specified), and missing values on *TEST6* are treated as an extra category. Objects with a missing value on *TEST8* are excluded from the analysis. For all other variables, the default is in effect; that is, missing values (not objects) are excluded from the analysis.
- CONFIGURATION specifies *iniconf.sav* as the file containing the coordinates of a configuration that is to be used as the initial configuration (default because unspecified).
- DIMENSION specifies 2 as the number of dimensions; that is, 2 components are computed. This setting is the default, so this subcommand could be omitted here.
- The NORMALIZATION subcommand specifies optimization of the association between variables. This setting is the default, so this subcommand could be omitted here.
- MAXITER specifies 150 as the maximum number of iterations (instead of the default value of 100).
- CRITITER sets the convergence criterion to a value that is smaller than the default value.
- PRINT specifies descriptives, component loadings and correlations (all default), quantifications for *TEST1* to *TEST3*, and the object (component) scores.

- PLOT requests transformation plots for the variables *TEST2* to *TEST5*, an object points plot labeled with the categories of *TEST2*, and an object points plot labeled with the categories of *TEST3*.
- The SAVE subcommand adds the transformed variables and the component scores to the working data file.
- The OUTFILE subcommand writes the transformed data to a data file called *trans.sav* and writes the component scores to a data file called *obs.sav*, both in the directory */data*.

VARIABLES Subcommand

VARIABLES specifies the variables that may be analyzed in the current CATPCA procedure.

- The VARIABLES subcommand is required.
- At least two variables must be specified, except when the CONFIGURATION subcommand is used with the FIXED keyword.
- The keyword TO on the VARIABLES subcommand refers to the order of variables in the working data file. This behavior of TO is different from the behavior in the variable list in the ANALYSIS subcommand.

ANALYSIS Subcommand

ANALYSIS specifies the variables to be used in the computations, the optimal scaling level, and the variable weight for each variable or variable list. ANALYSIS also specifies supplementary variables and their optimal scaling level. No weight can be specified for supplementary variables.

- At least two variables must be specified, except when the CONFIGURATION subcommand is used with the FIXED keyword.
- All variables on ANALYSIS must be specified on the VARIABLES subcommand.
- The ANALYSIS subcommand is required.
- The keyword TO in the variable list honors the order of variables in the VARIABLES subcommand.
- Optimal scaling levels and variable weights are indicated by the keywords LEVEL and WEIGHT in parentheses following the variable or variable list.

WEIGHT *Specifies the variable weight with a positive integer.* The default value is 1. If WEIGHT is specified for supplementary variables, it is ignored, and a syntax warning is issued.

LEVEL *Specifies the optimal scaling level.*

Level Keyword

The following keywords are used to indicate the optimal scaling level:

SPORD *Spline ordinal (monotonic).* This setting is the default. The order of the categories of the observed variable is preserved in the optimally scaled variable. Category points will lie on a straight line (vector) through the origin. The resulting transformation is a smooth monotonic piecewise polynomial of the chosen degree. The pieces are specified by the user-specified number and procedure-determined placement of the interior knots.

SPNOM *Spline nominal (nonmonotonic).* The only information in the observed variable that is preserved in the optimally scaled variable is the grouping of objects in categories. The order of the categories of the observed variable is not preserved. Category points will lie on a straight line (vector) through the origin. The resulting transformation is a smooth, possibly nonmonotonic, piecewise polynomial of the chosen degree. The pieces are specified by the user-specified number and procedure-determined placement of the interior knots.

MNOM *Multiple nominal.* The only information in the observed variable that is preserved in the optimally scaled variable is the grouping of objects in categories. The order of the categories of the observed variable is not preserved. Category points will be in the centroid of the objects in the particular categories. Multiple indicates that different sets of quantifications are obtained for each dimension.

ORDI *Ordinal.* The order of the categories on the observed variable is preserved in the optimally scaled variable. Category points will lie on a straight line (vector) through the origin. The resulting transformation fits better than SPORD transformation but is less smooth.

NOMI *Nominal.* The only information in the observed variable that is preserved in the optimally scaled variable is the grouping of objects in categories. The order of the categories of the observed variable is not preserved. Category points will lie on a straight line (vector) through the origin. The resulting transformation fits better than SPNOM transformation but is less smooth.

NUME *Numerical.* Categories are treated as equally spaced (interval level). The order of the categories and the equal distances between category numbers of the observed variables are preserved in the optimally scaled variable. Category points will lie on a straight line (vector) through the origin. When all variables are scaled at the numerical level, the CATPCA analysis is analogous to standard principal components analysis.

SPORD and SPNOM Keywords

The following keywords are used with SPORD and SPNOM:

DEGREE *The degree of the polynomial.* It can be any positive integer. The default degree is 2.

INKNOT *The number of interior knots.* The minimum is 0, and the maximum is the number of categories of the variable minus 2. If the specified value is too large, the procedure adjusts the number of interior knots to the maximum. The default number of interior knots is 2.

DISCRETIZATION Subcommand

DISCRETIZATION specifies fractional-value variables that you want to discretize. Also, you can use DISCRETIZATION for ranking or for two ways of recoding categorical variables.

- A string variable's values are always converted into positive integers, according to the internal numeric representations. DISCRETIZATION for string variables applies to these integers.

- When the DISCRETIZATION subcommand is omitted or used without a variable list, fractional-value variables are converted into positive integers by grouping them into seven categories with a distribution of close to "normal."
- When no specification is given for variables in a variable list following DISCRETIZATION, these variables are grouped into seven categories with a distribution of close to "normal."
- In CATPCA, values that are less than 1 are considered to be missing (see MISSING subcommand). However, when discretizing a variable, values that are less than 1 are considered to be valid and are thus included in the discretization process.

GROUPING	*Recode into the specified number of categories or recode intervals of equal size into categories.*
RANKING	*Rank cases.* Rank 1 is assigned to the case with the smallest value on the variable.
MULTIPLYING	*Multiply the standardized values of a fractional-value variable by 10, round, and add a value such that the lowest value is 1.*

GROUPING Keyword

GROUPING has the following keywords:

NCAT	*Number of categories.* When NCAT is not specified, the number of categories is set to 7.
EQINTV	*Recode intervals of equal size.* The size of the intervals must be specified (no default). The resulting number of categories depends on the interval size.

NCAT Keyword

NCAT has the keyword DISTR, which has the following keywords:

NORMAL	*Normal distribution.* This setting is the default when DISTR is not specified.
UNIFORM	*Uniform distribution.*

MISSING Subcommand

In CATPCA, we consider a system-missing value, user-defined missing values, and values that are less than 1 as missing values. The MISSING subcommand allows you to indicate how to handle missing values for each variable.

PASSIVE *Exclude missing values on a variable from analysis.* This setting is the default when MISSING is not specified. Passive treatment of missing values means that in optimizing the quantification of a variable, only objects with nonmissing values on the variable are involved and that only the nonmissing values of variables contribute to the solution. Thus, when PASSIVE is specified, missing values do not affect the analysis. Further, if all variables are given passive treatment of missing values, objects with missing values on every variable are treated as supplementary.

ACTIVE *Impute missing values.* You can choose to use mode imputation. You can also consider objects with missing values on a variable as belonging to the same category and impute missing values with an extra category indicator.

LISTWISE *Exclude cases with missing values on a variable.* The cases that are used in the analysis are cases without missing values on the specified variables. Also, any variable that is not included in the subcommand receives this specification.

- The ALL keyword may be used to indicate all variables. If ALL is used, it must be the only variable specification.
- A mode or extracat imputation is done before listwise deletion.

PASSIVE Keyword

If correlations are requested on the PRINT subcommand, and passive treatment of missing values is specified for a variable, the missing values must be imputed. For the correlations of the quantified variables, you can specify the imputation with one of the following keywords:

MODEIMPU *Impute missing values on a variable with the mode of the quantified variable.* MODEIMPU is the default.

EXTRACAT *Impute missing values on a variable with the quantification of an extra category.* This treatment implies that objects with a missing value are considered to belong to the same (extra) category.

Note that with passive treatment of missing values, imputation applies only to correlations and is done afterward. Thus, the imputation has no effect on the quantification or the solution.

ACTIVE Keyword

The ACTIVE keyword has the following keywords:

MODEIMPU *Impute missing values on a variable with the most frequent category (mode).* When there are multiple modes, the smallest category indicator is used. MODEIMPU is the default.

EXTRACAT *Impute missing values on a variable with an extra category indicator.* This implies that objects with a missing value are considered to belong to the same (extra) category.

Note that with active treatment of missing values, imputation is done before the analysis starts and thus will affect the quantification and the solution.

SUPPLEMENTARY Subcommand

The SUPPLEMENTARY subcommand specifies the objects and/or variables that you want to treat as supplementary. Supplementary variables must be found in the ANALYSIS subcommand. You cannot weight supplementary objects and variables (specified weights are ignored). For supplementary variables, all options on the MISSING subcommand can be specified except LISTWISE.

OBJECT *Objects that you want to treat as supplementary are indicated with an object number list in parentheses following OBJECT.* The keyword TO is allowed. The OBJECT specification is not allowed when CONFIGURATION = FIXED.

VARIABLE *Variables that you want to treat as supplementary are indicated with a variable list in parentheses following VARIABLE.* The keyword TO is allowed and honors the order of variables in the VARIABLES subcommand. The VARIABLE specification is ignored when CONFIGURATION = FIXED, because in that case all variables in the ANALYSIS subcommand are automatically treated as supplementary variables.

CONFIGURATION Subcommand

The CONFIGURATION subcommand allows you to read data from a file containing the coordinates of a configuration. The first variable in this file should contain the coordinates for the first dimension, the second variable should contain the coordinates for the second dimension, and so forth.

INITIAL(file) *Use the configuration in the external file as the starting point of the analysis.*

FIXED(file) *Fit variables in the fixed configuration that is found in the external file.* The variables to fit in should be specified on the ANALYSIS subcommand but will be treated as supplementary. The SUPPLEMENTARY subcommand and variable weights are ignored.

DIMENSION Subcommand

DIMENSION specifies the number of dimensions (components) that you want CATPCA to compute.

- The default number of dimensions is 2.
- DIMENSION is followed by an integer indicating the number of dimensions.
- If there are no variables specified as MNOM (multiple nominal), the maximum number of dimensions that you can specify is the smaller of the number of observations minus 1 and the total number of variables.
- If some or all of the variables are specified as MNOM (multiple nominal), the maximum number of dimensions is the smaller of a) the number of observations minus 1 and b) the total number of valid MNOM variable levels (categories) plus the number of SPORD, SPNOM, ORDI, NOMI, and NUME variables minus the number of MNOM variables (if the MNOM variables do not have missing values to be treated as passive). If there are MNOM variables with missing values to be treated as passive, the maximum number of dimensions is the smaller of a) the number of

observations minus 1 and b) the total number of valid MNOM variable levels (categories) plus the number of SPORD, SPNOM, ORDI, NOMI, and NUME variables, minus the larger of c) 1 and d) the number of MNOM variables without missing values to be treated as passive.

- If the specified value is too large, CATPCA adjusts the number of dimensions to the maximum.
- The minimum number of dimensions is 1.

NORMALIZATION Subcommand

The NORMALIZATION subcommand specifies one of five options for normalizing the object scores and the variables. Only one normalization method can be used in a given analysis.

VPRINCIPAL	*This option optimizes the association between variables.* With VPRINCIPAL, the coordinates of the variables in the object space are the component loadings (correlations with object scores) for SPORD, SPNOM, ORDI, NOMI, and NUME variables, and the centroids for MNOM variables. This setting is the default if the NORMALIZATION subcommand is not specified. This setting is useful when you are primarily interested in the correlations between the variables.
OPRINCIPAL	*This option optimizes distances between objects.* This setting is useful when you are primarily interested in differences or similarities between the objects.
SYMMETRICAL	*Use this normalization option if you are primarily interested in the relation between objects and variables.*
INDEPENDENT	*Use this normalization option if you want to examine distances between objects and correlations between variables separately.*

The fifth method allows the user to specify any real value in the closed interval [−1, 1]. A value of 1 is equal to the OPRINCIPAL method, a value of 0 is equal to the SYMMETRICAL method, and a value of −1 is equal to the VPRINCIPAL method. By specifying a value that is greater than −1 and less than 1, the user can spread the eigenvalue over both objects and variables. This method is useful for making a tailor-made biplot or triplot. If the user specifies a value outside of this interval, the procedure issues a syntax error message and terminates.

MAXITER Subcommand

MAXITER specifies the maximum number of iterations that the procedure can go through in its computations. If not all variables are specified as NUME and/or MNOM, the output starts from iteration 0, which is the last iteration of the initial phase, in which all variables except MNOM variables are treated as NUME.

- If MAXITER is not specified, the maximum number of iterations is 100.
- The specification on MAXITER is a positive integer indicating the maximum number of iterations. There is no uniquely predetermined (that is, hard-coded) maximum for the value that can be used.

CRITITER Subcommand

CRITITER specifies a convergence criterion value. CATPCA stops iterating if the difference in fit between the last two iterations is less than the CRITITER value.

- If CRITITER is not specified, the convergence value is 0.00001.
- The specification on CRITITER is any positive value.

PRINT Subcommand

The Model Summary (Cronbach's alpha and Variance Accounted For) and the HISTORY statistics (the variance accounted for, the loss, and the increase in variance accounted for) for the initial solution (if applicable) and last iteration are always displayed. That is, they cannot be controlled by the PRINT subcommand. The PRINT subcommand controls the display of additional optional output. The output of the procedure is based on the transformed variables. However, the keyword OCORR can be used to request the correlations of the original variables, as well.

The default keywords are DESCRIP, LOADING, and CORR. However, when some keywords are specified, the default is nullified and only what was specified comes into effect. If a keyword is duplicated or if a contradicting keyword is encountered, the last specified keyword silently becomes effective (in case of contradicting use of NONE, only the keywords following NONE are effective). An example is as follows:

```
/PRINT <=> /PRINT = DESCRIP LOADING CORR

/PRINT = VAF VAF <=> /PRINT = VAF

/PRINT = VAF NONE CORR <=> /PRINT = CORR
```

If a keyword that can be followed by a variable list is duplicated, a syntax error occurs, and the procedure will terminate.

The following keywords can be specified:

DESCRIP(varlist) *Descriptive statistics (frequencies, missing values, and mode).* The variables in the varlist must be specified on the VARIABLES subcommand but need not appear on the ANALYSIS subcommand. If DESCRIP is not followed by a varlist, descriptives tables are displayed for all variables in the varlist on the ANALYSIS subcommand.

VAF *Variance accounted for (centroid coordinates, vector coordinates, and total) per variable and per dimension.*

LOADING *Component loadings for variables with optimal scaling level that result in vector quantification* (that is, SPORD, SPNOM, ORDI, NOMI, and NUME).

QUANT(varlist) *Category quantifications and category coordinates for each dimension.* Any variable in the ANALYSIS subcommand may be specified in parentheses after QUANT. (For MNOM variables, the coordinates are the quantifications.) If QUANT is not followed by a variable list, quantification tables are displayed for all variables in the varlist on the ANALYSIS subcommand.

HISTORY *History of iterations.* For each iteration (including 0, if applicable), the variance accounted for, the loss (variance not accounted for), and the increase in variance accounted for are shown.

CORR *Correlations of the transformed variables and the eigenvalues of this correlation matrix.* If the analysis includes variables with optimal scaling level MNOM, *ndim* (the number of dimensions in the analysis) correlation matrices are computed; in the *i*th matrix, the quantifications of dimension *i*, *i* = 1, ... *ndim*, of MNOM variables are used to compute the correlations. For variables with missing values specified to be treated as PASSIVE on the MISSING subcommand, the missing values are imputed according to the specification on the PASSIVE keyword (if no specification is made, mode imputation is used).

OCORR *Correlations of the original variables and the eigenvalues of this correlation matrix.* For variables with missing values specified to be treated as PASSIVE on the MISSING subcommand, the missing values are imputed with the variable mode.

OBJECT((varname)varlist) *Object scores (component scores).* Following the keyword, a varlist can be given in parentheses to display variables (category indicators), along with object scores. If you want to use a variable to label the objects, this variable must occur in parentheses as the first variable in the varlist. If no labeling variable is specified, the objects are labeled with case numbers. The variables to display, along with the object scores and the variable to label the objects, must be specified on the VARIABLES subcommand but need not appear on the ANALYSIS subcommand. If no variable list is given, only the object scores are displayed.

NONE *No optional output is displayed.* The only output that is shown is the model summary and the HISTORY statistics for the initial iteration (if applicable) and last iteration.

The keyword TO in a variable list can only be used with variables that are in the ANALYSIS subcommand, and TO applies only to the order of the variables in the ANALYSIS subcommand. For variables that are in the VARIABLES subcommand but not in the ANALYSIS subcommand, the keyword TO cannot be used. For example, if /VARIABLES = v1 TO v5 and /ANALYSIS = v2 v1 v4, then /PLOT OBJECT(v1 TO v4) will give two object plots (one plot labeled with *v1* and one plot labeled with *v4*).

PLOT Subcommand

The PLOT subcommand controls the display of plots. The default keywords are OBJECT and LOADING. That is, the two keywords are in effect when the PLOT subcommand is omitted or when the PLOT subcommand is given without any keyword. If a keyword is duplicated (for example, /PLOT = RESID RESID), only the last keyword is effective. If the keyword NONE is used with other keywords (for example, /PLOT = RESID NONE LOADING), only the keywords following NONE are effective. When keywords contradict, the later keyword overwrites the earlier keywords.

- All the variables to be plotted must be specified on the ANALYSIS subcommand.
- If the variable list following the keywords CATEGORIES, TRANS, RESID, and PROJCENTR is empty, it will cause a syntax error, and the procedure will terminate.
- The variables in the variable list for labeling the object point following OBJECT, BIPLOT, and TRIPLOT must be specified on the VARIABLES subcommand but need not appear on the ANALYSIS subcommand. This flexibility means that variables that are not included in the analysis can still be used to label plots.

- The keyword TO in a variable list can only be used with variables that are in the ANALYSIS subcommand, and TO applies only to the order of the variables in the ANALYSIS subcommand. For variables that are in the VARIABLES subcommand but not in the ANALYSIS subcommand, the keyword TO cannot be used. For example, if /VARIABLES = v1 TO v5 and /ANALYSIS = v2 v1 v4, then /PLOT OBJECT(v1 TO v4) will give two object plots, one plot labeled with *v1* and one plot labeled with *v4*.
- For multidimensional plots, all of the dimensions in the solution are produced in a matrix scatterplot if the number of dimensions in the solution is greater than 2 and the NDIM plot keyword is not specified; if the number of dimensions in the solution is 2, a scatterplot is produced.

The following keywords can be specified:

OBJECT(varlist)(n) *Plots of the object points.* Following the keyword, a list of variables in parentheses can be given to indicate that plots of object points labeled with the categories of the variables should be produced (one plot for each variable). The variables to label the objects must be specified on the VARIABLES subcommand but need not appear on the ANALYSIS subcommand. If the variable list is omitted, a plot that is labeled with case numbers is produced.

CATEGORY(varlist)(n) *Plots of the category points.* Both the centroid coordinates and the vector coordinates are plotted. A list of variables must be given in parentheses following the keyword. For variables with optimal scaling level MNOM, categories are in the centroids of the objects in the particular categories. For all other optimal scaling levels, categories are on a vector through the origin.

LOADING(varlist (CENTR(varlist)))(l) *Plot of the component loadings optionally with centroids.* By default, all variables with an optimal scaling level that results in vector quantification (that is, SPORD, SPNOM, ORDI, NOMI, and NUME) are included in this plot. LOADING can be followed by a varlist to select the loadings to include in the plot. When "LOADING(" or the varlist following "LOADING(" is followed by the keyword CENTR in parentheses, centroids are included in the plot for all variables with optimal scaling level MNOM. CENTR can be followed by a varlist in parentheses to select MNOM variables whose centroids are to be included in the plot. When all variables have the MNOM scaling level, this plot cannot be produced.

TRANS(varlist(n))(n) *Transformation plots per variable (optimal category quantifications against category indicators).* Following the keyword, a list of variables in parentheses must be given. MNOM variables in the varlist can be followed by a number of dimensions in parentheses to indicate that you want to display *p* transformation plots, one plot for each of the first *p* dimensions. If the number of dimensions is not specified, a plot for the first dimension is produced.

RESID(varlist(n))(n) *Plot of residuals per variable (approximation against optimal category quantifications).* Following the keyword, a list of variables in parentheses must be given. MNOM variables in the varlist can be followed by a number of dimensions in parentheses to indicate that you want to display *p* residual plots, one plot for each of the first *p* dimensions. If the number of dimensions is not specified, a plot for the first dimension is produced.

BIPLOT(keyword(varlist))(varlist)(n) *Plot of objects and variables.* The coordinates for the variables can be chosen to be component loading or centroids, using the LOADING or CENTR keyword in parentheses following BIPLOT. When no keyword is given, component loadings are plotted. When NORMALIZATION = INDEPENDENT, this plot is incorrect and therefore not available. Following LOADING or CENTR, a list of variables in parentheses can be given to indicate the variables to be included in the plot. If the variable list is omitted, a plot including all variables is produced. Following BIPLOT, a list of variables in parentheses can be given to indicate that plots with objects that are labeled with the categories of the variables should be produced (one plot for each variable). The variables to label the objects must be specified on the VARIABLES subcommand but need not appear on the ANALYSIS subcommand. If the variable list is omitted, a plot with objects labeled with case numbers is produced.

TRIPLOT(varlist(varlist))(n) *A plot of object points, component loadings for variables with an optimal scaling level that results in vector quantification (that is,* SPORD, SPNOM, ORDI, NOMI, *and* NUME*), and centroids for variables with optimal scaling level* MNOM. Following the keyword, a list of variables in parentheses can be given to indicate the variables to include in the plot. If the variable list is omitted, all variables are included. The varlist can contain a second varlist in parentheses to indicate that triplots with objects labeled with the categories of the variables in this variable list should be produced (one plot for each variable). The variables to label the objects must be specified on the VARIABLES subcommand but need not appear on the ANALYSIS subcommand. If this second variable list is omitted, a plot with objects labeled with case numbers is produced. When NORMALIZATION = INDEPENDENT, this plot is incorrect and therefore not available.

JOINTCAT(varlist)(n) *Joint plot of the category points for the variables in the varlist.* If no varlist is given, the category points for all variables are displayed.

PROJCENTR(varname, varlist)(n) *Plot of the centroids of a variable projected on each of the variables in the varlist.* You cannot project centroids of a variable on variables with MNOM optimal scaling level; thus, a variable that has MNOM optimal scaling level can be specified as the variable to be projected but not in the list of variables to be projected on. When this plot is requested, a table with the coordinates of the projected centroids is also displayed.

NONE *No plots.*

- For all keywords except NONE, the user can specify an optional parameter *l* in parentheses after the variable list in order to control the global upper boundary of variable name/label and value label lengths in the plot. Note that this boundary is applied uniformly to all variables in the list. The label length parameter *l* can take any non-negative integer that is less than or equal to the applicable maximum length (64 for variable names, 255 for variable labels, and 60 for value labels). If *l* = 0, names/values instead of variable/value labels are displayed to indicate variables/categories. If *l* is not specified, CATPCA assumes that each variable name/label and value label is displayed at its full length. If *l* is an integer that is larger than the applicable maximum, we reset it to the applicable maximum but do not issue a warning. If a positive value of *l* is given but some or all variables/category values do not have labels, then, for those variables/values, the names/values themselves are used as the labels.

In addition to the plot keywords, the following keyword can be specified:

NDIM(value,value) *Dimension pairs to be plotted.* NDIM is followed by a pair of values in parentheses. If NDIM is not specified or is specified without parameter values, a matrix scatterplot including all dimensions is produced.

- The first value (an integer that can range from 1 to the number of dimensions in the solution minus 1) indicates the dimension that is plotted against higher dimensions.
- The second value (an integer that can range from 2 to the number of dimensions in the solution) indicates the highest dimension to be used in plotting the dimension pairs.
- The NDIM specification applies to all requested multidimensional plots.

BIPLOT Keyword

BIPLOT takes the following keywords:

LOADING(varlist)	*Object points and component loadings.*
CENTR(varlist)	*Object points and centroids.*

SAVE Subcommand

The SAVE subcommand is used to add the transformed variables (category indicators that are replaced with optimal quantifications), the object scores, and the approximation to the working data file. Excluded cases are represented by a dot (the system-missing symbol) on every saved variable.

TRDATA	*Transformed variables.* Missing values that are specified to be treated as passive are represented by a dot.
OBJECT	*Object (component) scores.*
APPROX	*Approximation for variables that do not have optimal scaling level MNOM.* For variables with MNOM scaling level, the approximations in dimension *s* are the object scores in dimension *s*.

- Following TRDATA, a rootname and the number of dimensions to be saved for variables that are specified as MNOM can be specified in parentheses.
- For variables that are not specified as MNOM, CATPCA adds two numbers separated by the symbol _. For variables that are specified as MNOM, CATPCA adds three numbers. The first number uniquely identifies the source variable names, and the last number uniquely identifies the CATPCA procedures with the successfully executed SAVE subcommands. For variables that are specified as MNOM, the middle number corresponds to the dimension number (see the next bullet for more details). Only one rootname can be specified, and it can contain up to five characters for variables that are not specified as MNOM and three characters for variables that are specified as MNOM. If more than one rootname is specified, the first rootname is used. If a rootname contains more than five characters (MNOM variables), the first five characters are used at most. If a rootname contains more than three characters (MNOM variables), the first three characters are used at most.
- If a rootname is not specified for TRDATA, rootname *TRA* is used to automatically generate unique variable names. The formulas are *ROOTNAMEk_n* and *ROOTNAMEk_m_n*. In this formula, *k* increments from 1 to identify the source variable names by using the source variables' position numbers in the ANALYSIS subcommand, *m* increments from 1 to identify the dimension number, and *n* increments from 1 to identify the CATPCA procedures with the successfully executed SAVE subcommands for a given data file in a continuous session.

For example, with three variables specified on ANALYSIS, LEVEL = MNOM for the second variable, and with two dimensions to save, the first set of default names—if they do not exist in the data file—would be *TRA1_1*, *TRA2_1_1*, *TRA2_2_1*, and *TRA3_1*. The next set of default names—if they do not exist in the data file—would be *TRA1_2*, *TRA2_1_2*, *TRA2_2_2*, and *TRA3_2*. However, if, for example, *TRA1_2* already exists in the data file, the default names should be attempted as *TRA1_3*, *TRA2_1_3*, *TRA2_2_3*, and *TRA3_3*. That is, the last number increments to the next available integer.

- Following OBJECT, a rootname and the number of dimensions can be specified in parentheses, to which CATPCA adds two numbers separated by the symbol _. The first number corresponds to the dimension number. The second number uniquely identifies the CATPCA procedures with the successfully executed SAVE subcommands (see the next bullet for more details). Only one rootname can be specified, and it can contain up to five characters. If more than one rootname is specified, the first rootname is used; if a rootname contains more than five characters, the first five characters are used at most.
- If a rootname is not specified for OBJECT, rootname *OBSCO* is used to automatically generate unique variable names. The formula is *ROOTNAMEm_n*. In this formula, *m* increments from 1 to identify the dimension number, and *n* increments from 1 to identify the CATPCA procedures with the successfully executed SAVE subcommands for a given data file in a continuous session. For example, if two dimensions are specified following OBJECT, the first set of default names—if they do not exist in the data file—would be *OBSCO1_1* and *OBSCO2_1*. The next set of default names—if they do not exist in the data file—would be *OBSCO1_2* and *OBSCO2_2*. However, if, for example, *OBSCO2_2* already exists in the data file, the default names should be attempted as *OBSCO1_3* and *OBSCO2_3*. That is, the second number increments to the next available integer.
- Following APPROX, a rootname can be specified in parentheses, to which CATPCA adds two numbers separated by the symbol _. The first number uniquely identifies the source variable names, and the last number uniquely identifies the CATPCA procedures with the successfully executed SAVE subcommands (see the next bullet for more details). Only one rootname can be specified, and it can contain up to five characters. If more than one rootname is specified, the first rootname is used; if a rootname contains more than five characters, the first five characters are used at most.
- If a rootname is not specified for APPROX, rootname *APP* is used to automatically generate unique variable names. The formula is *ROOTNAMEk_n*. In this formula, *k* increments from 1 to identify the source variable names by using the source variables' position numbers in the ANALYSIS subcommand. Additionally, *n* increments from 1 to identify the CATPCA procedures with the successfully executed SAVE subcommands for a given data file in a continuous session. For example, with three variables specified on ANALYSIS and LEVEL = MNOM for the second variable, the first set of default names—if they do not exist in the data file—would be *APP1_1*, *APP2_1*, and *APP3_1*. The next set of default names—if they do not exist in the data file—would be *APP1_2*, *APP2_2*, and *APP3_2*. However, if, for example, *APP1_2* already exists in the data file, the default names should be attempted as *APP1_3*, *APP2_3*, and *APP3_3*. That is, the last number increments to the next available integer.
- Variable labels are created automatically. (They are shown in the Notes table and can also be displayed in the Data Editor window.)
- If the number of dimensions is not specified, the SAVE subcommand saves all dimensions.

OUTFILE Subcommand

The OUTFILE subcommand is used to write the discretized data, transformed data (category indicators replaced with optimal quantifications), the object scores, and the approximation to a data file or previously declared data set. Excluded cases are represented by a dot (the system-missing symbol) on every saved variable.

DISCRDATA ('savfile'|'dataset')	*Discretized data.*
TRDATA ('savfile'|'dataset')	*Transformed variables.* This setting is the default if the OUTFILE subcommand is specified with a filename and without a keyword. Missing values that are specified to be treated as passive are represented by a dot.
OBJECT ('savfile'|'dataset')	*Object (component) scores.*
APPROX ('savfile'|'dataset')	*Approximation for variables that do not have optimal scaling level MNOM.*

- Filenames should be enclosed in quotes and are stored in the working directory unless a path is included as part of the file specification. Data sets are available during the current session but are not available in subsequent sessions unless you explicitly save them as data files. The names should be different for each of the keywords.

In principle, the active data set should not be replaced by this subcommand, and the asterisk (*) file specification is not supported. This strategy also prevents OUTFILE interference with the SAVE subcommand.

CATREG

CATREG is available in the Categories option.

```
CATREG VARIABLES = varlist

/ANALYSIS
         depvar [([LEVEL={SPORD**}] [DEGREE={2}] [INKNOT={2}])]
                                                {n}          {n}
                           {SPNOM  }  [DEGREE={2}] [INKNOT={2}]
                                                {n}          {n}
                           {ORDI   }
                           {NOMI   }
                           {NUME   }
   WITH indvarlist [([LEVEL={SPORD**}] [DEGREE={2}] [INKNOT={2}])]
                                                {n}          {n}
                              {SPNOM  }  [DEGREE={2}] [INKNOT={2}]
                                                {n}          {n}
                              {ORDI   }
                              {NOMI   }
                              {NUME   }

[/DISCRETIZATION = [varlist [([{GROUPING   }] [{NCAT*={7}}] [DISTR={NORMAL }])]]]
                                                    {n}          {UNIFORM}
                                {EQINTV=d   }
                                {RANKING    }
                                {MULTIPLYING}

              {n       }

[/PRINT = [R**] [COEFF**] [DESCRIP**[(varlist)]] [HISTORY] [ANOVA**]
          [CORR] [OCORR] [QUANT[(varlist)]] [NONE]]

[/PLOT = {TRANS(varlist)[(h)]} {RESID(varlist)[(h)]}]

[/SAVE = {TRDATA[({TRA     })]} {PRED[({PRE     })]} {RES[({RES        })]}]
                  {rootname}           {rootname}          {rootname}

[/OUTFILE = {TRDATA('savfile'|'dataset')} {DISCRDATA('savfile'|'dataset')}] .
```

** Default if the subcommand or keyword is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Release History

Release 13.0

- The maximum category label length on the PLOT subcommand is increased to 60 (previous value was 20).

Overview

CATREG (categorical regression with optimal scaling using alternating least squares) quantifies categorical variables using optimal scaling, resulting in an optimal linear regression equation for the transformed variables. The variables can be given mixed optimal scaling levels, and no distributional assumptions about the variables are made.

Options

Transformation Type. You can specify the transformation type (spline ordinal, spline nominal, ordinal, nominal, or numerical) at which you want to analyze each variable.

Discretization. You can use the DISCRETIZATION subcommand to discretize fractional-value variables or to recode categorical variables.

Initial Configuration. You can specify the kind of initial configuration through the INITIAL subcommand.

Tuning the Algorithm. You can control the values of algorithm-tuning parameters with the MAXITER and CRITITER subcommands.

Missing Data. You can specify the treatment of missing data with the MISSING subcommand.

Optional Output. You can request optional output through the PRINT subcommand.

Transformation Plot per Variable. You can request a plot per variable of its quantification against the category numbers.

Residual Plot per Variable. You can request an overlay plot per variable of the residuals and the weighted quantification against the category numbers.

Writing External Data. You can write the transformed data (category numbers replaced with optimal quantifications) to an outfile for use in further analyses. You can also write the discretized data to an outfile.

Saving Variables. You can save the transformed variables, the predicted values, and/or the residuals in the working data file.

Basic Specification

The basic specification is the command CATREG with the VARIABLES and ANALYSIS subcommands.

Syntax Rules

- The VARIABLES and ANALYSIS subcommands must always appear, and the VARIABLES subcommand must be the first subcommand specified. The other subcommands, if specified, can be in any order.
- Variables specified in the ANALYSIS subcommand must be found in the VARIABLES subcommand.
- In the ANALYSIS subcommand, exactly one variable must be specified as a dependent variable and at least one variable must be specified as an independent variable after the keyword WITH.

- The word WITH is reserved as a keyword in the CATREG procedure. Thus, it may not be a variable name in CATREG. Also, the word TO is a reserved word.

Operations

- If a subcommand is specified more than once, the last one is executed but with a syntax warning. Note this is true also for the VARIABLES and ANALYSIS subcommands.

Limitations

- If more than one dependent variable is specified in the ANALYSIS subcommand, CATREG is not executed.
- CATREG operates on category indicator variables. The category indicators should be positive integers. You can use the DISCRETIZATION subcommand to convert fractional-value variables and string variables into positive integers. If DISCRETIZATION is not specified, fractional-value variables are automatically converted into positive integers by grouping them into seven categories with a close to normal distribution and string variables are automatically converted into positive integers by ranking.
- In addition to system missing values and user defined missing values, CATREG treats category indicator values less than 1 as missing. If one of the values of a categorical variable has been coded 0 or some negative value and you want to treat it as a valid category, use the COMPUTE command to add a constant to the values of that variable such that the lowest value will be 1. (See COMPUTE or the *Base User's Guide* for more information on COMPUTE). You can also use the RANKING option of the DISCRETIZATION subcommand for this purpose, except for variables you want to treat as numerical, since the characteristic of equal intervals in the data will not be maintained.
- There must be at least three valid cases.
- The number of valid cases must be greater than the number of independent variables plus 1.
- The maximum number of independent variables is 200.
- Split-File has no implications for CATREG.

Example

```
CATREG VARIABLES = TEST1 TEST3 TEST2 TEST4 TEST5 TEST6
   TEST7 TO TEST9 STATUS01 STATUS02
  /ANALYSIS TEST4 (LEVEL=NUME)
   WITH TEST1 TO TEST2 (LEVEL=SPORD DEGREE=1 INKNOT=3)
   TEST5 TEST7 (LEVEL=SPNOM) TEST8 (LEVEL=ORDI)
   STATUS01 STATUS02 (LEVEL=NOMI)
  /DISCRETIZATION = TEST1(GROUPING NCAT=5 DISTR=UNIFORM)
                    TEST5(GROUPING) TEST7(MULTIPLYING)
  /INITIAL = RANDOM
  /MAXITER = 100
  /CRITITER = .000001
  /MISSING = MODEIMPU
  /PRINT = R COEFF DESCRIP ANOVA QUANT(TEST1 TO TEST2 STATUS01 STATUS02)
  /PLOT = TRANS (TEST2 TO TEST7 TEST4)
  /SAVE
  /OUTFILE = '/data/qdata.sav'.
```

- VARIABLES defines variables. The keyword TO refers to the order of the variables in the working data file.
- The ANALYSIS subcommand defines variables used in the analysis. It is specified that *TEST4* is the dependent variable, with optimal scaling level numerical and that the variables *TEST1*, *TEST2*, *TEST3*, *TEST5*, *TEST7*, *TEST8*, *STATUS01*, and *STATUS02* are the independent variables to be used in the analysis. (The keyword TO refers to the order of the variables in the VARIABLES subcommand.) The optimal scaling level for *TEST1*, *TEST2*, and *TEST3* is spline ordinal; for *TEST5* and *TEST7*, spline nominal; for *TEST8*, ordinal; and for *STATUS01* and *STATUS02*, nominal. The splines for *TEST1* and *TEST2* have degree 1 and three interior knots, and the splines for *TEST5* and *TEST7* have degree 2 and two interior knots (default because unspecified).
- DISCRETIZATION specifies that *TEST5* and *TEST7*, which are fractional-value variables, are discretized: *TEST5* by recoding into seven categories with a normal distribution (default because unspecified) and *TEST7* by "multiplying." *TEST1*, which is a categorical variable, is recoded into five categories with a close-to-uniform distribution.
- Because there are nominal variables, a random initial solution is requested by the INITIAL subcommand.
- MAXITER specifies the maximum number of iterations to be 100. This is the default, so this subcommand could be omitted here.
- CRITITER sets the convergence criterion to a value smaller than the default value.
- To include cases with missing values, the MISSING subcommand specifies that for each variable, missing values are replaced with the most frequent category (the mode).
- PRINT specifies the correlations, the coefficients, the descriptive statistics for all variables, the ANOVA table, the category quantifications for variables *TEST1*, *TEST2*, *TEST3*, *STATUS01*, and *STATUS02*, and the transformed data list of all cases.
- PLOT is used to request quantification plots for the variables *TEST2*, *TEST5*, *TEST7*, and *TEST4*.
- The SAVE subcommand adds the transformed variables to the working data file. The names of these new variables are *TRANS1_1*, ..., *TRANS9_1*.
- The OUTFILE subcommand writes the transformed data to a data file called *qdata.sav* in the directory */data*.

VARIABLES Subcommand

VARIABLES specifies the variables that may be analyzed in the current CATREG procedure.

- The VARIABLES subcommand is required and precedes all other subcommands.
- The keyword TO on the VARIABLES subcommand refers to the order of variables in the working data file. (Note that this behavior of TO is different from that in the indvarlist on the ANALYSIS subcommand.)

ANALYSIS Subcommand

ANALYSIS specifies the dependent variable and the independent variables following the keyword WITH.

- All the variables on ANALYSIS must be specified on the VARIABLES subcommand.
- The ANALYSIS subcommand is required and follows the VARIABLES subcommand.
- The first variable list contains exactly one variable as the dependent variable, while the second variable list following WITH contains at least one variable as an independent variable. Each variable may have at most one keyword in parentheses indicating the transformation type of the variable.
- The keyword TO in the independent variable list honors the order of variables on the VARIABLES subcommand.
- Optimal scaling levels are indicated by the keyword LEVEL in parentheses following the variable or variable list.

LEVEL *Specifies the optimal scaling level.*

LEVEL Keyword

The following keywords are used to indicate the optimal scaling level:

SPORD *Spline ordinal (monotonic).* This is the default for a variable listed without any optimal scaling level, for example, one without LEVEL in the parentheses after it or with LEVEL without a specification. Categories are treated as ordered. The order of the categories of the observed variable is preserved in the optimally scaled variable. Categories will be on a straight line through the origin. The resulting transformation is a smooth nondecreasing piecewise polynomial of the chosen degree. The pieces are specified by the number and the placement of the interior knots.

SPNOM *Spline nominal (non-monotonic).* Categories are treated as unordered. Objects in the same category obtain the same quantification. Categories will be on a straight line through the origin. The resulting transformation is a smooth piecewise polynomial of the chosen degree. The pieces are specified by the number and the placement of the interior knots.

ORDI *Ordinal.* Categories are treated as ordered. The order of the categories of the observed variable is preserved in the optimally scaled variable. Categories will be on a straight line through the origin. The resulting transformation fits better than SPORD transformation, but is less smooth.

NOMI *Nominal.* Categories are treated as unordered. Objects in the same category obtain the same quantification. Categories will be on a straight line through the origin. The resulting transformation fits better than SPNOM transformation, but is less smooth.

NUME *Numerical.* Categories are treated as equally spaced (interval level). The order of the categories and the differences between category numbers of the observed variables are preserved in the optimally scaled variable. Categories will be on a straight line through the origin. When all variables are scaled at the numerical level, the CATREG analysis is analogous to standard multiple regression analysis.

SPORD and SPNOM Keywords

The following keywords are used with SPORD and SPNOM :

DEGREE *The degree of the polynomial.* If DEGREE is not specified the degree is assumed to be 2.

INKNOT *The number of the interior knots.* If INKNOT is not specified the number of interior knots is assumed to be 2.

DISCRETIZATION Subcommand

DISCRETIZATION specifies fractional-value variables that you want to discretize. Also, you can use DISCRETIZATION for ranking or for two ways of recoding categorical variables.

- A string variable's values are always converted into positive integers by assigning category indicators according to the ascending alphanumeric order. DISCRETIZATION for string variables applies to these integers.
- When the DISCRETIZATION subcommand is omitted, or when the DISCRETIZATION subcommand is used without a varlist, fractional-value variables are converted into positive integers by grouping them into seven categories (or into the number of distinct values of the variable if this number is less than 7) with a close to normal distribution.
- When no specification is given for variables in a varlist following DISCRETIZATION, these variables are grouped into seven categories with a close-to-normal distribution.
- In CATREG, a system-missing value, user-defined missing values, and values less than 1 are considered to be missing values (see next section). However, in discretizing a variable, values less than 1 are considered to be valid values, and are thus included in the discretization process. System-missing values and user-defined missing values are excluded.

GROUPING *Recode into the specified number of categories.*

RANKING *Rank cases.* Rank 1 is assigned to the case with the smallest value on the variable.

MULTIPLYING *Multiplying the standardized values (z-scores) of a fractional-value variable by 10, rounding, and adding a value such that the lowest value is 1.*

GROUPING Keyword

NCAT *Recode into ncat categories.* When NCAT is not specified, the number of categories is set to 7 (or the number of distinct values of the variable if this number is less than 7). The valid range is from 2 to 36. You may either specify a number of categories or use the keyword DISTR.

EQINTV *Recode intervals of equal size into categories.* The interval size must be specified (there is no default value). The resulting number of categories depends on the interval size.

DISTR Keyword

DISTR has the following keywords:

NORMAL *Normal distribution.* This is the default when DISTR is not specified.

UNIFORM *Uniform distribution.*

MISSING Subcommand

In CATREG, we consider a system missing value, user defined missing values, and values less than 1 as missing values. However, in discretizing a variable (see previous section), values less than 1 are considered as valid values. The MISSING subcommand allows you to indicate how to handle missing values for each variable.

LISTWISE *Exclude cases with missing values on the specified variable(s).* The cases used in the analysis are cases without missing values on the variable(s) specified. This is the default applied to all variables, when the MISSING subcommand is omitted or is specified without variable names or keywords. Also, any variable that is not included in the subcommand gets this specification.

MODEIMPU *Impute missing value with mode.* All cases are included and the imputations are treated as valid observations for a given variable. When there are multiple modes, the smallest mode is used.

EXTRACAT *Impute missing values on a variable with an extra category indicator.* This implies that objects with a missing value are considered to belong to the same (extra) category. This category is treated as nominal, regardless of the optimal scaling level of the variable.

- The ALL keyword may be used to indicate all variables. If it is used, it must be the only variable specification.
- A mode or extra-category imputation is done before listwise deletion.

SUPPLEMENTARY Subcommand

The SUPPLEMENTARY subcommand specifies the objects that you want to treat as supplementary. You cannot weight supplementary objects (specified weights are ignored).

OBJECT *Supplementary objects.* Objects that you want to treat as supplementary are indicated with an object number list in parentheses following OBJECT. The keyword TO is allowed—for example, OBJECT(1 TO 1 3 5 TO 9).

INITIAL Subcommand

INITIAL specifies the method used to compute the initial value/configuration.

- The specification on INITIAL is keyword NUMERICAL or RANDOM. If INITIAL is not specified, NUMERICAL is the default.

NUMERICAL *Treat all variables as numerical.* This is usually best to use when there are only numerical and/or ordinal variables.

RANDOM *Provide a random initial value.* This should be used only when there is at least one nominal variable.

MAXITER Subcommand

MAXITER specifies the maximum number of iterations CATREG can go through in its computations. Note that the output starts from the iteration number 0, which is the initial value before any iteration, when INITIAL = NUMERICAL is in effect.

- If MAXITER is not specified, CATREG will iterate up to 100 times.
- The specification on MAXITER is a positive integer indicating the maximum number of iterations. There is no uniquely predetermined (hard coded) maximum for the value that can be used.

CRITITER Subcommand

CRITITER specifies a convergence criterion value. CATREG stops iterating if the difference in fit between the last two iterations is less than the CRITITER value.

- If CRITITER is not specified, the convergence value is 0.00001.
- The specification on CRITITER is any value less than or equal to 0.1 and greater than or equal to 0.000001. (Values less than the lower bound might seriously affect performance. Therefore, they are not supported.)

PRINT Subcommand

The PRINT subcommand controls the display of output. The output of the CATREG procedure is always based on the transformed variables. However, the correlations of the original predictor variables can be requested as well by the keyword OCORR. The default keywords are R, COEFF, DESCRIP, and ANOVA. That is, the four keywords are in effect when the PRINT subcommand is omitted or when the PRINT subcommand is given without any keyword. If a keyword is

duplicated or it encounters a contradicting keyword, such as /PRINT = R R NONE, then the last one silently becomes effective.

R	*Multiple R.* Includes R^2, adjusted R^2, and adjusted R^2 taking the optimal scaling into account.
COEFF	*Standardized regression coefficients (beta).* This option gives three tables: a Coefficients table that includes betas, standard error of the betas, *t* values, and significance; a Coefficients-Optimal Scaling table, with the standard error of the betas taking the optimal scaling degrees of freedom into account; and a table with the zero-order, part, and partial correlation, Pratt's relative importance measure for the transformed predictors, and the tolerance before and after transformation. If the tolerance for a transformed predictor is lower than the default tolerance value in the Regression procedure (0.0001) but higher than 10E–12, this is reported in an annotation. If the tolerance is lower than 10E–12, then the COEFF computation for this variable is not done and this is reported in an annotation. Note that the regression model includes the intercept coefficient but that its estimate does not exist because the coefficients are standardized.
DESCRIP(varlist)	*Descriptive statistics (frequencies, missing values, and mode).* The variables in the varlist must be specified on the VARIABLES subcommand but need not appear on the ANALYSIS subcommand. If DESCRIP is not followed by a varlist, Descriptives tables are displayed for all of the variables in the variable list on the ANALYSIS subcommand.
HISTORY	*History of iterations.* For each iteration, including the starting values for the algorithm, the multiple *R* and the regression error (square root of (1–multiple R^2)) are shown. The increase in multiple *R* is listed from the first iteration.
ANOVA	*Analysis-of-variance tables.* This option includes regression and residual sums of squares, mean squares, and *F*. This options gives two ANOVA tables: one with degrees of freedom for the regression equal to the number of predictor variables and one with degrees of freedom for the regression taking the optimal scaling into account.
CORR	*Correlations of the transformed predictors.*
OCORR	*Correlations of the original predictors.*
QUANT(varlist)	*Category quantifications.* Any variable in the ANALYSIS subcommand may be specified in parentheses after QUANT. If QUANT is not followed by a varlist, Quantification tables are displayed for all variables in the variable list on the ANALYSIS subcommand.
NONE	*No* PRINT *output is shown.* This is to suppress the default PRINT output.

- The keyword TO in a variable list can be used only with variables that are in the ANALYSIS subcommand, and TO applies only to the order of the variables in the ANALYSIS subcommand. For variables that are in the VARIABLES subcommand but not in the ANALYSIS subcommand, the keyword TO cannot be used. For example, if /VARIABLES = v1 TO v5 and /ANALYSIS is v2 v1 v4, then /PRINT QUANT(v1 TO v4) will give two quantification plots, one for *v1* and one for *v4*. (/PRINT QUANT(v1 TO v4 v2 v3 v5) will give quantification tables for *v1*, *v2*, *v3*, *v4*, and *v5*.)

PLOT Subcommand

The PLOT subcommand controls the display of plots.

- In this subcommand, if no plot keyword is given, then no plot is created. Further, if the variable list following the plot keyword is empty, then no plot is created, either.
- All of the variables to be plotted must be specified in the ANALYSIS subcommand. Further, for the residual plots, the variables must be independent variables.

TRANS(varlist)(l) *Transformation plots (optimal category quantifications against category indicators).* A list of variables must come from the ANALYSIS variable list and must be given in parentheses following the keyword. Further, the user can specify an optional parameter l in parentheses after the variable list in order to control the global upper boundary of category label lengths in the plot. Note that this boundary is applied uniformly to all transformation plots.

RESID(varlist)(l) *Residual plots (residuals when the dependent variable is predicted from all predictor variables in the analysis except the predictor variable in varlist, against category indicators, and the optimal category quantifications multiplied with beta against category indicators).* A list of variables must come from the ANALYSIS variable list's independent variables and must be given in parentheses following the keyword. Further, the user can specify an optional parameter l in parentheses after the variable list in order to control the global upper boundary of category label lengths in the plot. Note that this boundary is applied uniformly to all residual plots.

- The category label length parameter (l) can take any non-negative integer less than or equal to 60. If l = 0, values instead of value labels are displayed to indicate the categories on the *x* axis in the plot. If l is not specified, CATREG assumes that each value label at its full length is displayed as a plot's category label. If l is an integer larger than 60, then we reset it to 60 but do not issue a warning.
- If a positive value of l is given but if some or all of the values do not have value labels, then for those values, the values themselves are used as the category labels.
- The keyword TO in a variable list can be used only with variables that are in the ANALYSIS subcommand, and TO applies only to the order of the variables in the ANALYSIS subcommand. For variables that are in the VARIABLES subcommand but not in the ANALYSIS subcommand, the keyword TO cannot be used. For example, if /VARIABLES = v1 TO v5 and /ANALYSIS is v2 v1 v4, then /PLOT TRANS(v1 TO v4) will give two transformation plots, one for *v1* and for *v4*. (/PLOT TRANS(v1 TO v4 v2 v3 v5) will give transformation plots for *v1*, *v2*, *v3*, *v4*, and *v5*.)

SAVE Subcommand

The SAVE subcommand is used to add the transformed variables (category indicators replaced with optimal quantifications), the predicted values, and the residuals to the working data file.

Excluded cases are represented by a dot (the sysmis symbol) on every saved variable.

TRDATA *Transformed variables.*

PRED *Predicted values.*

RES *Residuals.*

- A variable rootname can be specified with each of the keywords. Only one rootname can be specified with each keyword, and it can contain up to five characters (if more than one rootname is specified with a keyword, the first rootname is used; if a rootname contains more than five characters, the first five characters are used at most). If a rootname is not specified, the default rootnames (TRA, PRE, and RES) are used.
- CATREG adds two numbers separated by an underscore (_) to the rootname. The formula is *ROOTNAMEk_n*, where *k* increments from 1 to identify the source variable names by using the source variables' position numbers in the ANALYSIS subcommand (that is, the dependent variable has the position number 1, and the independent variables have the position numbers 2, 3, ..., etc., as they are listed), and *n* increments from 1 to identify the CATREG procedures with the successfully executed SAVE subcommands for a given data file in a continuous session. For example, with two predictor variables specified on ANALYSIS, the first set of default names for the transformed data, if they do not exist in the data file, would be *TRA1_1* for the dependent variable, and *TRA2_1*, *TRA3_1* for the predictor variables. The next set of default names, if they do not exist in the data file, would be *TRA1_2*, *TRA2_2*, *TRA3_2*. However, if, for example, *TRA1_2* already exists in the data file, then the default names should be attempted as *TRA1_3*, *TRA2_3*, *TRA3_3*—that is, the last number increments to the next available integer.
- Variable labels are created automatically. (They are shown in the Procedure Information Table (the Notes table) and can also be displayed in the Data Editor window.)

OUTFILE Subcommand

The OUTFILE subcommand is used to write the discretized data and/or the transformed data (category indicators replaced with optimal quantifications) to a data file or previously declared data set name. Excluded cases are represented by a dot (the sysmis symbol) on every saved variable.

DISCRDATA('savfile'|'dataset')	*Discretized data.*
TRDATA('savfile'|'dataset')	*Transformed variables.*

- Filenames should be enclosed in quotes and are stored in the working directory unless a path is included as part of the file specification. Data sets are available during the current session but are not available in subsequent sessions unless you explicitly save them as data files.
- An active data set, in principle, should not be replaced by this subcommand, and the asterisk (*) file specification is not supported. This strategy also prevents the OUTFILE interference with the SAVE subcommand.

CCF

```
CCF VARIABLES= series names [WITH series names]

 [/DIFF={1}]
        {n}

 [/SDIFF={1}]
         {n}

 [/PERIOD=n]

 [/{NOLOG**}]
   {LN     }

 [/SEASONAL]

 [/MXCROSS={7**}]
           {n  }

 [/APPLY[='model name']]
```

**Default if the subcommand is omitted and there is no corresponding specification on the TSET command.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
CCF VARIABLES = VARX VARY.
```

Overview

CCF displays and plots the cross-correlation functions of two or more time series. You can also display and plot the cross-correlations of transformed series by requesting natural log and differencing transformations within the procedure.

Options

Modifying the Series. You can request a natural log transformation of the series using the LN subcommand and seasonal and nonseasonal differencing to any degree using the SDIFF and DIFF subcommands. With seasonal differencing, you can also specify the periodicity on the PERIOD subcommand.

Statistical Display. You can control which series are paired by using the keyword WITH. You can specify the range of lags for which you want values displayed and plotted with the MXCROSS subcommand, overriding the maximum specified on TSET. You can also display and plot values at periodic lags only using the SEASONAL subcommand.

Basic Specification

The basic specification is two or more series names. By default, CCF automatically displays the cross-correlation coefficient and standard error for the negative lags (second series leading), the positive lags (first series leading), and the 0 lag for all possible pair combinations in the series list. It also plots the cross-correlations and marks the bounds of two standard errors on the plot. By default, CCF displays and plots values up to 7 lags (lags −7 to +7), or the range specified on TSET.

Subcommand Order

- Subcommands can be specified in any order.

Syntax Rules

- The VARIABLES subcommand can be specified only once.
- Other subcommands can be specified more than once, but only the last specification of each one is executed.

Operations

- Subcommand specifications apply to all series named on the CCF command.
- If the LN subcommand is specified, any differencing requested on that CCF command is done on the log-transformed series.
- Confidence limits are displayed in the plot, marking the bounds of two standard errors at each lag.

Limitations

- A maximum of 1 VARIABLES subcommand. There is no limit on the number of series named on the list.

Example

```
CCF VARIABLES = VARX VARY
  /LN
  /DIFF=1
  /SDIFF=1
  /PERIOD=12
  /MXCROSS=25.
```

- This example produces a plot of the cross-correlation function for *VARX* and *VARY* after a natural log transformation, differencing, and seasonal differencing have been applied to both series. Along with the plot, the cross-correlation coefficients and standard errors are displayed for each lag.
- LN transforms the data using the natural logarithm (base *e*) of each series.
- DIFF differences each series once.
- SDIFF and PERIOD apply one degree of seasonal differencing with a periodicity of 12.
- MXCROSS specifies 25 for the maximum range of positive and negative lags for which output is to be produced (lags −25 to +25).

VARIABLES Subcommand

VARIABLES specifies the series to be plotted and is the only required subcommand.

- The minimum VARIABLES specification is a pair of series names.
- If you do not use the keyword WITH, each series is paired with every other series in the list.
- If you specify the keyword WITH, every series named before WITH is paired with every series named after WITH.

Example

```
CCF VARIABLES=VARA VARB WITH VARC VARD.
```

- This example displays and plots the cross-correlation functions for the following pairs of series: *VARA* with *VARC*, *VARA* with *VARD*, *VARB* with *VARC*, and *VARB* with *VARD*.
- *VARA* is not paired with *VARB*, and *VARC* is not paired with *VARD*.

DIFF Subcommand

DIFF specifies the degree of differencing used to convert a nonstationary series to a stationary one with a constant mean and variance before obtaining cross-correlations.

- You can specify 0 or any positive integer on DIFF.
- If DIFF is specified without a value, the default is 1.
- The number of values used in the calculations decreases by 1 for each degree of differencing.

Example

```
CCF VARIABLES = VARX VARY
  /DIFF=1.
```

- This command differences series *VARX* and *VARY* before calculating and plotting the cross-correlation function.

SDIFF Subcommand

If the series exhibits seasonal or periodic patterns, you can use SDIFF to seasonally difference the series before obtaining cross-correlations.

- The specification on SDIFF indicates the degree of seasonal differencing and can be 0 or any positive integer.
- If SDIFF is specified without a value, the degree of seasonal differencing defaults to 1.
- The number of seasons used in the calculations decreases by 1 for each degree of seasonal differencing.
- The length of the period used by SDIFF is specified on the PERIOD subcommand. If the PERIOD subcommand is not specified, the periodicity established on the TSET or DATE command is used (see the PERIOD subcommand).

Example

```
CCF VARIABLES = VAR01 WITH VAR02 VAR03
  /SDIFF=1.
```

- In this example, one degree of seasonal differencing using the periodicity established on the TSET or DATE command is applied to the three series.
- Two cross-correlation functions are then plotted, one for the pair *VAR01* and *VAR02*, and one for the pair *VAR01* and *VAR03*.

PERIOD Subcommand

PERIOD indicates the length of the period to be used by the SDIFF or SEASONAL subcommands.

- The specification on PERIOD indicates how many observations are in one period or season and can be any positive integer greater than 1.
- PERIOD is ignored if it is used without the SDIFF or SEASONAL subcommands.
- If PERIOD is not specified, the periodicity established on TSET PERIOD is in effect. If TSET PERIOD is not specified, the periodicity established on the DATE command is used. If periodicity was not established anywhere, the SDIFF and SEASONAL subcommands will not be executed.

Example

```
CCF VARIABLES = VARX WITH VARY
  /SDIFF=1
  /PERIOD=6.
```

- This command applies one degree of seasonal differencing with a periodicity of 6 to both series and computes and plots the cross-correlation function.

LN and NOLOG Subcommands

LN transforms the data using the natural logarithm (base *e*) of each series and is used to remove varying amplitude over time. NOLOG indicates that the data should not be log transformed. NOLOG is the default.

- There are no additional specifications on LN or NOLOG.
- Only the last LN or NOLOG subcommand on a CCF command is executed.
- LN and NOLOG apply to all series named on the CCF command.
- If a natural log transformation is requested and any values in either series in a pair are less than or equal to 0, the CCF for that pair will not be produced because nonpositive values cannot be log transformed.
- NOLOG is generally used with an APPLY subcommand to turn off a previous LN specification.

Example

```
CCF VARIABLES = VAR01 VAR02
```

```
  /LN.
```

- This command transforms the series *VAR01* and *VAR02* using the natural log before computing cross-correlations.

SEASONAL Subcommand

Use SEASONAL to focus attention on the seasonal component by displaying and plotting cross-correlations at periodic lags only.

- There are no additional specifications on SEASONAL.
- If SEASONAL is specified, values are displayed and plotted at the periodic lags indicated on the PERIOD subcommand. If no PERIOD subcommand is specified, the periodicity first defaults to the TSET PERIOD specification and then to the DATE command periodicity. If periodicity is not established anywhere, SEASONAL is ignored (see the PERIOD subcommand).
- If SEASONAL is not used, cross-correlations for all lags up to the maximum are displayed and plotted.

Example

```
CCF VARIABLES = VAR01 VAR02 VAR03
  /SEASONAL.
```

- This command plots and displays cross-correlations at periodic lags.
- By default, the periodicity established on TSET PERIOD (or the DATE command) is used. If no periodicity is established, cross-correlations for all lags are displayed and plotted.

MXCROSS Subcommand

MXCROSS specifies the maximum range of lags for a series.

- The specification on MXCROSS must be a positive integer.
- If MXCROSS is not specified, the default range is the value set on TSET MXCROSS. If TSET MXCROSS is not specified, the default is 7 (lags -7 to +7).
- The value specified on the MXCROSS subcommand overrides the value set on TSET MXCROSS.

Example

```
CCF VARIABLES = VARX VARY
  /MXCROSS=5.
```

- The maximum number of cross-correlations can range from lag −5 to lag +5.

APPLY Subcommand

APPLY allows you to use a previously defined CCF model without having to repeat the specifications.

- The only specification on APPLY is the name of a previous model enclosed in single or double quotes. If a model name is not specified, the model specified on the previous CCF command is used.
- To change one or more model specifications, specify the subcommands of only those portions you want to change after the APPLY subcommand.
- If no series are specified on the command, the series that were originally specified with the model being applied are used.
- To change the series used with the model, enter new series names before or after the APPLY subcommand.

Example

```
CCF VARIABLES = VARX VARY
  /LN
  /DIFF=1
  /MXCROSS=25.
CCF VARIABLES = VARX VARY
  /LN
  /DIFF=1
  /SDIFF=1
  /PERIOD=12
  /MXCROSS=25.
CCF VARIABLES = VARX VAR01
  /APPLY.
CCF VARIABLES = VARX VAR01
  /APPLY='MOD_1'.
```

- The first command displays and plots the cross-correlation function for *VARX* and *VARY* after each series is log transformed and differenced. The maximum range is set to 25 lags. This model is assigned the name *MOD_1* as soon as the command is executed.
- The second command displays and plots the cross-correlation function for *VARX* and *VARY* after each series is log transformed, differenced, and seasonally differenced with a periodicity of 12. The maximum range is again set to 25 lags. This model is assigned the name *MOD_2*.
- The third command requests the cross-correlation function for the series *VARX* and *VAR01* using the same model and the same range of lags as used for *MOD_2*.
- The fourth command applies *MOD_1* (from the first command) to the series *VARX* and *VAR01*.

CD

```
CD 'directory specification'.
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Release History

Release 13.0

- Command introduced.

Example

```
CD '/main/sales/consumer_division/2004/data'.
GET FILE='julydata.sav'.
INSERT FILE='../commands/monthly_report.sps'.
```

Overview

CD changes the working directory location, making it possible to use relative paths for subsequent file specifications in command syntax, including data files specified on commands such as GET and SAVE, command syntax files specified on commands such as INSERT and INCLUDE, and output files specified on commands such as OMS and WRITE.

Basic Specification

The only specification is the command name followed by a quoted directory specification.

- The directory specification can contain a drive specification.
- The directory specification can be a previously defined file handle (see the FILE HANDLE command for more information).
- The directory specification can include paths defined in operating system environment variables.

Operations

The change in the working directory remains in effect until some other condition occurs that changes the working directory during the session, such as explicitly changing the working directory on another CD command or an INSERT command with a CD keyword that specifies a different directory.

- If the directory path is a relative path, it is relative to the current working directory.
- If the directory specification contains a filename, the filename portion is ignored.

- If the last (most-nested) subdirectory in the directory specification does not exist, then it is assumed to be a filename and is ignored.
- If any directory specification prior to the last directory (or file) is invalid, the command will fail, and an error message is issued.

Limitations

The CD command has no effect on the relative directory location for SET command file specifications, including JOURNAL , CTEMPLATE, and TLOOK. File specifications on the SET command should include complete path information.

Examples

Working with Absolute Paths

```
CD '/sales/data/july.sav'.
CD '/sales/data/july'.
CD '/sales/data/july'.
```

If */sales/data* is a valid directory:

- The first CD command will ignore the filename *july.sav* and set the working directory to */sales/data*.
- If the subdirectory *july* exists, the second CD command will change the working directory to */sales/data/july*; otherwise, it will change the working directory to */sales/data*.
- The third CD command will fail if the *dqta* subdirectory doesn't exist.

Working with Relative Paths

```
CD '/sales'.
CD 'data'.
CD 'july'.
```

If */sales* is a valid directory:

- The first CD command will change the working directory to */sales*.
- The relative path in the second CD command will change the working directory to */sales/data*.
- The relative path in the third CD command will change the working directory to */sales/data/july*.

Preserving and Restoring the Working Directory Setting

The original working directory can be preserved with the PRESERVE command and later restored with the RESTORE command.

Example

```
CD '/sales/data'.
PRESERVE.
CD '/commands/examples'.
RESTORE.
```

- `PRESERVE` retains the working directory location set on the preceding `CD` command.
- The second `CD` command changes the working directory.
- `RESTORE` resets the working directory back to */sales/data*.

CLEAR TIME PROGRAM

```
CLEAR TIME PROGRAM.
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Overview

CLEAR TIME PROGRAM deletes all time-dependent covariates created in the previous TIME PROGRAM command. It is primarily used in interactive mode to remove temporary variables associated with the time program so that you can redefine time-dependent covariates. It is not necessary to use this command if you have run a procedure that executes the TIME PROGRAM transformations, since all temporary variables created by TIME PROGRAM are automatically deleted.

Basic Specification

The only specification is the command itself. CLEAR TIME PROGRAM has no additional specifications.

Example

```
TIME PROGRAM.
COMPUTE Z=AGE + T_.

CLEAR TIME PROGRAM.

TIME PROGRAM.
COMPUTE Z=AGE + T_ - 18.

COXREG SURVIVAL WITH Z
  /STATUS SURVSTA EVENT(1).
```

- The first TIME PROGRAM command defines the time-dependent covariate *Z* as the current age.
- The CLEAR TIME PROGRAM command deletes the time-dependent covariate *Z*.
- The second TIME PROGRAM command redefines the time-dependent covariate *Z* as the number of years since turning 18.. *Z* is then specified as a covariate in COXREG.

CLEAR TRANSFORMATIONS

```
CLEAR TRANSFORMATIONS
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Overview

`CLEAR TRANSFORMATIONS` discards previous data transformation commands.

Basic Specification

The only specification is the command itself. `CLEAR TRANSFORMATIONS` has no additional specifications.

Operations

- `CLEAR TRANSFORMATIONS` discards all data transformation commands that have accumulated since the last procedure.
- `CLEAR TRANSFORMATIONS` has no effect if a command file is submitted to your operating system for execution. It generates a warning when a command file is present.
- Be sure to delete `CLEAR TRANSFORMATIONS` and any unwanted transformation commands from the journal file if you plan to submit the file to the operating system for batch mode execution. Otherwise, the unwanted transformations will cause problems.

Examples

```
GET FILE="/data/query.sav".
FREQUENCIES=ITEM1 ITEM2 ITEM3.
RECODE ITEM1, ITEM2, ITEM3 (0=1) (1=0) (2=-1).
COMPUTE INDEXQ=(ITEM1 + ITEM2 + ITEM3)/3.
VARIABLE LABELS INDEXQ 'SUMMARY INDEX OF QUESTIONS'.
CLEAR TRANSFORMATIONS.
DISPLAY DICTIONARY.
```

- The `GET` and `FREQUENCIES` commands are executed.
- The `RECODE`, `COMPUTE`, and `VARIABLE LABELS` commands are transformations. They do not affect the data until the next procedure is executed.
- The `CLEAR TRANSFORMATIONS` command discards the `RECODE`, `COMPUTE`, and `VARIABLE LABELS` commands.
- The `DISPLAY` command displays the working file dictionary. Data values and labels are exactly as they were when the `FREQUENCIES` command was executed. The variable *INDEXQ* does not exist because `CLEAR TRANSFORMATIONS` discarded the `COMPUTE` command.

CLUSTER

```
CLUSTER varlist [/MISSING=[EXCLUDE**] [INCLUDE]]

[/MEASURE=[{SEUCLID**          }]
           {EUCLID             }
           {COSINE             }
           {CORRELATION        }
           {BLOCK              }
           {CHEBYCHEV          }
           {POWER(p,r)         }
           {MINKOWSKI(p)       }
           {CHISQ              }
           {PH2                }
           {RR[(p[,np])]       }
           {SM[(p[,np])]       }
           {JACCARD[(p[,np])] }
           {DICE[(p[,np])]     }
           {SS1[(p[,np])]      }
           {RT[(p[,np])]       }
           {SS2[(p[,np])]      }
           {K1[(p[,np])]       }
           {SS3[(p[,np])]      }
           {K2[(p[,np])]       }
           {SS4[(p[,np])]      }
           {HAMANN[(p[,np])]   }
           {OCHIAI[(p[,np])]   }
           {SS5[(p[,np])]      }
           {PHI[(p[,np])]      }
           {LAMBDA[(p[,np])]   }
           {D[(p[,np])]        }
           {Y[(p[,np])]        }
           {Q[(p[,np])]        }
           {BEUCLID[(p[,np])] }
           {SIZE[(p[,np])]     }
           {PATTERN[(p[,np])] }
           {BSEUCLID[(p[,np])]}
           {BSHAPE[(p[,np])]   }
           {DISPER[(p[,np])]   }
           {VARIANCE[(p[,np])]}
           {BLWMN[(p[,np])]    }

         {WAVERAGE  }
         {SINGLE    }
         {COMPLETE  }
         {CENTROID  }
         {MEDIAN    }
         {WARD      }
         {DEFAULT** }

 [/SAVE=CLUSTER({level  })]  [/ID=varname]
                {min,max}

 [/PRINT=[CLUSTER({level  })] [DISTANCE] [SCHEDULE**] [NONE]]
                  {min,max}

 [/PLOT=[VICICLE**[(min[,max[,inc]])]] [DENDROGRAM] [NONE]]
        [HICICLE[(min[,max[,inc]])]]

 [/MATRIX=[IN({'savfile'|'dataset'})] [OUT({'savfile'|'dataset'})]]
              {*                 }        {*                 }
```

** Default if the subcommand or keyword is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
CLUSTER V1 TO V4
 /PLOT=DENDROGRAM
 /PRINT=CLUSTER (2,4).
```

Overview

CLUSTER produces hierarchical clusters of items based on distance measures of dissimilarity or similarity. The items being clustered are usually cases from the active dataset, and the distance measures are computed from their values for one or more variables. You can also cluster variables if you read in a matrix measuring distances between variables. Cluster analysis is discussed in Anderberg (1973).

Options

Cluster Measures and Methods. You can specify one of 37 similarity or distance measures on the MEASURE subcommand and any of the seven methods on the METHOD subcommand.

New Variables. You can save cluster membership for specified solutions as new variables in the active dataset using the SAVE subcommand.

Display and Plots. You can display cluster membership, the distance or similarity matrix used to cluster variables or cases, and the agglomeration schedule for the cluster solution with the PRINT subcommand. You can request either a horizontal or vertical icicle plot or a dendrogram of the cluster solution and control the cluster levels displayed in the icicle plot with the PLOT subcommand. You can also specify a variable to be used as a case identifier in the display on the ID subcommand.

Matrix Input and Output. You can write out the distance matrix and use it in subsequent CLUSTER, PROXIMITIES, or ALSCAL analyses or read in matrices produced by other CLUSTER or PROXIMITIES procedures using the MATRIX subcommand.

Basic Specification

The basic specification is a variable list. CLUSTER assumes that the items being clustered are cases and uses the squared Euclidean distances between cases on the variables in the analysis as the measure of distance.

Subcommand Order

- The variable list must be specified first.
- The remaining subcommands can be specified in any order.

Syntax Rules

- The variable list and subcommands can each be specified once.
- More than one clustering method can be specified on the METHOD subcommand.

Operations

The CLUSTER procedure involves four steps:

- First, CLUSTER obtains distance measures of similarities between or distances separating initial clusters (individual cases or individual variables if the input is a matrix measuring distances between variables).
- Second, it combines the two nearest clusters to form a new cluster.
- Third, it recomputes similarities or distances of existing clusters to the new cluster.
- It then returns to the second step until all items are combined in one cluster.

This process yields a hierarchy of cluster solutions, ranging from one overall cluster to as many clusters as there are items being clustered. Clusters at a higher level can contain several lower-level clusters. Within each level, the clusters are disjoint (each item belongs to only one cluster).

- CLUSTER identifies clusters in solutions by sequential integers (1, 2, 3, and so on).

Limitations

- CLUSTER stores cases and a lower-triangular matrix of proximities in memory. Storage requirements increase rapidly with the number of cases. You should be able to cluster 100 cases using a small number of variables in an 80K workspace.
- CLUSTER does not honor weights.

Example

```
CLUSTER V1 TO V4
  /PLOT=DENDROGRAM
  /PRINT=CLUSTER (2 4).
```

- This example clusters cases based on their values for all variables between and including *V1* and *V4* in the active dataset.
- The analysis uses the default measure of distance (squared Euclidean) and the default clustering method (average linkage between groups).
- PLOT requests a dendrogram.
- PRINT displays a table of the cluster membership of each case for the two-, three-, and four-cluster solutions.

Variable List

The variable list identifies the variables used to compute similarities or distances between cases.

- The variable list is required except when matrix input is used. It must be specified before the optional subcommands.

- If matrix input is used, the variable list can be omitted. The names for the items in the matrix are used to compute similarities or distances.
- You can specify a variable list to override the names for the items in the matrix. This allows you to read in a subset of cases for analysis. Specifying a variable that does not exist in the matrix results in an error.

MEASURE Subcommand

MEASURE specifies the distance or similarity measure used to cluster cases.

- If the MEASURE subcommand is omitted or included without specifications, squared Euclidean distances are used.
- Only one measure can be specified.

Measures for Interval Data

For interval data, use any one of the following keywords on MEASURE:

SEUCLID *Squared Euclidean distance.* The distance between two items, *x* and *y*, is the sum of the squared differences between the values for the items. SEUCLID is the measure commonly used with centroid, median, and Ward's methods of clustering. SEUCLID is the default and can also be requested with keyword DEFAULT.

$$SEUCLID(x, y) = \Sigma_i(x_i - y_i)^2$$

EUCLID *Euclidean distance.* This is the default specification for MEASURE. The distance between two items, *x* and *y*, is the square root of the sum of the squared differences between the values for the items.

$$EUCLID(x, y) = \sqrt{\Sigma_i(x_i - y_i)^2}$$

CORRELATION *Correlation between vectors of values.* This is a pattern similarity measure.

$$CORRELATION(x, y) = \frac{\Sigma_i(Z_{xi}Z_{yi})}{N-1}$$

where Z_{xi} is the *z* score (standardized) value of *x* for the *i*th case or variable, and *N* is the number of cases or variables.

COSINE *Cosine of vectors of values.* This is a pattern similarity measure.

$$COSINE(x, y) = \frac{\Sigma_i(x_i y_i)}{\sqrt{(\Sigma_i x_i^2)(\Sigma_i y_i^2)}}$$

CHEBYCHEV *Chebychev distance metric.* The distance between two items is the maximum absolute difference between the values for the items.

$$CHEBYCHEV(x, y) = \max_i|x_i - y_i|$$

BLOCK *City-block or Manhattan distance.* The distance between two items is the sum of the absolute differences between the values for the items.

$$BLOCK(x, y) = \Sigma_i|x_i - y_i|$$

MINKOWSKI(p) *Distance in an absolute Minkowski power metric.* The distance between two items is the *p*th root of the sum of the absolute differences to the *p*th power between the values for the items. Appropriate selection of the integer parameter *p* yields Euclidean and many other distance metrics.

$$MINKOWSKI(x,y) = (\Sigma_i |x_i - y_i|^p)^{1/p}$$

POWER(p,r) *Distance in an absolute power metric.* The distance between two items is the *r*th root of the sum of the absolute differences to the *p*th power between the values for the items. Appropriate selection of the integer parameters *p* and *r* yields Euclidean, squared Euclidean, Minkowski, city-block, and many other distance metrics.

$$POWER(x,y) = (\Sigma_i |x_i - y_i|^p)^{1/r}$$

Measures for Frequency Count Data

For frequency count data, use any one of the following keywords on MEASURE:

CHISQ *Based on the chi-square test of equality for two sets of frequencies.* The magnitude of this dissimilarity measure depends on the total frequencies of the two cases or variables whose dissimilarity is computed. Expected values are from the model of independence of cases or variables *x* and *y*.

$$CHISQ(x,y) = \sqrt{\frac{\Sigma_i (x_i - E(x_i))^2}{E(x_i)} + \frac{\Sigma_i (y_i - E(y_i))^2}{E(y_i)}}$$

PH2 *Phi-square between sets of frequencies.* This is the CHISQ measure normalized by the square root of the combined frequency. Therefore, its value does not depend on the total frequencies of the two cases or variables whose dissimilarity is computed.

$$PH2(x,y) = \sqrt{\frac{\frac{\Sigma_i (x_i - E(x_i))^2}{E(x_i)} + \frac{\Sigma_i (y_i - E(y_i))^2}{E(y_i)}}{N}}$$

Measures for Binary Data

Different binary measures emphasize different aspects of the relationship between sets of binary values. However, all the measures are specified in the same way. Each measure has two optional integer-valued parameters, *p* (present) and *np* (not present).

- If both parameters are specified, CLUSTER uses the value of the first as an indicator that a characteristic is present and the value of the second as an indicator that a characteristic is absent. CLUSTER skips all other values.
- If only the first parameter is specified, CLUSTER uses that value to indicate presence and all other values to indicate absence.
- If no parameters are specified, CLUSTER assumes that 1 indicates presence and 0 indicates absence.

Using the indicators for presence and absence within each item (case or variable), CLUSTER constructs a 2×2 contingency table for each pair of items in turn. It uses this table to compute a proximity measure for the pair.

	Item 2 characteristics	
	Present	**Absent**
Item 1 characteristics		
Present	*a*	*b*
Absent	*c*	*d*

CLUSTER computes all binary measures from the values of *a*, *b*, *c*, and *d*. These values are tallied across variables (when the items are cases) or across cases (when the items are variables). For example, if the variables *V*, *W*, *X*, *Y*, *Z* have values 0, 1, 1, 0, 1 for case 1 and values 0, 1, 1, 0, 0 for case 2 (where 1 indicates presence and 0 indicates absence), the contingency table is as follows:

	Case 2 characteristics	
	Present	**Absent**
Case 1 characteristics		
Present	2	1
Absent	0	2

The contingency table indicates that both cases are present for two variables (*W* and *X*), both cases are absent for two variables (*V* and *Y*), and case 1 is present and case 2 is absent for one variable (*Z*). There are no variables for which case 1 is absent and case 2 is present.

The available binary measures include matching coefficients, conditional probabilities, predictability measures, and others.

Matching Coefficients. The table below shows a classification scheme for matching coefficients. In this scheme, *matches* are joint presences (value *a* in the contingency table) or joint absences (value *d*). *Nonmatches* are equal in number to value *b* plus value *c*. Matches and nonmatches may or may not be weighted equally. The three coefficients JACCARD, DICE, and SS2 are related monotonically, as are SM, SS1, and RT. All coefficients in the table are similarity measures, and all except two (K1 and SS3) range from 0 to 1. K1 and SS3 have a minimum value of 0 and no upper limit.

Table 29-1
Binary matching coefficients in CLUSTER

	Joint absences excluded from numerator	**Joint absences included in numerator**
All matches included in denominator		
Equal weight for matches and nonmatches	RR	SM

	Joint absences excluded from numerator	**Joint absences included in numerator**
All matches included in denominator		
Double weight for matches		SS1
Double weight for nonmatches		RT

Joint absences excluded from denominator		
Equal weight for matches and nonmatches	JACCARD	
Double weight for matches	DICE	
Double weight for nonmatches	SS2	

All matches excluded from denominator		
Equal weight for matches and nonmatches	K1	SS3

RR[(p[,np])] *Russell and Rao similarity measure.* This is the binary dot product.

$$RR(x,y) = \frac{a}{a+b+c+d}$$

SM[(p[,np])] *Simple matching similarity measure.* This is the ratio of the number of matches to the total number of characteristics.

$$SM(x,y) = \frac{a+d}{a+b+c+d}$$

JACCARD[(p[,np])] *Jaccard similarity measure.* This is also known as the *similarity ratio.*

$$JACCARD(x,y) = \frac{a}{a+b+c}$$

DICE[(p[,np])] *Dice (or Czekanowski or Sorenson) similarity measure.*

$$DICE(x,y) = \frac{2a}{2a+b+c}$$

SS1[(p[,np])] *Sokal and Sneath similarity measure 1.*

$$SS1(x,y) = \frac{2(a+d)}{2(a+d)+b+c+d}$$

RT[(p[,np])] *Rogers and Tanimoto similarity measure.*

$$RT(x,y) = \frac{a+d}{a+d+2(b+c)}$$

SS2[(p[,np])] *Sokal and Sneath similarity measure 2.*

$$SS2(x,y) = \frac{a}{a+2(b+c)}$$

K1[(p[,np])] *Kulczynski similarity measure 1.* This measure has a minimum value of 0 and no upper limit. It is undefined when there are no nonmatches (*b*=0 and *c*=0).

$$K1(x,y) = \frac{a}{b+c}$$

SS3[(p[,np])] *Sokal and Sneath similarity measure 3.* This measure has a minimum value of 0 and no upper limit. It is undefined when there are no nonmatches (*b*=0 and *c*=0).

$$SS3(x,y) = \frac{a+d}{b+c}$$

Conditional Probabilities. The following binary measures yield values that can be interpreted in terms of conditional probability. All three are similarity measures.

K2[(p[,np])] *Kulczynski similarity measure 2.* This yields the average conditional probability that a characteristic is present in one item given that the characteristic is present in the other item. The measure is an average over both items acting as predictors. It has a range of 0 to 1.

$$K2(x,y) = \frac{a/(a+b)+a/(a+c)}{2}$$

SS4[(p[,np])] *Sokal and Sneath similarity measure 4.* This yields the conditional probability that a characteristic of one item is in the same state (presence or absence) as the characteristic of the other item. The measure is an average over both items acting as predictors. It has a range of 0 to 1.

$$SS4(x,y) = \frac{a/(a+b)+a/(a+c)+d/(b+d)+d/(c+d)}{4}$$

HAMANN[(p[,np])] *Hamann similarity measure.* This measure gives the probability that a characteristic has the same state in both items (present in both or absent from both) minus the probability that a characteristic has different states in the two items (present in one and absent from the other). `HAMANN` has a range of −1 to +1 and is monotonically related to `SM`, `SS1`, and `RT`.

$$HAMANN(x,y) = \frac{(a+d)-(b+c)}{a+b+c+d}$$

Predictability Measures. The following four binary measures assess the association between items as the predictability of one given the other. All four measures yield similarities.

LAMBDA[(p[,np])] *Goodman and Kruskal's lambda (similarity).* This coefficient assesses the predictability of the state of a characteristic on one item (present or absent) given the state on the other item. Specifically, LAMBDA measures the proportional reduction in error using one item to predict the other when the directions of prediction are of equal importance. LAMBDA has a range of 0 to 1.

$$LAMBDA(x, y) = \frac{t_1 - t_2}{2(a+b+c+d) - t_2}$$

where

$t_1 = \max(a, b) + \max(c,d) + \max(a, c) + \max(b,d)$

$t_2 = \max(a + c, b + d) + \max(a + d, c + d)$.

D[(p[,np])] *Anderberg's* D *(similarity).* This coefficient assesses the predictability of the state of a characteristic on one item (present or absent) given the state on the other. D measures the actual reduction in the error probability when one item is used to predict the other. The range of D is 0 to 1.

$$D(x, y) = \frac{t_1 - t_2}{2(a+b+c+d)}$$

where

$t_1 = \max(a, b) + \max(c,d) + \max(a, c) + \max(b,d)$

$t_2 = \max(a + c, b + d) + \max(a + d, c + d)$.

Y[(p[,np])] *Yule's* Y *coefficient of colligation (similarity).* This is a function of the cross-ratio for a 2×2 table. It has a range of −1 to +1.

$$Y(x, y) = \frac{\sqrt{ad} - \sqrt{bc}}{\sqrt{ad} + \sqrt{bc}}$$

Q[(p[,np])] *Yule's* Q *(similarity).* This is the 2×2version of Goodman and Kruskal's ordinal measure *gamma.* Like Yule's *Y*, Q is a function of the cross-ratio for a 2×2 table and has a range of −1 to +1.

$$Q(x, y) = \frac{ad - bc}{ad + bc}$$

Other Binary Measures. The remaining binary measures available in CLUSTER are either binary equivalents of association measures for continuous variables or measures of special properties of the relationship between items.

OCHIAI[(p[,np])] *Ochiai similarity measure.* This is the binary form of the cosine. It has a range of 0 to 1.

$$OCHIAI(x, y) = \sqrt{\frac{a}{a+b} \cdot \frac{a}{a+c}}$$

SS5[(p[,np])] *Sokal and Sneath similarity measure 5.* The range is 0 to 1.

$$SS5(x, y) = \frac{ad}{\sqrt{(a+b)(a+c)(b+d)(c+d)}}$$

PHI[(p[,np])] *Fourfold point correlation (similarity).* This is the binary form of the Pearson product-moment correlation coefficient.

$$PHI(x,y) = \frac{ad-bc}{\sqrt{(a+b)(a+c)(b+d)(c+d)}}$$

BEUCLID[(p[,np])] *Binary Euclidean distance.* This is a distance measure. Its minimum value is 0, and it has no upper limit.

$$BEUCLID(x,y) = \sqrt{b+c}$$

BSEUCLID[(p[,np])] *Binary squared Euclidean distance.* This is a distance measure. Its minimum value is 0, and it has no upper limit.

$$BSEUCLID(x,y) = b+c$$

SIZE[(p[,np])] *Size difference.* This is a dissimilarity measure with a minimum value of 0 and no upper limit.

$$SIZE(x,y) = \frac{(b-c)^2}{(a+b+c+d)^2}$$

PATTERN[(p[,np])] *Pattern difference.* This is a dissimilarity measure. The range is 0 to 1.

$$PATTERN(x,y) = \frac{bc}{(a+b+c+d)^2}$$

BSHAPE[(p[,np])] *Binary shape difference.* This dissimilarity measure has no upper or lower limit.

$$BSHAPE(x,y) = \frac{(a+b+c+d)(b+c)-(b-c)^2}{(a+b+c+d)^2}$$

DISPER[(p[,np])] *Dispersion similarity measure.* The range is −1 to +1.

$$DISPER(x,y) = \frac{ad-bc}{(a+b+c+d)^2}$$

VARIANCE[(p[,np])] *Variance dissimilarity measure.* This measure has a minimum value of 0 and no upper limit.

$$VARIANCE(x,y) = \frac{b+c}{4(a+b+c+d)}$$

BLWMN[(p[,np])] *Binary Lance-and-Williams nonmetric dissimilarity measure.* This measure is also known as the Bray-Curtis nonmetric coefficient. The range is 0 to 1.

$$BLWMN(x,y) = \frac{b+c}{2a+b+c}$$

METHOD Subcommand

METHOD specifies one or more clustering methods.

- If the METHOD subcommand is omitted or included without specifications, the method of average linkage between groups is used.
- Only one METHOD subcommand can be used, but more than one method can be specified on it.

- When the number of items is large, CENTROID and MEDIAN require significantly more CPU time than other methods.

BAVERAGE	*Average linkage between groups (UPGMA).* BAVERAGE is the default and can also be requested with keyword DEFAULT.
WAVERAGE	*Average linkage within groups.*
SINGLE	*Single linkage or nearest neighbor.*
COMPLETE	*Complete linkage or furthest neighbor.*
CENTROID	*Centroid clustering (UPGMC).* Squared Euclidean distances are commonly used with this method.
MEDIAN	*Median clustering (WPGMC).* Squared Euclidean distances are commonly used with this method.
WARD	*Ward's method.* Squared Euclidean distances are commonly used with this method.

Example

```
CLUSTER V1 V2 V3
 /METHOD=SINGLE COMPLETE WARDS.
```

- This example clusters cases based on their values for the variables *V1*, *V2*, and *V3* and uses three clustering methods: single linkage, complete linkage, and Ward's method.

SAVE Subcommand

SAVE allows you to save cluster membership at specified solution levels as new variables in the active dataset.

- The specification on SAVE is the CLUSTER keyword, followed by either a single number indicating the level (number of clusters) of the cluster solution or a range separated by a comma indicating the minimum and maximum numbers of clusters when membership of more than one solution is to be saved. The number or range must be enclosed in parentheses and applies to all methods specified on METHOD.
- You can specify a rootname in parentheses after each method specification on the METHOD subcommand. CLUSTER forms new variable names by appending the number of the cluster solution to the rootname.
- If no rootname is specified, CLUSTER forms variable names using the formula *CLUn_m*, where *m* increments to create a unique rootname for the set of variables saved for one method and *n* is the number of the cluster solution.
- The names and descriptive labels of the new variables are displayed in the procedure information notes.
- You cannot use the SAVE subcommand if you are replacing the active dataset with matrix materials (For more information, see Matrix Output on p. 288.)

Example

```
CLUSTER A B C
 /METHOD=BAVERAGE SINGLE (SINMEM) WARD
 /SAVE=CLUSTERS(3,5).
```

- This command creates nine new variables: *CLU5_1*, *CLU4_1*, and *CLU3_1* for BAVERAGE, *SINMEM5*, *SINMEM4*, and *SINMEM3* for SINGLE, and *CLU5_2*, *CLU4_2*, and *CLU3_2* for WARD. The variables contain the cluster membership for each case at the five-, four-, and three-cluster solutions using the three clustering methods. Ward's method is the third specification on METHOD but uses the second set of default names, since it is the second method specified without a rootname.
- The order of the new variables in the active dataset is the same as listed above, since the solutions are obtained in the order from 5 to 3.
- New variables are listed in the procedure information notes.

ID Subcommand

ID names a string variable to be used as the case identifier in cluster membership tables, icicle plots, and dendrograms. If the ID subcommand is omitted, cases are identified by case numbers alone.

- When used with the MATRIX IN subcommand, the variable specified on the ID subcommand identifies the labeling variable in the matrix file.

PRINT Subcommand

PRINT controls the display of cluster output (except plots, which are controlled by the PLOT subcommand).

- If the PRINT subcommand is omitted or included without specifications, an agglomeration schedule is displayed. If any keywords are specified on PRINT, the agglomeration schedule is displayed only if explicitly requested.
- CLUSTER automatically displays summary information (the method and measure used, the number of cases) for each method named on the METHOD subcommand. This summary is displayed regardless of specifications on PRINT.

You can specify any or all of the following on the PRINT subcommand:

SCHEDULE *Agglomeration schedule.* The agglomeration schedule shows the order and distances at which items and clusters combine to form new clusters. It also shows the cluster level at which an item joins a cluster. SCHEDULE is the default and can also be requested with the keyword DEFAULT.

CLUSTER(min,max) *Cluster membership.* For each item, the display includes the value of the case identifier (or the variable name if matrix input is used), the case sequence number, and a value (1, 2, 3, and so on) identifying the cluster to which that case belongs in a given cluster solution. Specify either a single integer value in parentheses indicating the level of a single solution or a minimum value and a maximum value indicating a range of solutions for which display is desired. If the number of clusters specified exceeds the number produced, the largest number of clusters is used (the number of items minus 1). If CLUSTER is specified more than once, the last specification is used.

DISTANCE *Proximities matrix.* The proximities matrix table displays the distances or similarities between items computed by CLUSTER or obtained from an input matrix. DISTANCE produces a large volume of output and uses significant CPU time when the number of cases is large.

NONE *None of the above.* NONE overrides any other keywords specified on PRINT.

Example

```
CLUSTER V1 V2 V3 /PRINT=CLUSTER(3,5).
```

- This example displays cluster membership for each case for the three-, four-, and five-cluster solutions.

PLOT Subcommand

PLOT controls the plots produced for each method specified on the METHOD subcommand. For icicle plots, PLOT allows you to control the cluster solution at which the plot begins and ends and the increment for displaying intermediate cluster solutions.

- If the PLOT subcommand is omitted or included without specifications, a vertical icicle plot is produced.
- If any keywords are specified on PLOT, only those plots requested are produced.
- The icicle plots are generated as pivot tables and the dendrogram is generated as text output.
- If there is not enough memory for a dendrogram or an icicle plot, the plot is skipped and a warning is issued.
- The size of an icicle plot can be controlled by specifying range values or an increment for VICICLE or HICICLE. Smaller plots require significantly less workspace and time.

VICICLE(min,max,inc) *Vertical icicle plot.* This is the default. The range specifications are optional. If used, they must be integer and must be enclosed in parentheses. The specification *min* is the cluster solution at which to start the display (the default is 1), and the specification *max* is the cluster solution at which to end the display (the default is the number of cases minus 1). If *max* is greater than the number of cases minus 1, the default is used. The increment to use between cluster solutions is *inc* (the default is 1). If *max* is specified, *min* must be specified, and if *inc* is specified, both *min* and *max* must be specified. If VICICLE is specified more than once, only the last range specification is used.

HICICLE(min,max,inc) *Horizontal icicle plot.* The range specifications are the same as for VICICLE. If both VICICLE and HICICLE are specified, the last range specified is used for both. If a range is not specified on the last instance of VICICLE or HICICLE, the defaults are used even if a range is specified earlier.

DENDROGRAM *Tree diagram.* The dendrogram is scaled by the joining distances of the clusters.

NONE *No plots.*

Example

```
CLUSTER V1 V2 V3 /PLOT=VICICLE(1,20).
```

- This example produces a vertical icicle plot for the 1-cluster through the 20-cluster solution.

Example

```
CLUSTER V1 V2 V3 /PLOT=VICICLE(1,151,5).
```

- This example produces a vertical icicle plot for every fifth cluster solution starting with 1 and ending with 151 (1 cluster, 6 clusters, 11 clusters, and so on).

MISSING Subcommand

MISSING controls the treatment of cases with missing values. A case that has a missing value for any variable on the variable list is omitted from the analysis. By default, user-missing values are excluded from the analysis.

EXCLUDE	*Exclude cases with user-missing values.* This is the default.
INCLUDE	*Include cases with user-missing values.* Only cases with system-missing values are excluded.

MATRIX Subcommand

MATRIX reads and writes SPSS-format matrix data files.

- Either IN or OUT and a matrix file in parentheses are required. When both IN and OUT are used on the same CLUSTER procedure, they can be specified on separate MATRIX subcommands or on the same subcommand.
- The input or output matrix information is displayed in the procedure information notes.

OUT ('savfile'|'dataset')	*Write a matrix data file.* Specify either a quoted file specification, a previously declared dataset (DATASET DECLARE), or an asterisk in parentheses (*). If you specify an asterisk (*), the matrix data file replaces the active dataset.
IN ('savfile'|'dataset')	*Read a matrix data file.* Specify either a quoted file specification, a previously declared dataset (DATASET DECLARE), or an asterisk in parentheses (*). The asterisk specifies the active dataset. A matrix file read from an external file does not replace the active dataset.

When a matrix is produced using the MATRIX OUT subcommand, it corresponds to a unique dataset. All subsequent analyses performed on this matrix would match the corresponding analysis on the original data. However, if the data file is altered in any way, this would no longer be true.

For example, if the original file is edited or rearranged, it would in general no longer correspond to the initially produced matrix. You need to make sure that the data match the matrix whenever inferring the results from the matrix analysis. Specifically, when saving the cluster membership into an active dataset in the CLUSTER procedure, the proximity matrix in the MATRIX IN statement must match the current active dataset.

Matrix Output

- CLUSTER writes proximity-type matrices with *ROWTYPE_* values of PROX. CLUSTER neither reads nor writes additional statistics with its matrix materials. For more information, see Format of the Matrix Data File on p. 288.
- The matrices produced by CLUSTER can be used by subsequent CLUSTER procedures or by the PROXIMITIES and ALSCAL procedures.
- Any documents contained in the active dataset are not transferred to the matrix file.

Matrix Input

- CLUSTER can read matrices written by a previous CLUSTER command or by PROXIMITIES, or created by MATRIX DATA. When the input matrix contains distances between variables, CLUSTER clusters all or a subset of the variables.
- Values for split-file variables should precede values for *ROWTYPE_*. *CASENO_* and the labeling variable (if present) should come after *ROWTYPE_* and before *VARNAME_*.
- If *CASENO_* is of type string rather than numeric, it will be considered unavailable and a warning is issued.
- If *CASENO_* appears on a variable list, a syntax error results.
- CLUSTER ignores unrecognized *ROWTYPE_* values.
- When you are reading a matrix created with MATRIX DATA, you should supply a value label for PROX of either *SIMILARITY* or *DISSIMILARITY* so that the matrix is correctly identified. If you do not supply a label, CLUSTER assumes *DISSIMILARITY*. (See "Format of the Matrix Data File" below.)
- The program reads variable names, variable and value labels, and print and write formats from the dictionary of the matrix data file.
- MATRIX=IN cannot be specified unless an active dataset has already been defined. To read an existing matrix data file at the beginning of a session, use GET to retrieve the matrix file and then specify IN(*) on MATRIX.
- The variable list on CLUSTER can be omitted when a matrix data file is used as input. By default, all cases or variables in the matrix data file are used in the analysis. Specify a variable list when you want to read in a subset of items for analysis.

Format of the Matrix Data File

- The matrix data file can include three special variables created by the program: *ROWTYPE_*, *ID*, and *VARNAME_*.
- The variable *ROWTYPE_* is a string variable with the value PROX (for proximity measure). PROX is assigned value labels containing the distance measure used to create the matrix and either *SIMILARITY* or *DISSIMILARITY* as an identifier. The variable *VARNAME_* is a short string variable whose values are the names of the new variables. The variable *CASENO_* is a numeric variable with values equal to the original case numbers.
- *ID* is included only when an identifying variable is not specified on the ID subcommand. *ID* is a short string and takes the value CASE *m*, where *m* is the actual number of each case. Note that *m* may not be consecutive if cases have been selected.

- If an identifying variable is specified on the ID subcommand, it takes the place of *ID* between *ROWTYPE_* and *VARNAME_*. Up to 20 characters can be displayed for the identifying variable.
- *VARNAME_* is a string variable that takes the values VAR1, VAR2, ..., VAR*n* to correspond to the names of the distance variables in the matrix (*VAR1, VAR2, ...*, *VARn*, where *n* is the number of cases in the largest split file). The numeric suffix for the variable names is consecutive and may not be the same as the actual case number.
- The remaining variables in the matrix file are the distance variables used to form the matrix. The distance variables are assigned variable labels in the form of CASE *m* to identify the actual number of each case.

Split Files

- When split-file processing is in effect, the first variables in the matrix data file are the split variables, followed by *ROWTYPE_*, the case-identifier variable or *ID*, *VARNAME_*, and the distance variables.
- A full set of matrix materials is written for each split-file group defined by the split variables.
- A split variable cannot have the same name as any other variable written to the matrix data file.
- If split-file processing is in effect when a matrix is written, the same split file must be in effect when that matrix is read by any procedure.

Missing Values

Missing-value treatment affects the values written to a matrix data file. When reading a matrix data file, be sure to specify a missing-value treatment on CLUSTER that is compatible with the treatment that was in effect when the matrix materials were generated.

Example: Output to External File

```
DATA LIST FILE=ALMANAC1 RECORDS=3
  /1 CITY 6-18(A) POP80 53-60
  /2 CHURCHES 10-13 PARKS 14-17 PHONES 18-25 TVS 26-32
      RADIOST 33-35 TVST 36-38 TAXRATE 52-57(2).
N OF CASES 8.

CLUSTER CHURCHES TO TAXRATE
  /ID=CITY
  /MEASURE=EUCLID
  /MATRIX=OUT(CLUSMTX).
```

- CLUSTER reads raw data from file *ALMANAC1* and writes one set of matrix materials to file *CLUSMTX*.
- The active dataset is still the *ALMANAC1* file defined on DATA LIST. Subsequent commands are executed on *ALMANAC1*.

Example: Output Replacing Active Dataset

```
DATA LIST FILE=ALMANAC1 RECORDS=3
```

```
  /1 CITY 6-18(A) POP80 53-60
  /2 CHURCHES 10-13 PARKS 14-17 PHONES 18-25 TVS 26-32
      RADIOST 33-35 TVST 36-38 TAXRATE 52-57(2).
N OF CASES 8.

CLUSTER CHURCHES TO TAXRATE
  /ID=CITY
  /MEASURE=EUCLID
  /MATRIX=OUT(*).
LIST.
```

- CLUSTER writes the same matrix as in the previous example. However, the matrix data file replaces the active dataset. The LIST command is executed on the matrix file, not on *ALMANAC1*.

Example: Input from Active Dataset

```
GET FILE=CLUSMTX.
CLUSTER
  /ID=CITY
  /MATRIX=IN(*).
```

- This example starts a new session and reads an existing matrix data file. GET retrieves the matrix data file *CLUSMTX*.
- MATRIX=IN specifies an asterisk because the matrix data file is the active dataset. If MATRIX=IN(CLUSMTX) is specified, the program issues an error message.
- If the GET command is omitted, the program issues an error message.

Example: Input from External File

```
GET FILE=PRSNNL.
FREQUENCIES VARIABLE=AGE.

CLUSTER
  /ID=CITY
  /MATRIX=IN(CLUSMTX).
```

- This example performs a frequencies analysis on the file *PRSNNL* and then uses a different file for CLUSTER. The file is an existing matrix data file.
- The variable list is omitted on the CLUSTER command. By default, all cases in the matrix file are used in the analysis.
- MATRIX=IN specifies the matrix data file *CLUSMTX*.
- *CLUSMTX* does not replace *PRSNNL* as the active dataset.

Example: Input from Active Dataset

```
GET FILE=CRIME.
PROXIMITIES MURDER TO MOTOR
  /VIEW=VARIABLE
  /MEASURE=PH2
  /MATRIX=OUT(*).
CLUSTER
  /MATRIX=IN(*).
```

- GET retrieves an SPSS-format data file.
- PROXIMITIES uses the data from the *CRIME* file, which is now the active dataset. The VIEW subcommand specifies computation of proximity values between variables. The MATRIX subcommand writes the matrix to the active dataset.
- MATRIX=IN(*) on the CLUSTER command reads the matrix materials from the active dataset. Since the matrix contains distances between variables, CLUSTER clusters variables based on distance measures in the input. The variable list is omitted on the CLUSTER command, so all variables are used in the analysis. The slash preceding the MATRIX subcommand is required because there is an implied variable list. Without the slash, CLUSTER would attempt to interpret MATRIX as a variable name rather than a subcommand name.

COMMENT

```
{COMMENT} text
{   *   }
```

Overview

COMMENT inserts explanatory text within the command sequence. Comments are included among the commands printed back in the output; they do not become part of the information saved in an SPSS-format data file. To include commentary in the dictionary of a data file, use the DOCUMENT command.

Syntax Rules

- The first line of a comment can begin with the keyword COMMENT or with an asterisk (*). Comment text can extend for multiple lines and can contain any characters. A period is required at the end of the last line to terminate the comment.
- Use /* and */ to set off a comment within a command. The comment can be placed wherever a blank is valid (except within strings) and should be preceded by a blank. Comments within a command cannot be continued onto the next line.
- The closing */ is optional when the comment is at the end of the line. The command can continue onto the next line just as if the inserted comment was a blank.
- Comments cannot be inserted within data lines.

Examples

Comment As a Separate Command

```
* Create a new variable as a combination of two old variables;
  the new variable is a scratch variable used later in the
  session;  it will not be saved with the data file.

COMPUTE #XYVAR=0.
IF (XVAR EQ 1 AND YVAR EQ 1) #XYVAR=1.
```

- The three-line comment will be included in the display file but will not be part of the data file if the active dataset is saved.

Comments within Commands

```
IF (RACE EQ 1 AND SEX EQ 1) SEXRACE = 1.  /*White males.
```

- The comment is entered on a command line. The closing */ is not needed because the comment is at the end of the line.

COMPUTE

```
COMPUTE target variable=expression
```

This command does not read the active dataset. It is stored, pending execution with the next command that reads the dataset. For more information, see Command Order on p. 36.

Example

```
COMPUTE newvar1=var1+var2.
COMPUTE newvar2=RND(MEAN(var1 to var4).
COMPUTE logicalVar=(var1>5).
STRING newString (A10).
COMPUTE newString=CONCAT((RTRIM(stringVar1), stringVar2).
```

Functions and operators available for COMPUTE are described in Transformation Expressions on p. 63.

Overview

COMPUTE creates new numeric variables or modifies the values of existing string or numeric variables. The variable named on the left of the equals sign is the **target variable**. The variables, constants, and functions on the right side of the equals sign form an **assignment expression**. For a complete discussion of functions, see Transformation Expressions on p. 63.

Numeric Transformations

Numeric variables can be created or modified with COMPUTE. The assignment expression for numeric transformations can include combinations of constants, variables, numeric operators, and functions.

String Transformations

String variables can be modified but cannot be created with COMPUTE. However, a new string variable can be declared and assigned a width with the STRING command and then assigned values by COMPUTE. The assignment expression can include string constants, string variables, and any of the string functions. All other functions are available for numeric transformations only.

Basic Specification

The basic specification is a target variable, an equals sign (required), and an assignment expression.

Syntax Rules

- The target variable must be named first, and the equals sign is required. Only one target variable is allowed per COMPUTE command.

- If the target variable is numeric, the expression must yield a numeric value; if the target variable is a string, the expression must yield a string value.
- Each function must specify at least one argument enclosed in parentheses. If a function has two or more arguments, the arguments must be separated by commas. For a complete discussion of functions and their arguments, see Transformation Expressions on p. 63.
- You can use the TO keyword to refer to a set of variables where the argument is a list of variables.

Numeric Variables

- Parentheses are used to indicate the order of execution and to set off the arguments to a function.
- Numeric functions use simple or complex expressions as arguments. Expressions must be enclosed in parentheses.

String Variables

- String values and constants must be enclosed in single or double quotes.
- When strings of different lengths are compared using the ANY or RANGE functions, the shorter string is right-padded with blanks so that its length equals that of the longer string.

Operations

- If the target variable already exists, its values are replaced.
- If the target variable does not exist and the assignment expression is numeric, the program creates a new variable.
- If the target variable does not exist and the assignment expression is a string, the program displays an error message and does not execute the command. Use the STRING command to declare new string variables before using them as target variables.

Numeric Variables

- New numeric variables created with COMPUTE are assigned a dictionary format of F8.2 and are initialized to the system-missing value for each case (unless the LEAVE command is used). Existing numeric variables transformed with COMPUTE retain their original dictionary formats. The format of a numeric variable can be changed with the FORMATS command.
- All expressions are evaluated in the following order: first functions, then exponentiation, and then arithmetic operations. The order of operations can be changed with parentheses.
- COMPUTE returns the system-missing value when it doesn't have enough information to evaluate a function properly. Arithmetic functions that take only one argument cannot be evaluated if that argument is missing. The date and time functions cannot be evaluated if any argument is missing. Statistical functions are evaluated if a sufficient number of arguments is valid. For example, in the command

```
COMPUTE FACTOR = SCORE1 + SCORE2 + SCORE3.
```

FACTOR is assigned the system-missing value for a case if any of the three score values is missing. It is assigned a valid value only when all score values are valid. In the command

```
COMPUTE FACTOR = SUM(SCORE1 TO SCORE3).
```

FACTOR is assigned a valid value if at least one score value is valid. It is system-missing only when all three score values are missing. See Missing Values in Numeric Expressions for information on how to control the minimum number of non-missing arguments required to return a non-missing result.

String Variables

- String variables can be modified but not created on COMPUTE. However, a new string variable can be created and assigned a width with the STRING command and then assigned new values with COMPUTE.
- Existing string variables transformed with COMPUTE retain their original dictionary formats. String variables declared on STRING and transformed with COMPUTE retain the formats assigned to them on STRING.
- The format of string variables cannot be changed with FORMATS. Instead, use STRING to create a new variable with the desired width and then use COMPUTE to set the values of the new string equal to the values of the original.
- The string returned by a string expression does not have to be the same width as the target variable. If the target variable is shorter, the result is right-trimmed. If the target variable is longer, the result is right-padded. The program displays no warning messages when trimming or padding.
- To control the width of strings, use the functions that are available for padding (LPAD, RPAD), trimming (LTRIM, RTRIM), and selecting a portion of strings (SUBSTR).
- To determine whether a character in a string is single-byte or double-byte, use the MBLEN.BYTE function. Specify the string and, optionally, its beginning byte position. If the position is not specified, it defaults to 1.

For more information, see String Functions on p. 101.

Examples

A number of examples are provided to illustrate the use of COMPUTE. For a complete list of available functions and detailed function descriptions, see Transformation Expressions.

Arithmetic Operations

```
COMPUTE V1=25-V2.
COMPUTE V3=(V2/V4)*100.

DO IF Tenure GT 5.
COMPUTE Raise=Salary*.12.
ELSE IF Tenure GT 1.
COMPUTE Raise=Salary*.1.
ELSE.
COMPUTE Raise=0.
END IF.
```

- *V1* is 25 minus *V2* for all cases. *V3* is *V2* expressed as a percentage of *V4*.
- *Raise* is 12% of *Salary* if *Tenure* is greater than 5. For remaining cases, *Raise* is 10% of *Salary* if *Tenure* is greater than 1. For all other cases, *Raise* is 0.

Arithmetic Functions

```
COMPUTE WtChange=ABS(Weight1-Weight2).
COMPUTE NewVar=RND((V1/V2)*100).
COMPUTE Income=TRUNC(Income).
COMPUTE MinSqrt=SQRT(MIN(V1,V2,V3,V4)).

COMPUTE Test = TRUNC(SQRT(X/Y)) * .5.
COMPUTE Parens = TRUNC(SQRT(X/Y) * .5).
```

- *WtChange* is the absolute value of *Weight1* minus *Weight2*.
- *NewVar* is the percentage *V1* is of *V2*, rounded to an integer.
- *Income* is truncated to an integer.
- *MinSqrt* is the square root of the minimum value of the four variables *V1* to *V4*. `MIN` determines the minimum value of the four variables, and `SQRT` computes the square root.
- The last two examples above illustrate the use of parentheses to control the order of execution. For a case with value 2 for *X* and *Y*, *Test* equals 0.5, since 2 divided by 2 (*X*/*Y*) is 1, the square root of 1 is 1, truncating 1 returns 1, and 1 times 0.5 is 0.5. However, *Parens* equals 0 for the same case, since `SQRT`(*X/Y*) is 1, 1 times 0.5 is 0.5, and truncating 0.5 returns 0.

Statistical Functions

```
COMPUTE NewSalary = SUM(Salary,Raise).
COMPUTE MinValue = MIN(V1,V2,V3,V4).
COMPUTE MeanValue = MEAN(V1,V2,V3,V4).
COMPUTE NewMean = MEAN.3(V1,V2,V3,V4).
```

- *NewSalary* is the sum of *Salary* plus *Raise*.
- *MinValue* is the minimum of the values for *V1* to *V4*.
- *MeanValue* is the mean of the values for *V1* to *V4*. Since the mean can be computed for one, two, three, or four values, *MeanValue* is assigned a valid value as long as any one of the four variables has a valid value for that case.
- In the last example above, the `.3` suffix specifies the minimum number of valid arguments required. *NewMean* is the mean of variables *V1* to *V4 only* if at least three of these variables have valid values. Otherwise, *NewMean* is system-missing for that case.

Missing-Value Functions

```
MISSING VALUE V1 V2 V3 (0).
COMPUTE AllValid=V1 + V2 + V3.
COMPUTE UM=VALUE(V1) + VALUE(V2) + VALUE(V3).
COMPUTE SM=SYSMIS(V1) + SYSMIS(V2) + SYSMIS(V3).
COMPUTE M=MISSING(V1) + MISSING(V2) + MISSING(V3).
```

- The `MISSING VALUE` command declares the value 0 as missing for *V1*, *V2*, and *V3*.

- *AllValid* is the sum of three variables only for cases with valid values for all three variables. *AllValid* is assigned the system-missing value for a case if any variable in the assignment expression has a system- or user-missing value.
- The VALUE function overrides user-missing value status. Thus, *UM* is the sum of *V1*, *V2*, and *V3* for each case, including cases with the value 0 (the user-missing value) for any of the three variables. Cases with the system-missing value for *V1*, *V2*, and *V3* are system-missing.
- The SYSMIS function on the third COMPUTE returns the value 1 if the variable is system-missing. Thus, *SM* ranges from 0 to 3 for each case, depending on whether the variables *V1*, *V2*, and *V3* are system-missing for that case.
- The MISSING function on the fourth COMPUTE returns the value 1 if the variable named is system- or user-missing. Thus, *M* ranges from 0 to 3 for each case, depending on whether the variables *V1*, *V2*, and *V3* are user- or system-missing for that case.
- Alternatively, you could use the COUNT command to create the variables *SM* and *M*.

```
* Test for listwise deletion of missing values.

DATA LIST /V1 TO V6 1-6.
BEGIN DATA
213 56
123457
123457
9234 6
END DATA.
MISSING VALUES V1 TO V6(6,9).

COMPUTE NotValid=NMISS(V1 TO V6).
FREQUENCIES VAR=NotValid.
```

- COMPUTE determines the number of missing values for each case. For each case without missing values, the value of *NotValid* is 0. For each case with one missing value, the value of *NotValid* is 1, and so on. Both system- and user-missing values are counted.
- FREQUENCIES generates a frequency table for *NotValid*. The table gives a count of how many cases have all valid values, how many cases have one missing value, how many cases have two missing values, and so on, for variables *V1* to *V6*. This table can be used to determine how many cases would be dropped in an analysis that uses listwise deletion of missing values. For other ways to check listwise deletion, see the examples for the ELSE command (in the DO IF command) and those for the IF command.

For more information, see Missing Value Functions on p. 117.

String Functions

```
DATA LIST FREE / FullName (A20).
BEGIN DATA
"Fred Smith"
END DATA.
STRING FirstName LastName LastFirstName (A20).
COMPUTE #spaceLoc=INDEX(FullName, " ").
COMPUTE FirstName=SUBSTR(FullName, 1, (#spaceLoc-1)).
COMPUTE LastName=SUBSTR(FullName, (#spaceLoc+1)).
COMPUTE LastFirstName=CONCAT(RTRIM(LastName), ", ", FirstName).
COMPUTE LastFirstName=REPLACE(LastFirstName, "Fred", "Ted").
```

- The INDEX function returns a number that represents the location of the first blank space in the value of the string variable *FullName*.
- The first SUBSTR function sets *FirstName* to the portion of *FullName* prior to the first space in the value. So, in this example, the value of *FirstName* is "Fred".
- The second SUBSTR function sets *LastName* to the portion of *FullName* after the first blank space in the value. So, in this example, the value of *LastName* is "Smith".
- The CONCAT function combines the values of *LastName* and *FirstName*, with a comma and a space between the two values. So, in this example, the value of *LastFirstName* is "Smith, Fred". Since all string values are right-padded with blank spaces to the defined width of the string variable, the RTRIM function is needed to remove all the extra blank spaces from *LastName*.
- The REPLACE function changes any instances of the string "Fred" in *LastFirstName* to "Ted". So, in this example, the value of *LastFirstName* is changed to "Smith, Ted".

For more information, see String Functions on p. 101.

Scoring Functions (SPSS Server Only)

```
STRING SPECIES(A20).
COMPUTE SCOREPROB=ApplyModel(CREDITMOD1,'PROBABILIT').
COMPUTE SPECIES=StrApplyModel(QUESTMOD1,'PREDICT').
```

- *SCOREPROB* is the probability that the value predicted from the model specified by CREDITMOD1 is correct.
- *SPECIES* is the predicted result from the model specified by QUESTMOD1 as applied to the active dataset. The prediction is returned as a string value.

CONJOINT

CONJOINT is available in the Conjoint option.

```
CONJOINT  [PLAN={*                  }]
                {'savfile'|'dataset'}

 [/DATA={*                   }]
        {'savfile'|'dataset'}

  /{SEQUENCE}=varlist
   {RANK    }
   {SCORE   }

 [/SUBJECT=variable]

 [/FACTORS=varlist['labels'] ([{DISCRETE[{MORE}]}]
                              {          {LESS} }
                              {LINEAR[{MORE}]   }
                              {       {LESS}    }
                              {IDEAL            }
                              {ANTIIDEAL        }
           [values['labels']])]

           varlist...

 [/PRINT={ALL**       } [SUMMARYONLY]]
         {ANALYSIS    }
         {SIMULATION  }
         {NONE        }

 [/UTILITY=file]

 [/PLOT={[SUMMARY] [SUBJECT] [ALL]}]
        {[NONE**]                  }
```

**Default if the subcommand or keyword is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example:

```
CONJOINT PLAN='/DATA/CARPLAN.SAV'
 /FACTORS=SPEED (LINEAR MORE) WARRANTY (DISCRETE MORE)
  PRICE (LINEAR LESS) SEATS
 /SUBJECT=SUBJ /RANK=RANK1 TO RANK15 /UTILITY='UTIL.SAV'.
```

Overview

CONJOINT analyzes score or rank data from full-concept conjoint studies. A plan file that is generated by ORTHOPLAN or entered by the user describes the set of full concepts that are scored or ranked in terms of preference. A variety of continuous and discrete models is available to estimate utilities for each individual subject and for the group. Simulation estimates for concepts that are not rated can also be computed.

Options

Data Input. You can analyze data recorded as rankings of an ordered set of profiles (or cards) as the profile numbers arranged in rank order, or as preference scores of an ordered set of profiles.

Model Specification. You can specify how each factor is expected to be related to the scores or ranks.

Display Output. The output can include the analysis of the experimental data, results of simulation data, or both.

Writing an External File. An SPSS data file containing utility estimates and associated statistics for each subject can be written for use in further analyses or graphs.

Basic Specification

- The basic specification is `CONJOINT`, a `PLAN` or `DATA` subcommand, and a `SEQUENCE`, `RANK`, or `SCORE` subcommand to describe the type of data.
- `CONJOINT` requires two files: a plan file and a data file. If only the `PLAN` subcommand or the `DATA` subcommand—but not both—is specified, `CONJOINT` will read the file that is specified on the `PLAN` or `DATA` subcommand and use the active dataset as the other file.
- By default, estimates are computed by using the `DISCRETE` model for all variables in the plan file (except those named *STATUS_* and *CARD_*). Output includes Kendall's tau and Pearson's product-moment correlation coefficients measuring the relationship between predicted scores and actual scores. Significance levels for one-tailed tests are displayed.

Subcommand Order

- Subcommands can appear in any order.

Syntax Rules

- Multiple `FACTORS` subcommands are all executed. For all other subcommands, only the last occurrence is executed.

Operations

- Both the plan and data files can be external SPSS data files. In this case, `CONJOINT` can be used before an active dataset is defined.
- The variable *STATUS_* in the plan file must equal 0 for experimental profiles, 1 for holdout profiles, and 2 for simulation profiles. Holdout profiles are judged by the subjects but are not used when `CONJOINT` estimates utilities. Instead, these profiles are used as a check on the validity of the estimated utilities. Simulation profiles are factor-level combinations that are not rated by the subjects but are estimated by `CONJOINT` based on the ratings of the experimental profiles. If there is no *STATUS_* variable, all profiles in the plan file are assumed to be experimental profiles.
- All variables in the plan file except *STATUS_* and *CARD_* are used by `CONJOINT` as factors.
- In addition to the estimates for each individual subject, average estimates for each split-file group that is identified in the data file are computed. The plan file cannot have a split-file structure.

- Factors are tested for orthogonality by CONJOINT. If all of the factors are not orthogonal, a matrix of Cramér's *V* statistics is displayed to describe the non-orthogonality.
- When SEQUENCE or RANK data are used, CONJOINT internally reverses the ranking scale so that the computed coefficients are positive.
- The plan file cannot be sorted or modified in any way after the data are collected, because the sequence of profiles in the plan file must match the sequence of values in the data file in a one-to-one correspondence. (CONJOINT uses the order of profiles as they appear in the plan file, not the value of *CARD_*, to determine profile order.) If RANK or SCORE is the data-recording method, the first response from the first subject in the data file is the rank or score of the first profile in the plan file. If SEQUENCE is the data-recording method, the first response from the first subject in the data file is the profile number (determined by the order of profiles in the plan file) of the most preferred profile.

Limitations

- Factors must be numeric.
- The plan file cannot contain missing values or case weights. In the active dataset, profiles with missing values on the SUBJECT variable are grouped together and averaged at the end. If any preference data (the ranks, scores, or profile numbers) are missing, that subject is skipped.
- Factors must have at least two levels. The maximum number of levels for each factor is 99.

Examples

```
CONJOINT PLAN='/DATA/CARPLAN.SAV'
 /FACTORS=SPEED (LINEAR MORE) WARRANTY (DISCRETE MORE)
  PRICE (LINEAR LESS) SEATS
 /SUBJECT=SUBJ /RANK=RANK1 TO RANK15 /UTILITY='UTIL.SAV'.
```

- The PLAN subcommand specifies the SPSS data file *CARPLAN.SAV* as the plan file containing the full-concept profiles. Because there is no DATA subcommand, the active dataset is assumed to contain the subjects' rankings of these profiles.
- The FACTORS subcommand specifies the ways in which the factors are expected to be related to the rankings. For example, speed is expected to be linearly related to the rankings, so that cars with higher speeds will receive lower (more-preferred) rankings.
- The SUBJECT subcommand specifies the variable *SUBJ* in the active dataset as an identification variable. All consecutive cases with the same value on this variable are combined to estimate utilities.
- The RANK subcommand specifies that each data point is a ranking of a specific profile and identifies the variables in the active dataset that contain these rankings.
- UTILITY writes out an external data file named *UTIL.SAV* containing the utility estimates and associated statistics for each subject.

PLAN Subcommand

PLAN identifies the file containing the full-concept profiles.

- PLAN is followed by quoted file specification for an SPSS data file or currently open dataset containing the plan. An asterisk instead of a file specification indicates the active dataset.
- If the PLAN subcommand is omitted, the active dataset is assumed by default. However, you must specify at least one SPSS data file or dataset on a PLAN or DATA subcommand. The active dataset cannot be specified as both the plan file and data file.
- The plan file is a specially prepared file that is generated by ORTHOPLAN or entered by the user. The plan file can contain the variables *CARD_* and *STATUS_*, and it must contain the factors of the conjoint study. The value of *CARD_* is a profile identification number. The value of *STATUS_* is 0, 1, or 2, depending on whether the profile is an experimental profile (0), a holdout profile (1), or a simulation profile (2).
- The sequence of the profiles in the plan file must match the sequence of values in the data file.
- Any simulation profiles (*STATUS_*=2) must follow experimental and holdout profiles in the plan file.
- All variables in the plan file except *CARD_* and *STATUS_* are used as factors by CONJOINT.

Example

```
DATA LIST FREE /CARD_ WARRANTY SEATS PRICE SPEED STATUS_.
BEGIN DATA
1 1 4 14000 130 2
2 1 4 14000 100 2
3 3 4 14000 130 2
4 3 4 14000 100 2
END DATA.
ADD FILES FILE='/DATA/CARPLAN.SAV'/FILE=*.
CONJOINT PLAN=* /DATA='/DATA/CARDATA.SAV'
  /FACTORS=PRICE (ANTIIDEAL) SPEED (LINEAR) WARRANTY (DISCRETE MORE)
  /SUBJECT=SUBJ /RANK=RANK1 TO RANK15 /PRINT=SIMULATION.
```

- DATA LIST defines six variables—a *CARD_* identification variable, four factors, and a *STATUS_* variable.
- The data between BEGIN DATA and END DATA are four simulation profiles. Each profile contains a *CARD_* identification number and the specific combination of factor levels of interest.
- The variable *STATUS_* is equal to 2 for all cases (profiles). CONJOINT interprets profiles with *STATUS_* equal to 2 as simulation profiles.
- The ADD FILES command joins an old plan file, *CARPLAN.SAV*, with the active dataset. Note that the active dataset is indicated last on the ADD FILES command so that the simulation profiles are appended to the end of *CARPLAN.SAV*.
- The PLAN subcommand on CONJOINT defines the new active dataset as the plan file. The DATA subcommand specifies a data file from a previous CONJOINT analysis.

DATA Subcommand

DATA identifies the file containing the subjects' preference scores or rankings.

- DATA is followed by a quoted file specification for an SPSS data file or a currently open dataset containing the data. An asterisk instead of a file specification indicates the active dataset.

- If the DATA subcommand is omitted, the active dataset is assumed by default. However, you must specify at least one SPSS data file on a DATA or PLAN subcommand. The active dataset cannot be specified as both the plan file and data file.
- One variable in the data file can be a subject identification variable. All other variables are the subject responses and are equal in number to the number of experimental and holdout profiles in the plan file.
- The subject responses can be in the form of ranks assigned to an ordered sequence of profiles, scores assigned to an ordered sequence of profiles, or profile numbers in preference order from most liked to least liked.
- Tied ranks or scores are allowed. If tied ranks are present, CONJOINT issues a warning and then proceeds with the analysis. Data recorded in SEQUENCE format, however, cannot have ties, because each profile number must be unique.

Example

```
DATA LIST FREE /SUBJ RANK1 TO RANK15.
BEGIN DATA
01  3  7  6  1  2  4  9 12 15 13 14  5  8 10 11
02  7  3  4  9  6 15 10 13  5 11  1  8  4  2 12
03 12 13  5  1 14  8 11  2  7  6  3  4 15  9 10
04  3  6  7  4  2  1  9 12 15 11 14  5  8 10 13
05  9  3  4  7  6 10 15 13  5 12  1  8  4  2 11
50 12 13  8  1 14  5 11  6  7  2  3  4 15 10  9
END DATA.
SAVE OUTFILE='/DATA/RANKINGS.SAV'.
DATA LIST FREE /CARD_ WARRANTY SEATS PRICE SPEED.
BEGIN DATA
 1 1 4 14000 130
 2 1 4 14000 100
 3 3 4 14000 130
 4 3 4 14000 100
 5 5 2 10000 130
 6 1 4 10000 070
 7 3 4 10000 070
 8 5 2 10000 100
 9 1 4 07000 130
10 1 4 07000 100
11 5 2 07000 070
12 5 4 07000 070
13 1 4 07000 070
14 5 2 10000 070
15 5 2 14000 130
END DATA.
CONJOINT PLAN=* /DATA='/DATA/RANKINGS.SAV'
  /FACTORS=PRICE (ANTIIDEAL) SPEED (LINEAR)
   WARRANTY (DISCRETE MORE)
  /SUBJECT=SUBJ /RANK=RANK1 TO RANK15.
```

- The first set of DATA LIST and BEGIN–END DATA commands creates a data file containing the rankings. This file is saved in the external file *RANKINGS.SAV*.
- The second set of DATA LIST and BEGIN–END DATA commands defines the plan file as the active dataset.
- The CONJOINT command uses the active dataset as the plan file and uses *RANKINGS.SAV* as the data file.

SEQUENCE, RANK, or SCORE Subcommand

The SEQUENCE, RANK, or SCORE subcommand is specified to indicate the way in which the preference data were recorded.

SEQUENCE *Each data point in the data file is a profile number, starting with the most-preferred profile and ending with the least-preferred profile*. This is how the data are recorded if the subject is asked to order the deck of profiles from most preferred to least preferred. The researcher records which profile number was first, which profile number was second, and so on.

RANK *Each data point is a ranking, starting with the ranking of profile 1, then the ranking of profile 2, and so on*. This is how the data are recorded if the subject is asked to assign a rank to each profile, ranging from 1 to *n*, where *n* is the number of profiles. A lower rank implies greater preference.

SCORE *Each data point is a preference score assigned to the profiles, starting with the score of profile 1, then the score of profile 2, and so on*. These types of data might be generated, for example, by asking subjects to use a Likert scale to assign a score to each profile or by asking subjects to assign a number from 1 to 100 to show how much they like the profile. A higher score implies greater preference.

- You must specify one, and only one, of these three subcommands.
- After each subcommand, the names of the variables containing the preference data (the profile numbers, ranks, or scores) are listed. There must be as many variable names listed as there are experimental and holdout profiles in the plan file.

Example

```
CONJOINT PLAN=* /DATA='DATA.SAV'
  /FACTORS=PRICE (ANTIIDEAL) SPEED (LINEAR) WARRANTY (DISCRETE MORE)
  /SUBJECT=SUBJ
  /RANK=RANK1 TO RANK15.
```

- The RANK subcommand indicates that the data are rankings of an ordered sequence of profiles. The first data point after *SUBJ* is variable *RANK1*, which is the ranking that is given by subject 1 to profile 1.
- There are 15 profiles in the plan file, so there must be 15 variables listed on the RANK subcommand.
- The example uses the TO keyword to refer to the 15 rank variables.

SUBJECT Subcommand

SUBJECT specifies an identification variable. All consecutive cases having the same value on this variable are combined to estimate the utilities.

- If SUBJECT is not specified, all data are assumed to come from one subject, and only a group summary is displayed.
- SUBJECT is followed by the name of a variable in the active dataset.
- If the same SUBJECT value appears later in the data file, it is treated as a different subject.

FACTORS Subcommand

FACTORS specifies the way in which each factor is expected to be related to the rankings or scores.

- If FACTORS is not specified, the DISCRETE model is assumed for all factors.
- All variables in the plan file except *CARD_* and *STATUS_* are used as factors, even if they are not specified on FACTORS.
- FACTORS is followed by a variable list and a model specification in parentheses that describes the expected relationship between scores or ranks and factor levels for that variable list.
- The model specification consists of a model name and, for the DISCRETE and LINEAR models, an optional MORE or LESS keyword to indicate the direction of the expected relationship. Values and value labels can also be specified.
- MORE and LESS keywords will *not* affect estimates of utilities. They are used simply to identify subjects whose estimates do not match the expected direction.

The four available models are as follows:

DISCRETE *No assumption*. The factor levels are categorical, and no assumption is made about the relationship between the factor and the scores or ranks. This setting is the default. Specify keyword MORE after DISCRETE to indicate that higher levels of a factor are expected to be more preferred. Specify keyword LESS after DISCRETE to indicate that lower levels of a factor are expected to be more preferred.

LINEAR *Linear relationship*. The scores or ranks are expected to be linearly related to the factor. Specify keyword MORE after LINEAR to indicate that higher levels of a factor are expected to be more preferred. Specify keyword LESS after LINEAR to indicate that lower levels of a factor are expected to be more preferred.

IDEAL *Quadratic relationship, decreasing preference*. A quadratic relationship is expected between the scores or ranks and the factor. It is assumed that there is an ideal level for the factor, and distance from this ideal point, in either direction, is associated with decreasing preference. Factors that are described with this model should have at least three levels.

ANTIIDEAL *Quadratic relationship, increasing preference*. A quadratic relationship is expected between the scores or ranks and the factor. It is assumed that there is a worst level for the factor, and distance from this point, in either direction, is associated with increasing preference. Factors that are described with this model should have at least three levels.

- The DISCRETE model is assumed for those variables that are not listed on the FACTORS subcommand.
- When a MORE or LESS keyword is used with DISCRETE or LINEAR, a reversal is noted when the expected direction does not occur.
- Both IDEAL and ANTIIDEAL create a quadratic function for the factor. The only difference is whether preference increases or decreases with distance from the point. The estimated utilities are the same for these two models. A reversal is noted when the expected model (IDEAL or ANTIIDEAL) does not occur.
- The optional value and value label lists allow you to recode data and/or replace value labels. The new values, in the order in which they appear on the value list, replace existing values, starting with the smallest existing value. If a new value is not specified for an existing value, the value remains unchanged.

- New value labels are specified in apostrophes or quotation marks. New values without new labels retain existing labels; new value labels without new values are assigned to values in the order in which they appear, starting with the smallest existing value.
- For each factor that is recoded, a table is displayed, showing the original and recoded values and the value labels.
- If the factor levels are coded in discrete categories (for example, 1, 2, 3), these values are the values used by CONJOINT in computations, even if the value labels contain the actual values (for example, 80, 100, 130). Value labels are never used in computations. You can recode the values as described above to change the coded values to the real values. Recoding does not affect DISCRETE factors but does change the coefficients of LINEAR, IDEAL, and ANTIIDEAL factors.
- In the output, variables are described in the following order:

1. All DISCRETE variables in the order in which they appear on the FACTORS subcommand.
2. All LINEAR variables in the order in which they appear on the FACTORS subcommand.
3. All IDEAL and ANTIIDEAL factors in the order in which they appear on the FACTORS subcommand.

Example

```
CONJOINT DATA='DATA.SAV'
 /FACTORS=PRICE (LINEAR LESS) SPEED (IDEAL 70 100 130)
  WARRANTY (DISCRETE MORE)
 /RANK=RANK1 TO RANK15.
```

- The FACTORS subcommand specifies the expected relationships. A linear relationship is expected between price and rankings, so that the higher the price, the lower the preference (higher ranks). A quadratic relationship is expected between speed levels and rankings, and longer warranties are expected to be associated with greater preference (lower ranks).
- The *SPEED* factor has a new value list. If the existing values were 1, 2, and 3, 70 replaces 1, 100 replaces 2, and 130 replaces 3.
- Any variable in the plan file (except *CARD_* and *STATUS_*) that is not listed on the FACTORS subcommand uses the DISCRETE model.

PRINT Subcommand

PRINT controls whether your output includes the analysis of the experimental data, the results of the simulation data, both, or none.

The following keywords are available:

ANALYSIS	*Only the results of the experimental data analysis are included*.
SIMULATION	*Only the results of the simulation data analysis are included*. The results of three simulation models—maximum utility, Bradley-Terry-Luce (BTL), and logit—are displayed.

SUMMARYONLY	*Only the summaries in the output are included, not the individual subjects*. Thus, if you have a large number of subjects, you can see the summary results without having to generate output for each subject.
ALL	*The results of both the experimental data and simulation data analyses are included*. `ALL` is the default.
NONE	*No results are written to the display file*. This keyword is useful if you are interested only in writing the utility file (see "UTILITY Subcommand" below).

UTILITY Subcommand

`UTILITY` writes a utility file to the specified file. The utility file is an SPSS data file.

- If `UTILITY` is not specified, no utility file is written.
- `UTILITY` is followed by the name of the file to be written.
- The file is specified in the usual manner for your operating system.
- The utility file contains one case for each subject. If `SUBJECT` is not specified, the utility file contains a single case with statistics for the group as a whole.

The variables that are written to the utility file are in the following order:

- Any `SPLIT FILE` variables in the active dataset.
- Any `SUBJECT` variable.
- The constant for the regression equation for the subject. The regression equation constant is named `CONSTANT`.
- For `DISCRETE` factors, all of the utilities that are estimated for the subject. The names of the utilities that are estimated with `DISCRETE` factors are formed by appending a digit after the factor name. The first utility gets a 1, the second utility gets a 2, and so on.
- For `LINEAR` factors, a single coefficient. The name of the coefficient for `LINEAR` factors is formed by appending *_L* to the factor name. (To calculate the predicted score, multiply the factor value by the coefficient.)
- For `IDEAL` or `ANTIIDEAL` factors, two coefficients. The name of the two coefficients for `IDEAL` or `ANTIIDEAL` factors are formed by appending *_L* and *_Q*, respectively, to the factor name. (To use these coefficients in calculating the predicted score, multiply the factor value by the first coefficient and add that to the product of the second coefficient and the square of the factor value.)
- The estimated ranks or scores for all profiles in the plan file. The names of the estimated ranks or scores are of the form *SCOREn* for experimental and holdout profiles, or *SIMULn* for simulation profiles, where *n* is the position in the plan file. The name is *SCORE* for experimental and holdout profiles even if the data are ranks.

If the variable names that are created are too long, letters are truncated from the end of the original variable name before new suffixes are appended.

PLOT Subcommand

The PLOT subcommand produces plots in addition to the output that is usually produced by CONJOINT.

The following keywords are available for this subcommand:

SUMMARY *Produces a bar chart of the importance values for all variables, plus a utility bar chart for each variable*. This setting is the default if the PLOT subcommand is specified with no keywords.

SUBJECT *Plots a clustered bar chart of the importance values for each factor, clustered by subjects, and one clustered bar chart for each factor, showing the utilities for each factor level, clustered by subjects*. If no SUBJECT subcommand was specified naming the variables, no plots are produced and a warning is displayed.

ALL *Plots both summary and subject charts*.

NONE *Does not produce any charts*. This setting is the default if the subcommand is omitted.

CORRELATIONS

```
CORRELATIONS VARIABLES= varlist [WITH varlist] [/varlist...]

 [/MISSING={PAIRWISE**}  [{INCLUDE}]]
           {LISTWISE  }   {EXCLUDE}

 [/PRINT={TWOTAIL**}  {SIG**}]
         {ONETAIL  }  {NOSIG}

 [/MATRIX=OUT({*                  })]
              {'savfile'|'dataset'}

 [/STATISTICS=[DESCRIPTIVES] [XPROD] [ALL]]
```

**Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
CORRELATIONS VARIABLES=FOOD RENT PUBTRANS TEACHER COOK ENGINEER
  /MISSING=INCLUDE.
```

Overview

CORRELATIONS (alias PEARSON CORR) produces Pearson product-moment correlations with significance levels and, optionally, univariate statistics, covariances, and cross-product deviations. Other procedures that produce correlation matrices are PARTIAL CORR, REGRESSION, DISCRIMINANT, and FACTOR.

Options

Types of Matrices. A simple variable list on the VARIABLES subcommand produces a square matrix. You can also request a rectangular matrix of correlations between specific pairs of variables or between variable lists using the keyword WITH on VARIABLES.

Significance Levels. By default, CORRELATIONS displays the number of cases and significance levels for each coefficient. Significance levels are based on a two-tailed test. You can request a one-tailed test, and you can display the significance level for each coefficient as an annotation using the PRINT subcommand.

Additional Statistics. You can obtain the mean, standard deviation, and number of nonmissing cases for each variable, and the cross-product deviations and covariance for each pair of variables using the STATISTICS subcommand.

Matrix Output. You can write matrix materials to a data file using the MATRIX subcommand. The matrix materials include the mean, standard deviation, number of cases used to compute each coefficient, and Pearson correlation coefficient for each variable. The matrix data file can be read by several other procedures.

Basic Specification

- The basic specification is the VARIABLES subcommand, which specifies the variables to be analyzed.
- By default, CORRELATIONS produces a matrix of correlation coefficients. The number of cases and the significance level are displayed for each coefficient. The significance level is based on a two-tailed test.

Subcommand Order

- The VARIABLES subcommand must be first.
- The remaining subcommands can be specified in any order.

Operations

- The correlation of a variable with itself is displayed as 1.0000.
- A correlation that cannot be computed is displayed as a period (.).
- CORRELATIONS does not execute if string variables are specified on the variable list.
- This procedure uses the multithreaded options specified by SET THREADS and SET MCACHE.

Limitations

- A maximum of 40 variable lists.
- A maximum of 500 variables total per command.
- A maximum of 250 syntax elements. Each individual occurrence of a variable name, keyword, or special delimiter counts as 1 toward this total. Variables implied by the TO keyword do not count toward this total.

Examples

```
CORRELATIONS VARIABLES=FOOD RENT PUBTRANS TEACHER COOK ENGINEER
  /VARIABLES=FOOD RENT WITH COOK TEACHER MANAGER ENGINEER
  /MISSING=INCLUDE.
```

- The first VARIABLES subcommand requests a square matrix of correlation coefficients among the variables *FOOD*, *RENT*, *PUBTRANS*, *TEACHER*, *COOK*, and *ENGINEER*.
- The second VARIABLES subcommand requests a rectangular correlation matrix in which *FOOD* and *RENT* are the row variables and *COOK*, *TEACHER*, *MANAGER*, and *ENGINEER* are the column variables.
- MISSING requests that user-missing values be included in the computation of each coefficient.

VARIABLES Subcommand

VARIABLES specifies the variable list.

- A simple variable list produces a square matrix of correlations of each variable with every other variable.

- Variable lists joined by the keyword WITH produce a rectangular correlation matrix. Variables before WITH define the rows of the matrix and variables after WITH define the columns.
- The keyword ALL can be used on the variable list to refer to all user-defined variables.
- You can specify multiple VARIABLES subcommands on a single CORRELATIONS command. The slash between the subcommands is required; the keyword VARIABLES is not.

PRINT Subcommand

PRINT controls whether the significance level is based on a one- or two-tailed test and whether the number of cases and the significance level for each correlation coefficient are displayed.

TWOTAIL	*Two-tailed test of significance.* This test is appropriate when the direction of the relationship cannot be determined in advance, as is often the case in exploratory data analysis. This is the default.
ONETAIL	*One-tailed test of significance.* This test is appropriate when the direction of the relationship between a pair of variables can be specified in advance of the analysis.
SIG	*Do not flag significant values.* SIG is the default.
NOSIG	*Flag significant values.* Values significant at the 0.05 level are flagged with a single asterisk; those that are significant at the 0.01 level are flagged with two asterisks.

STATISTICS Subcommand

The correlation coefficients are automatically displayed in the Correlations table for an analysis specified by a VARIABLES list. STATISTICS requests additional statistics.

DESCRIPTIVES	*Display mean, standard deviation, and number of nonmissing cases for each variable on the Variables list in the Descriptive Statistics table.* This table precedes all Correlations tables. Variables specified on more than one VARIABLES list are displayed only once. Missing values are handled on a variable-by-variable basis regardless of the missing-value option in effect for the correlations.
XPROD	*Display cross-product deviations and covariance for each pair of variables in the Correlations table(s).*
ALL	*All additional statistics.* This produces the same statistics as DESCRIPTIVES and XPROD together.

MISSING Subcommand

MISSING controls the treatment of missing values.

- The PAIRWISE and LISTWISE keywords are alternatives; however, each can be specified with INCLUDE or EXCLUDE.
- The default is LISTWISE and EXCLUDE.

PAIRWISE	*Exclude missing values pairwise.* Cases that have missing values for one or both of a pair of variables for a specific correlation coefficient are excluded from the computation of that coefficient. Since each coefficient is based on all cases that have valid values for that particular pair of variables, this can result in a set of coefficients based on a varying number of cases. The valid number of cases is displayed in the Correlations table. This is the default.
LISTWISE	*Exclude missing values listwise.* Cases that have missing values for any variable named on any VARIABLES list are excluded from the computation of all coefficients across lists. The valid number of cases is the same for all analyses and is displayed in a single annotation.
INCLUDE	*Include user-missing values.* User-missing values are included in the analysis.
EXCLUDE	*Exclude all missing values.* Both user- and system-missing values are excluded from the analysis.

MATRIX Subcommand

MATRIX writes matrix materials to an SPSS-format data file or previously declared dataset (DATASET DECLARE command). The matrix materials include the mean and standard deviation for each variable, the number of cases used to compute each coefficient, and the Pearson correlation coefficients. Several procedures can read matrix materials produced by CORRELATIONS, including PARTIAL CORR, REGRESSION, FACTOR, and CLUSTER.

- CORRELATIONS cannot write rectangular matrices (those specified with the keyword WITH) to a file.
- If you specify more than one variable list on CORRELATIONS, only the last list that does not use the keyword WITH is written to the matrix data file.
- The keyword OUT specifies the file to which the matrix is written. Specify an asterisk to replace the active dataset or a quoted file specification or dataset name, enclosed in parentheses.
- Documents from the original file will not be included in the matrix file and will not be present if the matrix file becomes the working data file.

Format of the Matrix Data File

- The matrix data file has two special variables created by the program: *ROWTYPE_* and *VARNAME_*. The variable *ROWTYPE_* is a short string variable with values *MEAN*, *STDDEV*, *N*, and *CORR* (for Pearson correlation coefficient). The next variable, *VARNAME_*, is a short string variable whose values are the names of the variables used to form the correlation matrix. When *ROWTYPE_* is *CORR*, *VARNAME_* gives the variable associated with that row of the correlation matrix.
- The remaining variables in the file are the variables used to form the correlation matrix.

Split Files

- When split-file processing is in effect, the first variables in the matrix file will be split variables, followed by *ROWTYPE_*, *VARNAME_*, and the variables used to form the correlation matrix.
- A full set of matrix materials is written for each subgroup defined by the split variables.
- A split variable cannot have the same name as any other variable written to the matrix data file.
- If split-file processing is in effect when a matrix is written, the same split-file specifications must be in effect when that matrix is read by another procedure.

Missing Values

- With pairwise treatment of missing values (the default), a matrix of the number of cases used to compute each coefficient is included with the matrix materials.
- With listwise treatment, a single number indicating the number of cases used to calculate all coefficients is included.

Example

```
GET FILE=CITY /KEEP FOOD RENT PUBTRANS TEACHER COOK ENGINEER.
CORRELATIONS VARIABLES=FOOD TO ENGINEER
 /MATRIX OUT(CORRMAT).
```

- `CORRELATIONS` reads data from the file *CITY* and writes one set of matrix materials to the file *CORRMAT*. The working file is still *CITY*. Subsequent commands are executed on *CITY*.

Example

```
GET FILE=CITY /KEEP FOOD RENT PUBTRANS TEACHER COOK ENGINEER.
CORRELATIONS VARIABLES=FOOD TO ENGINEER
 /MATRIX OUT(*).
LIST.
DISPLAY DICTIONARY.
```

- `CORRELATIONS` writes the same matrix as in the example above. However, the matrix data file replaces the working file. The `LIST` and `DISPLAY` commands are executed on the matrix file, not on the *CITY* file.

Example

```
CORRELATIONS VARIABLES=FOOD RENT COOK TEACHER MANAGER ENGINEER
 /FOOD TO TEACHER /PUBTRANS WITH MECHANIC
 /MATRIX OUT(*).
```

- Only the matrix for *FOOD* `TO` *TEACHER* is written to the matrix data file because it is the last variable list that does not use the keyword `WITH`.

CORRESPONDENCE

CORRESPONDENCE is available in the Categories option.

```
CORRESPONDENCE

/TABLE = {rowvar (min, max) BY colvar (min, max)}
         {ALL (# of rows, # of columns)          }

[/SUPPLEMENTARY = [{rowvar (valuelist)}] [{colvar (valuelist)}]]
                   {ROW (valuelist)   }   {COLUMN (valuelist)}

[/EQUAL = [{rowvar (valuelist)}] [{colvar (valuelist)}]]
           {ROW (valuelist)   }   {COLUMN (valuelist)}

[/MEASURE = {CHISQ**}]
            {EUCLID }

[/STANDARDIZE = {RMEAN   }]
                {CMEAN   }
                {RCMEAN**}
                {RSUM    }
                {CSUM    }

[/DIMENSION = {2**  }]
              {value}

[/NORMALIZATION = {SYMMETRICAL**}]
                  {PRINCIPAL    }
                  {RPRINCIPAL   }
                  {CPRINCIPAL   }
                  {value        }

[/PRINT = [TABLE**] [RPROF] [CPROF] [RPOINTS**] [CPOINTS**]
          [RCONF] [CCONF] [PERMUTATION[(n)]] [DEFAULT] [NONE]]

[/PLOT = [NDIM({value,value})]
               {value,MAX  }
         [RPOINTS[(n)]] [CPOINTS[(n)] [TRROWS[(n)]]
         [TRCOLUMNS[(n)]] [BIPLOT**[(n)]] [NONE]]

[/OUTFILE = [SCORE('savfile'|'dataset')] [VARIANCE('savfile'|'dataset')]
```

**Default if the subcommand or keyword is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Release History

Release 13.0

- For the NDIM keyword on the PLOT subcommand, the default is changed to all dimensions.
- The maximum label length on the PLOT subcommand is increased to 60 (previous value was 20).

Overview

CORRESPONDENCE displays the relationships between rows and columns of a two-way table graphically by a biplot. It computes the row and column scores and statistics and produces plots based on the scores. Also, confidence statistics are computed.

Options

Number of Dimensions. You can specify how many dimensions CORRESPONDENCE should compute.

Supplementary Points. You can specify supplementary rows and columns.

Equality Restrictions. You can restrict rows and columns to have equal scores.

Measure. You can specify the distance measure to be the chi-square of Euclidean.

Standardization. You can specify one of five different standardization methods.

Method of Normalization. You can specify one of five different methods for normalizing the row and column scores.

Confidence Statistics. You can request computation of confidence statistics (standard deviations and correlations) for row and column scores. For singular values, confidence statistics are always computed.

Data Input. You can analyze individual casewise data, aggregated data, or table data.

Display Output. You can control which statistics are displayed and plotted.

Writing Matrices. You can write the row and column scores and the confidence statistics (variances and covariances) for the singular values to external files.

Basic Specification

- The basic specification is CORRESPONDENCE and the TABLE subcommand. By default, CORRESPONDENCE computes a two-dimensional solution and displays the correspondence table, the summary table, an overview of the row and column scores, and a biplot of the row and column points.

Subcommand Order

- The TABLE subcommand must appear first.
- All other subcommands can appear in any order.

Syntax Rules

- Only one keyword can be specified on the MEASURE subcommand.
- Only one keyword can be specified on the STANDARDIZE subcommand.
- Only one keyword can be specified on the NORMALIZATION subcommand.
- Only one parameter can be specified on the DIMENSION subcommand.

Operations

- If a subcommand is specified more than once, only the last occurrence is executed.

Limitations

- The table input data and the aggregated input data cannot contain negative values. CORRESPONDENCE will treat such values as 0.
- Rows and columns that are specified as supplementary cannot be equalized.
- The maximum number of supplementary points for a variable is 200.
- The maximum number of equalities for a variable is 200.

Example

```
CORRESPONDENCE TABLE=MENTAL(1,4) BY SES(1,6)
/PRINT=RPOINTS CPOINTS
/PLOT=RPOINTS CPOINTS.
```

- Two variables, *MENTAL* and *SES*, are specified on the TABLE subcommand. *MENTAL* has values ranging from 1 to 4, and *SES* has values ranging from 1 to 6.
- The summary table and overview tables of the row and column scores are displayed.
- The row points plot and the column points plot are produced.

TABLE Subcommand

TABLE specifies the row and column variables along with their integer value ranges. The two variables are separated by the keyword BY.

- The TABLE subcommand is required.

Casewise Data

- Each variable is followed by an integer value range in parentheses. The value range consists of the variable's minimum value and its maximum value.
- Values outside of the specified range are not included in the analysis.
- Values do not have to be sequential. Empty categories yield a zero in the input table and do not affect the statistics for other categories.

Example

```
DATA LIST FREE/VAR1 VAR2.
BEGIN DATA
3 1
6 1
3 1
4 2
4 2
6 3
6 3
6 3
3 2
```

```
4 2
6 3
END DATA.
CORRESPONDENCE TABLE=VAR1(3,6) BY VAR2(1,3).
```

- DATA LIST defines two variables, *VAR1* and *VAR2*.
- *VAR1* has three levels, coded 3, 4, and 6. *VAR2* also has three levels, coded 1, 2, and 3.
- Since a range of (3,6) is specified for *VAR1*, CORRESPONDENCE defines four categories, coded 3, 4, 5, and 6. The empty category, 5, for which there is no data, receives system-missing values for all statistics and does not affect the analysis.

Aggregated Data

To analyze aggregated data, such as data from a crosstabulation where cell counts are available but the original raw data are not, you can use the WEIGHT command before CORRESPONDENCE.

Example

To analyze a 3×3 table, such as the one shown below, you could use these commands:

```
DATA LIST FREE/ BIRTHORD ANXIETY COUNT.
BEGIN DATA
1 1 48
1 2 27
1 3 22
2 1 33
2 2 20
2 3 39
3 1 29
3 2 42
3 3 47
END DATA.
WEIGHT BY COUNT.
CORRESPONDENCE TABLE=BIRTHORD (1,3) BY ANXIETY (1,3).
```

- The WEIGHT command weights each case by the value of *COUNT*, as if there are 48 subjects with *BIRTHORD*=1 and *ANXIETY*=1, 27 subjects with *BIRTHORD*=1 and *ANXIETY*=2, and so on.
- CORRESPONDENCE can then be used to analyze the data.
- If any of the table cell values (the values of the WEIGHT variable) equals 0, the WEIGHT command issues a warning, but the CORRESPONDENCE analysis is done correctly.
- The table cell values (the values of the WEIGHT variable) cannot be negative.

Table 34-1
3 x 3 table

		Anxiety		
		High	**Med**	**Low**
Birth order	First	48	27	22
	Second	33	20	39
	Other	29	42	47

Table Data

- The cells of a table can be read and analyzed directly by using the keyword ALL after TABLE.
- The columns of the input table must be specified as variables on the DATA LIST command. Only columns are defined, not rows.
- ALL is followed by the number of rows in the table, a comma, and the number of columns in the table, all in parentheses.
- The row variable is named *ROW,* and the column variable is named *COLUMN*.
- The number of rows and columns specified can be smaller than the actual number of rows and columns if you want to analyze only a subset of the table.
- The variables (columns of the table) are treated as the column categories, and the cases (rows of the table) are treated as the row categories.
- Row categories can be assigned values (category codes) when you specify TABLE=ALL by the optional variable *ROWCAT_*. This variable must be defined as a numeric variable with unique values corresponding to the row categories. If *ROWCAT_* is not present, the row index (case) numbers are used as row category values.

Example

```
DATA LIST /ROWCAT_ 1 COL1 3-4 COL2 6-7 COL3 9-10.
BEGIN DATA
1 50 19 26
2 16 40 34
3 12 35 65
4 11 20 58
END DATA.
VALUE LABELS ROWCAT_ 1 'ROW1' 2 'ROW2' 3 'ROW3' 4 'ROW4'.
CORRESPONDENCE TABLE=ALL(4,3).
```

- DATA LIST defines the row category naming variable *ROWCAT_* and the three columns of the table as the variables.
- The TABLE=ALL specification indicates that the data are the cells of a table. The (4,3) specification indicates that there are four rows and three columns.
- The column variable is named *COLUMN* with categories labeled *COL1*, *COL2*, and *COL3*.
- The row variable is named *ROW* with categories labeled *ROW1*, *ROW2*, *ROW3*, and *ROW4*.

DIMENSION Subcommand

DIMENSION specifies the number of dimensions you want CORRESPONDENCE to compute.

- If you do not specify the DIMENSION subcommand, CORRESPONDENCE computes two dimensions.
- DIMENSION is followed by a positive integer indicating the number of dimensions. If this parameter is omitted, a value of 2 is assumed.
- In general, you should choose as few dimensions as needed to explain most of the variation. The minimum number of dimensions that can be specified is 1. The maximum number of dimensions that can be specified equals the minimum of the number of active rows and the number of active columns minus 1. An active row or column is a nonsupplementary row or

column that is used in the analysis. For example, in a table where the number of rows is 5 (2 of which are supplementary) and the number of columns is 4, the number of active rows (3) is smaller than the number of active columns (4). Thus, the maximum number of dimensions that can be specified is (5−2)−1, or 2. Rows and columns that are restricted to have equal scores count as 1 toward the number of active rows or columns. For example, in a table with five rows and four columns, where two columns are restricted to have equal scores, the number of active rows is 5 and the number of active columns is (4−1), or 3. The maximum number of dimensions that can be specified is (3−1), or 2. Empty rows and columns (rows or columns with no data, all zeros, or all missing data) are not counted toward the number of rows and columns.

- If more than the maximum allowed number of dimensions is specified, CORRESPONDENCE reduces the number of dimensions to the maximum.

SUPPLEMENTARY Subcommand

The SUPPLEMENTARY subcommand specifies the rows and/or columns that you want to treat as supplementary (also called passive or illustrative).

- For casewise data, the specification on SUPPLEMENTARY is the row and/or column variable name, followed by a value list in parentheses. The values must be in the value range specified on the TABLE subcommand for the row or column variable.
- For table data, the specification on SUPPLEMENTARY is *ROW* and/or *COLUMN*, followed by a value list in parentheses. The values represent the row or column indices of the table input data.
- The maximum number of supplementary rows or columns is the number of rows or columns minus 2. Rows and columns that are restricted to have equal scores count as 1 toward the number of rows or columns.
- Supplementary rows and columns cannot be equalized.

Example

```
CORRESPONDENCE TABLE=MENTAL(1,8) BY SES(1,6)
/SUPPLEMENTARY MENTAL(3) SES(2,6).
```

- SUPPLEMENTARY specifies the third level of *MENTAL* and the second and sixth levels of *SES* to be supplementary.

Example

```
CORRESPONDENCE TABLE=ALL(8,6)
/SUPPLEMENTARY ROW(3) COLUMN(2,6).
```

- SUPPLEMENTARY specifies the third level of the row variable and the second and sixth levels of the column variable to be supplementary.

EQUAL Subcommand

The EQUAL subcommand specifies the rows and/or columns that you want to restrict to have equal scores.

- For casewise data, the specification on EQUAL is the row and/or column variable name, followed by a list of at least two values in parentheses. The values must be in the value range specified on the TABLE subcommand for the row or column variable.
- For table data, the specification on EQUAL is *ROW* and/or *COLUMN*, followed by a value list in parentheses. The values represent the row or column indices of the table input data.
- Rows or columns that are restricted to have equal scores cannot be supplementary.
- The maximum number of equal rows or columns is the number of active rows or columns minus 1.

Example

```
CORRESPONDENCE TABLE=MENTAL(1,8) BY SES(1,6)
/EQUAL MENTAL(1,2) (6,7) SES(1,2,3).
```

- EQUAL specifies the first and second level of *MENTAL*, the sixth and seventh level of *MENTAL*, and the first, second, and third levels of *SES* to have equal scores.

MEASURE Subcommand

The MEASURE subcommand specifies the measure of distance between the row and column profiles.

- Only one keyword can be used.

The following keywords are available:

CHISQ	*Chi-square distance*. This is the weighted distance, where the weight is the mass of the rows or columns. This is the default specification for MEASURE and is the necessary specification for standard correspondence analysis.
EUCLID	*Euclidean distance.* The distance is the square root of the sum of squared differences between the values for two rows or columns.

STANDARDIZE Subcommand

When MEASURE=EUCLID, the STANDARDIZE subcommand specifies the method of standardization.

- Only one keyword can be used.
- If MEASURE is CHISQ, only RCMEAN standardization can be used, resulting in standard correspondence analysis.

The following keywords are available:

RMEAN	*The row means are removed.*
CMEAN	*The column means are removed.*
RCMEAN	*Both the row and column means are removed.* This is the default specification.
RSUM	*First the row totals are equalized and then the row means are removed.*
CSUM	*First the column totals are equalized and then the column means are removed.*

NORMALIZATION Subcommand

The NORMALIZATION subcommand specifies one of five methods for normalizing the row and column scores. Only the scores and confidence statistics are affected; contributions and profiles are not changed.

The following keywords are available:

SYMMETRICAL	*For each dimension, rows are the weighted average of columns divided by the matching singular value, and columns are the weighted average of rows divided by the matching singular value.* This is the default if the NORMALIZATION subcommand is not specified. Use this normalization method if you are primarily interested in differences or similarities between rows and columns.
PRINCIPAL	*Distances between row points and distances between column points are approximations of chi-square distances or of Euclidean distances (depending on MEASURE).* The distances represent the distance between the row or column and its corresponding average row or column profile. Use this normalization method if you want to examine both differences between categories of the row variable and differences between categories of the column variable (but not differences between variables).
RPRINCIPAL	*Distances between row points are approximations of chi-square distances or of Euclidean distances (depending on MEASURE).* This method maximizes distances between row points, resulting in row points that are weighted averages of the column points. This is useful when you are primarily interested in differences or similarities between categories of the row variable.
CPRINCIPAL	*Distances between column points are approximations of chi-square distances or of Euclidean distances (depending on MEASURE).* This method maximizes distances between column points, resulting in column points that are weighted averages of the row points. This is useful when you are primarily interested in differences or similarities between categories of the column variable.

The fifth method allows the user to specify any value in the range –1 to +1, inclusive. A value of 1 is equal to the RPRINCIPAL method, a value of 0 is equal to the SYMMETRICAL method, and a value of –1 is equal to the CPRINCIPAL method. By specifying a value between –1 and 1, the user can spread the inertia over both row and column scores to varying degrees. This method is useful for making tailor-made biplots.

PRINT Subcommand

Use PRINT to control which of several correspondence statistics are displayed. The summary table (singular values, inertia, proportion of inertia accounted for, cumulative proportion of inertia accounted for, and confidence statistics for the maximum number of dimensions) is always produced. If PRINT is not specified, the input table, the summary table, the overview of row points table, and the overview of column points table are displayed.

The following keywords are available:

TABLE	*A crosstabulation of the input variables showing row and column marginals*.
RPROFILES	*The row profiles*. PRINT=RPROFILES is analogous to the CELLS=ROW subcommand in CROSSTABS.
CPROFILES	*The column profiles*. PRINT=CPROFILES is analogous to the CELLS=COLUMN subcommand in CROSSTABS.
RPOINTS	*Overview of row points (mass, scores, inertia, contribution of the points to the inertia of the dimension, and the contribution of the dimensions to the inertia of the points).*
CPOINTS	*Overview of column points (mass, scores, inertia, contribution of the points to the inertia of the dimension, and the contribution of the dimensions to the inertia of the points).*
RCONF	*Confidence statistics (standard deviations and correlations) for the active row points.*
CCONF	*Confidence statistics (standard deviations and correlations) for the active column points.*
PERMUTATION(n)	*The original table permuted according to the scores of the rows and columns*. PERMUTATION can be followed by a number in parentheses indicating the maximum number of dimensions for which you want permuted tables. The default number of dimensions is 1.
NONE	*No output other than the SUMMARY table*.
DEFAULT	*TABLE, RPOINTS, CPOINTS, and the SUMMARY tables*. These statistics are displayed if you omit the PRINT subcommand.

PLOT Subcommand

Use PLOT to produce a biplot of row and column points, plus plots of the row points, column points, transformations of the categories of the row variable, and transformations of the categories of the column variable. If PLOT is not specified or is specified without keywords, a biplot is produced.

The following keywords are available:

TRROWS(n)	*Transformation plots for the rows (row category scores against row category indicator values).*
TRCOLUMNS(n)	*Transformation plots for the columns (column category scores against column category indicator values).*
RPOINTS(n)	*Plot of the row points*.
CPOINTS(n)	*Plot of the column points*.

BIPLOT(n)	*Biplot of the row and column points*. This is the default plot. This plot is not available when NORMALIZATION=PRINCIPAL.
NONE	*No plots*.

- For all of the keywords except NONE the user can specify an optional parameter *l* in parentheses in order to control the global upper boundary of value label lengths in the plot. The label length parameter *l* can take any nonnegative integer less than or equal to the applicable maximum length of 60. If *l* is not specified, CORRESPONDENCE assumes that each value label at its full length is displayed. If *l* is an integer larger than the applicable maximum, then we reset it to the applicable maximum, but do not issue a warning. If a positive value of *l* is given but if some or all of the category values do not have labels, then for those values the values themselves are used as the labels.

In addition to the plot keywords, the following can be specified:

NDIM(value,value)	*Dimension pairs to be plotted.* NDIM is followed by a pair of values in parentheses. If NDIM is not specified or if NDIM is specified without parameter values, a matrix scatterplot including all dimensions is produced.

- The first value must be any integer from 1 to the number of dimensions in the solution minus 1.
- The second value must be an integer from 2 to the number of dimensions in the solution. The second value must exceed the first. Alternatively, the keyword MAX can be used instead of a value to indicate the highest dimension of the solution.
- For TRROWS and TRCOLUMNS, the first and second values indicate the range of dimensions for which the plots are created.
- For RPOINTS, CPOINTS, and BIPLOT, the first and second values indicate plotting pairs of dimensions. The first value indicates the dimension that is plotted against higher dimensions. The second value indicates the highest dimension to be used in plotting the dimension pairs.

Example

```
CORRESPONDENCE TABLE=MENTAL(1,4) BY SES(1,6)
/PLOT NDIM(1,3) BIPLOT(5).
```

- BIPLOT and NDIM(1,3) requests that a scatterplot for dimensions 1 and 2, and a scatterplot for dimensions 1 and 3 should be produced.
- The 5 following BIPLOT indicates that only the first five characters of each label are to be shown in the biplot matrix.

Example

```
CORRESPONDENCE TABLE=MENTAL(1,4) BY SES(1,6)
/DIMENSION = 3
/PLOT NDIM(1,MAX) TRROWS.
```

- Three transformation plots for the row categories are produced, one for each dimension from 1 to the highest dimension of the analysis (in this case, 3). The label parameter is not specified, and so the category labels in the plot are shown up their full lengths.

OUTFILE Subcommand

Use OUTFILE to write row and column scores and/or confidence statistics (variances and covariances) for the singular values and row and column scores to an SPSS data file or previously declared dataset.

OUTFILE must be followed by one or both of the following keywords:

SCORE ('file'|'dataset')	*Write row and column scores*.
VARIANCE ('file'|'dataset')	*Write variances and covariances*.

- Filenames should be enclosed in quotes and are stored in the working directory unless a path is included as part of the file specification. Datasets are available during the current session but are not available in subsequent sessions unless you explicitly save them as data files. The names should be different for the each of the keywords.
- For VARIANCE, supplementary and equality constrained rows and columns are not produced in the external file.

The variables in the SCORE matrix data file and their values are:

ROWTYPE_	*String variable containing the value ROW for all of the rows and COLUMN for all of the columns*.
LEVEL_	*String variable containing the values (or value labels, if present) of each original variable*.
VARNAME_	*String variable containing the original variable names*.
DIM1...DIMn	*Numerical variables containing the row and column scores for each dimension*. Each variable is named *DIMn*, where *n* represents the dimension number.

The variables in the VARIANCE matrix data file and their values are:

ROWTYPE_	*String variable containing the value COV for all of the cases in the file*.
VARNAME_	*String variable containing the value SINGULAR, the row variable's name, and the column variable's name*.
LEVEL_	*String variable containing the row variable's values (or labels), the column variable's values (or labels), and a blank value for VARNAME_ = SINGULAR*.
DIMNMBR_	*String variable containing the dimension number*.
DIM1...DIMn	*Numerical variables containing the variances and covariances for each dimension*. Each variable is named *DIMn*, where *n* represents the dimension number.

COUNT

```
COUNT varname=varlist(value list) [/varname=...]
```

Keywords for numeric value lists:

```
LOWEST, LO, HIGHEST, HI, THRU, MISSING, SYSMIS
```

This command does not read the active dataset. It is stored, pending execution with the next command that reads the dataset. For more information, see Command Order on p. 36.

Example

```
COUNT TARGET=V1 V2 V3 (2).
```

Overview

COUNT creates a numeric variable that, for each case, counts the occurrences of the same value (or list of values) across a list of variables. The new variable is called the *target* variable. The variables and values that are counted are the *criterion* variables and values. Criterion variables can be either numeric or string.

Basic Specification

The basic specification is the target variable, an equals sign, the criterion variable(s), and the criterion value(s) enclosed in parentheses.

Syntax Rules

- Use a slash to separate the specifications for each target variable.
- The criterion variables specified for a single target variable must be either all numeric or all string.
- Each value on a list of criterion values must be separated by a comma or space. String values must be enclosed in quotes.
- The keywords THRU, LOWEST (LO), HIGHEST (HI), SYSMIS, and MISSING can be used only with numeric criterion variables.
- A variable can be specified on more than one criterion variable list.
- You can use the keyword TO to specify consecutive criterion variables that have the same criterion value or values.
- You can specify multiple variable lists for a single target variable to count different values for different variables.

Operations

- Target variables are always numeric and are initialized to 0 for each case. They are assigned a dictionary format of `F8.2`.
- If the target variable already exists, its previous values are replaced.
- `COUNT` ignores the missing-value status of user-missing values. It counts a value even if that value has been previously declared as missing.
- The target variable is never system-missing. To define user-missing values for target variables, use the `RECODE` or `MISSING VALUES` command.
- `SYSMIS` counts system-missing values for numeric variables.
- `MISSING` counts both user- and system-missing values for numeric variables.

Examples

Counting Occurrences of a Single Value

```
COUNT TARGET=V1 V2 V3 (2).
```

- The value of *TARGET* for each case will be either 0, 1, 2, or 3, depending on the number of times the value 2 occurs across the three variables for each case.
- *TARGET* is a numeric variable with an `F8.2` format.

Counting Occurrences of a Range of Values and System-Missing Values

```
COUNT QLOW=Q1 TO Q10 (LO THRU 0)
  /QSYSMIS=Q1 TO Q10 (SYSMIS).
```

- Assuming that there are 10 variables between and including *Q1* and *Q10* in the active dataset, *QLOW* ranges from 0 to 10, depending on the number of times a case has a negative or 0 value across the variables *Q1* to *Q10*.
- *QSYSMIS* ranges from 0 to 10, depending on how many system-missing values are encountered for *Q1* to *Q10* for each case. User-missing values are not counted.
- Both *QLOW* and *QSYSMIS* are numeric variables and have `F8.2` formats.

Counting Occurrences of String Values

```
COUNT SVAR=V1 V2 ('male  ') V3 V4 V5 ('female').
```

- *SVAR* ranges from 0 to 5, depending on the number of times a case has a value of male for *V1* and *V2* and a value of female for *V3*, *V4*, and *V5*.
- *SVAR* is a numeric variable with an `F8.2` format.

COXREG

COXREG is available in the Advanced Models option.

```
COXREG VARIABLES = survival varname [WITH varlist]
    / STATUS = varname [EVENT] (vallist) [LOST (vallist)]
   [/STRATA  = varname]
   [/CATEGORICAL = varname]
   [/CONTRAST (varname) = {DEVIATION (refcat)}]
                          {SIMPLE (refcat)   }
                          {DIFFERENCE        }
                          {HELMERT           }
                          {REPEATED          }
                          {POLYNOMIAL(metric)}
                          {SPECIAL (matrix)  }
                          {INDICATOR (refcat)}

   [/METHOD = {ENTER**      }   [{varlist}]]
              {BSTEP [{COND}]}    {ALL    }
                      {LR  }
                      {WALD}
              {FSTEP [{COND}]}
                      {LR  }
                      {WALD}

   [/MISSING = {EXCLUDE**}]
               {INCLUDE  }

   [/PRINT = [{DEFAULT**}]  [CI ({95})]]
             {SUMMARY  }        {n }
             {BASELINE }
             {CORR     }
             {ALL      }

   [/CRITERIA = [{BCON}({1E-4**})]   [LCON({1E-5**})]
                 {PCON} { n    }           { n    }
                [ITERATE({20**})]
                         { n  }
                [PIN({0.05**})]      [POUT({0.1**})]]
                     { n    }              { n   }

   [/PLOT = [NONE**] [SURVIVAL] [HAZARD] [LML] [OMS]]
   [/PATTERN = [varname(value)...] [BY varname]]
   [/OUTFILE = [COEFF('savfile' | 'dataset')] [TABLE('savfile' | 'dataset')]
               [PARAMETER('file')]]
   [/SAVE = tempvar [(newvarname)],tempvar ...]
   [/EXTERNAL]
```

**Default if subcommand or keyword is omitted.

Temporary variables created by COXREG are:

SURVIVAL

SE

HAZARD

RESID

LML

DFBETA

PRESID

XBETA

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
TIME PROGRAM.
COMPUTE Z=AGE + T_.

COXREG SURVIVAL WITH Z
  /STATUS SURVSTA EVENT(1).
```

Overview

COXREG applies Cox proportional hazards regression to analysis of survival times—that is, the length of time before the occurrence of an event. COXREG supports continuous and categorical independent variables (covariates), which can be time dependent. Unlike SURVIVAL and KM, which compare only distinct subgroups of cases, COXREG provides an easy way of considering differences in subgroups as well as analyzing effects of a set of covariates.

Options

Processing of Independent Variables. You can specify which of the independent variables are categorical with the CATEGORICAL subcommand and control treatment of these variables with the CONTRAST subcommand. You can select one of seven methods for entering independent variables into the model using the METHOD subcommand. You can also indicate interaction terms using the keyword BY between variable names on either the VARIABLES subcommand or the METHOD subcommand.

Specifying Termination and Model-Building Criteria. You can specify the criteria for termination of iteration and control variable entry and removal with the CRITERIA subcommand.

Adding New Variables to Active Dataset. You can use the SAVE subcommand to save the cumulative survival, standard error, cumulative hazard, log-minus-log-of-survival function, residuals, XBeta, and, wherever available, partial residuals and DfBeta.

Output. You can print optional output using the PRINT subcommand, suppress or request plots with the PLOT subcommand, and, with the OUTFILE subcommand, write SPSS data files containing coefficients from the final model or a survival table. When only time-constant covariates are used, you can use the PATTERN subcommand to specify a pattern of covariate values in addition to the covariate means to use for the plots and the survival table.

Basic Specification

- The minimum specification on COXREG is a dependent variable with the STATUS subcommand.
- To analyze the influence of time-constant covariates on the survival times, the minimum specification requires either the WITH keyword followed by at least one covariate (independent variable) on the VARIABLES subcommand or a METHOD subcommand with at least one independent variable.

- To analyze the influence of time-dependent covariates on the survival times, the TIME PROGRAM command and transformation language are required to define the functions for the time-dependent covariate(s).

Subcommand Order

- The VARIABLES subcommand must be specified first; the subcommand keyword is optional.
- Remaining subcommands can be named in any order.

Syntax Rules

- Only one dependent variable can be specified for each COXREG command.
- Any number of covariates (independent variables) can be specified. The dependent variable cannot appear on the covariate list.
- The covariate list is required if any of the METHOD subcommands are used without a variable list or if the METHOD subcommand is not used.
- Only one status variable can be specified on the STATUS subcommand. If multiple STATUS subcommands are specified, only the last specification is in effect.
- You can use the BY keyword to specify interaction between covariates.

Operations

- TIME PROGRAM computes the values for time-dependent covariates. For more information, see TIME PROGRAM on p. 1797.
- COXREG replaces covariates specified on CATEGORICAL with sets of contrast variables. In stepwise analyses, the set of contrast variables associated with one categorical variable is entered or removed from the model as a block.
- Covariates are screened to detect and eliminate redundancies.
- COXREG deletes all cases that have negative values for the dependent variable.

Limitations

- Only one dependent variable is allowed.
- Maximum 100 covariates in a single interaction term.
- Maximum 35 levels for a BY variable on PATTERN.

Examples

```
COXREG
  tenure  /STATUS=churn(1)
  /PATTERN BY custcat
  /CONTRAST (marital)=Indicator  /CONTRAST (ed)=Indicator  /CONTRAST
  (retire)=Indicator  /CONTRAST (gender)=Indicator  /CONTRAST
  (custcat)=Indicator
  /METHOD=FSTEP(LR) age marital address ed employ retire gender reside
 /METHOD=ENTER custcat
  /PLOT SURVIVAL HAZARD
  /CRITERIA=PIN(.05) POUT(.10) ITERATE(20) .
```

- The procedure fits a Cox regression model to the variable *tenure*.
- The STATUS subcommand specifies that a value of 1 on the variable *churn* indicates the event of interest has occurred.
- The PATTERN subcommand specifies that separate lines be produced for each value of *custcat* on the requested plots.
- The CONTRAST subcommand specifies that *marital*, *ed*, *retire*, *gender*, and *custcat* should be treated as categorical variables using indicator contrasts.
- The first METHOD subcommand specifies that *age*, *marital*, *address*, *ed*, *employ*, *retire*, *gender*, and *reside* should be tested for entry into the model using forward stepwise selection using the likelihood ratio statistic.
- The second METHOD subcommand specifies that *custcat* should be entered into the model after the forward stepwise selection is performed in the previous METHOD subcommand.
- The PLOT subcommand requests plots of the cumulative survival and cumulative hazard functions.
- All other options are set to their default values.

Using a Time-Dependent Covariate

```
TIME PROGRAM.
COMPUTE T_COV_ = T_*age .
COXREG
  time  /STATUS=arrest2(1)
  /METHOD=ENTER age T_COV_
  /CRITERIA=PIN(.05) POUT(.10) ITERATE(20) .
```

- TIME PROGRAM defines the time-dependent covariate *T_COV_* as the interaction between the current time and *age*.
- COXREG fits a Cox regression model to the variable *time*.
- The STATUS subcommand specifies that a value of 1 on the variable *arrest2* indicates the event of interest (a second arrest) has occurred.
- The METHOD subcommand specifies that *age* and *T_COV_* should be entered into the model.
- All other options are set to their default values.

For more information, see TIME PROGRAM on p. 1797.

VARIABLES Subcommand

VARIABLES identifies the dependent variable and the covariates to be included in the analysis.

- The minimum specification is the dependent variable.
- Cases whose dependent variable values are negative are excluded from the analysis.
- You must specify the keyword WITH and a list of all covariates if no METHOD subcommand is specified or if a METHOD subcommand is specified without naming the variables to be used.

- If the covariate list is not specified on VARIABLES but one or more METHOD subcommands are used, the covariate list is assumed to be the union of the sets of variables listed on all of the METHOD subcommands.
- You can specify an interaction of two or more covariates using the keyword BY. For example, A B BY C D specifies the three terms *A*, *B***C*, and *D*.
- The keyword TO can be used to specify a list of covariates. The implied variable order is the same as in the active dataset.

STATUS Subcommand

To determine whether the event has occurred for a particular observation, COXREG checks the value of a status variable. STATUS lists the status variable and the code for the occurrence of the event.

- Only one status variable can be specified. If multiple STATUS subcommands are specified, COXREG uses the last specification and displays a warning.
- The keyword EVENT is optional, but the value list in parentheses must be specified.
- The value list must be enclosed in parentheses. All cases with non-negative times that do not have a code within the range specified after EVENT are classified as **censored cases**—that is, cases for which the event has not yet occurred.
- The value list can be one value, a list of values separated by blanks or commas, a range of values using the keyword THRU, or a combination.
- If missing values occur within the specified ranges, they are ignored if MISSING=EXCLUDE (the default) is specified, but they are treated as valid values for the range if MISSING=INCLUDE is specified.
- The status variable can be either numeric or string. If a string variable is specified, the EVENT values must be enclosed in apostrophes and the keyword THRU cannot be used.

Example

```
COXREG VARIABLES = SURVIVAL WITH GROUP
  /STATUS SURVSTA (3 THRU 5, 8 THRU 10).
```

- STATUS specifies that *SURVSTA* is the status variable.
- A value between either 3 and 5 or 8 and 10, inclusive, means that the terminal event occurred.
- Values outside the specified ranges indicate censored cases.

STRATA Subcommand

STRATA identifies a stratification variable. A different baseline survival function is computed for each stratum.

- The only specification is the subcommand keyword with one, and only one, variable name.
- If you have more than one stratification variable, create a new variable that corresponds to the combination of categories of the individual variables before invoking the COXREG command.
- There is no limit to the number of levels for the strata variable.

Example

```
COXREG VARIABLES = SURVIVAL WITH GROUP
 /STATUS SURVSTA (1)
 /STRATA=LOCATION.
```

- STRATA specifies *LOCATION* as the strata variable.
- Different baseline survival functions are computed for each value of *LOCATION*.

CATEGORICAL Subcommand

CATEGORICAL identifies covariates that are nominal or ordinal. Variables that are declared to be categorical are automatically transformed to a set of contrast variables (see CONTRAST Subcommand on p. 332). If a variable coded as 0–1 is declared as categorical, by default, its coding scheme will be changed to deviation contrasts.

- Covariates not specified on CATEGORICAL are assumed to be at least interval, except for strings.
- Variables specified on CATEGORICAL but not on VARIABLES or any METHOD subcommand are ignored.
- Variables specified on CATEGORICAL are replaced by sets of contrast variables. If the categorical variable has *n* distinct values, *n*−1 contrast variables will be generated. The set of contrast variables associated with one categorical variable are entered or removed from the model together.
- If any one of the variables in an interaction term is specified on CATEGORICAL, the interaction term is replaced by contrast variables.
- All string variables are categorical. Only the first eight bytes of each value of a string variable are used in distinguishing among values. Thus, if two values of a string variable are identical for the first eight characters, the values are treated as though they were the same.

CONTRAST Subcommand

CONTRAST specifies the type of contrast used for categorical covariates. The interpretation of the regression coefficients for categorical covariates depends on the contrasts used. The default is DEVIATION. For illustration of contrast types, see the appendix.

- The categorical covariate is specified in parentheses following CONTRAST.
- If the categorical variable has *n* values, there will be *n*−1 rows in the contrast matrix. Each contrast matrix is treated as a set of independent variables in the analysis.
- Only one variable can be specified per CONTRAST subcommand, but multiple CONTRAST subcommands can be specified.
- You can specify one of the contrast keywords in parentheses following the variable specification to request a specific contrast type.

The following contrast types are available:

DEVIATION(refcat) *Deviations from the overall effect.* This is the default. The effect for each category of the independent variable except one is compared to the overall effect. *Refcat* is the category for which parameter estimates are not displayed (they must be calculated from the others). By default, *refcat* is the last category. To omit a category other than the last, specify the sequence number of the omitted category (which is not necessarily the same as its value) in parentheses following the keyword DEVIATION.

SIMPLE(refcat) *Each category of the independent variable except the last is compared to the last category.* To use a category other than the last as the omitted reference category, specify its sequence number (which is not necessarily the same as its value) in parentheses following the keyword SIMPLE.

DIFFERENCE *Difference or reverse Helmert contrasts.* The effects for each category of the covariate except the first are compared to the mean effect of the previous categories.

HELMERT *Helmert contrasts.* The effects for each category of the independent variable except the last are compared to the mean effects of subsequent categories.

POLYNOMIAL(metric) *Polynomial contrasts.* The first degree of freedom contains the linear effect across the categories of the independent variable, the second contains the quadratic effect, and so on. By default, the categories are assumed to be equally spaced; unequal spacing can be specified by entering a metric consisting of one integer for each category of the independent variable in parentheses after the keyword POLYNOMIAL. For example, CONTRAST (STIMULUS) = POLYNOMIAL(1,2,4) indicates that the three levels of *STIMULUS* are actually in the proportion 1:2:4. The default metric is always (1,2,...,*k*), where *k* categories are involved. Only the relative differences between the terms of the metric matter: (1,2,4) is the same metric as (2,3,5) or (20,30,50) because, in each instance, the difference between the second and third numbers is twice the difference between the first and second.

REPEATED *Comparison of adjacent categories.* Each category of the independent variable except the last is compared to the next category.

SPECIAL(matrix) *A user-defined contrast.* After this keyword, a matrix is entered in parentheses with *k*−1 rows and *k* columns, where *k* is the number of categories of the independent variable. The rows of the contrast matrix contain the special contrasts indicating the desired comparisons between categories. If the special contrasts are linear combinations of each other, COXREG reports the linear dependency and stops processing. If *k* rows are entered, the first row is discarded and only the last *k*−1 rows are used as the contrast matrix in the analysis.

INDICATOR(refcat) *Indicator variables.* Contrasts indicate the presence or absence of category membership. By default, refcat is the last category (represented in the contrast matrix as a row of zeros). To omit a category other than the last, specify the sequence number of the category (which is not necessarily the same as its value) in parentheses after the keyword INDICATOR.

Example

```
COXREG VARIABLES = SURVIVAL WITH GROUP
 /STATUS SURVSTA (1)
 /STRATA=LOCATION
 /CATEGORICAL = GROUP
 /CONTRAST(GROUP)=SPECIAL(2 -1 -1
                          0  1 -1).
```

- The specification of *GROUP* on CATEGORICAL replaces the variable with a set of contrast variables.
- *GROUP* identifies whether a case is in one of the three treatment groups.
- A SPECIAL type contrast is requested. A three-column, two-row contrast matrix is entered in parentheses.

METHOD Subcommand

METHOD specifies the order of processing and the manner in which the covariates enter the model. If no METHOD subcommand is specified, the default method is ENTER.

- The subcommand keyword METHOD can be omitted.
- You can list all covariates to be used for the method on a variable list. If no variable list is specified, the default is ALL; all covariates named after WITH on the VARIABLES subcommand are used for the method.
- The keyword BY can be used between two variable names to specify an interaction term.
- Variables specified on CATEGORICAL are replaced by sets of contrast variables. The contrast variables associated with a categorical variable are entered or removed from the model together.
- Three keywords are available to specify how the model is to be built:

ENTER *Forced entry.* All variables are entered in a single step. This is the default if the METHOD subcommand is omitted.

FSTEP *Forward stepwise.* The covariates specified on FSTEP are tested for entry into the model one by one based on the significance level of the score statistic. The variable with the smallest significance less than PIN is entered into the model. After each entry, variables that are already in the model are tested for possible removal based on the significance of the Wald statistic, likelihood ratio, or conditional criterion. The variable with the largest probability greater than the specified POUT value is removed and the model is reestimated. Variables in the model are then again evaluated for removal. Once no more variables satisfy the removal criteria, covariates not in the model are evaluated for entry. Model building stops when no more variables meet entry or removal criteria, or when the current model is the same as a previous one.

BSTEP *Backward stepwise.* As a first step, the covariates specified on BSTEP are entered into the model together and are tested for removal one by one. Stepwise removal and entry then follow the same process as described for FSTEP until no more variables meet entry and removal criteria, or when the current model is the same as a previous one.

- Multiple METHOD subcommands are allowed and are processed in the order in which they are specified. Each method starts with the results from the previous method. If BSTEP is used, all eligible variables are entered at the first step. All variables are then eligible for entry and removal unless they have been excluded from the METHOD variable list.

- The statistic used in the test for removal can be specified by an additional keyword in parentheses following FSTEP or BSTEP. If FSTEP or BSTEP is specified by itself, the default is COND.

COND	*Conditional statistic.* This is the default if FSTEP or BSTEP is specified by itself
WALD	*Wald statistic.* The removal of a covariate from the model is based on the significance of the Wald statistic.
LR	*Likelihood ratio.* The removal of a covariate from the model is based on the significance of the change in the log-likelihood. If LR is specified, the model must be reestimated without each of the variables in the model. This can substantially increase computational time. However, the likelihood-ratio statistic is better than the Wald statistic for deciding which variables are to be removed.

Example

```
COXREG VARIABLES = SURVIVAL WITH GROUP SMOKE DRINK
 /STATUS SURVSTA (1)
 /CATEGORICAL = GROUP SMOKE DRINK
 /METHOD ENTER GROUP
 /METHOD BSTEP (LR) SMOKE DRINK SMOKE BY DRINK.
```

- *GROUP*, *SMOKE*, and *DRINK* are specified as covariates and as categorical variables.
- The first METHOD subcommand enters GROUP into the model.
- Variables in the model at the termination of the first METHOD subcommand are included in the model at the beginning of the second METHOD subcommand.
- The second METHOD subcommand adds *SMOKE*, *DRINK*, and the interaction of *SMOKE* with *DRINK* to the previous model.
- Backward stepwise regression analysis is then done using the likelihood-ratio statistic as the removal criterion. The variable *GROUP* is not eligible for removal because it was not specified on the BSTEP subcommand.
- The procedure continues until the removal of a variable will result in a decrease in the log-likelihood with a probability smaller than POUT.

MISSING Subcommand

MISSING controls missing value treatments. If MISSING is omitted, the default is EXCLUDE.

- Cases with negative values on the dependent variable are automatically treated as missing and are excluded.
- To be included in the model, a case must have nonmissing values for the dependent, status, strata, and all independent variables specified on the COXREG command.

EXCLUDE	*Exclude user-missing values.* User-missing values are treated as missing. This is the default if MISSING is omitted.
INCLUDE	*Include user-missing values.* User-missing values are included in the analysis.

PRINT Subcommand

By default, COXREG prints a full regression report for each step. You can use the PRINT subcommand to request specific output. If PRINT is not specified, the default is DEFAULT.

DEFAULT	*Full regression output including overall model statistics and statistics for variables in the equation and variables not in the equation.* This is the default when PRINT is omitted.
SUMMARY	*Summary information.* The output includes –2 log-likelihood for the initial model, one line of summary for each step, and the final model printed with full detail.
CORR	*Correlation/covariance matrix of parameter estimates for the variables in the model.*
BASELINE	*Baseline table.* For each stratum, a table is displayed showing the baseline cumulative hazard, as well as survival, standard error, and cumulative hazard evaluated at the covariate means for each observed time point in that stratum.
CI (value)	*Confidence intervals for* e^{β}. Specify the confidence level in parentheses. The requested intervals are displayed whenever a variables-in-equation table is printed. The default is 95%.
ALL	*All available output.*

Estimation histories showing the last 10 iterations are printed if the solution fails to converge.

Example

```
COXREG VARIABLES = SURVIVAL WITH GROUP
 /STATUS = SURVSTA (1)
 /STRATA = LOCATION
 /CATEGORICAL = GROUP
 /METHOD = ENTER
 /PRINT ALL.
```

PRINT requests summary information, a correlation matrix for parameter estimates, a baseline survival table for each stratum, and confidence intervals for e^{β} with each variables-in-equation table, in addition to the default output.

CRITERIA Subcommand

CRITERIA controls the statistical criteria used in building the Cox Regression models. The way in which these criteria are used depends on the method specified on the METHOD subcommand. The default criteria are noted in the description of each keyword below. Iterations will stop if any of the criteria for BCON, LCON, or ITERATE are satisfied.

BCON(value)	*Change in parameter estimates for terminating iteration.* Alias PCON. Iteration terminates when the parameters change by less than the specified value. BCON defaults to 1E−4. To eliminate this criterion, specify a value of 0.
ITERATE(value)	*Maximum number of iterations.* If a solution fails to converge after the maximum number of iterations has been reached, COXREG displays an iteration history showing the last 10 iterations and terminates the procedure. The default for ITERATE is 20.

LCON(value) *Percentage change in the log-likelihood ratio for terminating iteration.* If the log-likelihood decreases by less than the specified value, iteration terminates. LCON defaults to 1E−5. To eliminate this criterion, specify a value of 0.

PIN(value) *Probability of score statistic for variable entry.* A variable whose significance level is greater than PIN cannot enter the model. The default for PIN is 0.05.

POUT(value) *Probability of Wald, LR, or conditional LR statistic to remove a variable.* A variable whose significance is less than POUT cannot be removed. The default for POUT is 0.1.

Example

```
COXREG VARIABLES = SURVIVAL WITH GROUP AGE BP TMRSZ
 /STATUS = SURVSTA (1)
 /STRATA = LOCATION
 /CATEGORICAL = GROUP
 /METHOD BSTEP
 /CRITERIA BCON(0) ITERATE(10) PIN(0.01) POUT(0.05).
```

- A backward stepwise Cox Regression analysis is performed.
- CRITERIA alters four of the default statistical criteria that control the building of a model.
- Zero specified on BCON indicates that change in parameter estimates is not a criterion for termination. BCON can be set to 0 if only LCON and ITER are to be used.
- ITERATE specifies that the maximum number of iterations is 10. LCON is not changed and the default remains in effect. If either ITERATE or LCON is met, iterations will terminate.
- POUT requires that the probability of the statistic used to test whether a variable should remain in the model be smaller than 0.05. This is more stringent than the default value of 0.1.
- PIN requires that the probability of the score statistic used to test whether a variable should be included be smaller than 0.01. This makes it more difficult for variables to be included in the model than does the default PIN, which has a value of 0.05.

PLOT Subcommand

You can request specific plots to be produced with the PLOT subcommand. Each requested plot is produced once for each pattern specified on the PATTERN subcommand. If PLOT is not specified, the default is NONE (no plots are printed). Requested plots are displayed at the end of the final model.

- The set of plots requested is displayed for the functions at the mean of the covariates and at each combination of covariate values specified on PATTERN.
- If time-dependent covariates are included in the model, no plots are produced.
- Lines on a plot are connected as step functions.

NONE *Do not display plots.*

SURVIVAL *Plot the cumulative survival distribution.*

HAZARD *Plot the cumulative hazard function.*

LML	*Plot the log-minus-log-of-survival function.*
OMS	*Plot the one-minus-survival function.*

PATTERN Subcommand

PATTERN specifies the pattern of covariate values to be used for the requested plots and coefficient tables.

- A value must be specified for each variable specified on PATTERN.
- Continuous variables that are included in the model but not named on PATTERN are evaluated at their means.
- Categorical variables that are included in the model but not named on PATTERN are evaluated at the means of the set of contrasts generated to replace them.
- You can request separate lines for each category of a variable that is in the model. Specify the name of the categorical variable after the keyword BY. The BY variable must be a categorical covariate. You cannot specify a value for the BY covariate.
- Multiple PATTERN subcommands can be specified. COXREG produces a set of requested plots for each specified pattern.
- PATTERN cannot be used when time-dependent covariates are included in the model.

OUTFILE Subcommand

OUTFILE writes data to an external SPSS data file or a previously declared dataset (DATASET DECLARE command). COXREG writes two types of data files. You can specify the file type to be created with one of the two keywords, followed by a quoted file specification in parentheses. It also saves model information in XML format.

COEFF('savfile' | 'dataset')

Write an SPSS data file containing the coefficients from the final model.

TABLE('savfile' | 'dataset')

Write the survival table to an SPSS data file. The file contains cumulative survival, standard error, and cumulative hazard statistics for each uncensored time within each stratum evaluated at the baseline and at the mean of the covariates. Additional covariate patterns can be requested on PATTERN.

PARAMETER('file')

Write parameter estimates only to an XML file. SmartScore and SPSS Server (a separate product) can use this model file to apply the model information to other data files for scoring purposes.

SAVE Subcommand

SAVE saves the temporary variables created by COXREG. The temporary variables include:

SURVIVAL	*Survival function evaluated at the current case.*
SE	*Standard error of the survival function.*

HAZARD	*Cumulative hazard function evaluated at the current case.* Alias RESID.
LML	*Log-minus-log-of-survival function.*
DFBETA	*Change in the coefficient if the current case is removed.* There is one *DFBETA* for each covariate in the final model. If there are time-dependent covariates, only *DFBETA* can be requested. Requests for any other temporary variable are ignored.
PRESID	*Partial residuals.* There is one residual variable for each covariate in the final model. If a covariate is not in the final model, the corresponding new variable has the system-missing value.
XBETA	*Linear combination of mean corrected covariates times regression coefficients from the final model.*

- To specify variable names for the new variables, assign the new names in parentheses following each temporary variable name.
- Assigned variable names must be unique in the active dataset. Scratch or system variable names cannot be used (that is, the variable names cannot begin with # or $).
- If new variable names are not specified, COXREG generates default names. The default name is composed of the first three characters of the name of the temporary variable (two for *SE*), followed by an underscore and a number to make it unique.
- A temporary variable can be saved only once on the same SAVE subcommand.

Example

```
COXREG VARIABLES = SURVIVAL WITH GROUP
 /STATUS = SURVSTA (1)
 /STRATA = LOCATION
 /CATEGORICAL = GROUP
 /METHOD = ENTER
 /SAVE SURVIVAL HAZARD.
```

COXREG saves cumulative survival and hazard in two new variables, *SUR_1* and *HAZ_1*, provided that neither of the two names exists in the active dataset. If one does, the numeric suffixes will be incremented to make a distinction.

EXTERNAL Subcommand

EXTERNAL specifies that the data for each split-file group should be held in an external scratch file during processing. This helps conserve working space when running analyses with large datasets.

- The EXTERNAL subcommand takes no other keyword and is specified by itself.
- If time-dependent covariates exist, external data storage is unavailable, and EXTERNAL is ignored.

CREATE

```
CREATE new series={CSUM (series)                        }
                  {DIFF (series, order)                 }
                  {FFT (series)                         }
                  {IFFT (series)                        }
                  {LAG (series, order [,order ])        }
                  {LEAD (series, order [,order ])       }
                  {MA (series, span [,minimum span])    }
                  {PMA (series, span)                   }
                  {RMED (series, span [,minimum span]) }
                  {SDIFF (series, order [,periodicity])}
                  {T4253H (series)                      }

[/new series=function (series {,span  {,minimum span}})]
                              {,order {,order       }}
                                      {,periodicity }
```

Function keywords:

CSUM	Cumulative sum
DIFF	Difference
FFT	Fast Fourier transform
IFFT	Inverse fast Fourier transform
LAG	Lag
LEAD	Lead
MA	Centered moving averages
PMA	Prior moving averages
RMED	Running medians
SDIFF	Seasonal difference
T4253H	Smoothing

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
CREATE NEWVAR1 NEWVAR2 = CSUM(TICKETS RNDTRP).
```

Overview

CREATE produces new series as a function of existing series. You can also use CREATE to replace the values of existing series. The new or revised series can be used in any procedure and can be saved in an SPSS-format data file.

CREATE displays a list of the new series, the case numbers of the first and last nonmissing cases, the number of valid cases, and the functions used to create the variables.

Basic Specification

The basic specification is a new series name, an equals sign, a function, and the existing series, along with any additional specifications needed.

Syntax Rules

- The existing series together with any additional specifications (order, span, or periodicity) must be enclosed in parentheses.
- The equals sign is required.
- Series names and additional specifications must be separated by commas or spaces.
- You can specify only one function per equation.
- You can create more than one new series per equation by specifying more than one new series name on the left side of the equation and either multiple existing series names or multiple orders on the right.
- The number of new series named on the left side of the equation must equal the number of series created on the right. Note that the `FFT` function creates two new series for each existing series, and `IFFT` creates one series from two existing series.
- You can specify more than one equation on a `CREATE` command. Equations are separated by slashes.
- A newly created series can be specified in subsequent equations on the same `CREATE` command.

Operations

- Each new series created is added to the active dataset.
- If the new series named already exist, their values are replaced.
- If the new series named do not already exist, they are created.
- Series are created in the order in which they are specified on the `CREATE` command.
- If multiple series are created by a single equation, the first new series named is assigned the values of the first series created, the second series named is assigned the values of the second series created, and so on.
- `CREATE` automatically generates a variable label for each new series describing the function and series used to create it.
- The format of the new series is based on the function specified and the format of the existing series.
- `CREATE` honors the `TSET MISSING` setting that is currently in effect.
- `CREATE` does not honor the `USE` command.
- When an even-length span is specified for the functions `MA` and `RMED`, the centering algorithm uses an average of two spans of the specified length. The first span ranges from span/2 cases before the current observation to the span length. The second span ranges from (span/2)−1 cases before the current observation to the span length.

Limitations

- A maximum of 1 function per equation.
- There is no limit on the number of series created by an equation.
- There is no limit on the number of equations.

Examples

```
CREATE NEWVAR1 = DIFF(OLDVAR,1).
```

- In this example, the series *NEWVAR1* is created by taking the first-order difference of *OLDVAR*.

CSUM Function

CSUM produces new series based on the cumulative sums of the existing series. Cumulative sums are the inverse of first-order differencing.

- The only specification on CSUM is the name or names of the existing series in parentheses.
- Cases with missing values in the existing series are not used to compute values for the new series. The values of these cases are system-missing in the new series.

Example

```
CREATE NEWVAR1 NEWVAR2 = CSUM(TICKETS RNDTRP).
```

- This example produces a new series called *NEWVAR1*, which is the cumulative sum of the series *TICKETS*, and a new series called *NEWVAR2*, which is the cumulative sum of the series *RNDTRP*.

DIFF Function

DIFF produces new series based on nonseasonal differences of existing series.

- The specification on DIFF is the name or names of the existing series and the degree of differencing, in parentheses.
- The degree of differencing must be specified; there is no default.
- Since one observation is lost for each order of differencing, system-missing values will appear at the beginning of the new series.
- You can specify only one degree of differencing per DIFF function.
- If either of the pair of values involved in a difference computation is missing, the result is set to system-missing in the new series.

Example

```
CREATE ADIF2 = DIFF(VARA,2) /
       YDIF1 ZDIF1 = DIFF(VARY VARZ,1).
```

- The series *ADIF2* is created by differencing *VARA* twice.

- The series *YDIF1* is created by differencing *VARY* once.
- The series *ZDIF1* is created by differencing *VARZ* once.

FFT Function

FFT produces new series based on fast Fourier transformations of existing series (Brigham, 1974).

- The only specification on FFT is the name or names of the existing series in parentheses.
- FFT creates two series, the cosine and sine parts (also called real and imaginary parts), for each existing series named. Thus, you must specify two new series names on the left side of the equation for each existing series specified on the right side.
- The first new series named becomes the real series, and the second new series named becomes the imaginary series.
- The existing series cannot have embedded missing values.
- The existing series must be of even length. If an odd-length series is specified, FFT pads it with a 0 to make it even. Alternatively, you can make the series even by adding or dropping an observation.
- The new series will be only half as long as the existing series. The remaining cases are assigned the system-missing value.

Example

```
CREATE A B = FFT(C).
```

- Two series, *A* (real) and *B* (imaginary), are created by applying a fast Fourier transformation to series *C*.

IFFT Function

IFFT produces new series based on the inverse Fourier transformation of existing series.

- The only specification on IFFT is the name or names of the existing series in parentheses.
- IFFT needs two existing series to compute each new series. Thus, you must specify two existing series names on the right side of the equation for each new series specified on the left.
- The first existing series specified is the real series and the second series is the imaginary series.
- The existing series cannot have embedded missing values.
- The new series will be twice as long as the existing series. Thus, the last half of each existing series must be system-missing to allow enough room to create the new series.

Example

```
CREATE C = IFFT(A B).
```

- This command creates one new series, *C*, from the series *A* (real) and *B* (imaginary).

LAG Function

LAG creates new series by copying the values of the existing series and moving them forward the specified number of observations. This number is called the **lag order**. The table below shows a first-order lag for a hypothetical dataset.

- The specification on LAG is the name or names of the existing series and one or two lag orders, in parentheses.
- At least one lag order must be specified; there is no default.
- Two lag orders indicate a range. For example, 2,6 indicates lag orders two through six. A new series is created for each lag order in the range.
- The number of new series specified must equal the number of existing series specified times the number of lag orders in the range.
- The first *n* cases at the beginning of the new series, where *n* is the lag order, are assigned the system-missing value.
- Missing values in the existing series are lagged and are assigned the system-missing value in the new series.
- A first-order lagged series can also be created using COMPUTE. COMPUTE does not cause a data pass (see COMPUTE).

Table 37-1
First-order lag and lead of series X

X	Lag	Lead
198	.	220
220	198	305
305	220	470
470	305	.

Example

```
CREATE LAGVAR2 TO LAGVAR5 = LAG(VARA,2,5).
```

- Four new variables are created based on lags on *VARA*. *LAGVAR2* is *VARA* lagged two steps, *LAGVAR3* is *VARA* lagged three steps, *LAGVAR4* is *VARA* lagged four steps, and *LAGVAR5* is *VARA* lagged five steps.

LEAD Function

LEAD creates new series by copying the values of the existing series and moving them back the specified number of observations. This number is called the lead order.

- The specification on LEAD is the name or names of the existing series and one or two lead orders, in parentheses.
- At least one lead order must be specified; there is no default.
- Two lead orders indicate a range. For example, 1,5 indicates lead orders one through five. A new series is created for each lead order in the range.

- The number of new series must equal the number of existing series specified times the number of lead orders in the range.
- The last *n* cases at the end of the new series, where *n* equals the lead order, are assigned the system-missing value.
- Missing values in the existing series are moved back and are assigned the system-missing value in the new series.

Example

```
CREATE LEAD1 TO LEAD4 = LEAD(VARA,1,4).
```

- Four new series are created based on leads of *VARA*. *LEAD1* is *VARA* led one step, *LEAD2* is *VARA* led two steps, *LEAD3* is *VARA* led three steps, and *LEAD4* is *VARA* led four steps.

MA Function

MA produces new series based on the centered moving averages of existing series.

- The specification on MA is the name or names of the existing series and the span to be used in averaging, in parentheses.
- A span must be specified; there is no default.
- If the specified span is odd, the MA is naturally associated with the middle term. If the specified span is even, the MA is centered by averaging each pair of uncentered means (Velleman and Hoaglin, 1981).
- After the initial span, a second span can be specified to indicate the minimum number of values to use in averaging when the number specified for the initial span is unavailable. This makes it possible to produce nonmissing values at or near the ends of the new series.
- The second span must be greater than or equal to 1 and less than or equal to the first span.
- The second span should be even (or 1) if the first span is even; it should be odd if the first span is odd. Otherwise, the next higher span value will be used.
- If no second span is specified, the minimum span is simply the value of the first span.
- If the number of values specified for the span or the minimum span is not available, the case in the new series is set to system-missing. Thus, unless a minimum span of 1 is specified, the endpoints of the new series will contain system-missing values.
- When MA encounters an embedded missing value in the existing series, it creates two subsets, one containing cases before the missing value and one containing cases after the missing value. Each subset is treated as a separate series for computational purposes.
- The endpoints of these subset series will have missing values according to the rules described above for the endpoints of the entire series. Thus, if the minimum span is 1, the endpoints of the subsets will be nonmissing; the only cases that will be missing in the new series are cases that were missing in the original series.

Example

```
CREATE TICKMA = MA(TICKETS,4,2).
```

- This example creates the series *TICKMA* based on centered moving average values of the series *TICKETS*.
- A span of 4 is used for computing averages. At the endpoints, where four values are not available, the average is based on the specified minimum of two values.

PMA Function

PMA creates new series based on the prior moving averages of existing series. The prior moving average for each case in the original series is computed by averaging the values of a span of cases preceding it.

- The specification on PMA is the name or names of the existing series and the span to be used, in parentheses.
- Only one span can be specified and it is required. There is no default span.
- If the number of values specified for the span is not available, the case is set to system-missing. Thus, the number of cases with system-missing values at the beginning of the new series equals the number specified for the span.
- When PMA encounters an imbedded missing value in the existing series, it creates two subsets, one containing cases before the missing value and one containing cases after the missing value. Each subset is treated as a separate series for computational purposes. The first *n* cases in the second subset will be system-missing, where *n* is the span.

Example

```
CREATE PRIORA = PMA(VARA,3).
```

- This command creates the series *PRIORA* by computing prior moving averages for the series *VARA*. Since the span is 3, the first three cases in the series *PRIORA* are system-missing. The fourth case equals the average of cases 1, 2, and 3 of *VARA*, the fifth case equals the average of cases 2, 3, and 4 of *VARA*, and so on.

RMED Function

RMED produces new series based on the centered running medians of existing series.

- The specification on RMED is the name or names of the existing series and the span to be used in finding the median, in parentheses.
- A span must be specified; there is no default.
- If the specified span is odd, RMED is naturally the middle term. If the specified span is even, the RMED is centered by averaging each pair of uncentered medians (Velleman et al., 1981).
- After the initial span, a second span can be specified to indicate the minimum number of values to use in finding the median when the number specified for the initial span is unavailable. This makes it possible to produce nonmissing values at or near the ends of the new series.
- The second span must be greater than or equal to 1 and less than or equal to the first span.
- The second span should be even (or 1) if the first span is even; it should be odd if the first span is odd. Otherwise, the next higher span value will be used.

- If no second span is specified, the minimum span is simply the value of the first span.
- If the number of values specified for the span or the minimum span is not available, the case in the new series is set to system-missing. Thus, unless a minimum span of 1 is specified, the endpoints of the new series will contain system-missing values.
- When RMED encounters an imbedded missing value in the existing series, it creates two subsets, one containing cases before the missing value and one containing cases after the missing value. Each subset is treated as a separate series for computational purposes.
- The endpoints of these subset series will have missing values according to the rules described above for the endpoints of the entire series. Thus, if the minimum span is 1, the endpoints of the subsets will be nonmissing; the only cases that will be missing in the new series are cases that were missing in the original series.

Example

```
CREATE TICKRMED = RMED(TICKETS,4,2).
```

- This example creates the series *TICKRMED* using centered running median values of the series *TICKETS*.
- A span of 4 is used for computing medians. At the endpoints, where four values are not available, the median is based on the specified minimum of two values.

SDIFF Function

SDIFF produces new series based on seasonal differences of existing series.

- The specification on SDIFF is the name or names of the existing series, the degree of differencing, and, optionally, the periodicity, all in parentheses.
- The degree of differencing must be specified; there is no default.
- Since the number of seasons used in the calculations decreases by 1 for each order of differencing, system-missing values will appear at the beginning of the new series.
- You can specify only one degree of differencing per SDIFF function.
- If no periodicity is specified, the periodicity established on TSET PERIOD is in effect. If TSET PERIOD has not been specified, the periodicity established on the DATE command is used. If periodicity was not established anywhere, the SDIFF function cannot be executed.
- If either of the pair of values involved in a seasonal difference computation is missing, the result is set to system-missing in the new series.

Example

```
CREATE SDVAR = SDIFF(VARA,1,12).
```

- The series *SDVAR* is created by applying one seasonal difference with a periodicity of 12 to the series *VARA*.

T4253H Function

T4253H produces new series by applying a compound data smoother to the original series. The smoother starts with a running median of 4, which is centered by a running median of 2. It then resmooths these values by applying a running median of 5, a running median of 3, and hanning (running weighted averages). Residuals are computed by subtracting the smoothed series from the original series. This whole process is then repeated on the computed residuals. Finally, the smoothed residuals are added to the smoothed values obtained the first time through the process (Velleman et al., 1981).

- The only specification on T4253H is the name or names of the existing series in parentheses.
- The existing series cannot contain imbedded missing values.
- Endpoints are smoothed through extrapolation and are not system-missing.

Example

```
CREATE SMOOTHA = T4253H(VARA).
```

- The series *SMOOTHA* is a smoothed version of the series *VARA*.

```

**Default if the subcommand is omitted.

†† The METHOD subcommand is available only if the Exact Tests option is installed (available only on Windows operating systems).

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
CROSSTABS TABLES=FEAR BY SEX
 /CELLS=ROW COLUMN EXPECTED RESIDUALS
 /STATISTICS=CHISQ.
```

Overview

CROSSTABS produces contingency tables showing the joint distribution of two or more variables that have a limited number of distinct values. The frequency distribution of one variable is subdivided according to the values of one or more variables. The unique combination of values for two or more variables defines a cell.

CROSSTABS can operate in two different modes: *general* and *integer*. Integer mode builds some tables more efficiently but requires more specifications than general mode. Some subcommand specifications and statistics are available only in integer mode.

Options

Methods for Building Tables. To build tables in general mode, use the TABLES subcommand. Integer mode requires the TABLES and VARIABLES subcommands and minimum and maximum values for the variables.

Cell Contents. By default, CROSSTABS displays only the number of cases in each cell. You can request row, column, and total percentages, and also expected values and residuals, by using the CELLS subcommand.

Statistics. In addition to the tables, you can obtain measures of association and tests of hypotheses for each subtable using the STATISTICS subcommand.

Formatting Options. With the FORMAT subcommand, you can control the display order for categories in rows and columns of subtables and suppress crosstabulation.

Writing and Reproducing Tables. You can write cell frequencies to a file and reproduce the original tables with the WRITE subcommand.

Basic Specification

In general mode, the basic specification is TABLES with a table list. The actual keyword TABLES can be omitted. In integer mode, the minimum specification is the VARIABLES subcommand, specifying the variables to be used and their value ranges, and the TABLES subcommand with a table list.

- The minimum table list specifies a list of row variables, the keyword BY, and a list of column variables.
- In integer mode, all variables must be numeric with integer values. In general mode, variables can be numeric (integer or non-integer) or string.
- The default table shows cell counts.

Subcommand Order

- In general mode, the table list must be first if the keyword TABLES is omitted. If the keyword TABLES is explicitly used, subcommands can be specified in any order.
- In integer mode, VARIABLES must precede TABLES. The keyword TABLES must be explicitly specified.

Operations

- Integer mode builds tables more quickly but requires more workspace if a table has many empty cells.
- Statistics are calculated separately for each two-way table or two-way subtable. Missing values are reported for the table as a whole.
- In general mode, the keyword TO on the TABLES subcommand refers to the order of variables in the active dataset. ALL refers to all variables in the active dataset. In integer mode, TO and ALL refer to the position and subset of variables specified on the VARIABLES subcommand.

Limitations

The following limitations apply to CROSSTABS in *general mode*:

- A maximum of 200 variables named or implied on the TABLES subcommand
- A maximum of 1000 non-empty rows or columns for each table
- A maximum of 20 table lists per CROSSTABS command
- A maximum of 10 dimensions (9 BY keywords) per table
- A maximum of 400 value labels displayed on any single table

The following limitations apply to CROSSTABS in *integer mode*:

- A maximum of 100 variables named or implied on the VARIABLES subcommand
- A maximum of 100 variables named or implied on the TABLES subcommand
- A maximum of 1000 non-empty rows or columns for each table
- A maximum of 20 table lists per CROSSTABS command
- A maximum of 8 dimensions (7 BY keywords) per table
- A maximum of 20 rows or columns of missing values when REPORT is specified on MISSING
- The minimum value that can be specified is –99,999
- The maximum value that can be specified is 999,999

Examples

Example Description

```
CROSSTABS TABLES=FEAR BY SEX
 /CELLS=ROW COLUMN EXPECTED RESIDUALS
 /STATISTICS=CHISQ.
```

- CROSSTABS generates a Case Processing Summary table, a Crosstabulation table, and a Chi-Square Tests table.
- The variable *FEAR* defines the rows and the variable *SEX* defines the columns of the Crosstabulation table. CELLS requests row and column percentages, expected cell frequencies, and residuals.
- STATISTICS requests the chi-square statistics displayed in the Chi-Square Tests table.

Example Description

```
CROSSTABS TABLES=JOBCAT BY EDCAT BY SEX BY INCOME3.
```

- This table list produces a subtable of *JOBCAT* by *EDCAT* for each combination of values of *SEX* and *INCOME3*.

VARIABLES Subcommand

The VARIABLES subcommand is required for integer mode. VARIABLES specifies a list of variables to be used in the crosstabulations and the lowest and highest values for each variable. Values are specified in parentheses and must be integers. Non-integer values are truncated.

- Variables can be specified in any order. However, the order in which they are named on VARIABLES determines their implied order on TABLES (see the TABLES subcommand below).
- A range must be specified for each variable. If several variables can have the same range, it can be specified once after the last variable to which it applies.
- CROSSTABS uses the specified ranges to allocate tables. One cell is allocated for each possible combination of values of the row and column variables before the data are read. Thus, if the specified ranges are larger than the actual ranges, workspace will be wasted.
- Cases with values outside the specified range are considered missing and are not used in the computation of the table. This allows you to select a subset of values within CROSSTABS.
- If the table is sparse because the variables do not have values throughout the specified range, consider using general mode or recoding the variables.

Example

```
CROSSTABS VARIABLES=FEAR SEX RACE (1,2) MOBILE16 (1,3)
   /TABLES=FEAR BY SEX MOBILE16 BY RACE.
```

- VARIABLES defines values 1 and 2 for *FEAR*, *SEX*, and *RACE* and values 1, 2, and 3 for *MOBILE16*.

TABLES Subcommand

TABLES specifies the table lists and is required in both integer mode and general mode. The following rules apply to both modes:

- You can specify multiple TABLES subcommands on a single CROSSTABS command. The slash between the subcommands is required; the keyword TABLES is required only in integer mode.

- Variables named before the first BY on a table list are row variables, and variables named after the first BY on a table list are column variables.
- When the table list specifies two dimensions (one BY keyword), the first variable before BY is crosstabulated with each variable after BY, then the second variable before BY with each variable after BY, and so on.
- Each subsequent use of the keyword BY on a table list adds a new dimension to the tables requested. Variables named after the second (or subsequent) BY are control variables.
- When the table list specifies more than two dimensions, a two-way subtable is produced for each combination of values of control variables. The value of the last specified control variable changes the most slowly in determining the order in which tables are displayed.
- You can name more than one variable in each dimension.

General Mode

- The actual keyword TABLES can be omitted in general mode.
- In general mode, both numeric and string variables can be specified.
- The keywords ALL and TO can be specified in any dimension. In general mode, TO refers to the order of variables in the active dataset and ALL refers to all variables defined in the active dataset.

Example

```
CROSSTABS  TABLES=FEAR BY SEX BY RACE.
```

- This example crosstabulates *FEAR* by *SEX* controlling for *RACE*. In each subtable, *FEAR* is the row variable and *SEX* is the column variable.
- A subtable is produced for each value of the control variable *RACE*.

Example

```
CROSSTABS  TABLES=CONFINAN TO CONARMY BY SEX TO REGION.
```

- This command produces crosstabulations of all variables in the active dataset between and including *CONFINAN* and *CONARMY* by all variables between and including *SEX* and *REGION*.

Integer Mode

- In integer mode, variables specified on TABLES must first be named on VARIABLES.
- The keywords TO and ALL can be specified in any dimension. In integer mode, TO and ALL refer to the position and subset of variables specified on the VARIABLES subcommand, not to the variables in the active dataset.

Example

```
CROSSTABS  VARIABLES=FEAR (1,2) MOBILE16 (1,3)
  /TABLES=FEAR BY MOBILE16.
```

- VARIABLES names two variables, *FEAR* and *MOBILE16*. Values 1 and 2 for *FEAR* are used in the tables, and values 1, 2, and 3 are used for the variable *MOBILE16*.
- TABLES specifies a Crosstabulation table with two rows (values 1 and 2 for *FEAR*) and three columns (values 1, 2, and 3 for *MOBILE16*). *FEAR* and *MOBILE16* can be named on TABLES because they were named on the previous VARIABLES subcommand.

Example

```
CROSSTABS  VARIABLES=FEAR SEX RACE DEGREE (1,2)
  /TABLES=FEAR BY SEX BY RACE BY DEGREE.
```

- This command produces four subtables. The first subtable crosstabulates *FEAR* by *SEX*, controlling for the first value of *RACE* and the first value of *DEGREE*; the second subtable controls for the second value of *RACE* and the first value of *DEGREE*; the third subtable controls for the first value of *RACE* and the second value of *DEGREE*; and the fourth subtable controls for the second value of *RACE* and the second value of *DEGREE*.

CELLS Subcommand

By default, CROSSTABS displays only the number of cases in each cell of the Crosstabulation table. Use CELLS to display row, column, or total percentages, expected counts, or residuals. These are calculated separately for each Crosstabulation table or subtable.

- CELLS specified without keywords displays cell counts plus row, column, and total percentages for each cell.
- If CELLS is specified with keywords, CROSSTABS displays only the requested cell information.
- Scientific notation is used for cell contents when necessary.

COUNT	*Observed cell counts.* This is the default if CELLS is omitted.
ROW	*Row percentages.* The number of cases in each cell in a row is expressed as a percentage of all cases in that row.
COLUMN	*Column percentages.* The number of cases in each cell in a column is expressed as a percentage of all cases in that column.
TOTAL	*Two-way table total percentages.* The number of cases in each cell of a subtable is expressed as a percentage of all cases in that subtable.
EXPECTED	*Expected counts.* Expected counts are the number of cases expected in each cell if the two variables in the subtable are statistically independent.
RESID	*Residuals.* Residuals are the difference between the observed and expected cell counts.
SRESID	*Standardized residuals*(Haberman, 1978).
ASRESID	*Adjusted standardized residuals* (Haberman, 1978).
ALL	*All cell information.* This includes cell counts; row, column, and total percentages; expected counts; residuals; standardized residuals; and adjusted standardized residuals.
NONE	*No cell information.* Use NONE when you want to write tables to a procedure output file without displaying them. For more information, see WRITE Subcommand on p. 358. This is the same as specifying NOTABLES on FORMAT.

STATISTICS Subcommand

STATISTICS requests measures of association and related statistics. By default, CROSSTABS does not display any additional statistics.

- STATISTICS without keywords displays the chi-square test.
- If STATISTICS is specified with keywords, CROSSTABS calculates only the requested statistics.
- In integer mode, values that are not included in the specified range are *not* used in the calculation of the statistics, even if these values exist in the data.
- If user-missing values are included with MISSING, cases with user-missing values are included in the calculation of statistics as well as in the tables.

CHISQ	*Display the Chi-Square Test table*. Chi-square statistics include Pearson chi-square, likelihood-ratio chi-square, and Mantel-Haenszel chi-square (linear-by-linear association). Mantel-Haenszel is valid only if both variables are numeric. Fisher's exact test and Yates' corrected chi-square are computed for all 2 × 2 tables. This is the default if STATISTICS is specified with no keywords.
PHI	*Display phi and Cramér's* V *in the Symmetric Measures table*.
CC	*Display contingency coefficient in the Symmetric Measures table*.
LAMBDA	*Display lambda (symmetric and asymmetric) and Goodman and Kruskal's tau in the Directional Measures table*.
UC	*Display uncertainty coefficient (symmetric and asymmetric) in the Directional Measures table*.
BTAU	*Display Kendall's tau*-b *in the Symmetric Measures table*.
CTAU	*Display Kendall's tau*-c *in the Symmetric Measures table*.
GAMMA	*Display gamma in the Symmetric Measures table or Zero-Order and Partial Gammas table*. The Zero-Order and Partial Gammas table is produced only for tables with more than two variable dimensions in integer mode.
D	*Display Somers'* d *(symmetric and asymmetric) in the Directional Measures table*.
ETA	*Display eta in the Directional Measures table*. Available for numeric data only.
CORR	*Display Pearson's* r *and Spearman's correlation coefficient in the Symmetric Measures table*. This is available for numeric data only.
KAPPA	*Display kappa coefficient*(Kraemer, 1982) *in the Symmetric Measures table*. Kappa can be computed only for square tables in which the row and column values are identical.
RISK	*Display relative risk*(Bishop, Feinberg, and Holland, 1975) *in the Risk Estimate table*. Relative risk can be calculated only for 2 x 2 tables.
MCNEMAR	*Display a test of symmetry for square tables.* The McNemar test is displayed for 2 x 2 tables, and the McNemar-Bowker test, for larger tables.

CMH(1*) *Conditional independence and homogeneity tests.* Cochran's and the Mantel-Haenszel statistics are computed for the test for conditional independence. The Breslow-Day and Tarone's statistics are computed for the test for homogeneity. For each test, the chi-squared statistic with its degrees of freedom and asymptotic *p* value are computed. *Mantel-Haenszel relative risk (common odds ratio) estimate*. The Mantel-Haenszel relative risk (common odds ratio) estimate, the natural log of the estimate, the standard error of the natural log of the estimate, the asymptotic *p* value, and the asymptotic confidence intervals for common odds ratio and for the natural log of the common odds ratio are computed. The user can specify the null hypothesis for the common odds ratio in parentheses after the keyword. The passive default is 1. (The parameter value must be positive.)

ALL *All statistics available.*

NONE *No summary statistics.* This is the default if STATISTICS is omitted.

METHOD Subcommand

METHOD displays additional results for each statistic requested. If no METHOD subcommand is specified, the standard asymptotic results are displayed. If fractional weights have been specified, results for all methods will be calculated on the weight rounded to the nearest integer. This subcommand is available only if you have the Exact Tests add-on option installed, which is only available on Windows operating systems.

MC Displays an unbiased point estimate and confidence interval based on the Monte Carlo sampling method, for all statistics. Asymptotic results are also displayed. When exact results can be calculated, they will be provided instead of the Monte Carlo results.

CIN(n) Controls the confidence level for the Monte Carlo estimate. CIN is available only when /METHOD=MC is specified. CIN has a default value of 99.0. You can specify a confidence interval between 0.01 and 99.9, inclusive.

SAMPLES Specifies the number of tables sampled from the reference set when calculating the Monte Carlo estimate of the exact *p* value. Larger sample sizes lead to narrower confidence limits but also take longer to calculate. You can specify any integer between 1 and 1,000,000,000 as the sample size. SAMPLES has a default value of 10,000.

EXACT Computes the exact significance level for all statistics in addition to the asymptotic results. EXACT and MC are mutually exclusive alternatives (you cannot specify both on the same command). Calculating the exact *p* value can be memory-intensive. If you have specified /METHOD=EXACT and find that you have insufficient memory to calculate results, you should first close any other applications that are currently running in order to make more memory available. You can also enlarge the size of your swap file (see your Windows documentation for more information). If you still cannot obtain exact results, specify /METHOD=MC to obtain the Monte Carlo estimate of the exact *p* value. An optional TIMER keyword is available if you choose /METHOD=EXACT.

TIMER(n) Specifies the maximum number of minutes allowed to run the exact analysis for each statistic. If the time limit is reached, the test is terminated, no exact results are provided, and the program begins to calculate the next test in the analysis. TIMER is available only when /METHOD=EXACT is specified. You can specify any integer value for TIMER. Specifying a value of 0 for TIMER turns the timer off completely. TIMER has a default value of 5 minutes. If a test exceeds a time limit of 30 minutes, it is recommended that you use the Monte Carlo, rather than the exact, method.

Example

```
CROSSTABS TABLES=FEAR BY SEX
 /CELLS=ROW COLUMN EXPECTED RESIDUALS
 /STATISTICS=CHISQ
 /METHOD=MC SAMPLES(10000) CIN(95).
```

- This example requests chi-square statistics.
- An unbiased point estimate and confidence interval based on the Monte Carlo sampling method are displayed with the asymptotic results.

MISSING Subcommand

By default, CROSSTABS deletes cases with missing values on a table-by-table basis. Cases with missing values for any variable specified for a table are not used in the table or in the calculation of statistics. Use MISSING to specify alternative missing-value treatments.

- The only specification is a single keyword.
- The number of missing cases is always displayed in the Case Processing Summary table.
- If the missing values are not included in the range specified on VARIABLES, they are excluded from the table regardless of the keyword you specify on MISSING.

TABLE	*Delete cases with missing values on a table-by-table basis.* When multiple table lists are specified, missing values are handled separately for each list. This is the default.
INCLUDE	*Include user-missing values.*
REPORT	*Report missing values in the tables.* This option includes missing values in tables but not in the calculation of percentages or statistics. The missing status is indicated on the categorical label. REPORT is available only in integer mode.

FORMAT Subcommand

By default, CROSSTABS displays tables and subtables. The values for the row and column variables are displayed in order from lowest to highest. Use FORMAT to modify the default table display.

AVALUE	*Display row and column variables from lowest to highest value.* This is the default.
DVALUE	*Display row variables from highest to lowest. This setting has no effect on column variables.*
TABLES	*Display tables.* This is the default.
NOTABLES	*Suppress Crosstabulation tables.* NOTABLES is useful when you want to write tables to a file without displaying them or when you want only the Statistics table. This is the same as specifying NONE on CELLS.

COUNT Subcommand

The COUNT subcommand controls how case weights are handled.

ASIS	*The case weights are used as is.* However, when Exact Statistics are requested, the accumulated weights in the cells are either truncated or rounded before computing the Exact test statistics.
CASE	*The case weights are either rounded or truncated before use.*
CELL	*The case weights are used as is but the accumulated weights in the cells are either truncated or rounded before computing any statistics.*
ROUND	*Performs Rounding operation.*
TRUNCATE	*Performs Truncation operation.*

BARCHART Subcommand

BARCHART produces a clustered bar chart where bars represent categories defined by the first variable in a crosstabulation while clusters represent categories defined by the second variable in a crosstabulation. Any controlling variables in a crosstabulation are collapsed over before the clustered bar chart is created.

- BARCHART takes no further specification.
- If integer mode is in effect and MISSING=REPORT, BARCHART displays valid and user-missing values. Otherwise only valid values are used.

WRITE Subcommand

Use the WRITE subcommand to write cell frequencies to a file for subsequent use by the current program or another program. CROSSTABS can also use these cell frequencies as input to reproduce tables and compute statistics. When WRITE is specified, an Output File Summary table is displayed before all other tables.

- The only specification is a single keyword.
- The name of the file must be specified on the PROCEDURE OUTPUT command preceding CROSSTABS.
- If you include missing values with INCLUDE or REPORT on MISSING, no values are considered missing and all non-empty cells, including those with missing values, are written, even if CELLS is specified.
- If you exclude missing values on a table-by-table basis (the default), no records are written for combinations of values that include a missing value.
- If multiple tables are specified, the tables are written in the same order as they are displayed.

NONE	*Do not write cell counts to a file.* This is the default.
CELLS	*Write cell counts for non-empty and nonmissing cells to a file.* Combinations of values that include a missing value are not written to the file.
ALL	*Write cell counts for all cells to a file.* A record for each combination of values defined by VARIABLES and TABLES is written to the file. ALL is available only in integer mode.

The file contains one record for each cell. Each record contains the following:

Columns	Contents
1–4	*Split-file group number, numbered consecutively from 1.* Note that this is not the value of the variable or variables used to define the splits.
5–8	*Table number.* Tables are defined by the TABLES subcommand.
9–16	*Cell frequency.* The number of times this combination of variable values occurred in the data, or, if case weights are used, the sum of case weights for cases having this combination of values.
17–24	*The value of the row variable* (the one named before the first BY).
25–32	*The value of the column variable* (the one named after the first BY).
33–40	*The value of the first control variable* (the one named after the second BY).
41–48	*The value of the second control variable* (the one named after the third BY).
49–56	*The value of the third control variable* (the one named after the fourth BY).
57–64	*The value of the fourth control variable* (the one named after the fifth BY).
65–72	*The value of the fifth control variable* (the one named after the sixth BY).
73–80	*The value of the sixth control variable* (the one named after the seventh BY).

- The split-file group number, table number, and frequency are written as integers.
- In integer mode, the values of variables are also written as integers. In general mode, the values are written according to the print format specified for each variable. Alphanumeric values are written at the left end of any field in which they occur.
- Within each table, records are written from one column of the table at a time, and the value of the last control variable changes the most slowly.

Example

```
PROCEDURE OUTPUT  OUTFILE='/data/celldata.txt'.
CROSSTABS VARIABLES=FEAR SEX (1,2)
 /TABLES=FEAR BY SEX
 /WRITE=ALL.
```

- CROSSTABS writes a record for each cell in the table *FEAR* by *SEX* to the file *celldata.txt*.

Example

```
PROCEDURE OUTPUT  OUTFILE='/data/xtabdata.txt'.
CROSSTABS  TABLES=V1 TO V3 BY V4 BY V10 TO V15
  /WRITE=CELLS.
```

- CROSSTABS writes a set of records for each table to file *xtabdata.txt*.
- Records for the table *V1* by *V4* by *V10* are written first, followed by records for *V1* by *V4* by *V11*, and so on. The records for *V3* by *V4* by *V15* are written last.

Reading a CROSSTABS Procedure Output File

You can use the file created by WRITE in a subsequent session to reproduce a table and compute statistics for it. Each record in the file contains all of the information used to build the original table. The cell frequency information can be used as a weight variable on the WEIGHT command to replicate the original cases.

Example

```
DATA LIST FILE='/celldata.txt'
 /WGHT 9-16 FEAR 17-24 SEX 25-32.
VARIABLE LABELS FEAR 'AFRAID TO WALK AT NIGHT IN NEIGHBORHOODS'.
VALUE LABELS  FEAR 1 'YES' 2 'NO'/ SEX 1 'MALE' 2 'FEMALE'.
WEIGHT BY WGHT.
CROSSTABS TABLES=FEAR BY SEX
 /STATISTICS=ALL.
```

- DATA LIST reads the cell frequencies and row and column values from the *celldata.txt* file. The cell frequency is read as a weighting factor (variable *WGHT*). The values for the rows are read as *FEAR*, and the values for the columns are read as *SEX*, the two original variables.
- The WEIGHT command recreates the sample size by weighting each of the four cases (cells) by the cell frequency.

If you do not have the original data or the CROSSTABS procedure output file, you can reproduce a crosstabulation and compute statistics simply by entering the values from the table:

```
DATA LIST  /FEAR 1 SEX 3 WGHT 5-7.
VARIABLE LABELS  FEAR 'AFRAID TO WALK AT NIGHT IN NEIGHBORHOOD'.
VALUE LABELS  FEAR 1 'YES' 2 'NO'/ SEX 1 'MALE' 2 'FEMALE'.
 WEIGHT  BY WGHT.
BEGIN DATA
1 1  55
2 1 172
1 2 180
2 2  89
END DATA.
CROSSTABS  TABLES=FEAR BY SEX
/STATISTICS=ALL.
```

```

** Default if the subcommand or keyword is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Release History

Release 16.0

- Command introduced.

Example

```
CSCOXREG endtime_var BY a b c WITH x y z
  /VARIABLES STATUS=status_var(1)
  /PLAN FILE='/survey/myfile.csplan'.
```

Overview

For samples drawn by complex sampling methods, CSCOXREG applies Cox proportional hazards regression to analysis of survival times—that is, the length of time before the occurrence of an event. CSCOXREG supports scale and categorical predictors, which can be time dependent. CSCOXREG provides an easy way of considering differences in subgroups as well as analyzing effects of a set of predictors. The procedure estimates variances by taking into account the sample design used to select the sample, including equal probability and probability proportional to size (PPS) methods and with replacement (WR) and without replacement (WOR) sampling procedures. Optionally, CSCOXREG performs analyses for a subpopulation.

Basic Specification

- The basic specification is a variable list identifying the time variables (at least one but can be up to two), the factors (if any), and the covariates (if any); a VARIABLES subcommand specifying the event status variable; and a PLAN subcommand with the name of a complex sample analysis plan file, which may be generated by the CSPLAN procedure.
- The default model includes main effects for any factors and any covariates.
- The basic specification displays summary information about the sample and all analysis variables, model summary statistics, and Wald F tests for all model effects. Additional subcommands must be used for other output.
- Minimum syntax is a time variable, a status variable, and the PLAN subcommand. This specification fits a baseline-only model.

Syntax Rules

- The *endtime* variable, STATUS in VARIABLES subcommand, and PLAN subcommand are required. All other variables and subcommands are optional.
- Multiple CUSTOM and PATTERN subcommands may be specified; each is treated independently. All other subcommands may be specified only once.
- Empty subcommands are not allowed; all subcommands must be specified with options.
- Each keyword may be specified only once within a subcommand.
- Subcommand names and keywords must be spelled in full.
- Equals signs (=) and slashes shown in the syntax chart are required.
- Bold square brackets shown in the syntax chart are required parts of the syntax and are not used to indicate optional elements.
- Subcommands may be specified in any order.
- The factors, ID variable, baseline strata variable, and the subpopulation can be numeric or string variables, but covariates must be numeric.
- Across the time variables, factor, and covariate variable lists, a variable may be specified only once.
- The status variable, ID variable, baseline strata variable, and subpopulation variables may not be specified on the variable list
- Minimum syntax is a time variable, a status variable, and the PLAN subcommand. This specification fits a baseline-only model.
- Only factors and covariates can be defined by the TIME PROGRAM, all other variables cannot be defined there. For more information, see TIME PROGRAM on p. 1797.

Operations

- TIME PROGRAM computes the values for time-dependent predictors (see TIME PROGRAM syntax help).
- CSCOXREG performs Cox proportional hazards regression analysis for sampling designs supported by the CSPLAN and CSSELECT procedures.

- The input dataset must contain the variables to be analyzed and variables related to the sampling design.
- The complex sample analysis plan file provides an analysis plan based on the sampling design.
- By default, CSCOXREG uses a model that includes main effects for any factors and any covariates.
- Other effects, including interaction and nested effects, may be specified using the MODEL subcommand.
- The default output for the specified model is summary information about the sample and all analysis variables, model summary statistics, and Wald F tests for all model effects.

Limitations

WEIGHT and SPLIT FILE settings are ignored with a warning by the CSCOXREG procedure.

Examples

```
CSCOXREG t BY a b c WITH x
  /VARIABLES STATUS = dead(1)
  /PLAN FILE='c:\survey\myfile.csplan'.
```

- *t* is the time variable; *a*, *b*, and *c* are factors; *x* is a covariate.
- The status variable is *dead* with a value of 1 representing the terminal event.
- The complex sampling plan is given in the file *c:\survey\myfile.csplan*.
- CSCOXREG will fit the default model including the main effects for factors *a*, *b*, and *c* and the covariate *x*.

Multiple Cases per Subject

```
* Complex Samples Cox Regression.
CSCOXREG start_time time_to_event  BY mi is hs
  /PLAN FILE='samplesDirectory\srs.csaplan'
  /VARIABLES STATUS=event(4)  ID=patid
  /MODEL mi is hs
  /PRINT SAMPLEINFO EVENTINFO
  /STATISTICS PARAMETER EXP SE CINTERVAL
  /PLOT LML CI=NO
  /PATTERN is(1) hs(0) BY mi
  /TEST TYPE=F PADJUST=LSD
  /CRITERIA MXITER=100 MXSTEP=5 PCONVERGE=[1E-006 RELATIVE] LCONVERGE=[0] TIES=BRESLOW CILEVEL=95
  /SURVIVALMETHOD BASELINE=EFRON CI=LOG
  /MISSING CLASSMISSING=EXCLUDE.
```

- The CSCOXREG procedure creates a Cox regression model for survival times defined by *start_time* and *time_to_event*, using *mi*, *is*, and *hs* as factors. The sampling design is defined in *srs.csaplan*.
- The VARIABLES subcommand specifies on the STATUS keyword that a value of 4 for *event* indicates that the terminal event (death) has occurred. The ID keyword specifies *patid* as the subject ID variable. All cases sharing the same value of *patid* belong to the same subject.
- The STATISTICS subcommand requests estimates, exponentiated estimates, standard errors, and confidence intervals for model parameters.

- The PLOT subcommand requests log-minus-log plots of the estimated survival for the reference pattern (which uses the highest value of each factor), plus each pattern defined in any PATTERN subcommands.
- The PATTERN subcommand requests a plot to be produced using 1 as the value for *is* and 0 as the value for *hs*. Separate lines in the plot will be produced for each value of *mi*.
- The CRITERIA subcommand requests that the Breslow method be used for breaking ties.
- All other options are set to their default values.

Time-Dependent Covariates

```
* Complex Samples Cox Regression.
CLEAR TIME PROGRAM.
TIME PROGRAM.
COMPUTE t_age=ln(T_)*age.
CSCOXREG time_to_event  WITH age t_age
  /PLAN FILE='samplesDirectory\recidivism_cs.csplan'
  /JOINTPROB FILE='samplesDirectory\recidivism_cs_jointprob.sav'
  /VARIABLES STATUS=arrest2(1)
  /MODEL age t_age
  /PRINT SAMPLEINFO EVENTINFO
  /STATISTICS PARAMETER SE CINTERVAL DEFF
  /TEST TYPE=F PADJUST=LSD
  /CRITERIA MXITER=100 MXSTEP=5 PCONVERGE=[1E-006 RELATIVE]
    LCONVERGE=[0] TIES=EFRON CILEVEL=95
  /SURVIVALMETHOD BASELINE=EFRON CI=LOG
  /MISSING CLASSMISSING=EXCLUDE.
```

- The TIME PROGRAM command indicates that the following COMPUTE statement defines a time-dependent predictor for use with CSCOXREG. The time-dependent predictor is the interaction between the covariate *age* and the natural log of the internal time variable *T_*.
- The CSCOXREG procedure fits a model for *time_to_event* given covariates *age* and *t_age*. The sampling design is defined in *recidivism_cs.csplan*, and joint probabilities are stored in *recidivism_cs_jointprob.sav*.
- The VARIABLES subcommand specifies that a value of 1 for *arrest2* indicates that the event of interest (rearrest) has occurred.
- The STATISTICS subcommand requests estimates, standard errors, confidence intervals, and design effects for model parameters.
- All other options are set to their default values.

Variable List Subcommand

The variable list specifies the time variable(s), the factors, and the covariates in the model.

- The time variables *starttime* (if specified) and *endtime* must be listed first. These variables represent the endpoints of a time interval (*starttime*, *endtime*) during which the case is at risk.
- When *starttime* is not specified, it is implied that *starttime* = 0 for all cases if an ID variable is not specified. If an ID variable is specified, it is assumed that *starttime* = 0 for the first observation for that subject and *starttime* for following observations equals *endtime* of the previous observation. See the example below.
- The time variables must be numeric and non-negative.

- If the time variables are of SPSS Date or Time type, the internal numeric representation will be used and a warning will be given. For example, November 8, 1957, is 1.2E+10 (the number of seconds from midnight, October 14, 1582). See Date and Time Functions for detailed internal numeric representation of different date and time formats.
- The names of the factors and covariates, if any, follow the time variables. Specify any factors following the keyword BY. Specify any covariates following the keyword WITH.
- Factors can be numeric or string variables, but covariates must be numeric.
- Each variable may be specified only once on the variable list.
- The status variable, ID variable, baseline strata variable, and subpopulation variables may not be specified on the variable list.

Example

```
CSCOXREG tstart tend BY a b c WITH x
  /VARIABLES STATUS = dead(1) ID = SSN
  /PLAN FILE='c:\survey\myfile.csplan'
  /MODEL a b c a*b a*c b*c x.
```

- Two time variables, *tstart* and *tend*, are specified.
- ID specifies *SSN* as the subject ID variable. All cases sharing the same value of *SSN* belong to the same subject.
- This example fits a model that includes the main effects for factors *a*, *b*, and *c*; all two-way interactions among the factors; and the covariate *x*.

```
CSCOXREG tend BY a b c WITH x
  /VARIABLES STATUS = dead(1) ID = SSN
  /PLAN FILE='c:\survey\myfile.csplan'
  /MODEL a b c a*b a*c b*c x.
```

- This is the same as the above example except that only one time variable, *tend*, is specified.
- The values of *starttime* derived from *tend*. For example, for the following subject,

SSN	tend	
123456789	10	...
123456789	20	...
123456789	25	...

it is implied that *starttime* = 0, 10, and 20 for these three cases.

VARIABLES Subcommand

VARIABLES specifies the status variable, ID variable, and baseline strata variable.

STATUS = varname

Event status variable. To determine whether the event has occurred at *endtime* for a particular observation, CSCOXREG checks the value of a status variable. STATUS lists the status variable and the values that indicate the occurrence of the event.

The value list must be enclosed in parentheses. All cases with non-negative times that do not have a value within the range specified are classified as censored cases—that is, cases for which the event has not yet occurred at *endtime*.

The value list can be one value, a list of values separated by blanks or commas, a range of values using the keyword THRU, or a combination.

The status variable can be either numeric or string. If a string variable is specified, the event values must be enclosed in apostrophes and the keyword THRU cannot be used.

ID = varname

ID variable. Cases with the same ID value are repeated observations from the same subject. If ID is not specified, each case represents one subject.

BASELINESTRATA = varname

Baseline stratification variable. A separate baseline hazard and survival function is computed for each value of this variable, while a single set of model coefficients is estimated across strata.

Example

```
CSCOXREG SURVIVAL by GROUP
/VARIABLES STATUS=SURVSTA(3 THRU 5, 8 THRU 10) BASELINESTRATA=LOCATION
/PLAN FILE='c:\survey\myfile.csplan'.
```

- STATUS specifies that *SURVSTA* is the status variable.
- A value between either 3 and 5 or 8 and 10, inclusive, means that the terminal event occurred.
- Values outside the specified ranges indicate censored cases.
- BASELINESTRATA specifies *LOCATION* as the strata variable.
- Different baseline survival functions are computed for each value of *LOCATION*.

PLAN Subcommand

The PLAN subcommand specifies the name of an XML file containing analysis design specifications. This file is written by the CSPLAN procedure.

- The PLAN subcommand is required.

FILE *Specifies the name of an external file*.

JOINTPROB Subcommand

The JOINTPROB subcommand is used to specify the file or dataset containing the first stage joint inclusion probabilities for UNEQUAL_WOR estimation. The CSSELECT procedure writes this file in the same location and with the same name (but a different extension) as the plan file. When UNEQUAL_WOR estimation is specified, the procedure will use the default location and name of the file unless the JOINTPROB subcommand is used to override them.

FILE *Specifies the name of the file or dataset containing the joint inclusion probabilities*.

MODEL Subcommand

The MODEL subcommand is used to specify the effects to be included in the model.

- Specify a list of terms to be included in the model, separated by spaces or commas.
- If the MODEL subcommand is not specified, CSCOXREG uses a model that includes main effects for any factors, and any covariates, in the order specified on the variable list.
- To include a term for the main effect of a factor, enter the name of the factor.
- To include a term for an interaction among factors, use the keyword BY or the asterisk (*) to join the factors involved in the interaction. For example, A*B means a two-way interaction effect of A and B, where A and B are factors. A*A is not allowed because factors inside an interaction effect must be distinct.
- To include a term for nesting one factor within another, use a pair of parentheses. For example, A(B) means that A is nested within B. A(A) is not allowed because factors inside a nested effect must be distinct.
- Multiple nesting is allowed. For example, A(B(C)) means that B is nested within C, and A is nested within B(C). When more than one pair of parentheses is present, each pair of parentheses must be enclosed or nested within another pair of parentheses. Thus, A(B)(C) is not valid.
- Nesting within an interaction effect is valid. For example, A(B*C) means that A is nested within B*C.
- Interactions among nested effects are allowed. The correct syntax is the interaction followed by the common nested effect inside the parentheses. For example, interaction between A and B within levels of C should be specified as A*B(C) instead of A(C)*B(C).
- To include a covariate term in the design, enter the name of the covariate.
- Covariates can be connected, but not nested, through the * operator or using the keyword BY to form another covariate effect. Interactions among covariates such as X1*X1 and X1*X2 are valid, but X1(X2) is not.
- Factor and covariate effects can be connected in various ways except that no effects can be nested within a covariate effect. Suppose A and B are factors and X1 and X2 are covariates, examples of valid combinations of factor and covariate effects are A*X1, A*B*X1, X1(A), X1(A*B), X1*A(B), X1*X2(A*B), and A*B*X1*X2.

CUSTOM Subcommand

The CUSTOM subcommand defines custom hypothesis tests by specifying the **L** matrix (contrast coefficients matrix) and the **K** matrix (contrast results matrix) in the general form of the linear hypothesis **LB** = **K**. The vector **B** is the parameter vector in the linear model.

- Multiple CUSTOM subcommands are allowed. Each subcommand is treated independently.
- An optional label may be specified by using the LABEL keyword. The label is a string with a maximum length of 255 characters. Only one label can be specified.

- Either the LMATRIX or KMATRIX keyword, or both, must be specified.

LMATRIX	*Contrast coefficients matrix.* This matrix specifies coefficients of contrasts, which can be used for studying the effects in the model. An **L** matrix can be specified by using the LMATRIX keyword.
KMATRIX	*Contrast results matrix.* This matrix specifies the results of the linear hypothesis. A **K** matrix can be specified by using the KMATRIX keyword.

- The number of rows in the **L** and **K** matrices must be equal.
- A custom hypothesis test can be formed by specifying an **L** or **K** matrix, or both. If only one matrix is specified, the unspecified matrix uses the defaults described below.
- If KMATRIX is specified but LMATRIX is not specified, the **L** matrix is assumed to be the row vector corresponding to the intercept in the estimable function, provided that INCLUDE = YES or ONLY is specified on the INTERCEPT subcommand. In this case, the **K** matrix can be only a scalar matrix.
- The default **K** matrix is a zero matrix—that is, **LB** = **0** is assumed.
- There are three general formats that can be used on the LMATRIX keyword: (1) Specify a coefficient value for the intercept, followed optionally by an effect name and a list of real numbers. (2) Specify an effect name and a list of real numbers. (3) Specify keyword ALL and a list of real numbers. In all three formats, there can be multiple effect names (or instances of the keyword ALL) and number lists.
- Only valid effects in the default model or on the MODEL subcommand can be specified on the LMATRIX keyword.
- The length of the list of real numbers on the LMATRIX keyword must be equal to the number of parameters (including the redundant parameters) corresponding to the specified effect. For example, if the effect A*B takes up six columns in the design matrix, the list after A*B must contain exactly six numbers.
- When ALL is specified, the length of the list that follows ALL must be equal to the total number of parameters (including the redundant parameters) in the model.
- Effects that are in the model but not specified on the LMATRIX keyword are assumed to have entries of 0 in the corresponding columns of the **L** matrix.
- When an **L** matrix is being defined, a number can be specified as a fraction with a positive denominator. For example, 1/3 and –1/3 are valid, but 1/–3 is invalid.
- A semicolon (;) indicates the end of a row in the **L** matrix.
- The format for the KMATRIX keyword is one or more real numbers. If more than one number is specified, then separate adjacent numbers using a semicolon (;). Each semicolon indicates the end of a row in the **K** matrix. Each number is the hypothesized value for a contrast, which is defined by a row in the **L** matrix.
- For the KMATRIX keyword to be valid, either the LMATRIX keyword, or INCLUDE = YES on the INTERCEPT subcommand, must be specified.

Example

Suppose that factors A and B each have three levels.

```
CSCOXREG t BY a b
  /VARIABLES STATUS=death(1)
  /PLAN FILE='c:\survey\myfile.csplan'
  /MODEL a b a*b
  /CUSTOM  LABEL = "Effect A"
     LMATRIX = a 1 0 -1
         a*b  1/3  1/3  1/3
              0    0    0
             -1/3 -1/3 -1/3;
         a 0 1 -1
         a*b  0    0    0
              1/3  1/3  1/3
             -1/3 -1/3 -1/3.
```

- The preceding syntax specifies a test of effect A.
- Because there are three levels in effect A, two independent contrasts can be formed at most; thus, there are two rows in the **L** matrix separated by a semicolon (;).
- There are three levels each in effects A and B; thus, the interaction effect A*B takes nine columns in the design matrix.
- The first row in the **L** matrix tests the difference between levels 1 and 3 of effect A; the second row tests the difference between levels 2 and 3 of effect A.
- The `KMATRIX` keyword is not specified, so the null hypothesis value for both tests is 0.

Example

Suppose that factor A has three levels.

```
CSCOXREG t BY a
  /VARIABLES STATUS=death(1)
  /PLAN FILE='c:\survey\myfile.csplan'
  /MODEL a
  /CUSTOM  LABEL = 'Effect A'
   LMATRIX = a 1 0 -1;
             a 0 1 -1
   KMATRIX = 1; 1.
```

- The syntax specifies a model with a main effect for factor A and a custom hypothesis test of effect A.
- The equivalent `LMATRIX` keyword using the `ALL` option follows.

```
LMATRIX = ALL 1  0 -1;
          ALL 0  1 -1
```

- The `KMATRIX` keyword is specified and the hypothesis that the difference between levels 1 and 3 and levels 2 and 3 of effect A are both equal to 1 is tested.

CRITERIA Subcommand

The CRITERIA subcommand controls the iterative algorithm used for estimation, specifies the numerical tolerance for checking for singularity, and specifies the ties breaking method used in estimating regression parameters.

CILEVEL = number

Confidence interval level for coefficient estimates, exponentiated coefficient estimates, survival function estimates, and cumulative hazard function estimates. Specify a value greater than or equal to 0 and less than 100. The default value is 95.

DF = number

Sampling design degrees of freedom to use in computing p values for all test statistics. Specify a positive number. The default value is the difference between the number of primary sampling units and the number of strata in the first stage of sampling.

LCONVERGE = [number RELATIVE|ABSOLUTE]

Log-likelihood function convergence criterion. Convergence is assumed if the relative or absolute change in the log-likelihood function is less than the given value. This criterion is not used if the value is 0.

Specify square brackets containing a non-negative number followed optionally by keyword RELATIVE or ABSOLUTE, which indicates the type of change. The default value is 0; the default type is RELATIVE.

MXITER = integer

Maximum number of iterations. Specify a non-negative integer. The default value is 100.

MXSTEP = integer

Maximum step-halving allowed. Specify a positive integer. The default value is 5.

PCONVERGE = [number RELATIVE|ABSOLUTE]

Parameter estimates convergence criterion. Convergence is assumed if the relative or absolute change in the parameter estimates is less than the given value. This criterion is not used if the value is 0.

Specify square brackets containing a non-negative number followed optionally by keyword RELATIVE or ABSOLUTE, which indicates the type of change. The default value is 10^{-6}; the default type is RELATIVE.

SINGULAR = number

Tolerance value used to test for singularity. Specify a positive value. The default value is 10^{-12}.

TIES = EFRON|BRESLOW

Tie breaking method in estimating parameters. The default Efron method is specified by the keyword EFRON; the default Breslow method is specified by the keyword BRESLOW.

STATISTICS Subcommand

The STATISTICS subcommand requests various statistics associated with the parameter estimates.

There are no default keywords on the STATISTICS subcommand. If this subcommand is not specified, then none of the statistics listed below are displayed.

PARAMETER	*Parameter estimates.*
EXP	*The exponentiated parameter estimates.*
SE	*Standard error for each parameter estimate.*
TTEST	*t test for each parameter estimate.*
CINTERVAL	*Confidence interval for each parameter estimate and/or exponentiated parameter estimate.*
DEFF	*Design effect for each parameter estimate.*
DEFFSQRT	*Square root of design effect for each parameter estimate.*

TEST Subcommand

The TEST subcommand specifies the type of test statistic and the method of adjusting the significance level to be used for hypothesis tests requested on the MODEL, CUSTOM, and PRINT subcommands.

TYPE Keyword

The TYPE keyword indicates the type of test statistic.

F	*Wald F test.* This is the default test statistic if the TYPE keyword is not specified.
ADJF	*Adjusted Wald F test.*
CHISQUARE	*Wald chi-square test.*
ADJCHISQUARE	*Adjusted Wald chi-square test.*

PADJUST Keyword

The PADJUST keyword indicates the method of adjusting the significance level.

LSD	*Least significant difference.* This method does not control the overall probability of rejecting the hypotheses that some linear contrasts are different from the null hypothesis value(s). This is the default.
BONFERRONI	*Bonferroni.* This method adjusts the observed significance level for the fact that multiple contrasts are being tested.
SEQBONFERRONI	*Sequential Bonferroni.* This is a sequentially step-down rejective Bonferroni procedure that is much less conservative in terms of rejecting individual hypotheses but maintains the same overall significance level.
SIDAK	*Sidak.* This method provides tighter bounds than the Bonferroni approach.
SEQSIDAK	*Sequential Sidak.* This is a sequentially step-down rejective Sidak procedure that is much less conservative in terms of rejecting individual hypotheses but maintains the same overall significance level.

TESTASSUMPTIONS Subcommand

The TESTASSUMPTIONS subcommand produces tests of the proportional hazards and covariate form model assumptions. You can request various statistics associated with the alternative models.

PROPHAZARD Keyword

The PROPHAZARD keyword produces a test for proportional hazards assumption. The time function used in testing for proportional hazards is specified in parentheses. Specify one of the following options.

KM	*Kaplan-Meier estimation of survival function.* This is the default.
IDENTITY	*Identity function of time.*
LOG	*Log function of time.*
RANK	*Rank of death time.*

PARAMETER Keyword

The PARAMETER keyword displays the parameter estimates of the alternative model. The alternative model is estimated using the same convergence criteria as the original model. Both parameters and their standard errors are estimated.

COVB Keyword

The COVB keyword displays the covariance matrix for the alternative model parameters

DOMAIN Subcommand

The DOMAIN subcommand specifies the subpopulation for which the analysis is to be performed.

- The keyword VARIABLE, followed by an equals sign, a variable, and a value in parentheses are required. Put the value inside a pair of quotes if the value is formatted (such as date or currency) or if the factor is of string type.
- The subpopulation is defined by all cases having the given value on the specified variable.
- Analyses are performed only for the specified subpopulation.
- For example, `DOMAIN VARIABLE = myvar (1)` defines the subpopulation by all cases for which variable *MYVAR* has value 1.
- The specified variable may be numeric or string and must exist at the time the CSCOXREG procedure is invoked.
- Stratification or cluster variables may be specified, but no other plan file variables are allowed on the DOMAIN subcommand.
- Analysis variables may not be specified on the DOMAIN subcommand.

MISSING Subcommand

The MISSING subcommand specifies how missing values are handled.

- In general, cases must have valid data for all design variables as well as for the dependent variable and any covariates. Cases with invalid data for any of these variables are excluded from the analysis.
- There is one important exception to the preceding rule. This exception applies when an inclusion probability or population size variable is defined in an analysis plan file. Within a stratum at a given stage, if the inclusion probability or population size values are unequal across cases or missing for a case, then the first valid value found within that stratum is used as the value for the stratum. If strata are not defined, then the first valid value found in the sample is used. If the inclusion probability or population size values are missing for all cases within a stratum (or within the sample if strata are not defined) at a given stage, then an error message is issued.
- The CLASSMISSING keyword specifies whether user-missing values are treated as valid. This specification is applied to categorical design variables (that is, strata, cluster, and subpopulation variables), the dependent variable, and any factors.

EXCLUDE	*Exclude user-missing values among the strata, cluster, subpopulation, dependent variable, and factor variables.* This is the default.
INCLUDE	*Include user-missing values among the strata, cluster, subpopulation, dependent variable, and factor variables.* Treat user-missing values for these variables as valid data.

SURVIVALMETHOD Subcommand

The SURVIVALMETHOD subcommand controls the methods for estimating baseline functions and the confidence interval of the survival function.

BASELINE Keyword

The BASELINE keyword controls the method for estimating baseline functions. Specify one of the following options.

EFRON	*Efron method.* Default if EFRON is chosen in TIES.
BRESLOW	*Breslow method.* Default if BRESLOW is chosen in TIES.
PRODUCTLIMIT	*Product limit method.*

CI Keyword

The CI keyword controls the method for estimating the confidence interval of the survival function. Specify one of the following options.

ORIGINAL *Based on original scale.* Calculate the confidence interval for the survival function directly.

LOG *Based on log scale.* Calculate the confidence interval for ln(survival) first, then back transform to get the confidence interval for the survival function.

LML *Based on log-log scale.* Calculate the confidence interval for ln(−ln(survival)) first, then back transform to get the confidence interval for the survival function.

PRINT Subcommand

The PRINT subcommand is used to display optional output.

- If the PRINT subcommand is not specified, then the default output includes sample information, variable and factor information, and model summary statistics.
- If the PRINT subcommand is specified, then CSCOXREG displays output only for those keywords that are specified.

SAMPLEINFO *Sample information table.* Displays summary information about the sample, including the unweighted count, the event and censoring counts, and the population size. This is default output if the PRINT subcommand is not specified.

EVENTINFO *Event and censoring information.* Displays event and censoring information for each baseline stratum. This is the default output if the PRINT subcommand is not specified.

RISKINFO *Risk and event information.* Displays number of events and number at risk for each event time in each baseline stratum.

HISTORY(n) *Iteration history.* Displays coefficient estimates and statistics at every *n*th iteration beginning with the *0*th iteration (the initial estimates). The default is to print every iteration ($n = 1$). The last iteration is always printed if HISTORY is specified, regardless of the value of *n*.

GEF *General estimable function table.*

LMATRIX *Set of contrast coefficients (L) matrices.* These are the Type III contrast matrices used in testing model effects.

COVB *Covariance matrix for model parameters.*

CORB *Correlation matrix for model parameters.*

BASELINE *Baseline functions.* Displays the baseline survival function, baseline cumulative hazards function and their standard errors. If time-dependent covariates defined by TIME PROGRAM are included in the model, no baseline functions are produced.

NONE *No PRINT output.* None of the PRINT subcommand default output is displayed. However, if NONE is specified with one or more other keywords, then the other keywords override NONE.

SAVE Subcommand

The SAVE subcommand writes optional model variables to the working data file.

- Specify one or more temporary variables, each followed by an optional new name in parentheses.
- The optional names must be valid variable names.
- If new names are not specified, CSCOXREG uses the default names.
- The optional variable name must be unique. If the default name is used and it conflicts with existing variable names, then a suffix is added to the default name to make it unique.
- If a subpopulation is defined on the DOMAIN subcommand, then SAVE applies only to cases within the subpopulation.
- Aggregated residuals are residuals aggregated over records with the same ID value. If ID is not specified, aggregated residuals are not available and a warning is issued if they are requested. The aggregated residual for a subject is written in the last case (or first case if it is easier) of that subject.
- If time-dependent covariates defined by TIME PROGRAM are included in the model, the following options are not available: MARTINGALE, DEVIANCE, COXSNELL, AGGMARTINGALE, AGGDEVIANCE, AGGCOXSNELL, SURVIVAL, LCL_SURVIVAL, UCL_SURVIVAL, CUMHAZARD, LCL_CUMHAZARD, and UCL_CUMHAZARD. A warning is issued if they are requested.
- In situations when rootname is needed, the rootname can be followed by a colon and a positive integer giving the maximum number of variables with the same rootname to be saved. The first *n* variables are saved. The default *n* is 25. To specify *n* without a rootname, enter a colon before the number.

SCHOENFELD(rootname:n)

Schoenfeld residual. A separate variable is saved for each nonredundant parameter and calculated only for noncensored observations. The default variable name is *Resid_Schoenfeld*.

MARTINGALE(varname)

Martingale residual. The default variable name is *Resid_Martingale*.

DEVIANCE(varname)

Deviance residual. The default variable name is *Resid_Deviance*.

COXSNELL(varname)

Cox_Snell residual. The default variable name is *Resid_CoxSnell*.

SCORE(rootname:n)

Score residual. A separate variable is saved for each nonredundant parameter. The default variable name is *Resid_Score*.

DFBETA(rootname:n)

DFBETA. A separate variable is saved for each nonredundant parameter. The default variable name is *Resid_DFBETA*.

AGGMARTINGALE(varname)

Aggregated Martingale residual. The default variable name is *AggResid_Martingale*.

AGGDEVIANCE(varname)

Aggregated Deviance residual. The default variable name is *AggResid_Deviance*.

AGGCOXSNELL(varname)

Aggregated CoxSnell residual. The default variable name is *AggResid_CoxSnell*.

AGGSCORE(rootname:n)

Aggregated Score residual. A separate variable is saved for each nonredundant parameter. The default variable name is *AggResid_Score*.

AGGDFBETA(rootname:n)

Aggregated DFBETA. A separate variable is saved for each nonredundant parameter. The default variable name is *AggResid_DFBETA*.

XBETA(varname)

Linear combination of reference value corrected predictors times regression coefficients. The default variable name is *XBETA*.

SURVIVAL(varname)

Survival function. For one-time input data, it is the survival function at the observed time and predictor pattern for each record. For two-time input data, it is the survival function at *endtime* assuming that the predictor is fixed. The default variable name is *Survival*.

LCL_SURVIVAL(varname)

Lower confidence level of survival function. The default variable name is *LCL_Survival*.

UCL_SURVIVAL(varname)

Upper confidence level of survival function. The default variable name is *UCL_Survival*.

CUMHAZARD(varname)

Cumulative hazards function. The default variable name is *CumHazard*.

LCL_CUMHAZARD(varname)

Lower confidence level of cumulative hazards function. The default variable name is *LCL_CumHazard*.

UCL_CUMHAZARD(varname)

Upper confidence level of cumulative hazards function. The default variable name is *SECumHazard*.

PLOT Subcommand

You can request specific plots to be produced with the `PLOT` subcommand. Each requested plot is produced once for each pattern specified on the `PATTERN` subcommand.

- The set of plots requested is displayed for the functions at the mean of the covariates and at each combination of covariate values specified on `PATTERN`.
- Lines on a plot are connected as step functions.

SURVIVAL	*Plot the survival function.*
HAZARD	*Plot the cumulative hazard function.*
LML	*Plot the log-minus-log-of-survival function.*

OMS *Plot the one-minus-survival function.*

CI = NO | YES *Plot confidence intervals along with the specified functions.* NO is the default.

PATTERN Subcommand

PATTERN specifies the pattern of predictor values to be used for requested plots on the PLOT subcommand and the exported survival file on the OUTFILE subcommand. PATTERN cannot be used when time-dependent predictors calculated by TIME PROGRAM are included in the model.

- A value must be specified for each variable specified on PATTERN.
- Covariates that are included in the model but not named on PATTERN are evaluated at their means.
- Factors that are included in the model but not named on PATTERN are evaluated at the reference category.
- You can request separate lines for each category of a factor that is in the model. Specify the name of the categorical variable after the keyword BY. The BY variable must be a categorical variable. You cannot specify a value for the BY variable.
- Multiple PATTERN subcommands can be specified. CSCOXREG produces a set of requested plots for each specified pattern.
- Piecewise constant predictor paths are also allowed. The path is specified by endtime(valuelist) varname(valuelist) varname(value)…. If varname(valuelist) is used, the length of valuelist must be the same as that for endtime. The varname(value) means that the value of the variable is constant over time.

Example

```
CSCOXREG t by A with x1 x2
/VARIABLES STATUS=dead(1)
/PLAN FILE='c:\survey\myfile.csplan'
/PATTERN x1(0.1) x2(3) A(3)
/PLOT SURVIVAL.
```

- Predictor pattern x1 = 0.1, x2 = 3, A = 3 is specified by PATTERN.
- The survival function is plotted for the specified pattern.

Example: Piecewise constant predictor path

```
CSCOXREG t1 t2 by A with x1 x2
/VARIABLES STATUS=dead(1)
/PLAN FILE='c:\survey\myfile.csplan'.
/PATTERN t2(10 20 30 50) x1(1 1.2 1.7 1.9) x2(3) BY A
/OUTFILE SURVIVAL='surv.sav'.
```

- Two time variables are specified on the CSCOXREG variable list.

- PATTERN defines the following predictor paths for x1 and x2.

starttime	endtime	x1	x2
0	10	1.0	3
10	20	1.2	3
20	30	1.7	3
30	50	1.9	3

- PATTERN, through BY A, also specifies that each category of factor A is considered separately. Combining different categories of A with the paths for x1 and x2, the total number of paths considered here actually equals the number of categories of A.
- The survival table for the specified predictor paths are calculated and written to the file *surv.sav*.

OUTFILE Subcommand

The OUTFILE subcommand saves an SPSS-format data file containing the parameter covariance or correlation matrix with parameter estimates, standard errors, significance values, and sampling design degrees of freedom. It also saves the parameter estimates and the parameter covariance matrix in XML format.

- At least one keyword and a filename are required.
- The COVB and CORB keywords are mutually exclusive, as are the MODEL and PARAMETER keywords.
- The filename must be specified in full. CSCOXREG does not supply an extension.

COVB = 'savfile'|'dataset'

Writes the parameter covariance matrix and other statistics to an SPSS data file.

CORB = 'savfile'|'dataset'

Writes the parameter correlation matrix and other statistics to an SPSS data file.

MODEL = 'file'

Writes all information needed to predict the survival function, including the parameter estimates and baseline survival function, to a PMML file.

SURVIVAL= 'savfile'|'dataset'

Writes survival table to an SPSS data file. The file contains the survival function, standard error of the survival function, upper and lower bounds of the confidence interval of the survival function, and the cumulative hazards function for each failure or event time evaluated at the baseline and at the covariate patterns specified on PATTERN. If time-dependent covariates are included in the model, no file is written.

CSDESCRIPTIVES

CSDESCRIPTIVES is available in the Complex Samples option.

```
CSDESCRIPTIVES

/PLAN FILE = file

[/JOINTPROB FILE = file]

[/SUMMARY VARIABLES = varlist]

[/MEAN [TTEST = {value    }]
               {valuelist}

[/SUM [TTEST = {value    }]
              {valuelist}

[/RATIO NUMERATOR = varlist DENOMINATOR = varlist

        [TTEST = {value    }]]
                 {valuelist}

[/RATIO...]

[/STATISTICS [COUNT] [POPSIZE] [SE] [CV] [DEFF] [DEFFSQRT]
             [CIN [({95** })]]]
                    {value}

[/SUBPOP TABLE = varname [BY varname [BY ...]] [DISPLAY = {LAYERED }]]
                                                          {SEPARATE}

[/MISSING [SCOPE = {ANALYSIS}] [CLASSMISSING = {EXCLUDE}]]
                   {LISTWISE}                  {INCLUDE}
```

**Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
CSDESCRIPTIVES
  /PLAN FILE = '/survey/myfile.xml'
  /SUMMARY VARIABLES = y1 y2
  /MEAN.
```

Overview

CSDESCRIPTIVES estimates means, sums, and ratios, and computes their standard errors, design effects, confidence intervals, and hypothesis tests, for samples that are drawn by complex sampling methods. The procedure estimates variances by taking into account the sample design that is used to select the sample, including equal probability and probability proportional to size (PPS) methods, and with replacement (WR) and without replacement (WOR) sampling procedures. Optionally, CSDESCRIPTIVES performs analyses for subpopulations.

Basic Specification

- The basic specification is a PLAN subcommand and the name of a complex sample analysis plan file (which may be generated by the CSPLAN procedure) and a MEAN, SUM, or RATIO subcommand. If a MEAN or SUM subcommand is specified, a SUMMARY subcommand must also be present.
- The basic specification displays the overall population size estimate. Additional subcommands must be used for other results.

Operations

- CSDESCRIPTIVES computes estimates for sampling designs that are supported by the CSPLAN and CSSELECT procedures.
- The input dataset must contain the variables to be analyzed and variables that are related to the sampling design.
- The complex sample analysis plan file provides an analysis plan based on the sampling design.
- The default output for each requested mean, sum, or ratio is the estimate and its standard error.
- WEIGHT and SPLIT FILE settings are ignored by the CSDESCRIPTIVES procedure.

Syntax Rules

- The PLAN subcommand is required. In addition, the SUMMARY subcommand and the MEAN or SUM subcommand must be specified, or the RATIO subcommand must be specified. All other subcommands are optional.
- Multiple instances of the RATIO subcommand are allowed—each instance is treated independently. All other subcommands may be specified only once.
- Subcommands can be specified in any order.
- All subcommand names and keywords must be spelled in full.
- Equals signs (=) that are shown in the syntax chart are required.
- The MEAN and SUM subcommands can be specified without further keywords, but no other subcommands may be empty.

Examples

Example: Univariate Descriptive Statistics

```
* Complex Samples Descriptives.
CSDESCRIPTIVES
 /PLAN FILE = 'samplesDirectory\nhis2000_subset.csaplan'
 /JOINTPROB FILE = 'samplesDirectory\nhis2000_subset.sav'
 /SUMMARY VARIABLES =VIGFREQW MODFREQW STRFREQW
 /SUBPOP TABLE = age_cat  DISPLAY=LAYERED
 /MEAN
 /STATISTICS SE CIN (95)
 /MISSING SCOPE = ANALYSIS CLASSMISSING = EXCLUDE.
```

- The procedure computes estimates based on the complex sample analysis plan that is given in *nhis2000_subset.csaplan*.

- The procedure estimates the mean, its standard error, and 95% confidence interval for variables *vigfreqw*, *modfreqw*, and *strfreqw*.
- In addition, these statistics are computed for the variables by values of *age_cat*. The results for subpopulations are displayed in a single table.
- Other subcommands and keywords are set to their default values.

Example: Ratio Statistics

```
* Complex Samples Ratios.
CSDESCRIPTIVES
 /PLAN FILE = 'samplesDirectory\property_assess.csplan'
 /RATIO NUMERATOR = currval  DENOMINATOR = lastval  TTEST = 1.3
 /STATISTICS SE COUNT POPSIZE CIN (95)
 /SUBPOP TABLE = county  DISPLAY=LAYERED
 /MISSING SCOPE = ANALYSIS CLASSMISSING = EXCLUDE.
```

- The procedure computes estimates based on the complex sample analysis plan that is given in *property_assess.csplan*.
- The ratio estimate for *currval*/*lastval*, its standard error, 95% confidence interval, observed count of cases used in the computations, and estimated population size are displayed.
- A *t* test of the ratio is performed against a hypothesized value of 1.3.
- In addition, these statistics are computed for the variables by values of *county*. The results for subpopulations are displayed in a single table.
- Other subcommands and keywords are set to their default values.

PLAN Subcommand

PLAN specifies the name of an XML file containing analysis design specifications. This file is written by the CSPLAN procedure.

- The PLAN subcommand is required.

FILE *Specifies the name of an external file.*

JOINTPROB Subcommand

JOINTPROB is used to specify the file or dataset containing the first-stage joint inclusion probabilities for UNEQUAL_WOR estimation. The CSSELECT procedure writes this file in the same location and with the same name (but different extension) as the plan file. When UNEQUAL_WOR estimation is specified, the CSDESCRIPTIVES procedure will use the default location and name of the file unless the JOINTPROB subcommand is used to override them.

FILE *Specifies the name of the file or dataset containing the joint inclusion probabilities.*

SUMMARY Subcommand

SUMMARY specifies the analysis variables that are used by the MEAN and SUM subcommands.

- A variable list is required only if means or sums are to be estimated. If only ratios are to be estimated (that is, if the RATIO subcommand is specified but the MEAN and SUM subcommands are not specified), the SUMMARY subcommand is ignored.
- All specified variables must be numeric.
- All specified variables must be unique.
- Plan file and subpopulation variables may not be specified on the SUMMARY subcommand.

VARIABLES *Specifies the variables used by the MEAN and SUM subcommands.*

MEAN Subcommand

MEAN is used to request that means be estimated for variables that are specified on the SUMMARY subcommand.

The TTEST keyword requests *t* tests of the population means(s) and gives the null hypothesis value(s). If subpopulations are defined on the SUBPOP subcommand, null hypothesis values are used in the test(s) for each subpopulation, as well as for the entire population.

value The null hypothesis is that the population mean equals the specified value for all *t* tests.

valuelist This list gives the null hypothesis value of the population mean for each variable on the SUMMARY subcommand. The number and order of values must correspond to the variables on the SUMMARY subcommand.

- Commas or spaces must be used to separate the values.

SUM Subcommand

SUM is used to request that sums be estimated for variables specified on the SUMMARY subcommand.

The TTEST keyword requests *t* tests of the population sum(s) and gives the null hypothesis value(s). If subpopulations are defined on the SUBPOP subcommand, then null hypothesis values are used in the test(s) for each subpopulation as well as for the entire population.

value The null hypothesis is that the population sum equals the specified value for all *t* tests.

valuelist This list gives the null hypothesis value of the population sum for each variable on the SUMMARY subcommand. The number and order of values must correspond to the variables on the SUMMARY subcommand.

- Commas or spaces must be used to separate the values.

RATIO Subcommand

RATIO specifies ratios of variables to be estimated.

- Ratios are defined by crossing variables on the NUMERATOR keyword with variables on the DENOMINATOR keyword, with DENOMINATOR variables looping fastest, irrespective of the order of the keywords. For example, /RATIO NUMERATOR = N1 N2 DENOMINATOR = D1 D2 yields the following ordered list of ratios: N1/D1, N1/D2, N2/D1, N2/D2.
- Multiple RATIO subcommands are allowed. Each subcommand is treated independently.
- Variables that are specified on the RATIO subcommand do not need to be specified on the SUMMARY subcommand.
- All specified variables must be numeric.
- Within each variable list, all specified variables must be unique.
- Plan file and subpopulation variables may not be specified on the RATIO subcommand.

The TTEST keyword requests *t* tests of the population ratio(s) and gives the null hypothesis value(s). If subpopulations are defined on the SUBPOP subcommand, then null hypothesis values are used in the test(s) for each subpopulation as well as for the entire population.

value	The null hypothesis is that the population ratio equals the specified value for all *t* tests.
valuelist	This list gives the null hypothesis value of the population ratio for each ratio specified on the RATIO subcommand. The number and order of values must correspond to the ratios defined on the RATIO subcommand.

- Commas or spaces must be used to separate the values.

STATISTICS Subcommand

STATISTICS requests various statistics that are associated with the mean, sum, or ratio estimates. If the STATISTICS subcommand is not specified, the standard error is computed for any displayed estimates. If the STATISTICS subcommand is specified, only statistics that are requested are computed.

COUNT	*The number of valid observations in the dataset for each mean, sum, or ratio estimate*.
POPSIZE	*The population size for each mean, sum, or ratio estimate*.
SE	*The standard error for each mean, sum, or ratio estimate*. This output is default output if the STATISTICS subcommand is not specified.
CV	*Coefficient of variation*.
DEFF	*Design effect*.
DEFFSQRT	*Square root of the design effect*.
CIN [(value)]	*Confidence interval*. If the CIN keyword is specified alone, the default 95% confidence interval is computed. Optionally, CIN may be followed by a value in parentheses, where $0 \leq$ value < 100.

SUBPOP Subcommand

SUBPOP specifies subpopulations for which analyses are to be performed.

- The set of subpopulations is defined by specifying a single categorical variable or specifying two or more categorical variables, separated by the BY keyword, whose values are crossed.
- For example, /SUBPOP TABLE = A defines subpopulations based on the levels of variable *A*.
- For example, /SUBPOP TABLE = A BY B defines subpopulations based on crossing the levels of variables *A* and *B*.
- A maximum of 17 variables may be specified.
- Numeric or string variables may be specified.
- All specified variables must be unique.
- Stratification or cluster variables may be specified, but no other plan file variables are allowed on the SUBPOP subcommand.
- Analysis variables may not be specified on the SUBPOP subcommand.
- The BY keyword is used to separate variables.

The DISPLAY keyword specifies the layout of results for subpopulations.

LAYERED *Results for all subpopulations are displayed in the same table*. This is the default.

SEPARATE *Results for different subpopulations are displayed in different tables.*

MISSING Subcommand

MISSING specifies how missing values are handled.

- All design variables must have valid data. Cases with invalid data for any design variable are deleted from the analysis.

The SCOPE keyword specifies which cases are used in the analyses. This specification is applied to analysis variables but not design variables.

ANALYSIS *Each statistic is based on all valid data for the analysis variable(s) used in computing the statistic*. Ratios are computed by using all cases with valid data for both of the specified variables. Statistics for different variables may be based on different sample sizes. This setting is the default.

LISTWISE *Only cases with valid data for all analysis variables are used in computing any statistics*. Statistics for different variables are always based on the same sample size.

The CLASSMISSING keyword specifies whether user-missing values are treated as valid. This specification is applied only to categorical design variables (strata, cluster, and subpopulation variables).

EXCLUDE *Exclude user-missing values among the strata, cluster, and subpopulation variables*. This setting is the default.

INCLUDE *Include user-missing values among the strata, cluster, and subpopulation variables*. Treat user-missing values for these variables as valid data.

CSGLM

CSGLM is available in the Complex Samples option.

Note: Square brackets that are used in the CSGLM syntax chart are required parts of the syntax and are not used to indicate optional elements. Equals signs (=) that are used in the syntax chart are required elements. All subcommands, save the PLAN subcommand, are optional.

```
CSGLM dependent var BY factor list WITH covariate list

Release History

Release 13.0

- Command introduced.

Example

```
CSGLM y BY a b c WITH x
  /PLAN FILE='/survey/myfile.csplan'.
```

Overview

CSGLM performs linear regression analysis, as well as analysis of variance and covariance, for samples that are drawn by complex sampling methods. The procedure estimates variances by taking into account the sample design that is used to select the sample, including equal probability and probability proportional to size (PPS) methods, and with replacement (WR) and without replacement (WOR) sampling procedures. Optionally, CSGLM performs analyses for a subpopulation.

Basic Specification

- The basic specification is a variable list (identifying the dependent variable, the factors, if any, and the covariates, if any) and a PLAN subcommand with the name of a complex sample analysis plan file, which may be generated by the CSPLAN procedure.
- The default model includes the intercept term, main effects for any factors, and any covariates.
- The basic specification displays summary information about the sample design, *R*-square and root mean square error for the model, regression coefficient estimates and *t* tests, and Wald *F* tests for all model effects. Additional subcommands must be used for other results.

Operations

- CSGLM computes linear model estimates for sampling designs that are supported by the CSPLAN and CSSELECT procedures.
- The input dataset must contain the variables to be analyzed and variables that are related to the sampling design.
- The complex sample analysis plan file provides an analysis plan based on the sampling design.

- By default, CSGLM uses a model that includes the intercept term, main effects for any factors, and any covariates.
- Other effects, including interaction and nested effects, may be specified by using the MODEL subcommand.
- The default output for the specified model is summary information about the sample design, *R*-square and root mean square error, regression coefficient estimates and *t* tests, and Wald *F* tests for all effects.
- WEIGHT and SPLIT FILE settings are ignored by the CSGLM procedure.

Syntax Rules

- The dependent variable and PLAN subcommand are required. All other variables and subcommands are optional.
- Multiple CUSTOM and EMMEANS subcommands may be specified; each subcommand is treated independently. All other subcommands may be specified only once.
- The EMMEANS subcommand may be specified without options. All other subcommands must be specified with options.
- Each keyword may be specified only once within a subcommand.
- Subcommand names and keywords must be spelled in full.
- Equals signs (=) that are shown in the syntax chart are required.
- Subcommands may be specified in any order.
- The dependent variable and covariates must be numeric, but factors and the subpopulation variable can be numeric or string variables.
- Across the dependent, factor, and covariate variable lists, a variable may be specified only once.
- Plan file and subpopulation variables may not be specified on the variable list.
- Minimum syntax is a dependent variable and the PLAN subcommand. This specification fits an intercept-only model.

Limitations

- WEIGHT and SPLIT FILE settings are ignored with a warning by the CSGLM procedure.

Examples

```
* Complex Samples General Linear Model.
CSGLM amtspent BY shopfor usecoup
 /PLAN FILE = 'samplesDirectory\grocery.csplan'
 /JOINTPROB FILE = 'samplesDirectory\grocery.sav'
 /MODEL shopfor usecoup shopfor*usecoup
 /INTERCEPT INCLUDE=YES SHOW=YES
 /STATISTICS PARAMETER SE CINTERVAL DEFF
 /PRINT SUMMARY VARIABLEINFO SAMPLEINFO
 /TEST TYPE=F PADJUST=LSD
 /EMMEANS TABLES=shopfor COMPARE CONTRAST=SIMPLE(3)
 /EMMEANS TABLES=usecoup COMPARE CONTRAST=SIMPLE(1)
 /EMMEANS TABLES=shopfor*usecoup
 /MISSING CLASSMISSING=EXCLUDE
```

```
/CRITERIA CILEVEL=95.
```

- The procedure fits a general linear model for the dependent variable *amtspent* using *shopfor* and *usecoup* as factors.
- The complex sampling plan is located in *grocery.csplan*; the file containing the joint inclusion probabilities is *grocery.sav*.
- The model specification calls for a full factorial model with intercept.
- Parameter estimates, their standard errors, 95% confidence intervals, and design effects will be displayed.
- Estimated marginal means are computed for each of the model effects. The third level of *shopfor* is specified as the reference category for contrast comparisons; the first level of *usecoup* is specified as the reference category.
- All other options are set to their default values.

CSGLM Variable List

The variable list specifies the dependent variable, the factors, and the covariates in the model.

- The dependent variable must be the first specification on CSGLM.
- The names of the factors and covariates, if any, follow the dependent variable. Specify any factors following the keyword BY. Specify any covariates following the keyword WITH.
- The dependent variable and covariates must be numeric, but factors can be numeric or string variables.
- Each variable may be specified only once on the variable list.
- Plan file and subpopulation variables may not be specified on the variable list.

PLAN Subcommand

The PLAN subcommand specifies the name of an XML file containing analysis design specifications. This file is written by the CSPLAN procedure.

- The PLAN subcommand is required.

FILE *Specifies the name of an external file.*

JOINTPROB Subcommand

The JOINTPROB subcommand is used to specify the file or dataset containing the first stage joint inclusion probabilities for UNEQUAL_WOR estimation. The CSSELECT procedure writes this file in the same location and with the same name (but different extension) as the plan file. When UNEQUAL_WOR estimation is specified, the CSGLM procedure will use the default location and name of the file unless the JOINTPROB subcommand is used to override them.

FILE *Specifies the name of the file or dataset containing the joint inclusion probabilities.*

MODEL Subcommand

The MODEL subcommand is used to specify the effects to be included in the model. Use the INTERCEPT subcommand to control whether the intercept is included.

- The MODEL subcommand defines the cells in a design. In particular, cells are defined by all of the possible combinations of levels of the factors in the design. The number of cells equals the product of the number of levels of all the factors. A design is balanced if each cell contains the same number of cases. CSGLM can analyze balanced and unbalanced designs.
- The format is a list of effects to be included in the model, separated by spaces or commas.
- If the MODEL subcommand is not specified, CSGLM uses a model that includes the intercept term (unless it is excluded on the INTERCEPT subcommand), main effects for any factors, and any covariates.
- To include a term for the main effect of a factor, enter the name of the factor.
- To include a term for an interaction between factors, use the keyword BY or the asterisk (*) to join the factors that are involved in the interaction. For example, A*B means a two-way interaction effect of A and B, where A and B are factors. A*A is not allowed because factors inside an interaction effect must be distinct.
- To include a term for nesting one effect within another effect, use a pair of parentheses. For example, A(B) means that A is nested within B. When more than one pair of parentheses is present, each pair of parentheses must be enclosed or nested within another pair of parentheses. Thus, A(B)(C) is not valid.
- Multiple nesting is allowed. For example, A(B(C)) means that B is nested within C, and A is nested within B(C).
- Interactions between nested effects are not valid. For example, neither A(C)*B(C) nor A(C)*B(D) is valid.
- To include a covariate term in the design, enter the name of the covariate.
- Covariates can be connected, but not nested, through the * operator to form another covariate effect. Interactions among covariates such as X1*X1 and X1*X2 are valid, but X1(X2) is not.
- Factor and covariate effects can be connected only by the * operator. Suppose A and B are factors, and X1 and X2 are covariates. Examples of valid factor-by-covariate interaction effects are A*X1, A*B*X1, X1*A(B), A*X1*X1, and B*X1*X2.

INTERCEPT Subcommand

The INTERCEPT subcommand controls whether an intercept term is included in the model. This subcommand can also be used to display or suppress the intercept term in output tables.

INCLUDE Keyword

The INCLUDE keyword specifies whether the intercept is included in the model, or the keyword requests the intercept-only model.

YES *The intercept is included in the model.* This setting is the default.

NO *The intercept is not included in the model.* If no factors or covariates are defined, specifying INCLUDE = NO is invalid syntax.

ONLY *The intercept-only model is fit.* If the MODEL subcommand is specified, specifying INCLUDE = ONLY is invalid syntax.

SHOW Keyword

The SHOW keyword specifies whether the intercept is displayed or suppressed in output tables.

YES *The intercept is displayed in output tables.* This setting is the default.

NO *The intercept is not displayed in output tables.* If INCLUDE = NO or ONLY is specified, SHOW = NO is ignored.

Example

```
CSGLM y BY a b c
  /PLAN FILE='/survey/myfile.csplan'
  /INTERCEPT INCLUDE = ONLY.
```

- The preceding syntax defines the model space using factors A, B, and C but fits the intercept-only model.

CUSTOM Subcommand

The CUSTOM subcommand defines custom hypothesis tests by specifying the **L** matrix (contrast coefficients matrix) and the **K** matrix (contrast results matrix) in the general form of the linear hypothesis **LB** = **K**. The vector **B** is the parameter vector in the linear model.

- Multiple CUSTOM subcommands are allowed. Each subcommand is treated independently.
- An optional label may be specified by using the LABEL keyword. The label is a string with a maximum length of 255 characters. Only one label can be specified.
- Either the LMATRIX or KMATRIX keyword, or both, must be specified.

LMATRIX *Contrast coefficients matrix.* This matrix specifies coefficients of contrasts, which can be used for studying the effects in the model. An **L** matrix can be specified by using the LMATRIX keyword.

KMATRIX *Contrast results matrix.* This matrix specifies the results of the linear hypothesis. A **K** matrix can be specified by using the KMATRIX keyword.

- The number of rows in the **L** and **K** matrices must be equal.
- A custom hypothesis test can be formed by specifying an **L** or **K** matrix, or both. If only one matrix is specified, the unspecified matrix uses the defaults described below.

- If KMATRIX is specified but LMATRIX is not specified, the **L** matrix is assumed to be the row vector corresponding to the intercept in the estimable function, provided that INCLUDE = YES or ONLY is specified on the INTERCEPT subcommand. In this case, the **K** matrix can be only a scalar matrix.
- The default **K** matrix is a zero matrix; that is, **LB** = **0** is assumed.
- There are three general formats that can be used on the LMATRIX keyword: (1) Specify a coefficient value for the intercept, followed optionally by an effect name and a list of real numbers. (2) Specify an effect name and a list of real numbers. (3) Specify keyword ALL and a list of real numbers. In all three formats, there can be multiple effect names (or instances of the keyword ALL) and number lists.
- Only valid effects in the default model or on the MODEL subcommand can be specified on the LMATRIX keyword.
- The length of the list of real numbers on the LMATRIX keyword must be equal to the number of parameters (including the redundant parameters) corresponding to the specified effect. For example, if the effect A*B takes up six columns in the design matrix, the list after A*B must contain exactly six numbers.
- When ALL is specified, the length of the list that follows ALL must be equal to the total number of parameters (including the redundant parameters) in the model.
- Effects that are in the model but not specified on the LMATRIX keyword are assumed to have entries of 0 in the corresponding columns of the **L** matrix.
- When an **L** matrix is being defined, a number can be specified as a fraction with a positive denominator. For example, 1/3 and –1/3 are valid, but 1/–3 is invalid.
- A semicolon (;) indicates the end of a row in the **L** matrix.
- The format for the KMATRIX keyword is one or more real numbers. If more than one number is specified, then separate adjacent numbers using a semicolon (;). Each semicolon indicates the end of a row in the **K** matrix. Each number is the hypothesized value for a contrast, which is defined by a row in the **L** matrix.
- For the KMATRIX keyword to be valid, either the LMATRIX keyword, or INCLUDE = YES on the INTERCEPT subcommand, must be specified.

Example

Suppose that factors A and B each have three levels.

```
CSGLM y BY a b
  /PLAN FILE='/survey/myfile.csplan'
  /MODEL a b a*b
  /CUSTOM  LABEL = "Effect A"
     LMATRIX = a 1 0 -1
         a*b  1/3  1/3  1/3
              0    0    0
             -1/3 -1/3 -1/3;
          a 0 1 -1
         a*b  0    0    0
              1/3  1/3  1/3
             -1/3 -1/3 -1/3.
```

- The preceding syntax specifies a test of effect A.

- Because there are three levels in effect A, two independent contrasts can be formed at most; thus, there are two rows in the **L** matrix, separated by a semicolon (;).
- There are three levels each in effects A and B; thus, the interaction effect A*B takes nine columns in the design matrix.
- The first row in the **L** matrix tests the difference between levels 1 and 3 of effect A; the second row tests the difference between levels 2 and 3 of effect A.
- The KMATRIX keyword is not specified, so the null hypothesis value for both tests is 0.

Example

Suppose that factors A and B each have three levels.

```
CSGLM y BY a b
  /PLAN FILE='/survey/myfile.csplan'
  /CUSTOM LABEL = "Effect A"
     LMATRIX = a 1 0 -1; a 1 -1 0
  /CUSTOM LABEL = "Effect B"
     LMATRIX = b 1 0 -1; b 1 -1 0
     KMATRIX = 0; 0.
```

- The preceding syntax specifies tests of effects A and B.
- The MODEL subcommand is not specified, so the default model—which includes the intercept and main effects for A and B—is used.
- There are two CUSTOM subcommands; each subcommand specifies two rows in the **L** matrix.
- The first CUSTOM subcommand does not specify the KMATRIX keyword. By default, this subcommand tests whether the effect of factor A is 0.
- The second CUSTOM subcommand specifies the KMATRIX keyword. This subcommand tests whether the effect of factor B is 0.

EMMEANS Subcommand

The EMMEANS subcommand displays estimated marginal means of the dependent variable in the cells for the specified factors. Note that these means are predicted, not observed, means.

- Multiple EMMEANS subcommands are allowed. Each subcommand is treated independently.
- The EMMEANS subcommand may be specified with no additional keywords. The output for an empty EMMEANS subcommand is the overall estimated marginal mean of the dependent variable, collapsing over any factors, and with any covariates held at their overall means.

TABLES = option

Valid options are factors appearing on the factor list and crossed factors that are constructed of factors on the factor list. Crossed factors can be specified by using an asterisk (*) or the keyword BY. All factors in a crossed factor specification must be unique. If a factor or a crossing of factors is specified on the TABLES keyword, CSGLM collapses over any other factors before computing the estimated marginal means for the dependent variable. If the TABLES keyword is not specified, the overall estimated marginal mean of the dependent variable, collapsing over any factors, is computed.

OTHER = [option]

Specifies the covariate values to use when computing the estimated marginal means. If the OTHER keyword is used, it must be followed by an equals sign and one or more elements enclosed in square brackets. Valid elements are covariates appearing on the CSGLM covariate list, each of which must be followed by a numeric value or the keyword MEAN in parentheses.

If a numeric value is used, the estimated marginal mean will be computed by holding the specified covariate at the supplied value. If the keyword MEAN is used, the estimated marginal mean will be computed by holding the covariate at its overall mean. If a covariate is not specified on the OTHER option, its overall mean will be used in estimated marginal mean calculations.

Any covariate may occur only once on the OTHER keyword.

CONTRAST = type

Specifies the type of contrast that is desired among the levels of the factor that is given on the COMPARE keyword. This keyword creates an **L** matrix such that the columns corresponding to the factor match the contrast that is given. The other columns are adjusted so that the **L** matrix is estimable. Available contrast types and their options are described in a separate table below. The CONTRAST keyword is ignored if the COMPARE keyword is not specified.

COMPARE = factor

Compares levels of a factor specified on the TABLES keyword and displays results for each individual comparison as well as for the overall set of comparisons. If only one factor is specified on TABLES, COMPARE can be specified by itself; otherwise, the factor specification is required. In the latter case, levels of the specified factor are compared for each level of the other factors that are specified on TABLES. The type of comparison that is performed is determined by the CONTRAST keyword. The TABLES keyword must be specified for the COMPARE keyword to be valid.

CONTRAST Keyword

The contrast types that may be specified on the CONTRAST keyword are described below.

The CSGLM procedure sorts levels of the factor in ascending order and defines the highest level as the last level. (If the factor is a string variable, the value of the highest level is locale-dependent.)

SIMPLE (value) *Each level of the factor (except the highest level) is compared to the highest level.* SIMPLE is the default contrast type if the COMPARE keyword is specified.

The SIMPLE keyword may be followed optionally by parentheses containing a value. Put the value inside a pair of quotation marks if the value is formatted (such as date or currency) or if the factor is of string type. If a value is specified, the factor level with that value is used as the omitted reference category. If the specified value does not exist in the data, a warning is issued and the highest level is used.

An example is as follows: `CSGLM y BY a … /EMMEANS TABLES=a COMPARE=a CONTRAST=SIMPLE(1).` The specified contrast compares all levels of factor A (except level 1) to level 1. Simple contrasts are not orthogonal.

DEVIATION (value) *Each level of the factor (except the highest level) is compared to the grand mean.*

The DEVIATION keyword may be followed optionally by parentheses containing a value. Put the value inside a pair of quotation marks if the value is formatted (such as date or currency) or if the factor is of string type. If a value is specified, the factor level with that value is used as the omitted reference category. If the specified value does not exist in the data, a warning is issued and the highest level is used.

An example is as follows: `CSGLM y BY a … /EMMEANS TABLES=a COMPARE=a CONTRAST=DEVIATION(1).` The specified contrast omits level 1 of A. Deviation contrasts are not orthogonal.

DIFFERENCE *Each level of the factor (except the lowest level) is compared to the mean of previous levels.* In a balanced design, difference contrasts are orthogonal.

HELMERT *Each level of the factor (except the highest level) is compared to the mean of subsequent levels.* In a balanced design, Helmert contrasts are orthogonal.

REPEATED *Each level of the factor (except the highest level) is compared to the previous level.* Repeated contrasts are not orthogonal.

POLYNOMIAL (number list) *Polynomial contrasts.* The first degree of freedom contains the linear effect across the levels of the factor, the second contains the quadratic effect, and so on. By default, the levels are assumed to be equally spaced; the default metric is (1 2 . . . k), where k levels are involved.

The POLYNOMIAL keyword may be followed optionally by parentheses containing a number list. Numbers in the list must be separated by spaces or commas. Unequal spacing may be specified by entering a metric consisting of one integer for each level of the factor. Only the relative differences between the terms of the metric matter. Thus, for example, (1 2 4) is the same metric as (2 3 5) or (20 30 50) because, in each instance, the difference between the second and third numbers is twice the difference between the first and second numbers. All numbers in the metric must be unique; thus, (1 1 2) is not valid.

An example is as follows: `CSGLM y BY a … /EMMEANS TABLES=a COMPARE=a CONTRAST=POLYNOMIAL(1 2 4).` Suppose that factor A has three levels. The specified contrast indicates that the three levels of A are actually in the proportion 1:2:4. In a balanced design, polynomial contrasts are orthogonal.

Orthogonal contrasts are particularly useful. In a balanced design, contrasts are orthogonal if the sum of the coefficients in each contrast row is 0 and if, for any pair of contrast rows, the products of corresponding coefficients sum to 0.

CRITERIA Subcommand

The CRITERIA subcommand controls statistical criteria and specifies numerical tolerance for checking singularity.

CILEVEL = value *Confidence interval level for coefficient estimates and estimated marginal means.* Specify a value that is greater than or equal to 0 and less than 100. The default value is 95.

DF = value *Sampling design degrees of freedom to use in computing* p *values for all test statistics.* Specify a positive number. The default value is the difference between the number of primary sampling units and the number of strata in the first stage of sampling.

SINGULAR = value *Tolerance value used to test for singularity.* Specify a positive value. The default value is 10^{-12}.

STATISTICS Subcommand

The STATISTICS subcommand requests various statistics associated with the coefficient estimates.

- There are no default keywords on the STATISTICS subcommand. If this subcommand is not specified, no statistics that are listed below are displayed.

PARAMETER *Coefficient estimates.*

SE *Standard error for each coefficient estimate.*

TTEST t *test for each coefficient estimate.*

CINTERVAL *Confidence interval for each coefficient estimate.*

DEFF *Design effect for each coefficient estimate.*

DEFFSQRT *Square root of the design effect for each coefficient estimate.*

TEST Subcommand

The TEST subcommand specifies the type of test statistic and the method of adjusting the significance level to be used for hypothesis tests that are requested on the MODEL, CUSTOM, and EMMEANS subcommands.

TYPE Keyword

The TYPE keyword indicates the type of test statistic.

F *Wald* F *test.* This is the default test statistic if the TYPE keyword is not specified.

ADJF *Adjusted Wald* F *test.*

CHISQUARE	*Wald chi-square test.*
ADJCHISQUARE	*Adjusted Wald chi-square test.*

PADJUST keyword

The PADJUST keyword indicates the method of adjusting the significance level.

LSD	*Least significant difference.* This method does not control the overall probability of rejecting the hypotheses that some linear contrasts are different from the null hypothesis value(s). This setting is the default.
BONFERRONI	*Bonferroni.* This method adjusts the observed significance level for the fact that multiple contrasts are being tested.
SEQBONFERRONI	*Sequential Bonferroni.* This procedure is a sequentially step-down rejective Bonferroni procedure that is much less conservative in terms of rejecting individual hypotheses but maintains the same overall significance level.
SIDAK	*Sidak.* This method provides tighter bounds than the Bonferroni approach.
SEQSIDAK	*Sequential Sidak.* This procedure is a sequentially rejective step-down rejective Sidak procedure that is much less conservative in terms of rejecting individual hypotheses but maintains the same overall significance level.

DOMAIN Subcommand

The DOMAIN subcommand specifies the subpopulation for which the analysis is to be performed.

- Keyword VARIABLE, followed by an equals sign, a variable, and a value in parentheses, are required. Put the value inside a pair of quotation marks if the value is formatted (such as date or currency) or if the variable is of string type.
- The subpopulation is defined by all cases having the given value on the specified variable.
- Analyses are performed only for the specified subpopulation.
- For example, `DOMAIN VARIABLE = myvar (1)` defines the subpopulation by all cases for which variable *MYVAR* has value 1.
- The specified variable may be numeric or string and must exist at the time that the CSGLM procedure is invoked.
- Stratification or cluster variables may be specified, but no other plan file variables are allowed on the DOMAIN subcommand.
- Analysis variables may not be specified on the DOMAIN subcommand.

MISSING Subcommand

The MISSING subcommand specifies how missing values are handled.

- All design variables, as well as the dependent variable and any covariates, must have valid data. Cases with invalid data for any of these variables are deleted from the analysis.
- The CLASSMISSING keyword specifies whether user-missing values are treated as valid. This specification is applied to categorical design variables (i.e., strata, cluster, and subpopulation variables) and any factors.

EXCLUDE *Exclude user-missing values among the strata, cluster, subpopulation, and factor variables.* This setting is the default.

INCLUDE *Include user-missing values among the strata, cluster, subpopulation, and factor variables.* Treat user-missing values for these variables as valid data.

PRINT Subcommand

The PRINT subcommand is used to display optional output.

- If the PRINT subcommand is not specified, the default output includes sample information, variable and factor information, and model summary statistics.
- If the PRINT subcommand is specified, CSGLM displays output only for those keywords that are specified.

SAMPLEINFO *Sample information table.* Displays summary information about the sample, including the unweighted count and the population size. This output is default output if the PRINT subcommand is not specified.

VARIABLEINFO *Variable information.* Displays summary information about the dependent variable, covariates, and factors. This output is default output if the PRINT subcommand is not specified.

SUMMARY *Model summary statistics.* Displays R^2 and root mean squared error statistics. This output is default output if the PRINT subcommand is not specified.

GEF *General estimable function table.*

LMATRIX *Set of contrast coefficients (L) matrices.*

COVB *Covariance matrix for regression coefficients.*

CORB *Correlation matrix for regression coefficients.*

NONE *No PRINT subcommand output.* None of the PRINT subcommand output is displayed. However, if NONE is specified with one or more other keywords, the other keywords override NONE.

SAVE Subcommand

The SAVE subcommand adds predicted or residual values to the active dataset.

- Specify one or more temporary variables, each variable followed by an optional new name in parentheses.

- The optional names must be unique, valid variable names.
- If new names are not specified, CSGLM uses the default names. If the default names conflict with existing variable names, a suffix is added to the default name to make it unique.

PRED *Saves predicted values.* The default variable name is Predicted.

RESID *Saves residuals.* The default variable name is Residual.

OUTFILE Subcommand

The OUTFILE subcommand saves an SPSS-format data file containing the parameter covariance or correlation matrix with parameter estimates, standard errors, significance values, and sampling design degrees of freedom. It also saves the parameter estimates and the parameter covariance matrix in XML format.

- At least one keyword and a filename are required. Specify the keyword followed by a quoted file specification.
- The COVB and CORB keywords are mutually exclusive, as are the MODEL and PARAMETER keywords.
- The filename must be specified in full. CSGLM does not supply an extension.
- For COVB and CORB, you can specify a previously declared dataset name (DATASET DECLARE command) instead of a file specification.

COVB = 'savfile'|'dataset' *Writes the parameter covariance matrix and other statistics to an SPSS data file.*

CORB = 'savfile'|'dataset' *Writes the parameter correlation matrix and other statistics to an SPSS data file.*

MODEL = 'file' *Writes the parameter estimates and the parameter covariance matrix to an XML file.*

PARAMETER = 'file' *Writes the parameter estimates to an XML file.*

CSLOGISTIC

CSLOGISTIC is available in the Complex Samples option.

Note: Square brackets that are used in the CSLOGISTIC syntax chart are required parts of the syntax and are not used to indicate optional elements. Equals signs (=) that are used in the syntax chart are required elements. All subcommands, save the PLAN subcommand, are optional.

```
CSLOGISTIC dependent var ({LOW   }) BY factor list WITH covariate list
                         {HIGH**}
                         {value }

**Default if the keyword or subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Release History

Release 13.0

- Command introduced.

Example

```
CSLOGISTIC y BY a b c WITH x
  /PLAN FILE='/survey/myfile.csplan'.
```

Overview

CSLOGISTIC performs logistic regression analysis on a binary or multinomial dependent variable using the generalized link function for samples that are drawn by complex sampling methods. The procedure estimates variances by taking into account the sample design that is used to select the sample, including equal probability and probability proportional to size (PPS) methods, and with replacement (WR) and without replacement (WOR) sampling procedures. Optionally, CSLOGISTIC performs analyses for a subpopulation.

Basic Specification

- The basic specification is a variable list (identifying the dependent variable, the factors, if any, and the covariates, if any) and a PLAN subcommand with the name of a complex sample analysis plan file, which may be generated by the CSPLAN procedure.
- The default model includes the intercept term, main effects for any factors, and any covariates.
- The basic specification displays summary information about the sample and all analysis variables, model summary statistics, and Wald *F* tests for all model effects. Additional subcommands must be used for other output.

Operations

- CSLOGISTIC performs logistic regression analysis for sampling designs that are supported by the CSPLAN and CSSELECT procedures.
- The input dataset must contain the variables to be analyzed and variables that are related to the sampling design.
- The complex sample analysis plan file provides an analysis plan based on the sampling design.
- By default, CSLOGISTIC uses a model that includes the intercept term, main effects for any factors, and any covariates.
- Other effects, including interaction and nested effects, may be specified by using the MODEL subcommand.
- The default output for the specified model is summary information about the sample and all analysis variables, model summary statistics, and Wald *F* tests for all model effects.
- WEIGHT and SPLIT FILE settings are ignored by the CSLOGISTIC procedure.

Syntax Rules

- The dependent variable and PLAN subcommand are required. All other variables and subcommands are optional.
- Multiple CUSTOM and ODDSRATIOS subcommands may be specified; each subcommand is treated independently. All other subcommands may be specified only once.
- Empty subcommands are not allowed; all subcommands must be specified with options.
- Each keyword may be specified only once within a subcommand.
- Subcommand names and keywords must be spelled in full.
- Equals signs (=) that are shown in the syntax chart are required.
- Subcommands may be specified in any order.
- The dependent variable, factors, and the subpopulation variable can be numeric or string variables, but covariates must be numeric.
- Across the dependent, factor, and covariate variable lists, a variable may be specified only once.
- Plan file and subpopulation variables may not be specified on the variable list.
- Minimum syntax is a dependent variable and the PLAN subcommand. This specification fits an intercept-only model.

Limitations

- WEIGHT and SPLIT FILE settings are ignored with a warning by the CSLOGISTIC procedure.

Examples

```
* Complex Samples Logistic Regression.
CSLOGISTIC default(LOW) BY ed WITH age employ address income debtinc creddebt othdebt
 /PLAN FILE = 'samplesDirectory\bankloan.csaplan'
 /MODEL ed age employ address income debtinc creddebt othdebt
 /INTERCEPT INCLUDE=YES SHOW=YES
 /STATISTICS PARAMETER EXP SE CINTERVAL DEFF
```

```
/TEST TYPE=F PADJUST=LSD
/ODDSRATIOS FACTOR=[ed(HIGH)]
/ODDSRATIOS COVARIATE=[employ(1)]
/ODDSRATIOS COVARIATE=[debtinc(1)]
/MISSING CLASSMISSING=EXCLUDE
/CRITERIA MXITER=100 MXSTEP=5
 PCONVERGE=[1e-006 RELATIVE] CHKSEP=20
 CILEVEL=95
/PRINT SUMMARY CLASSTABLE VARIABLEINFO SAMPLEINFO .
```

- The procedure fits a logistic regression model for the dependent variable *default* (with the lowest value as the reference category) using *ed* as a factor and *age*, *employ*, *address*, *income*, *debtinc*, *creddebt*, and *othdebt* as covariates.
- The complex sampling analysis plan is contained in the file *bankloan.csaplan*.
- The model specification calls for a main effects model with intercept.
- Parameter estimates, their standard errors, 95% confidence intervals, and exponentiated parameter estimates and their 95% confidence intervals are requested.
- A classification table is requested in addition to the default model output.
- Odds ratios are produced for the factor *ed* and the covariates *employ* and *debtinc*, using the default reference category and change in value, respectively.
- All other options are set to their default values.

CSLOGISTIC Variable List

The variable list specifies the dependent variable and reference category, the factors, and the covariates in the model.

- The dependent variable must be the first specification on `CLOGISTIC`.
- The dependent variable can be numeric or string.
- The `CSLOGISTIC` procedure sorts levels of the dependent variable in ascending order and defines the highest level as the last level. (If the dependent variable is a string variable, the value of the highest level is locale-dependent.) By default, the highest response category is used as the base (or reference) category.
- A custom reference category may be specified in parentheses immediately following the dependent variable.

LOW	*The lowest category is the reference category.*
HIGH	*The highest category is the reference category.* This setting is the default.
value	*User-specified reference category.* The category that corresponds to the specified value is the reference category. Put the value inside a pair of quotation marks if the value is formatted (such as date or time) or if the dependent variable is of string type. Note, however, that this does not work for custom currency formats.

- If a value is specified as the reference category of the dependent variable, but the value does not exist in the data, a warning is issued and the default `HIGH` is used.
- The names of the factors and covariates, if any, follow the dependent variable. Specify any factors following the keyword `BY`. Specify any covariates following the keyword `WITH`.

- Factors can be numeric or string variables, but covariates must be numeric.
- Each variable may be specified only once on the variable list.
- Plan file and subpopulation variables may not be specified on the variable list.

PLAN Subcommand

The PLAN subcommand specifies the name of an XML file containing analysis design specifications. This file is written by the CSPLAN procedure.

- The PLAN subcommand is required.

FILE *Specifies the name of an external file.*

JOINTPROB Subcommand

The JOINTPROB subcommand is used to specify the file or dataset containing the first stage joint inclusion probabilities for UNEQUAL_WOR estimation. The CSSELECT procedure writes this file in the same location and with the same name (but different extension) as the plan file. When UNEQUAL_WOR estimation is specified, the CSLOGISTIC procedure will use the default location and name of the file unless the JOINTPROB subcommand is used to override them.

FILE *Specifies the name of the file or dataset containing the joint inclusion probabilities.*

MODEL Subcommand

The MODEL subcommand is used to specify the effects to be included in the model. Use the INTERCEPT subcommand to control whether the intercept is included.

- The MODEL subcommand defines the cells in a design. In particular, cells are defined by all of the possible combinations of levels of the factors in the design. The number of cells equals the product of the number of levels of all the factors. A design is balanced if each cell contains the same number of cases. CSLOGISTIC can analyze balanced and unbalanced designs.
- The format is a list of effects to be included in the model, separated by spaces or commas.
- If the MODEL subcommand is not specified, CSLOGISTIC uses a model that includes the intercept term (unless it is excluded on the INTERCEPT subcommand), main effects for any factors, and any covariates.
- To include a term for the main effect of a factor, enter the name of the factor.
- To include a term for an interaction between factors, use the keyword BY or the asterisk (*) to join the factors that are involved in the interaction. For example, A*B means a two-way interaction effect of A and B, where A and B are factors. A*A is not allowed because factors that are inside an interaction effect must be distinct.
- To include a term for nesting one effect within another effect, use a pair of parentheses. For example, A(B) means that A is nested within B. When more than one pair of parentheses is present, each pair of parentheses must be enclosed or nested within another pair of parentheses. Thus, A(B)(C) is not valid.

- Multiple nesting is allowed. For example, A(B(C)) means that B is nested within C, and A is nested within B(C).
- Interactions between nested effects are not valid. For example, neither A(C)*B(C) nor A(C)*B(D) is valid.
- To include a covariate term in the design, enter the name of the covariate.
- Covariates can be connected, but not nested, through the * operator to form another covariate effect. Interactions among covariates such as X1*X1 and X1*X2 are valid, but X1(X2) is not.
- Factor and covariate effects can be connected only by the * operator. Suppose A and B are factors, and X1 and X2 are covariates. Examples of valid factor-by-covariate interaction effects are A*X1, A*B*X1, X1*A(B), A*X1*X1, and B*X1*X2.

INTERCEPT Subcommand

The INTERCEPT subcommand controls whether an intercept term is included in the model. This subcommand can also be used to display or suppress the intercept term in output tables.

INCLUDE Keyword

The INCLUDE keyword specifies whether the intercept is included in the model, or the keyword requests the intercept-only model.

YES *The intercept is included in the model.* This setting is the default.

NO *The intercept is not included in the model.* If no factors or covariates are defined, specifying INCLUDE = NO is invalid syntax.

ONLY *The intercept-only model is fit.* If the MODEL subcommand is specified, specifying INCLUDE = ONLY is invalid syntax.

SHOW Keyword

The SHOW keyword specifies whether the intercept is displayed or suppressed in output tables.

YES *The intercept is displayed in output tables.* This setting is the default.

NO *The intercept is not displayed in output tables.* If INCLUDE = NO or ONLY is specified, SHOW = NO is ignored.

Example

```
CSLOGISTIC y BY a b c
  /PLAN FILE='/survey/myfile.csplan'
  /INTERCEPT INCLUDE = ONLY.
```

- The preceding syntax defines the model space using factors A, B, and C but fits the intercept-only model.

CUSTOM Subcommand

The CUSTOM subcommand defines custom hypothesis tests by specifying the **L** matrix (contrast coefficients matrix) and the **K** matrix (contrast results matrix) in the general form of the linear hypothesis **LB** = **K**. The vector **B** is the parameter vector in the linear model.

For a binary dependent variable, CSLOGISTIC models a single logit. In this case, there is one set of parameters associated with the logit.

For a multinomial dependent variable with K levels, CSLOGISTIC models K−1 logits. In this case, there are K−1 sets of parameters, each associated with a different logit. The CUSTOM subcommand allows you to specify an **L** matrix in which the same or different contrast coefficients are used across logits.

- Multiple CUSTOM subcommands are allowed. Each subcommand is treated independently.
- An optional label may be specified by using the LABEL keyword. The label is a string with a maximum length of 255 characters. Only one label can be specified.
- Either the LMATRIX or KMATRIX keyword, or both, must be specified.

LMATRIX	*Contrast coefficients matrix.* This matrix specifies coefficients of contrasts, which can be used for studying the effects in the model. An **L** matrix can be specified by using the LMATRIX keyword.
KMATRIX	*Contrast results matrix.* This matrix specifies the results of the linear hypothesis. A **K** matrix can be specified by using the KMATRIX keyword.

- The number of rows in the **L** and **K** matrices must be equal.
- A custom hypothesis test can be formed by specifying an **L** or **K** matrix, or both. If only one matrix is specified, the unspecified matrix uses the defaults described below.
- If KMATRIX is specified but LMATRIX is not specified, the **L** matrix is assumed to be the row vector corresponding to the intercept in the estimable function, provided that INCLUDE = YES or ONLY is specified on the INTERCEPT subcommand.
- The default **K** matrix is a zero matrix; that is, **LB = 0** is assumed.
- There are three general formats that can be used on the LMATRIX keyword: (1) Specify a coefficient value for the intercept, followed optionally by an effect name and a list of real numbers. (2) Specify an effect name and a list of real numbers. (3) Specify keyword ALL and a list of real numbers. In all three formats, there can be multiple effect names (or instances of the keyword ALL) and number lists.
- Only valid effects in the default model or on the MODEL subcommand can be specified on the LMATRIX keyword.
- The length of the list of real numbers on the LMATRIX keyword must be equal to the number of parameters (including the redundant parameters) corresponding to the specified effect. For example, if the effect A*B takes up six columns in the design matrix, the list after A*B must contain exactly six numbers.
- When ALL is specified, the length of the list that follows ALL must be equal to the total number of parameters (including the redundant parameters) in the model. For a binary dependent variable, the contrast coefficients for the one set of parameters must be listed following the ALL keyword. For a multinomial dependent variable with K levels, the contrast coefficients

for the K−1 sets of parameters must be listed in order following the ALL keyword. That is, first list all parameters (including the redundant parameters) for the first logit, then list all parameters for the second logit, and so forth.

- In general, for a multinomial dependent variable with K levels, each contrast and its associated hypothesized value are generated separately for each of the K−1 logits; that is, any given contrast is generated K−1 times. However, if the LMATRIX ALL keyword is used to define a contrast, then that contrast and its associated hypothesized value are generated once, simultaneously covering all logits.
- Effects that are in the model but not specified on the LMATRIX keyword are assumed to have entries of 0 in the corresponding columns of the **L** matrix.
- When an **L** matrix is defined, a number can be specified as a fraction with a positive denominator. For example, 1/3 and –1/3 are valid, but 1/–3 is invalid.
- A semicolon (;) indicates the end of a row in the **L** matrix.
- The format for the KMATRIX keyword is one or more real numbers. If more than one number is specified, then separate adjacent numbers using a semicolon (;). Each semicolon indicates the end of a row in the **K** matrix. Each number is the hypothesized value for a contrast, which is defined by a row in the **L** matrix.
- For the KMATRIX keyword to be valid, either the LMATRIX keyword, or INCLUDE = YES on the INTERCEPT subcommand, must be specified.

Example

Suppose that dependent variable *Y* is binary, and factors A and B each have three levels.

```
CSLOGISTIC y BY a b
  /PLAN FILE='/survey/myfile.csplan'
  /MODEL a b a*b
  /CUSTOM  LABEL = 'Effect A'
     LMATRIX = a 1 0 -1
       a*b  1/3  1/3  1/3
            0    0    0
           -1/3 -1/3 -1/3;
       a 0 1 -1
       a*b  0    0    0
            1/3  1/3  1/3
           -1/3 -1/3 -1/3.
```

- The preceding syntax specifies a test of effect A.
- Because there are three levels in effect A, two independent contrasts can be formed at most; thus, there are two rows in the **L** matrix, separated by a semicolon (;).
- There are three levels each in effects A and B; thus, the interaction effect A*B takes nine columns in the design matrix.
- The first row in the **L** matrix tests the difference between levels 1 and 3 of effect A; the second row tests the difference between levels 2 and 3 of effect A.
- The KMATRIX keyword is not specified, so the null hypothesis value for both tests is 0.

Example

Suppose that dependent variable *Z* and factor A each have three levels.

```
CSLOGISTIC z BY a
  /PLAN FILE='/survey/myfile.csplan'
  /MODEL a
  /CUSTOM LABEL = 'Effect A'
     LMATRIX = a 1 0 -1;
               a 0 1 -1
```

- The dependent variable *Z* has three categories, so there will be two logits.
- The syntax specifies a model with an intercept and a main effect for factor A and a custom hypothesis test of effect A.
- Because the ALL option is not used on the LMATRIX keyword, the same set of contrast coefficients for the parameters will be used across both logits. That is, the resulting **L** matrix is block diagonal with the same 2-by-4 matrix of coefficients in each block. The equivalent LMATRIX keyword using the ALL option is as follows:

```
LMATRIX = ALL 0 1  0 -1 0 0  0  0;
          ALL 0 0  1 -1 0 0  0  0;
          ALL 0 0  0  0 0 1  0 -1;
          ALL 0 0  0  0 0 0  1 -1
```

Example

Suppose that dependent variable *Z* has three categories, and factors A and B each have three levels.

```
CSLOGISTIC z BY a b
  /PLAN FILE='/survey/myfile.csplan'
  /CUSTOM LABEL = 'Effect A for All Logits'
     LMATRIX = a 1 0 -1; a 0 1 -1
  /CUSTOM LABEL = 'Effect A for 1st Logit, Effect B for 2nd Logit'
     LMATRIX = ALL 0 1 0 -1 0 0 0 0 0 0 0 1 0 -1;
       ALL 0 0 1 -1 0 0 0 0 0 0 0 0 1 -1
     KMATRIX = 0; 0.
```

- The dependent variable *Z* has three categories, so there will be two logits.
- The MODEL subcommand is not specified; thus the default model—which includes the intercept and main effects for A and B—is used.
- The first CUSTOM subcommand tests whether the effect of factor A is 0 across both logits.
- The second CUSTOM subcommand specifies different contrast coefficients for each logit. In particular, the **L** matrix tests the effect of factor A for the first logit and factor B for the second logit. The KMATRIX keyword explicitly states that each linear combination that is formed from the contrast coefficients and the parameter estimates is tested against the value 0.

ODDSRATIOS Subcommand

The ODDSRATIOS subcommand estimates odds ratios for the specified factor(s) or covariate(s). Note that these odds ratios are model-based and are not directly computed by using the observed data.

A separate set of odds ratios is computed for each category of the dependent variable (except the reference category).

If the FACTOR keyword is specified, the odds ratios compare the odds at each category j with the odds at category J, where J is the reference category defined in parentheses following the variable name of the factor. All other factors and covariates are fixed as defined on the CONTROL keyword.

If the COVARIATE keyword is specified, the odds ratios compare the odds at value x with the odds at value x + Δx, where Δx is the change in x defined in parentheses following the variable name of the covariate. To define the value x, specify the covariate and the value on the CONTROL keyword. All other factors and covariates are fixed as defined on the CONTROL keyword.

If a specified factor or covariate interacts with other predictors in the model, the odds ratios depend not only on the change in the specified variable but also on the values of the variables with which it interacts. If a specified covariate interacts with itself in the model (for example, X*X), the odds ratios depend on both the change in the covariate and the value of the covariate. The values of interacting factors and covariates can be customized by using the CONTROL keyword.

The CSLOGISTIC procedure sorts levels of each factor in ascending order and defines the highest level as the last level. (If the factor is a string variable, the value of the highest level is locale-dependent.)

- Multiple ODDSRATIOS subcommands are allowed. Each subcommand is treated independently.
- Either the FACTOR keyword and one or more factors, or the COVARIATE keyword and one or more covariates, but not both, are required. All other keywords are optional.
- The FACTOR, COVARIATE, and CONTROL keywords must be followed by an equals sign and one or more elements enclosed in square brackets.
- If a variable is specified on the FACTOR or COVARIATE keyword and is also specified on the CONTROL keyword, the CONTROL specification for that variable is ignored when the variable's odds ratios are computed. Thus, FACTOR = [A B] CONTROL = [A(1) B(2)] estimates odds ratios for factor A holding factor B at level 2 and for factor B holding factor A at level 1.

FACTOR = [option]

Valid options are one or more factors appearing on the factor list. Optionally, each factor may be followed by parentheses containing the level to use as the reference category when computing odds ratios. Keyword LOW or HIGH, or a value, may be specified. Put the value inside a pair of quotes if the value is formatted (such as date or currency) or if the factor is of string type. By default, the highest category is used as the reference category.

If a value is specified but the value does not exist in the data, a warning is issued and the default HIGH is used.

Any factor may occur only once on the FACTOR keyword.

COVARIATE = [option]

Valid options are one or more covariates appearing on the covariate list. Optionally, each covariate may be followed by parentheses containing one or more nonzero numbers giving unit(s) of change to use for covariates when computing odds ratios. Odds ratios are estimated for each distinct value. The default value is 1.

Any covariate may occur only once on the COVARIATE keyword.

CONTROL= [option]

Specifies the factor and/or covariate values to use when computing odds ratios. Factors must appear on the factor list, and covariates must appear on the covariate list, of the CSLOGISTIC command.

Factors must be followed by the keyword LOW or HIGH, or a value, in parentheses. Put the value inside a pair of quotation marks if the value is formatted (such as date or currency) or if the factor is of string type. If keyword LOW or HIGH is used, each odds ratio is computed by holding the factor at its lowest or highest level, respectively. If a value is used, each odds ratio is computed by holding the specified factor at the supplied value. If a factor is not specified on the CONTROL option, its highest category is used in odds ratio calculations.

If a factor value is specified but the value does not exist in the data, a warning is issued and the default HIGH is used.

Covariates must be followed by the keyword MEAN or a number in parentheses. If the keyword MEAN is used, each odds ratio is computed by holding the covariate at its overall mean. If a number is used, each odds ratio is computed by holding the specified covariate at the supplied value. If a covariate is not specified on the CONTROL option, its overall mean is used in odds ratio calculations.

Any factor or covariate may occur only once on the CONTROL keyword.

Example

Suppose that dependent variable *Y* is binary; factor A has two levels; and factor B has three levels coded 1, 2, and 3.

```
CSLOGISTIC y BY a b WITH x
  /PLAN FILE='/survey/myfile.csplan'
  /MODEL a b a*b x
  /ODDSRATIOS FACTOR=[a] CONTROL=[b(1)]
  /ODDSRATIOS FACTOR=[a] CONTROL=[b(2)]
  /ODDSRATIOS FACTOR=[a] CONTROL=[b(3)].
```

- The default reference category (the highest category) is used for the dependent variable.
- The model includes the intercept, main effects for factors A and B, the A*B interaction effect, and the covariate X.
- Odds ratios are requested for factor A. Assuming the A*B interaction effect is significant, the odds ratio for factor A will differ across levels of factor B. The specified syntax requests three odds ratios for factor A; each odds ratio is computed at a different level of factor B.

Example

```
CSLOGISTIC y BY a b c WITH x
  /PLAN FILE='/survey/myfile.csplan'
  /MODEL a b c x
  /ODDSRATIOS COVARIATE=[x(1 3 5)].
```

- The preceding syntax will compute three odds ratios for covariate X.
- The parenthesized list following variable X provides the unit of change values to use when computing odds ratios. Odds ratios will be computed for X increasing by 1, 3, and 5 units.

CRITERIA Subcommand

The CRITERIA subcommand offers controls on the iterative algorithm that is used for estimation, and the subcommand specifies numerical tolerance for checking singularity.

CHKSEP = value *Starting iteration for checking complete separation.* Specify a non-negative integer. This criterion is not used if the value is 0. The default value is 20.

CILEVEL = value *Confidence interval level for coefficient estimates, exponentiated coefficient estimates, and odds ratio estimates.* Specify a value that is greater than or equal to 0 and less than 100. The default value is 95.

DF = value *Sampling design degrees of freedom to use in computing* p *values for all test statistics.* Specify a positive number. The default value is the difference between the number of primary sampling units and the number of strata in the first stage of sampling.

LCONVERGE = [option] *Log-likelihood function convergence criterion.* Convergence is assumed if the absolute or relative change in the log-likelihood function is less than the given value. This criterion is not used if the value is 0. Specify square brackets containing a non-negative number followed optionally by keyword ABSOLUTE or RELATIVE, which indicates the type of change. The default value is 0, and the default type is RELATIVE.

MXITER = value *Maximum number of iterations.* Specify a non-negative integer. The default value is 100.

MXSTEP = value *Maximum step-halving allowed.* Specify a positive integer. The default value is 5.

PCONVERGE = [option] *Parameter estimates convergence criterion.* Convergence is assumed if the absolute or relative change in the parameter estimates is less than the given value. This criterion is not used if the value is 0. Specify square brackets containing a non-negative number followed optionally by keyword ABSOLUTE or RELATIVE, which indicates the type of change. The default value is 10^{-6}, and the default type is RELATIVE.

SINGULAR = value *Tolerance value used to test for singularity.* Specify a positive value. The default value is 10^{-12}.

STATISTICS Subcommand

The STATISTICS subcommand requests various statistics that are associated with the coefficient estimates.

- There are no default keywords on the STATISTICS subcommand. If this subcommand is not specified, no statistics that are listed below are displayed.

PARAMETER *Coefficient estimates.*

EXP *The exponentiated coefficient estimates.*

SE *Standard error for each coefficient estimate.*

TTEST t *test for each coefficient estimate.*

CINTERVAL *Confidence interval for each coefficient estimate and/or exponentiated coefficient estimate.*

DEFFSQRT *Square root of the design effect for each coefficient estimate.*

DEFF *Design effect for each coefficient estimate.*

TEST Subcommand

The TEST subcommand specifies the type of test statistic and the method of adjusting the significance level to be used for hypothesis tests that are requested on the MODEL and CUSTOM subcommands.

TYPE Keyword

The TYPE keyword indicates the type of test statistic.

F	*Wald* F *test.* This is the default test statistic if the TYPE keyword is not specified.
ADJF	*Adjusted Wald* F *test.*
CHISQUARE	*Wald chi-square test.*
ADJCHISQUARE	*Adjusted Wald chi-square test.*

PADJUST Keyword

The PADJUST keyword indicates the method of adjusting the significance level.

LSD	*Least significant difference.* This method does not control the overall probability of rejecting the hypotheses that some linear contrasts are different from the null hypothesis value(s). This setting is the default.
BONFERRONI	*Bonferroni.* This method adjusts the observed significance level for the fact that multiple contrasts are being tested.
SEQBONFERRONI	*Sequential Bonferroni.* This procedure is a sequentially step-down rejective Bonferroni procedure that is much less conservative in terms of rejecting individual hypotheses but maintains the same overall significance level.
SIDAK	*Sidak.* This method provides tighter bounds than the Bonferroni approach.
SEQSIDAK	*Sequential Sidak.* This procedure is a sequentially rejective step-down rejective Sidak procedure that is much less conservative in terms of rejecting individual hypotheses but maintains the same overall significance level.

DOMAIN Subcommand

The DOMAIN subcommand specifies the subpopulation for which the analysis is to be performed.

- Keyword VARIABLE, followed by an equals sign, a variable, and a value in parentheses, are required. Put the value inside a pair of quotation marks if the value is formatted (such as date or currency) or if the factor is of string type.
- The subpopulation is defined by all cases having the given value on the specified variable.
- Analyses are performed only for the specified subpopulation.
- For example, `DOMAIN VARIABLE = myvar (1)` defines the subpopulation by all cases for which variable *MYVAR* has value 1.
- The specified variable may be numeric or string and must exist at the time that the CSLOGISTIC procedure is invoked.

- Stratification or cluster variables may be specified, but no other plan file variables are allowed on the DOMAIN subcommand.
- Analysis variables may not be specified on the DOMAIN subcommand.

MISSING Subcommand

The MISSING subcommand specifies how missing values are handled.

- All design variables, as well as the dependent variable and any covariates, must have valid data. Cases with invalid data for any of these variables are deleted from the analysis.
- The CLASSMISSING keyword specifies whether user-missing values are treated as valid. This specification is applied to categorical design variables (i.e., strata, cluster, and subpopulation variables), the dependent variable, and any factors.

EXCLUDE *Exclude user-missing values among the strata, cluster, subpopulation, and factor variables.* This setting is the default.

INCLUDE *Include user-missing values among the strata, cluster, subpopulation, and factor variables.* Treat user-missing values for these variables as valid data.

PRINT Subcommand

The PRINT subcommand is used to display optional output.

- If the PRINT subcommand is not specified, the default output includes sample information, variable and factor information, and model summary statistics.
- If the PRINT subcommand is specified, CSLOGISTIC displays output only for those keywords that are specified.

SAMPLEINFO *Sample information table.* Displays summary information about the sample, including the unweighted count and the population size. This output is default output if the PRINT subcommand is not specified.

VARIABLEINFO *Variable information.* Displays summary information about the dependent variable, covariates, and factors. This output is default output if the PRINT subcommand is not specified.

SUMMARY *Model summary statistics.* Displays pseudo-R^2 statistics. This output is default output if the PRINT subcommand is not specified.

HISTORY(n) *Iteration history.* Displays coefficient estimates and statistics at every *n*th iteration beginning with the zeroth iteration (the initial estimates). The default is to print every iteration (n = 1). The last iteration is always printed if HISTORY is specified, regardless of the value of *n*.

GEF *General estimable function table.*

LMATRIX *Set of contrast coefficients (L) matrices.*

COVB *Covariance matrix for regression coefficients.*

CORB *Correlation matrix for regression coefficients.*

CLASSTABLE *Classification table.* Displays frequencies of observed versus predicted response categories.

NONE *No PRINT subcommand output.* None of the PRINT subcommand output is displayed. However, if NONE is specified with one or more other keywords, the other keywords override NONE.

SAVE Subcommand

The SAVE subcommand writes optional model variables to the active dataset.

- Specify one or more temporary variables, each variable followed by an optional new name in parentheses.
- The optional names must be unique, valid variable names.
- If new names are not specified, CSLOGISTIC generates a name using the temporary variable name with a suffix.

PREDPROB *Predicted probability.* The user-specified or default name is treated as the rootname, and a suffix is added to get new unique variables names. The rootname can be followed by a colon and a positive integer giving the number of predicted probabilities to save. The predicted probabilities of the first *n* response categories are saved. One predicted probability variable can be saved for each category of the dependent variable. The default rootname is PredictedProbability. The default *n* of predicted probabilities to save is 25. To specify *n* without a rootname, enter a colon before the number.

PREDVAL *Predicted value.* The class or value that is predicted by the model. The optional variable name must be unique. If the default name is used and it conflicts with existing variable names, a suffix is added to the default name to make it unique. The default variable name is PredictedValue.

OUTFILE Subcommand

The OUTFILE subcommand saves an SPSS-format data file containing the parameter covariance or correlation matrix with parameter estimates, standard errors, significance values, and sampling design degrees of freedom. It also saves the parameter estimates and the parameter covariance matrix in XML format.

- At least one keyword and a file specification are required. The file specification should be enclosed in quotes.
- The COVB and CORB keywords are mutually exclusive, as are the MODEL and PARAMETER keywords.
- The filename must be specified in full. CSLOGISTIC does not supply an extension.
- For COVB and CORB, you can specify a previously declared dataset name (DATASET DECLARE command) instead of a file specification.

COVB = 'savfile'|'dataset' *Writes the parameter covariance matrix and other statistics to an SPSS data file.*

CORB = 'savfile'|'dataset' *Writes the parameter correlation matrix and other statistics to an SPSS data file.*

MODEL = 'file' *Writes the parameter estimates and the parameter covariance matrix to an XML file.*

PARAMETER = 'file' *Writes the parameter estimates to an XML file.*

CSORDINAL

CSORDINAL is available in the Complex Samples option.

Note: Square brackets that are used in the CSORDINAL syntax chart are required parts of the syntax and are not used to indicate optional elements. Equals signs (=) that are used in the syntax chart are required elements. Except for the PLAN subcommand, all subcommands are optional.

```
CSORDINAL dependent varname ({ASCENDING**}) BY factor list
                            {DESCENDING }
          WITH covariate list

** Default if the subcommand or keyword is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Release History

Release 15.0

- Command introduced.

Example

```
CSORDINAL y BY a b c WITH x
  /PLAN FILE='/survey/myfile.csplan'.
```

Overview

CSORDINAL performs regression analysis on a binary or ordinal polytomous dependent variable using the selected cumulative link function for samples drawn by complex sampling methods. The procedure estimates variances by taking into account the sample design used to select the sample, including equal probability and probability proportional to size (PPS) methods and with replacement (WR) and without replacement (WOR) sampling procedures. Optionally, CSORDINAL performs analyses for a subpopulation.

Basic Specification

- The basic specification is a variable list identifying the dependent variable, the factors (if any), and the covariates (if any) and a PLAN subcommand with the name of a complex sample analysis plan file, which may be generated by the CSPLAN procedure.
- The default model includes threshold parameters, main effects for any factors, and any covariates.

- The basic specification displays summary information about the sample and all analysis variables, model summary statistics, and Wald *F* tests for all model effects. Additional subcommands must be used for other output.

Syntax Rules

- The dependent variable and PLAN subcommand are required. All other variables and subcommands are optional.
- Multiple CUSTOM and ODDSRATIOS subcommands may be specified; each is treated independently. All other subcommands may be specified only once.
- Empty subcommands are not allowed; all subcommands must be specified with options.
- Each keyword may be specified only once within a subcommand.
- Subcommand names and keywords must be spelled in full.
- Equals signs (=) shown in the syntax chart are required.
- Square brackets shown in the syntax chart are required parts of the syntax and are not used to indicate optional elements. (See the ODDSRATIOS and CRITERIA subcommands.)
- Subcommands may be specified in any order.
- The dependent variable, factors, and the subpopulation variable can be numeric or string variables, but covariates must be numeric.
- Across the dependent, factor, and covariate variable lists, a variable may be specified only once.
- Plan file and subpopulation variables may not be specified on the variable list.
- Minimum syntax is a dependent variable and the PLAN subcommand. This specification fits a thresholds-only model.

Operations

- CSORDINAL performs ordinal regression analysis for sampling designs supported by the CSPLAN and CSSELECT procedures.
- The input data set must contain the variables to be analyzed and variables related to the sampling design.
- The complex sample analysis plan file provides an analysis plan based on the sampling design.
- By default, CSORDINAL uses a model that includes thresholds, main effects for any factors, and any covariates.
- Other effects, including interaction and nested effects, may be specified using the MODEL subcommand.
- The default output for the specified model is summary information about the sample and all analysis variables, model summary statistics, and Wald *F* tests for all model effects.
- WEIGHT and SPLIT FILE settings are ignored by the CSORDINAL procedure.

Limitations

- WEIGHT and SPLIT FILE settings are ignored with a warning by the CSORDINAL procedure.

Examples

```
* Complex Samples Ordinal Regression.
CSORDINAL  opinion_gastax (ASCENDING) BY agecat gender votelast drivefreq
 /PLAN FILE = 'samplesDirectory\poll.csplan'
 /JOINTPROB FILE = 'samplesDirectory\poll_jointprob.sav'
 /LINK FUNCTION=LOGIT
 /MODEL agecat gender votelast drivefreq
 /STATISTICS PARAMETER EXP SE CINTERVAL DEFF
 /NONPARALLEL TEST PARAMETER
 /TEST TYPE=ADJF PADJUST=SEQSIDAK
 /ODDSRATIOS FACTOR=[agecat(HIGH)]
 /ODDSRATIOS FACTOR=[drivefreq(3)]
 /MISSING CLASSMISSING=EXCLUDE
 /CRITERIA MXITER=100 MXSTEP=5
 PCONVERGE=[1e-006 RELATIVE] LCONVERGE=[0]
 METHOD=NEWTON CHKSEP=20
 CILEVEL=95
 /PRINT SUMMARY CLASSTABLE VARIABLEINFO SAMPLEINFO.
```

- The procedure builds a model for *opinion_gastax* using *agecat*, *gender*, *votelast*, and *drivefreq* as factors.
- The complex sampling plan is located in *poll.csplan*, and the joint inclusion probabilities are in *poll_jointprob.sav*.
- The model specifically calls for a main-effects model.
- Parameter estimates, their standard errors, 95% confidence intervals, and design effects are requested, along with exponentiated parameter estimates and their 95% confidence intervals.
- The test of parallel lines is requested, and the parameter estimates for the generalized cumulative model will be displayed.
- For all appropriate tests, the adjusted Wald *F* statistic will be computed, and *p* values for multiple comparisons will be adjusted according to the sequential Sidak method.
- Cumulative odds ratios are requested for *agecat*, with the highest level as the reference category, and *drivefreq*, with the third level as the reference category.
- A classification table is requested in addition to the default model output.
- All other options are set to their default values.

Variable List

The variable list specifies the dependent variable with the categories order, the factors, and the covariates in the model.

- The dependent variable must be the first specification on `CSORDINAL`.
- The dependent variable can be numeric or string.
- The `CSORDINAL` procedure sorts levels of the dependent variable in ascending or descending order. (If the dependent variable is a string variable, then the order is locale-dependent.)

- Sorting order for the values of the dependent variable may be specified in parentheses immediately following the dependent variable.

ASCENDING *Sort dependent variable values in ascending order.* This is the default setting.

DESCENDING *Sort dependent variable values in descending order.*

- The names of the factors and covariates, if any, follow the dependent variable. Specify any factors following the keyword BY. Specify any covariates following the keyword WITH.
- Factors can be numeric or string variables, but covariates must be numeric.
- Each variable may be specified only once on the variable list.
- Plan file and subpopulation variables may not be specified on the variable list.

PLAN Subcommand

The PLAN subcommand specifies the name of an XML file containing analysis design specifications. This file is written by the CSPLAN procedure.

- The PLAN subcommand is required.

'FILE' *Specifies the name of an external file.*

JOINTPROB Subcommand

The JOINTPROB subcommand is used to specify the file containing the first stage joint inclusion probabilities for UNEQUAL_WOR estimation. The CSSELECT procedure writes this file in the same location and with the same name (but different extension) as the plan file. When UNEQUAL_WOR estimation is specified, the CSORDINAL procedure will use the default location and name of the file unless the JOINTPROB subcommand is used to override them.

'FILE' | 'dataset'

The name of the joint inclusion probabilities file. It can be an external file or an open dataset.

MODEL Subcommand

The MODEL subcommand is used to specify the effects to be included in the model. Threshold parameters are included automatically. Their number is one less then the number of categories of the dependent variable found in the data.

- Specify a list of terms to be included in the model, separated by spaces or commas.
- If the MODEL subcommand is not specified, CSORDINAL uses a model that includes threshold parameters, main effects for any factors, and any covariates in the order specified on the variable list.
- To include a term for the main effect of a factor, enter the name of the factor.

- To include a term for an interaction among factors, use the keyword BY or the asterisk (*) to join the factors involved in the interaction. For example, A*B means a two-way interaction effect of A and B, where A and B are factors. A*A is not allowed because factors inside an interaction effect must be distinct.
- To include a term for nesting one factor within another, use a pair of parentheses. For example, A(B) means that A is nested within B. A(A) is not allowed because factors inside a nested effect must be distinct.
- Multiple nesting is allowed. For example, A(B(C)) means that B is nested within C, and A is nested within B(C). When more than one pair of parentheses is present, each pair of parentheses must be enclosed or nested within another pair of parentheses. Thus, A(B)(C) is not valid.
- Nesting within an interaction effect is valid. For example, A(B*C) means that A is nested within B*C.
- Interactions among nested effects are allowed. The correct syntax is the interaction followed by the common nested effect inside the parentheses. For example, interaction between A and B within levels of C should be specified as A*B(C) instead of A(C)*B(C).
- To include a covariate term in the design, enter the name of the covariate.
- Covariates can be connected, but not nested, through the * operator or using the keyword BY to form another covariate effect. Interactions among covariates such as X1*X1 and X1*X2 are valid, but X1(X2) is not.
- Factor and covariate effects can be connected in various ways except that no effects can be nested within a covariate effect. Suppose A and B are factors and X1 and X2 are covariates. Examples of valid combinations of factor and covariate effects are A*X1, A*B*X1, X1(A), X1(A*B), X1*A(B), X1*X2(A*B), and A*B*X1*X2.

LINK Subcommand

The LINK subcommand offers the choice of a cumulative link function to specify the model.

- The keyword FUNCTION, followed by an equals sign, and a link function keyword are required.
- If the subcommand is not specified, LOGIT is the default cumulative link function.
- Only a single cumulative link function can be specified.

CAUCHIT	*Cauchit function.* $f(x)=\tan(\pi(x-0.5))$
CLOGLOG	*Complementary log-log function.* $f(x)=\log(-\log(1-x)$
LOGIT	*Logit function.* $f(x)=\log(x / (1-x))$. This is the default link function.
NLOGLOG	*Negative log-log function.* $f(x)=-\log(-\log(x))$
PROBIT	*Probit function.* $f(x)=\Phi^{-1}(x)$, where Φ^{-1} is the inverse standard normal cumulative distribution function.

CUSTOM Subcommand

The CUSTOM subcommand defines custom hypothesis tests by specifying the **L** matrix (contrast coefficients matrix) and the **K** matrix (contrast results matrix) in the general form of the linear hypothesis **LB** = **K**. The vector **B** is the parameter vector in the cumulative link model.

For a binary dependent variable, CSORDINAL models a single threshold parameter and a set of regression parameters. For a polytomous ordinal dependent variable with *K* levels, CSORDINAL models a threshold parameter for each category except the last and a single set of regression parameters for all response categories. The CUSTOM subcommand allows you to specify an **L** matrix with contrast coefficients for all thresholds and regression parameters.

- Multiple CUSTOM subcommands are allowed. Each is treated independently.
- An optional label may be specified using the LABEL keyword. The label is a string with a maximum length of 255 characters. Only one label can be specified.
- The **L** matrix is the contrast coefficients matrix. This matrix specifies coefficients of contrasts, which can be used for studying the effects in the model. An **L** matrix must always be specified using the LMATRIX keyword.
- The **K** matrix is the contrast results matrix. This matrix specifies the results of the linear hypothesis. A **K** matrix can be specified using the KMATRIX keyword.
- The number of rows in the **L** and **K** matrices must be equal.
- The default **K** matrix is a zero matrix; that is, **LB** = **0** is assumed.
- There are three general formats that can be used on the LMATRIX keyword: (1) Specify coefficient values for thresholds, followed optionally by an effect name and a list of real numbers. (2) Specify an effect name and a list of real numbers. (3) Specify the keyword ALL and a list of real numbers. In all three formats, there can be multiple effect names (or instances of the keyword ALL) and number lists.
- When specifying threshold coeffients in the first or the third general format, a complete list of *K*−1 coefficient values must be given in the increasing threshold order.
- Only valid effects in the default model or on the MODEL subcommand can be specified on the LMATRIX keyword.
- The length of the list of real numbers on the LMATRIX keyword must be equal to the number of parameters (including the redundant ones) corresponding to the specified effect. For example, if the effect A*B takes up six columns in the design matrix, then the list after A*B must contain exactly six numbers.
- When ALL is specified, the length of the list that follows ALL must be equal to the total number of parameters (including the redundant ones) in the model. For a binary dependent variable, the contrast coefficients for the single threshold and all regression parameters must be listed following the ALL keyword. For a polytomous dependent variable with *K* levels, the contrast coefficients for the *K*−1 thresholds and all regression parameters must be listed in order following the ALL keyword.
- Effects that are in the model but not specified on the LMATRIX keyword are assumed to have entries of 0 in the corresponding columns of the **L** matrix.
- When defining an **L** matrix, a number can be specified as a fraction with a positive denominator—for example, 1/3 and –1/3 are valid, but 1/–3 is invalid.

- A semicolon (;) indicates the end of a row in the **L** matrix.
- The format for the KMATRIX keyword is one or more real numbers. If more than one number is specified, then separate adjacent numbers using a semicolon (;). Each semicolon indicates the end of a row in the **K** matrix. Each number is the hypothesized value for a contrast, which is defined by a row in the **L** matrix.
- If rows of the **L** matrix are not independent, a submatrix of **L** with independent rows is used for testing. Tested rows are indicated when the **K** matrix is not a zero matrix.

Example

Suppose that factors A and B each have three levels.

```
CSORDINAL y BY a b
  /PLAN FILE='/survey/myfile.csplan'
  /MODEL a b a*b
  /CUSTOM  LABEL = 'Effect A'
   LMATRIX = a 1 0 -1
             a*b  1/3  1/3  1/3
                    0    0    0
                 -1/3 -1/3 -1/3;
             a 0 1 -1
             a*b    0    0    0
                  1/3  1/3  1/3
                 -1/3 -1/3 -1/3.
```

- The preceding syntax specifies a test of effect A.
- Because there are three levels in effect A, at most two independent contrasts can be formed; thus, there are two rows in the **L** matrix, separated by a semicolon (;).
- There are three levels each in effects A and B; thus, the interaction effect A*B takes nine columns in the design matrix.
- The first row in the **L** matrix tests the difference between levels 1 and 3 of effect A; the second row tests the difference between levels 2 and 3 of effect A.
- The KMATRIX keyword is not specified, so the null hypothesis value for both tests is 0.

Example

Suppose that dependent variable Z and factor A each have three levels.

```
CSORDINAL z BY a
  /PLAN FILE='/survey/myfile.csplan'
  /MODEL a
  /CUSTOM  LABEL = 'Effect A'
   LMATRIX = a 1 0 -1;
             a 0 1 -1
   KMATRIX = 1; 1.
```

- The dependent variable Z has three categories, so there will be two thresholds.
- The syntax specifies a model with thresholds and a main effect for factor A, and a custom hypothesis test of effect A.

- Because the ALL option is not used on the LMATRIX keyword, threshold coefficients are set to zero. The equivalent LMATRIX keyword using the ALL option follows.

```
LMATRIX = ALL 0 0  1  0 -1;
          ALL 0 0  0  1 -1
```

- The KMATRIX keyword is specified and the hypothesis that the difference between levels 1 and 3 and levels 2 and 3 of effect A are both equal to 1 is tested.

ODDSRATIOS Subcommand

The ODDSRATIOS subcommand estimates cumulative odds ratios for the specified factor(s) or covariate(s). The subcommand is available only for LOGIT link. For other link functions, the subcommand is ignored and a warning is issued. Note that these cumulative odds ratios are model-based and are not directly computed using the observed data.

A single cumulative odds ratio is computed for all categories of the dependent variable except the last; the proportional odds model postulates that they are all equal.

If the FACTOR keyword is specified, the cumulative odds ratios compare the cumulative odds at each factor category j with the cumulative odds at category J, where J is the reference category defined in parentheses following the variable name of the factor. All other factors and covariates are fixed as defined on the CONTROL keyword.

If the COVARIATE keyword is specified, the cumulative odds ratios compare the cumulative odds at value x with the cumulative odds at value $x + \Delta x$, where Δx is the change in x defined in parentheses following the variable name of the covariate. To define the value x, specify the covariate and the value on the CONTROL keyword. The value of all other factors and covariates are fixed as defined on the CONTROL keyword also.

If a specified factor or covariate interacts with other predictors in the model, then the cumulative odds ratios depend not only on the change in the specified variable but also on the values of the variables with which it interacts. If a specified covariate interacts with itself in the model (for example, X*X), then the cumulative odds ratios depend on both the change in the covariate and the value of the covariate. The values of interacting factors and covariates can be customized using the CONTROL keyword.

The CSORDINAL procedure sorts levels of each factor in ascending order and defines the highest level as the last level. (If the factor is a string variable, then the value of the highest level is locale-dependent.)

- Multiple ODDSRATIOS subcommands are allowed. Each is treated independently.
- Either the FACTOR keyword and one or more factors, or the COVARIATE keyword and one or more covariates, but not both, are required. All other keywords are optional.

- The FACTOR, COVARIATE, and CONTROL keywords must be followed by an equals sign and one or more elements enclosed in square brackets.
- If a variable is specified on the FACTOR keyword and is also specified on the CONTROL keyword, then the CONTROL specification for that variable is ignored when the variable's odds ratios are computed. Thus, FACTOR = [A B] CONTROL = [A(1) B(2)] estimates odds ratios for factor A holding factor B at level 2, and for factor B holding factor A at level 1.

FACTOR = [option]

Valid options are one or more factors appearing on the factor list. Optionally, each factor may be followed by parentheses containing the level to use as the reference category when computing cumulative odds ratios. The keyword LOW or HIGH, or a value, may be specified. Put the value inside a pair of quotes if the value is formatted (such as date or currency) or if the factor is of string type. By default, the highest category is used as the reference category.

If a value is specified but the value does not exist in the data, then a warning is issued and the default HIGH is used.

Any factor may occur only once on the FACTOR keyword.

COVARIATE = [option]

Valid options are one or more covariates appearing on the covariate list. Optionally, each covariate may be followed by parentheses containing one or more nonzero numbers giving unit(s) of change to use for covariates when computing cumulative odds ratios. Cumulative odds ratios are estimated for each distinct value. The default value is 1.

Any covariate may occur only once on the COVARIATE keyword.

CONTROL = [option]

Specifies the factor and/or covariate values to use when computing cumulative odds ratios. Factors must appear on the factor list, and covariates on the covariate list, of the CSORDINAL command.

Factors must be followed by the keyword LOW or HIGH, or a value, in parentheses. Put the value inside a pair of quotes if the value is formatted (such as date or currency) or if the factor is of string type. If keyword LOW or HIGH is used, then each cumulative odds ratio is computed by holding the factor at its lowest or highest level, respectively. If a value is used, then each cumulative odds ratio is computed by holding the specified factor at the supplied value. If a factor is not specified on the CONTROL option, then its highest category is used in cumulative odds ratio calculations.

If a factor value is specified but the value does not exist in the data, then a warning is issued and the default HIGH is used.

Covariates must be followed by keyword MEAN or a number in parentheses. If keyword MEAN is used, then each cumulative odds ratio is computed by holding the covariate at its overall mean. If a number is used, then each cumulative odds ratio is computed by holding the specified covariate at the supplied value. If a covariate is not specified on the CONTROL option, then its overall mean is used in cumulative odds ratio calculations.

Any factor or covariate may occur only once on the CONTROL keyword.

Example

Suppose that dependent variable Y has three levels; factor A has two levels; and factor B has three levels coded 1, 2, and 3.

```
CSORDINAL y BY a b WITH x
```

```
  /PLAN FILE='/survey/myfile.csplan'
  /MODEL a b a*b x
  /ODDSRATIOS FACTOR=[a] CONTROL=[b(1)]
  /ODDSRATIOS FACTOR=[a] CONTROL=[b(2)]
  /ODDSRATIOS FACTOR=[a] CONTROL=[b(3)].
```

- The default LOGIT cumulative link function is used and the cumulative odds ratios are computed. They are equal across all response levels by the model definition.
- The model includes two thresholds, main effects for factors A and B, the A*B interaction effect, and the covariate X.
- Cumulative odds ratios are requested for factor A. Assuming the A*B interaction effect is significant, the cumulative odds ratio for factor A will differ across levels of factor B. The specified syntax requests three cumulative odds ratios for factor A; each is computed at a different level of factor B.

Example

```
CSORDINAL z BY a b c WITH x y
  /PLAN FILE='/survey/myfile.csplan'
  /MODEL a b c x*y
  /ODDSRATIOS COVARIATE=[x(1 3 5)] CONTROL=[y(1)].
```

- The preceding syntax will compute three cumulative odds ratios for covariate X.
- The parenthesized list following variable X provides the unit of change values to use when computing cumulative odds ratios. Cumulative odds ratios will be computed for X increasing by 1, 3, and 5 units and holding covariate Y equal to 1.

CRITERIA Subcommand

The CRITERIA subcommand offers controls on the iterative algorithm used for estimation, and specifies numerical tolerance for checking singularity.

CHKSEP = integer

Starting iteration for checking complete and quasi-complete separation. Specify a non-negative integer. This criterion is not used if the value is 0. The default value is 20.

CILEVEL = value

Confidence interval level for coefficient estimates, exponentiated coefficient estimates, and cumulative odds ratio estimates. Specify a value greater than or equal to 0, and less than 100. The default value is 95.

DF = value

Sampling design degrees of freedom to use in computing p values for all test statistics. Specify a positive number. The default value is the difference between the number of primary sampling units and the number of strata in the first stage of sampling.

LCONVERGE = [number (RELATIVE | ABSOLUTE)]

Log-likelihood function convergence criterion. Convergence is assumed if the relative or absolute change in the log-likelihood function is less than the given value. This criterion is not used if the value is 0.

Specify square brackets containing a non-negative number followed optionally by the keyword RELATIVE or ABSOLUTE, which indicates the type of change. The default value is 0; the default type is RELATIVE.

METHOD = FISHER(number) | NEWTON

Model parameters estimation method. The Fisher scoring method is specified by the keyword FISHER, the Newton-Raphson method, by the keyword NEWTON, and a hybrid method is available by specifying FISHER(n). In the hybrid method, *n* is the maximal number of Fisher scoring iterations before switching to the Newton-Raphson method. If convergence is achieved during the Fisher scoring phase of the hybrid method, iterations continue with the Newton-Raphson method.

MXITER = integer

Maximum number of iterations. Specify a non-negative integer. The default value is 100.

MXSTEP = integer

Maximum step-halving allowed. Specify a positive integer. The default value is 5.

PCONVERGE = [number (RELATIVE | ABSOLUTE)]

Parameter estimates convergence criterion. Convergence is assumed if the relative or absolute change in the parameter estimates is less than the given value. This criterion is not used if the value is 0.

Specify square brackets containing a non-negative number followed optionally by the keyword RELATIVE or ABSOLUTE, which indicates the type of change. The default value is 10^{-6}; the default type is RELATIVE.

SINGULAR = value

Tolerance value used to test for singularity. Specify a positive value. The default value is 10^{-12}.

STATISTICS Subcommand

The STATISTICS subcommand requests various statistics associated with the parameter estimates.

- There are no default keywords on the STATISTICS subcommand. If this subcommand is not specified, then none of the statistics listed below are displayed

PARAMETER	*Parameter estimates.*
EXP	*The exponentiated parameter estimates.* It is available only for the LOGIT link.
SE	*Standard error for each parameter estimate.*
TTEST	*t test for each parameter estimate.*
CINTERVAL	*Confidence interval for each parameter estimate and/or exponentiated parameter estimate.*
DEFF	*Design effect for each parameter estimate.*
DEFFSQRT	*Square root of design effect for each parameter estimate.*

NONPARALLEL Subcommand

The NONPARALLEL subcommand requests various statistics associated with a general cumulative link model with non-parallel lines where a separate regression line is fitted for each response category except for the last.

TEST *Test of parallel lines assumption.* Test whether regression parameters are equal for all cumulative responses. The general model with non-parallel lines is estimated and the Wald test of equal parameters is applied.

PARAMETER *Parameters of the general model with non-parallel lines.* The general model is estimated using the same convergence criteria as for the original model. Both parameters and their standard errors are estimated.

COVB *Covariance matrix for the general model parameters.*

TEST Subcommand

The TEST subcommand specifies the type of test statistic and the method of adjusting the significance level to be used for hypothesis tests requested on the MODEL, CUSTOM, and PRINT subcommands.

TYPE Keyword

The TYPE keyword indicates the type of test statistic.

F *Wald F test.* This is the default test statistic if the TYPE keyword is not specified.

ADJF *Adjusted Wald F test.*

CHISQUARE *Wald chi-square test.*

ADJCHISQUARE *Adjusted Wald chi-square test.*

PADJUST Keyword

The PADJUST keyword indicates the method of adjusting the significance level.

LSD *Least significant difference.* This method does not control the overall probability of rejecting the hypotheses that some linear contrasts are different from the null hypothesis value(s). This is the default.

BONFERRONI *Bonferroni.* This method adjusts the observed significance level for the fact that multiple contrasts are being tested.

SEQBONFERRONI *Sequential Bonferroni.* This is a sequentially step-down rejective Bonferroni procedure that is much less conservative in terms of rejecting individual hypotheses but maintains the same overall significance level.

SIDAK	*Sidak.* This method provides tighter bounds than the Bonferroni approach.
SEQSIDAK	*Sequential Sidak.* This is a sequentially step-down rejective Sidak procedure that is much less conservative in terms of rejecting individual hypotheses but maintains the same overall significance level.

DOMAIN Subcommand

The DOMAIN subcommand specifies the subpopulation for which the analysis is to be performed.

- The keyword VARIABLE, followed by an equals sign, a variable, and a value in parentheses, are required. Put the value inside a pair of quotes if the value is formatted (such as date or currency) or if the factor is of string type.
- The subpopulation is defined by all cases having the given value on the specified variable.
- Analyses are performed only for the specified subpopulation.
- For example, `DOMAIN VARIABLE = myvar (1)` defines the subpopulation by all cases for which variable *MYVAR* has value 1.
- The specified variable may be numeric or string and must exist at the time the CSORDINAL procedure is invoked.
- Stratification or cluster variables may be specified, but no other plan file variables are allowed on the DOMAIN subcommand.
- Analysis variables may not be specified on the DOMAIN subcommand.

MISSING Subcommand

The MISSING subcommand specifies how missing values are handled.

- In general, cases must have valid data for all design variables as well as for the dependent variable and any covariates. Cases with invalid data for any of these variables are excluded from the analysis.
- There is one important exception to the preceding rule. This exception applies when an inclusion probability or population size variable is defined in an analysis plan file. Within a stratum at a given stage, if the inclusion probability or population size values are unequal across cases or missing for a case, then the first valid value found within that stratum is used as the value for the stratum. If strata are not defined, then the first valid value found in the sample is used. If the inclusion probability or population size values are missing for all cases within a stratum (or within the sample if strata are not defined) at a given stage, then an error message is issued.
- The CLASSMISSING keyword specifies whether user-missing values are treated as valid. This specification is applied to categorical design variables that is, strata, cluster, and subpopulation variables), the dependent variable, and any factors.

EXCLUDE	*Exclude user-missing values among the strata, cluster, subpopulation, the dependent variable, and factor variables.* This is the default.
INCLUDE	*Include user-missing values among the strata, cluster, subpopulation, the dependent variable, and factor variables.* Treat user-missing values for these variables as valid data.

PRINT Subcommand

The PRINT subcommand is used to display optional output.

- If the PRINT subcommand is not specified, then the default output includes sample information, variable and factor information, and model summary statistics.
- If the PRINT subcommand is specified, then CSORDINAL displays output only for those keywords that are specified.

SAMPLEINFO *Sample information table.* Displays summary information about the sample, including the unweighted count and the population size. This is default output if the PRINT subcommand is not specified.

VARIABLEINFO *Variable information.* Displays summary information about the dependent variable, covariates, and factors. This is default output if the PRINT subcommand is not specified.

SUMMARY *Model summary statistics.* Displays pseudo-R^2 statistics. This is default output if the PRINT subcommand is not specified.

HISTORY(n) *Iteration history.* Displays coefficient estimates and statistics at every n^{th} iteration beginning with the 0^{th} iteration (the initial estimates). The default is to print every iteration ($n = 1$). The last iteration is always printed if HISTORY is specified, regardless of the value of n.

GEF *General estimable function table.*

LMATRIX *Set of contrast coefficients (L) matrices.* These are the Type III contrast matrices used in testing model effects.

COVB *Covariance matrix for model parameters.*

CORB *Correlation matrix for model parameters.*

CLASSTABLE *Classification table.* Displays frequencies of observed versus predicted response categories.

NONE *No PRINT subcommand output.* None of the PRINT subcommand output is displayed. However, if NONE is specified with one or more other keywords, then the other keywords override NONE.

SAVE Subcommand

The SAVE subcommand writes optional model variables to the active dataset.

- Specify one or more temporary variables, each followed by an optional new name in parentheses.
- The optional names must be valid variable names.
- If new names are not specified, CSORDINAL uses the default names.
- If a subpopulation is defined on the DOMAIN subcommand, then SAVE applies only to cases within the subpopulation.

The following rules describe the functionality of the SAVE subcommand in relation to the predictor values for each case.

- If all factors and covariates in the model have valid values for the case, then the procedure computes the predicted values. (The `MISSING` subcommand setting is taken into account when defining valid/invalid values for a factor.)
- An additional restriction for factors is that only those values of the factor actually used in building the model are considered valid. For example, suppose factor A takes values 1, 2, and 3 when the procedure builds the model. Also suppose there is a case with a value of 4 on factor A, and valid values on all other factors and covariates. For this case, no predicted values are saved because there is no model coefficient corresponding to factor A = 4.

Computation of predicted values for a given case does not depend on the value of the dependent variable; it could be missing.

CUMPROB (rootname:n)

Cumulative probability. The user-specified or default name is treated as the root name, and a suffix is added to get new unique variable names. The root name can be followed by a colon and a positive integer giving the number of predicted cumulative probabilities to save. The predicted cumulative probabilities of the first *n* response categories are saved. One cumulative predicted probability variable can be saved for each category of the dependent variable. The default root name is *CumulativeProbability*. The default *n* is 25. To specify *n* without a root name, enter a colon before the number.

PREDPROB (rootname:n)

Predicted probability. The user-specified or default name is treated as the root name, and a suffix is added to get new unique variable names. The root name can be followed by a colon and a positive integer giving the number of predicted probabilities to save. The predicted probabilities of the first *n* response categories are saved. One predicted probability variable can be saved for each category of the dependent variable. The default root name is *PredictedProbability*. The default *n* is 25. To specify *n* without a root name, enter a colon before the number.

PREDVAL (varname)

Predicted value. The class or value predicted by the model. The optional variable name must be unique. If the default name is used and it conflicts with existing variable names, then a suffix is added to the default name to make it unique. The default variable name is *PredictedValue*.

PREDVALPROB (varname)

Predicted value probability. The probability of value predicted by the model. This probability is the maximum probability predicted by the model for a given case. The optional variable name must be unique. If the default name is used and it conflicts with existing variable names, then a suffix is added to the default name to make it unique. The default variable name is *PredictedValueProbability*.

OBSVALPROB (varname)

Observed value probability. The probability predicted for the observed response value. The optional variable name must be unique. If the default name is used and it conflicts with existing variable names, then a suffix is added to the default name to make it unique. The default variable name is *ObservedValueProbability*.

OUTFILE Subcommand

The OUTFILE subcommand saves an SPSS-format data file containing the parameter covariance or correlation matrix with parameter estimates, standard errors, significance values, and sampling design degrees of freedom. It also saves the parameter estimates and the parameter covariance matrix in XML format.

- At least one keyword and a filename are required.
- The COVB and CORB keywords are mutually exclusive, as are the MODEL and PARAMETER keywords.
- The filename must be specified in full. CSORDINAL does not supply an extension.

COVB = 'savfile' | 'dataset'

Writes the parameter covariance matrix and other statistics to an SPSS data file.

CORB = 'savfile' | 'dataset'

Writes the parameter correlation matrix and other statistics to an SPSS data file.

MODEL = 'file'

Writes the parameter estimates and the parameter covariance matrix to an XML file.

PARAMETER = 'file'

Writes the parameter estimates to an XML file.

CSPLAN

CSPLAN is available in the Complex Samples option.

```
CSPLAN SAMPLE

  /INCLPROB VARIABLE=sprob.

CSPLAN  VIEW
  /PLAN FILE= '/survey/myfile.csplan'.
```

Overview

CSPLAN creates a complex sample design or analysis specification that is used by companion procedures in the Complex Samples option. CSSELECT uses specifications from a plan file when selecting cases from the active file. Analysis procedures in the Complex Samples option, such as CSDESCRIPTIVES, require a plan file in order to produce summary statistics for a complex sample. You can also use CSPLAN to view sample or analysis specifications within an existing plan file.

The CSPLAN design specification is used only by procedures in the Complex Samples option.

Options

Design Specification. CSPLAN writes a sample or analysis design to a file. A sample design can be used to extract sampling units from the active file. An analysis design is used to analyze a complex sample. When a sample design is created, the procedure automatically saves an appropriate analysis design to the plan file. Thus, a plan file created for designing a sample can be used for both sample selection and analysis.

Both sample and analysis designs can specify **stratification**, or independent sampling within nonoverlapping groups, as well as **cluster sampling**, in which groups of sampling units are selected. A single or multistage design can be specified with a maximum of three stages.

CSPLAN does not actually execute the plan (that is, it does not extract the sample or analyze data). To sample cases, use a sample design created by CSPLAN as input to CSSELECT. To analyze sample data, use an analysis design created by CSPLAN as input to Complex Samples procedures, such as CSDESCRIPTIVES.

Sample Design. A variety of equal- and unequal-probability methods are available for sample selection, including simple and systematic random sampling. CSPLAN offers several methods for sampling with probability proportionate to size (**PPS**), including Brewer's method, Murthy's method, and Sampford's method. Units can be drawn with replacement (**WR**) or without replacement (**WOR**) from the population. At each stage of the design, you can control the number or percentage of units to be drawn. You can also choose output variables, such as stagewise sampling weights, that are created when the sample design is executed.

Analysis Design. The following estimation methods are available: with replacement, equal probability without replacement, and unequal probability without replacement. Unequal probability estimation without replacement can be requested in the first stage only. You can specify variables to be used as input to the estimation process, such as overall sample weights and inclusion probabilities.

Operations

- If a sample design is created, the procedure automatically writes a suitable analysis design to the plan file. The default analysis design specifies stratification variables and cluster variables for each stage, as well as an estimation method appropriate for the chosen extraction method.
- CSPLAN writes design specifications in XML format.
- By default, CSPLAN displays output that summarizes the sample or analysis design.

Subcommand Order

- The first DESIGN subcommand must precede all other subcommands except PLAN, PLANVARS, and PRINT.
- PLAN, PLANVARS, and PRINT subcommands can be used in any order.

Limitations

- A maximum of three design blocks can be specified.
- CSPLAN ignores SPLIT FILE and WEIGHT commands with a warning.

Basic Specification

You can specify a sample or analysis design to be created or a plan file to be displayed.

Creating a Sample Plan

- The SAMPLE keyword must be specified on the CSPLAN command.
- A PLAN subcommand is required that specifies a file that will contain the design specification.
- A DESIGN subcommand is required.
- A METHOD subcommand must specify an extraction method.

- Sample size or rate must be specified unless the PPS_MURTHY or PPS_BREWER extraction method is chosen.

Creating an Analysis Plan

- The ANALYSIS keyword must be specified on the CSPLAN command.
- A PLAN subcommand is required that specifies a file that will contain the analysis specification.
- A PLANVARS subcommand is required that specifies a sample weight variable.
- A DESIGN subcommand is required.
- An ESTIMATOR subcommand must specify an estimator.
- The POPSIZE or INCLPROB subcommand must be specified if the EQUAL_WOR estimator is selected.

Displaying an Existing Plan

- The VIEW keyword must be specified on the CSPLAN command.
- A PLAN subcommand is required that specifies a file whose specifications are to be displayed.

Syntax Rules

General

- PLAN, PLANVARS, and PRINT are global. Only a single instance of each global subcommand is allowed.
- Within a subcommand, an error occurs if a keyword or attribute is specified more than once.
- Equals signs shown in the syntax chart are required.
- Subcommand names and keywords (for example, PPS_WR) must be spelled in full.
- In general, empty subcommands (that is, those that have no specifications) generate an error. DESIGN is the only subcommand that can be empty.
- Any variable names that are specified must be valid SPSS variable names.

Creating a Plan

- Stages are specified in design blocks. The DESIGN subcommand signals the start of a block. The first block corresponds to stage 1, the second to stage 2, and the third to stage 3. One DESIGN subcommand must be specified per stage.
- The following subcommands are local and apply to the immediately preceding DESIGN subcommand: METHOD, MOS, SIZE, RATE, STAGEVARS, ESTIMATOR, POPSIZE, and INCLPROB. An error occurs if any of these subcommands appears more than once within a block.
- Available METHOD and ESTIMATOR options depend on the stage.
- The following subcommands are honored only if a sample design is requested: METHOD, MOS, SIZE, RATE, and STAGEVARS. An error occurs if any of these subcommands is specified for an analysis design.
- MOS can be specified in stage 1 only.

- The following subcommands can be used only if an analysis design is requested: ESTIMATOR, POPSIZE, and INCLPROB. An error occurs if any of these subcommands is specified for a sample design.
- In general, each variable specified in the design can assume only one role. For example, a weight variable cannot be used as a stratification or cluster variable. Exceptions are listed below.

Displaying a Plan

- If CSPLAN VIEW is used, only the PLAN and PRINT subcommands can be specified.

Examples

Simple Sample Design

```
CSPLAN SAMPLE
  /PLAN FILE='/survey/myfile.csplan'
  /DESIGN
  /METHOD TYPE=SIMPLE_WOR
  /SIZE VALUE=100.
```

- A single-stage sample design is created that is saved in *myfile.csplan*.
- One hundred cases will be selected from the active file when the sample design is executed by the CSSELECT procedure.
- The extraction method is simple random sampling without replacement.
- The plan file also includes a default analysis design that uses the EQUAL_WOR estimator (the default when units are extracted using the SIMPLE_WOR method).

Stratified Sample Design

```
CSPLAN SAMPLE
  /PLAN FILE='/survey/myfile.csplan'
  /DESIGN STRATA=region
  /METHOD TYPE=SIMPLE_WOR
  /RATE MATRIX=REGION; 'East' 0.1 ; 'West' 0.2;
                       'North' 0.1; 'South' 0.3.
```

- A stratified sample design is specified with disproportionate sampling rates for the strata. Sample elements will be drawn independently within each region.
- The extraction method is simple random sampling without replacement.
- CSPLAN generates a default analysis design using *region* as a stratification variable and the EQUAL_WOR estimator.

Stratified Cluster Sample Design

```
CSPLAN SAMPLE
  /PLAN FILE='/survey/myfile.csplan'
  /DESIGN STRATA=region CLUSTER=school
  /METHOD TYPE=PPS_WOR
  /SIZE VALUE=10
  /MOS VARIABLE=mysizevar.
```

- A stratified cluster sample design is specified.
- Ten schools will be selected within each region with probability proportionate to size.
- Size values for the strata are read from *mysizevar*.
- CSPLAN generates a default analysis design using *region* as a stratification variable and *school* as a cluster variable.
- The UNEQUAL_WOR estimator will be used for analysis. UNEQUAL_WOR is the default when units are sampled with probability proportionate to size.

Multistage Cluster Sample Design

```
CSPLAN SAMPLE
  /PLAN FILE='/survey/myfile.csplan'
  /DESIGN STAGELABEL='school districts' CLUSTER=district
  /METHOD TYPE=PPS_WOR
  /RATE VALUE=.2
  /MOS VARIABLE=districtsize
  /DESIGN STAGELABEL='schools' CLUSTER=school
  /METHOD TYPE=SIMPLE_WOR
  /RATE VALUE=0.3.
```

- A multistage cluster sample design is specified.
- Twenty percent of school districts will be drawn with probability proportionate to size.
- Within each selected school district, 30% of schools will be drawn without replacement.
- CSPLAN generates a default analysis design. Since the PPS_WOR sampling method is specified in stage 1, the UNEQUAL_WOR estimator will be used for analysis for that stage. The EQUAL_WOR method will be used to analyze stage 2.

Simple Analysis Design

```
CSPLAN ANALYSIS
  /PLAN FILE='/survey/myfile.csaplan'
  /PLANVARS ANALYSISWEIGHT=sampleweight
  /DESIGN
  /ESTIMATOR TYPE=EQUAL_WOR
  /POPSIZE VALUE=5000.
```

- An analysis design is specified.
- The variable *sampleweight* is specified as the variable containing sample weights for analysis.
- The EQUAL_WOR estimator will be used for analysis.
- POPSIZE specifies that the sample was drawn from a population of 5,000.

Simple Analysis Design

```
CSPLAN ANALYSIS
  /PLAN FILE='/survey/myfile.csaplan'
  /PLANVARS ANALYSISWEIGHT=sampleweight
  /DESIGN
  /ESTIMATOR TYPE=EQUAL_WOR
  /INCLPROB VALUE=0.10.
```

- An analysis design is specified.

- The variable *sampleweight* is specified as the variable containing sample weights for analysis.
- The EQUAL_WOR estimator will be used for analysis.
- INCLPROB specifies that 10% of population units were selected for inclusion in the sample.

Stratified Analysis Design

```
CSPLAN ANALYSIS
  /PLAN FILE='/survey/myfile.csaplan'
  /PLANVARS ANALYSISWEIGHT=sampleweight
  /DESIGN STRATA=region
  /ESTIMATOR TYPE=EQUAL_WOR
  /INCLPROB MATRIX=REGION; 'East' 0.1; 'West' 0.2;
                           'North' 0.1; 'South' 0.3.
```

- The analysis design specifies that the sample is stratified by *region*.
- Inclusion probabilities are specified for each stratum.
- The variable *sampleweight* is specified as the variable containing sample weights for analysis.

Stratified Clustering Analysis Design

```
CSPLAN ANALYSIS
  /PLAN FILE='/survey/myfile.csaplan'
  /PLANVARS ANALYSISWEIGHT=sampleweight
  /DESIGN STRATA=district CLUSTER=school
  /ESTIMATOR TYPE=UNEQUAL_WOR.
```

- The analysis design specifies that units were sampled using stratified clustering.
- The variable *sampleweight* is specified as the variable containing sample weights for analysis.
- *District* is defined as a stratification variable and *school* is defined as a cluster variable.
- The UNEQUAL_WOR estimator will be used for analysis.

Multistage Analysis Design

```
CSPLAN ANALYSIS
  /PLAN FILE='/survey/myfile.csaplan'
  /PLANVARS ANALYSISWEIGHT=sampleweight
  /DESIGN CLUSTER=district
  /ESTIMATOR TYPE=UNEQUAL_WOR
  /DESIGN CLUSTER=school
  /ESTIMATOR TYPE=EQUAL_WOR
  /INCLPROB VARIABLE=sprob.
```

- The analysis design specifies that cases were sampled using multistage clustering. Schools were sampled within districts.
- The UNEQUAL_WOR estimator will be used in stage 1.
- The EQUAL_WOR estimator will be used in stage 2.
- The variable *sprob* contains inclusion probabilities, which are required for analysis of the second stage.
- The variable *sampleweight* is specified as the variable containing sample weights for analysis.

Display Plan

```
CSPLAN  VIEW
  /PLAN FILE='/survey/myfile.csplan'.
```

- The syntax displays the specifications in the plan file *myfile.csplan*.

CSPLAN Command

CSPLAN creates a complex sample design or analysis specification.

SAMPLE	*Creates a sample design.*
ANALYSIS	*Creates an analysis design.*
VIEW	*Displays a sample or analysis design.*

PLAN Subcommand

The PLAN subcommand specifies the name of a design file to be written or displayed by CSPLAN. The file contains sample and/or analysis design specifications.

FILE	*Sampling design file.* Specify the filename in full. If you are creating a plan and the file already exists, it is overwritten without warning.

PLANVARS Subcommand

PLANVARS is used to name planwise variables to be created when a sample is extracted or used as input to the selection or estimation process.

ANALYSISWEIGHT	*Final sample weights for each unit to be used by Complex Samples analysis procedures in the estimation process.* ANALYSISWEIGHT is required if an analysis design is specified. It is ignored with a warning if a sample design is specified.
SAMPLEWEIGHT	*Overall sample weights that will be generated when the sample design is executed using CSSELECT.* A final sampling weight is created automatically when the sample plan is executed. SAMPLEWEIGHT is honored only if a sampling design is specified. It is ignored with a warning if an analysis design is specified. Sample weights are positive for selected units. They take into account all stages of the design as well as previous sampling weights if specified. If SAMPLEWEIGHT is not specified, a default name (*SampleWeight_Final_*) is used for the sample weight variable.
PREVIOUSWEIGHT	*Weights to be used in computing final sampling weights in a multistage design.* PREVIOUSWEIGHT is honored only if a sampling design is specified. It is ignored with a warning if an analysis design is specified. Typically, the previous weight variable is produced in an earlier stage of a stage-by-stage sample selection process. CSSELECT multiplies previous weights with those for the current stage to obtain final sampling weights.

For example, suppose that you want to sample individuals within cities but only city data are available at the outset of the study. For the first stage of extraction, a design plan is created that specifies that 10 cities are to be sampled from the active file. The PLANVARS subcommand specifies that sampling weights are to be saved under the name *CityWeights*:

```
CSPLAN SAMPLE
  /PLAN FILE='/survey/city.csplan'
  /PLANVARS SAMPLEWEIGHT=CityWeights
  /DESIGN CLUSTER=city
  /METHOD TYPE=PPS_WOR
  /MOS VARIABLE=SizeVar
  /SIZE VALUE=10.
```

This plan would be executed using CSSELECT on an active file in which each case is a city.

For the next stage of extraction, a design plan is created that specifies that 50 individuals are to be sampled within cities. The design uses the PREVIOUSWEIGHT keyword to specify that sample weights generated in the first stage are to be used when computing final sampling weights for selected individuals. Final weights are saved to the variable *FinalWeights*.

```
CSPLAN SAMPLE
  /PLAN FILE='/survey/individuals.csplan'
  /PLANVARS PREVIOUSWEIGHT=CityWeights
            SAMPLEWEIGHT=FinalWeights
  /DESIGN STRATA=city
  /METHOD TYPE=SIMPLE_WOR
  /SIZE VALUE=50.
```

The plan for stage 2 would be executed using CSSELECT on an active file in which cases represent individuals and both *city* and *CityWeights* are recorded for each individual. Note that *city* is identified as a stratification variable in this stage, so individuals are sampled within cities.

SRSESTIMATOR Subcommand

The SRSESTIMATOR subcommand specifies the variance estimator used under the simple random sampling assumption. This estimate is needed, for example, in computation of design effects in Complex Samples analysis procedures.

WOR *SRS variance estimator includes the finite population correction.* This estimator is the default.

WR *SRS variance estimator does not include the finite population correction.* This estimator is recommended when the analysis weights have been scaled so that they do not add up to the population size.

PRINT Subcommand

PLAN *Displays a summary of plan specifications.* The output reflects your specifications at each stage of the design. The plan is shown by default. The PRINT subcommand is used to control output from CSPLAN.

MATRIX *Displays a table of MATRIX specifications.* MATRIX is ignored if you do not use the MATRIX form of the SIZE, RATE, POPSIZE, or INCLPROB subcommand. By default, the table is not shown.

DESIGN Subcommand

The DESIGN subcommand signals a stage of the design. It also can be used to define stratification variables, cluster variables, or a descriptive label for a particular stage.

STAGELABEL Keyword

STAGELABEL allows a descriptive label to be entered for the stage that appears in Complex Samples procedure output.

'Label' *Descriptive stage label.* The label must be specified within quotes. If a label is not provided, a default label is generated that indicates the stage number.

STRATA Keyword

STRATA is used to identify stratification variables whose values represent nonoverlapping subgroups. Stratification is typically done to decrease sampling variation and/or to ensure adequate representation of small groups in a sample.

If STRATA is used, CSSELECT draws samples independently within each stratum. For example, if *region* is a stratification variable, separate samples are drawn for each region (for example, East, West, North, and South). If multiple STRATA variables are specified, sampling is performed within each combination of strata.

varlist *Stratification variables.*

CLUSTER Keyword

CLUSTER is used to sample groups of sampling units, such as states, counties, or school districts. Cluster sampling is often performed to reduce travel and/or interview costs in social surveys. For example, if census tracts are sampled within a particular city and each interviewer works within a particular tract, he or she would be able to conduct interviews within a small area, thus minimizing time and travel expenses.

- If CLUSTER is used, CSSELECT samples from values of the cluster variable as opposed to sampling elements (cases).
- If two or more cluster variables are specified, samples are drawn from among all combinations of values of the variables.
- CLUSTER is required for nonfinal stages of a sample or analysis plan.
- CLUSTER is required if any of the following sampling methods is specified: PPS_WOR, PPS_BREWER, PPS_MURTHY, or PPS_SAMPFORD.
- CLUSTER is required if the UNEQUAL_WOR estimator is specified.

varlist *Cluster variables.*

METHOD Subcommand

The METHOD subcommand specifies the sample extraction method. A variety of equal- and unequal-probability methods are available.

The following table lists extraction methods and their availability at each stage of the design. For details on each method, see the CSSELECT algorithms document.

- PPS methods are available only in stage 1. WR methods are available only in the final stage. Other methods are available in any stage.
- If a PPS method is chosen, a measure of size (MOS) must be specified.
- If the PPS_WOR, PPS_BREWER, PPS_SAMPFORD, or PPS_MURTHY method is selected, first-stage joint inclusion probabilities are written to an external file when the sample plan is executed. Joint probabilities are needed for UNEQUAL_WOR estimation by Complex Samples analysis procedures.
- By default, CSPLAN chooses an appropriate estimation method for the selected sampling method. If ESTIMATION=WR, Complex Samples analysis procedures use the WR (with replacement) estimator regardless of the sampling method.

Type	Description	Default estimator
SIMPLE_WOR	Selects units with equal probability. Units are extracted without replacement.	EQUAL_WOR
SIMPLE_WR	Selects units with equal probability. Units are extracted with replacement.	WR
SIMPLE_SYSTEMATIC	Selects units at a fixed interval throughout the sampling frame or stratum. A random starting point is chosen within the first interval.	WR
SIMPLE_CHROMY	Selects units sequentially with equal probability. Units are extracted without replacement.	WR
PPS_WOR	Selects units with probability proportional to size. Units are extracted without replacement.	UNEQUAL_WOR
PPS_WR	Selects units with probability proportional to size. Units are extracted with replacement.	WR
PPS_SYSTEMATIC	Selects units by systematic random sampling with probability proportional to size. Units are extracted without replacement.	WR
PPS_CHROMY	Selects units sequentially with probability proportional to size without replacement.	WR
PPS_BREWER	Selects two units from each stratum with probability proportional to size. Units are extracted without replacement.	UNEQUAL_WOR
PPS_MURTHY	Selects two units from each stratum with probability proportional to size. Units are extracted without replacement.	UNEQUAL_WOR
PPS_SAMPFORD	An extension of the Brewer's method that selects more than two units from each stratum with probability proportional to size. Units are extracted without replacement.	UNEQUAL_WOR

ESTIMATION Keyword

By default, the estimation method used when sample data are analyzed is implied by the specified extraction method. If ESTIMATION=WR is specified, the with-replacement estimator is used when summary statistics are produced using Complex Samples analysis procedures.

- The WR keyword has no effect if the specified METHOD implies WR estimation.
- If ESTIMATION=WR is specified, the joint probabilities file is not created when the sample plan is executed.
- ESTIMATION=WR is available only in the first stage.

SIZE Subcommand

The SIZE subcommand specifies the number of sampling units to draw at the current stage.

- You can specify a single value, a variable name, or a matrix of counts for design strata.
- Size values must be positive integers.
- The SIZE subcommand is ignored with a warning if the PPS_MURTHY or PPS_BREWER method is specified.
- The SIZE or RATE subcommand must be specified for each stage. An error occurs if both are specified.

VALUE *Apply a single value to all strata.* For example, VALUE=10 selects 10 units per stratum.

MATRIX *Specify disproportionate sample sizes for different strata.* Specify one or more variables after the MATRIX keyword. Then provide one size specification per stratum. A size specification includes a set of category values and a size value. Category values should be listed in the same order as variables to which they apply. Semicolons are used to separate the size specifications.

For example, the following syntax selects 10 units from the North stratum and 20 from the South stratum:

```
/SIZE MATRIX=region;  'North' 10; 'South' 20
```

If there is more than one variable, specify one size per combination of strata. For example, the following syntax specifies rate values for combinations of Region and Sex strata:

```
/SIZE MATRIX=region sex; 'North' 'Male' 10; 'North' 'Female'15;
                         'South' 'Male' 24; 'South' 'Female' 30
```

The variable list must contain all or a subset of stratification variables from the same and previous stages and cluster variables from the previous stages. An error occurs if the list contains variables that are not defined as strata or cluster variables.

Each size specification must contain one category value per variable. If multiple size specifications are provided for the same strata or combination of strata, only the last one is honored.

String and date category values must be quoted.

A semicolon must appear after the variable list and after each size specification. The semicolon is not allowed after the last size specification.

VARIABLE *Specify the name of a single variable that contains the sample sizes.*

RATE Subcommand

The RATE subcommand specifies the percentage of units to draw at the current stage—that is, the sampling fraction.

- Specify a single value, a variable name, or a matrix of rates for design strata. In all cases, the value 1 is treated as 100%.
- Rate values must be positive.
- RATE is ignored with a warning if the PPS_MURTHY or PPS_BREWER method is specified.
- Either SIZE or RATE must be specified for each stage. An error occurs if both are specified.

VALUE *Apply a single value to all strata.* For example, VALUE=.10 selects 10% of units per stratum.

MATRIX *Specify disproportionate rates for different strata.* Specify one or more variables after the MATRIX keyword. Then provide one rate specification per stratum. A rate specification includes a set of category values and a rate value. Category values should be listed in the same order as variables to which they apply. Semicolons are used to separate the rate specifications.

For example, the following syntax selects 10% of units from the North stratum and 20% from the South stratum:

```
/RATE MATRIX=region;  'North' .1; 'South' .2
```

If there is more than one variable, specify one rate per combination of strata. For example, the following syntax specifies rate values for combinations of Region and Sex strata:

```
/RATE MATRIX=region sex; 'North' 'Male' .1; 'North' 'Female' .15;
                         'South' 'Male' .24; 'South' 'Female' .3
```

The variable list must contain all or a subset of stratification variables from the same and previous stages and cluster variables from the previous stages. An error occurs if the list contains variables that are not defined as strata or cluster variables.

Each rate specification must contain one category value per variable. If multiple rate specifications are provided for the same strata or combination of strata, only the last one is honored.

String and date category values must be quoted. A semicolon must appear after the variable list and after each rate specification.

The semicolon is not allowed after the last rate specification.

VARIABLE *Specify the name of a single variable that contains the sample rates.*

MINSIZE Keyword

MINSIZE specifies the minimum number of units to draw when RATE is specified. MINSIZE is useful when the sampling rate for a particular stratum turns out to be very small due to rounding.

value *The value must be a positive integer.* An error occurs if the value exceeds MAXSIZE.

MAXSIZE Keyword

MAXSIZE specifies the maximum number of units to draw when RATE is specified. MAXSIZE is useful when the sampling rate for a particular stratum turns out to be larger than desired due to rounding.

value *The value must be a positive integer.* An error occurs if the value is less than MINSIZE.

MOS Subcommand

The MOS subcommand specifies the measure of size for population units in a PPS design. Specify a variable that contains the sizes or request that sizes be determined when CSSELECT scans the sample frame.

VARIABLE *Specify a variable containing the sizes.*

SOURCE=FROMDATA *The CSSELECT procedure counts the number of cases that belong to each cluster to determine the MOS.* SOURCE=FROMDATA can be used only if a CLUSTER variable is defined. Otherwise, an error is generated.

- The MOS subcommand is required for PPS designs. Otherwise, it is ignored with a warning.

MIN Keyword

MIN specifies a minimum MOS for population units that overrides the value specified in the MOS variable or obtained by scanning the data.

value *The value must be positive.* MIN must be less than or equal to MAX.

- MIN is optional for PPS methods. It is ignored for other methods.

MAX Keyword

MAX specifies a maximum MOS for population units that overrides the value specified in the MOS variable or obtained by scanning the data.

value *The value must be positive.* MAX must be greater than or equal to MIN.

- MAX is optional for PPS methods. It is ignored for other methods.

STAGEVARS Subcommand

The STAGEVARS subcommand is used to obtain stagewise sample information variables when a sample design is executed. Certain variables are created automatically and cannot be suppressed. The names of both automatic and optional stagewise variables can be user-specified.

- Stagewise inclusion probabilities and cumulative sampling weights are always created.

- A stagewise duplication index is created only when sampling is done with replacement. A warning occurs if index variables are requested when sampling is done without replacement.
- If a keyword is specified without a variable name, a default name is used. The default name indicates the stage to which the variable applies.

Example

```
/STAGEVARS POPSIZE
           INCLPROB(SelectionProb)
```

- The syntax requests that the population size for the stage be saved using a default name.
- Inclusion probabilities for the stage will be saved using the name *SelectionProb*. (Note that inclusion probabilities are always saved when the sample design is executed. The syntax shown here requests that they be saved using a nondefault name.)

STAGEVARS Variables

The following table shows available `STAGEVARS` variables. See the `CSSELECT` algorithms document for a detailed explanation of each quantity.

If the default variable name is used, a numeric suffix that corresponds to the stage number is added to the root shown below. All names end in an underscore—for example, *InclusionProbability_1_*.

Keyword	Default root name	Description	Generated automatically when sample executed?
`INCLPROB`	*InclusionProbability_*	Stagewise inclusion (selection) probabilities. The proportion of units drawn from the population at a particular stage.	Yes
`CUMWEIGHT`	*SampleWeightCumulative_*	Cumulative sampling weight for a given stage. Takes into account prior stages.	Yes
`INDEX`	*Index_*	Duplication index for units selected in a given stage. The index uniquely identifies units selected more than once when sampling is done with replacement.	Yes, when sampling is done with replacement.
`POPSIZE`	*PopulationSize_*	Population size for a given stage.	No
`SAMPSIZE`	*SampleSize_*	Number of units drawn at a given stage.	No

Keyword	Default root name	Description	Generated automatically when sample executed?
RATE	*SamplingRate_*	Stagewise sampling rate.	No
WEIGHT	*SampleWeight_*	Sampling weight for a given stage. The inverse of the stagewise inclusion probability. Stage weights are positive for each unit selected in a particular stage.	No

ESTIMATOR Subcommand

The ESTIMATOR subcommand is used to choose an estimation method for the current stage. There is no default estimator.

Available estimators depend on the stage:

- EQUAL_WOR can be specified in any stage of the design.
- UNEQUAL_WOR can be specified in the first stage only. An error occurs if it is used in stage 2 or 3.
- WR can be specified in any stage. However, the stage in which it is specified is treated as the last stage. Any subsequent stages are ignored when the data are analyzed.

EQUAL_WOR *Equal selection probabilities without replacement.* POPSIZE or INCLPROB must be specified.

UNEQUAL_WOR *Unequal selection probabilities without replacement.* If POPSIZE or INCLPROB is specified, it is ignored and a warning is issued.

WR *Selection with replacement.* If POPSIZE or INCLPROB is specified, it is ignored and a warning is issued.

POPSIZE Subcommand

The POPSIZE subcommand specifies the population size for each sample element. Specify a single value, a variable name, or a matrix of counts for design strata.

- The POPSIZE and INCLPROB subcommands are mutually exclusive. An error occurs if both are specified for a particular stage.
- Population size values must be positive integers.

VALUE *Apply a single value to all strata.* For example, VALUE=1000 indicates that each stratum has a population size of 1,000.

MATRIX *Specify disproportionate population sizes for different strata.* Specify one or more variables after the MATRIX keyword. Then provide one size specification per stratum. A size specification includes a set of category values and a population size value. Category values should be listed in the same order as variables to which they apply. Semicolons are used to separate the size specifications.

For example, the following syntax specifies that units in the North stratum were sampled from a population of 1,000. The population size for the South stratum is specified as 2,000:

```
/SIZE MATRIX=region;  'North' 1000; 'South' 2000
```

If there is more than one variable, specify one size per combination of strata. For example, the following syntax specifies rate values for combinations of Region and Sex strata:

```
/SIZE MATRIX=region sex; 'North' 'Male' 1000; 'North' 'Female' 1500;
                         'South' 'Male' 2400; 'South' 'Female' 3000
```

The variable list must contain all or a subset of stratification variables from the same and previous stages and cluster variables from the previous stages. An error occurs if the list contains variables that are not defined as strata or cluster variables.

Each size specification must contain one category value per variable. If multiple size specifications are provided for the same strata or combination of strata, only the last one is honored.

String and date category values must be quoted.

A semicolon must appear after the variable list and after each size specification. The semicolon is not allowed after the last size specification.

VARIABLE *Specify the name of a single variable that contains the population sizes.*

INCLPROB Subcommand

The INCLPROB subcommand specifies the proportion of units drawn from the population at a given stage. Specify a single value, a variable name, or a matrix of inclusion probabilities for design strata.

- The POPSIZE and INCLPROB subcommands are mutually exclusive. An error occurs if both are specified for a particular stage.
- Proportions must be a positive value less than or equal to 1.

VALUE *Apply a single value to all strata.* For example, VALUE=0.10 indicates that 10% of elements in each stratum were selected.

MATRIX *Specify unequal proportions for different strata.* Specify one or more variables after the MATRIX keyword. Then provide one proportion per stratum. A proportion specification includes a set of category values and a proportion value. Category values should be listed in the same order as variables to which they apply. Semicolons are used to separate the proportion specifications.

For example, the following syntax indicates that 10% of units were selected from the North stratum and 20% were selected from the South stratum:

```
/INCLPROB MATRIX=region;  'North' 0.1; 'South' 0.2
```

If there is more than one variable, specify one proportion per combination of strata. For example, the following syntax specifies proportions for combinations of Region and Sex strata:

```
/INCLPROB MATRIX=region sex; 'North' 'Male' 0.1; 'North' 'Female' 0.15;
                             'South' 'Male' 0.24; 'South' 'Female' 0.3
```

The variable list must contain all or a subset of stratification variables from the same and previous stages and cluster variables from the previous stages. An error occurs if the list contains variables that are not defined as strata or cluster variables.

Each proportion specification must contain one category value per variable. If multiple proportions are provided for the same strata or combination of strata, only the last one is honored.

String and date category values must be quoted.

A semicolon must appear after the variable list and after each proportion specification. The semicolon is not allowed after the last proportion specification.

VARIABLE *Specify the name of a single variable that contains inclusion probabilities.*

CSSELECT

CSSELECT is available in the Complex Samples option.

```
CSSELECT

/PLAN FILE='file'

[/CRITERIA [STAGES=n [n [n]]] [SEED={RANDOM**}]]
                                    {value   }

[/CLASSMISSING {EXCLUDE**}]
               {INCLUDE  }

[/DATA [RENAMEVARS] [PRESORTED]]

[/SAMPLEFILE OUTFILE='savfile'|'dataset' [KEEP=varlist] [DROP=varlist]]

[/JOINTPROB OUTFILE='savfile'|'dataset']

[/SELECTRULE OUTFILE='file']

[/PRINT [SELECTION**] [CPS]]
```

**Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
CSSELECT
  /PLAN FILE='/survey/myfile.csplan'.
```

Overview

CSSELECT selects complex, probability-based samples from a population. CSSELECT selects units according to a sample design created using the CSPLAN procedure.

Options

Scope of Execution. By default, CSSELECT executes all stages defined in the sampling plan. Optionally, you can execute specific stages of the design. This capability is useful if a full sampling frame is not available at the outset of the sampling process, in which case new stages can be sampled as they become available. For example, CSSELECT might first be used to sample cities, then to sample blocks, and finally to sample individuals. Each time a different stage of the sampling plan would be executed.

Seed. By default, a random seed value is used by the CSSELECT random number generator. You can specify a seed to ensure that the same sample will be drawn when CSSELECT is invoked repeatedly using the same sample plan and population frame. The CSSELECT seed value is independent of the global seed specified via the SET command.

Missing Values. A case is excluded from the sample frame if it has a system-missing value for any input variable in the plan file. You can control whether user-missing values of stratification and cluster variables are treated as invalid. User-missing values of measure variables are always treated as invalid.

Input Data. If the sampling frame is sorted in advance, you can specify that the data are presorted, which may improve performance when stratification and/or clustering is requested for a large sampling frame.

Sample Data. CSSELECT writes data to the active dataset (the default) or an external file. Regardless of the data destination, CSSELECT generates final sampling weights, stagewise inclusion probabilities, stagewise cumulative sampling weights, as well as variables requested in the sampling plan.

External files or datasets produced by CSSELECT include selected cases only. By default, all variables in the active dataset are copied to the external file or dataset. Optionally, you can specify that only certain variables are to be copied.

Joint Probabilities. First-stage joint inclusion probabilities are automatically saved to an external file when the plan file specifies a PPS without-replacement sampling method. Joint probabilities are used by Complex Samples analysis procedures, such as CSDESCRIPTIVES and CSTABULATE. You can control the name and location of the joint probabilities file.

Output. By default, CSSELECT displays the distribution of selected cases by stratum. Optionally, you can display a case-processing summary.

Basic Specification

- The basic specification is a PLAN subcommand that specifies a sample design file.
- By default, CSPLAN writes output data to the active dataset including final sample weights, stagewise cumulative weights, and stagewise inclusion probabilities. See the CSPLAN design for a description of available output variables.

Operations

- CSSELECT selects sampling units according to specifications given in a sample plan. Typically, the plan is created using the CSPLAN procedure.
- In general, elements are selected. If cluster sampling is performed, groups of elements are selected.
- CSSELECT assumes that the active dataset represents the sampling frame. If a multistage sample design is executed, the active dataset should contain data for all stages. For example, if you want to sample individuals within cities and city blocks, then each case should be an individual, and city and block variables should be coded for each individual. When CSSELECT is used to execute particular stages of the sample design, the active dataset should represent the subframe for those stages only.
- A case is excluded from the sample frame if it has a system-missing value for any input variable in the plan.
- You can control whether user-missing values of stratification and cluster variables are treated as valid. By default, they are treated as invalid.

- User-missing values of measure variables are always treated as invalid.
- The CSSELECT procedure has its own seed specification that is independent of the global SET command.
- First-stage joint inclusion probabilities are automatically saved to an external file when the plan file specifies a PPS without-replacement sampling method. By default, the joint probabilities file is given the same name as the plan file (with a different extension) and is written to the same location.
- Output data must be written to an external data file if with-replacement sampling is specified in the plan file.
- This procedure uses the multithreaded options specified by SET THREADS.

Syntax Rules

- The PLAN subcommand is required. All other subcommands are optional.
- Only a single instance of each subcommand is allowed.
- An error occurs if an attribute or keyword is specified more than once within a subcommand.
- An error occurs if the same output file is specified for more than one subcommand.
- Equals signs shown in the syntax chart are required.
- Subcommand names and keywords must be spelled in full.
- Empty subcommands are not allowed.

Limitations

- WEIGHT and SPLIT FILE settings are ignored with a warning by the CSSELECT procedure.

Example

```
CSSELECT
  /PLAN FILE='/survey/myfile.csplan'
  /CRITERIA SEED=99999
  /SAMPLEFILE OUTFILE='/survey/sample.sav'.
```

- CSSELECT reads the plan file *myfile.csplan*.
- CSSELECT draws cases according to the sampling design specified in the plan file.
- Sampled cases and weights are written to an external file. By default, output data include final sample weights, stagewise inclusion probabilities, stagewise cumulative weights, and any other variables requested in the sample plan.
- The seed value for the random number generator is 99999.

PLAN Subcommand

PLAN identifies the plan file whose specifications are to be used for selecting sampling units. FILE specifies the name of the file. An error occurs if the file does not exist.

CRITERIA Subcommand

CRITERIA is used to control the scope of execution and specify a seed value.

STAGES Keyword

STAGES specifies the scope of execution.

- By default, all stages defined in the sampling plan are executed. STAGES is used to limit execution to specific stages of the design.
- Specify one or more stages. The list can include up to three integer values—for example, STAGES=1 2 3. If two or more values are provided, they must be consecutive. An error occurs if a stage is specified that does not correspond to a stage in the plan file.
- If the sample plan specifies a previous weight variable, it is used in the first stage of the plan.
- When executing latter stages of a multistage sampling design in which the earlier stages have already been sampled, CSSELECT requires the cumulative sampling weights of the last stage sampled, in order to compute the correct final sampling weights for the whole design. For example, if you have executed the first two stages of a three-stage design and saved the second-stage cumulative weights to *SampleWeightCumulative_2_*, when you sample the third stage of the design, the active dataset must contain *SampleWeightCumulative_2_* to compute the final sampling weights.

SEED Keyword

SEED specifies the random number seed used by the CSSELECT procedure.

- By default, a random seed value is selected. To replicate a particular sample, the same seed, sample plan, and sample frame should be specified when the procedure is executed.
- The CSSELECT seed value is independent of the global seed specified via the SET command.

RANDOM	*A seed value is selected at random*. This is the default.
value	*Specifies a custom seed value*. The seed value must be a positive integer.

CLASSMISSING Subcommand

CLASSMISSING is used to control whether user-missing values of classification (stratification and clustering) variables are treated as valid values. By default, they are treated as invalid.

EXCLUDE	*User-missing values of stratification and cluster variables are treated as invalid.* This is the default.
INCLUDE	*User-missing values of stratification and cluster variables are treated as valid values.*

CSSELECT always treats user-missing values of measure variables (previous weight, MOS, size, and rate) as invalid.

DATA Subcommand

DATA specifies general options concerning input and output files.

RENAMEVARS Keyword

The RENAMEVARS keyword handles name conflicts between existing variables and variables to be created by the CSSELECT procedure.

- If the RENAMEVARS keyword is not specified, conflicting variable names generate an error. This is the default.
- If output data are directed to the active dataset, RENAMEVARS specifies that an existing variable should be renamed with a warning if its name conflicts with that of a variable created by the CSSELECT procedure.
- If output data are directed to an external file or dataset, RENAMEVARS specifies that a variable to be copied from the active dataset should be renamed, with a warning if its name conflicts with that of a variable created by the CSSELECT procedure. See the SAMPLEFILE subcommand for details about copying variables from the active dataset.

PRESORTED Keyword

By default, CSSELECT assumes that the active dataset is unsorted. The PRESORTED keyword specifies that the data are sorted in advance, which may improve performance when stratification and/or clustering is requested for a large sample frame.

If PRESORTED is used, the data should be sorted first by all stratification variables then by cluster variables consecutively in each stage. The data can be sorted in ascending or descending order. For example, given a sample plan created using the following CSPLAN syntax, the sample frame should be sorted by region, ses, district, type, and school, in that order.

Example

```
CSPLAN
  /PLAN OUTFILE='/survey/myfile.csplan'
  /DESIGN STRATA=region ses CLUSTER=district type
  /SAMPLE RATE=.2 MOS=districtsize METHOD=PPS_WOR
  /DESIGN CLUSTER=school
  /SAMPLE RATE=.3 METHOD=SIMPLE_WOR.
```

An error occurs if PRESORTED is specified and the data are not sorted in proper order.

SAMPLEFILE Subcommand

SAMPLEFILE is used to write sampled units to an external file or dataset. Datasets are available during the current session but are not available in subsequent sessions unless you explicitly save them as data files.

- The external file or dataset contains sampled cases only. By default, all variables in the active dataset are copied to the external file or dataset.

- If SAMPLEFILE is specified, data are not written to the active dataset.
- SAMPLEFILE must be used if with-replacement sampling is specified in the plan file. Otherwise, an error is generated.
- KEEP and DROP can be used simultaneously; the effect is cumulative. An error occurs if you specify a variable already named on a previous DROP or one not named on a previous KEEP.

OUTFILE Keyword

The OUTFILE keyword specifies the name of the external file or the name of a dataset. An external file, a file handle, or a dataset name must be specified. If the file or dataset exists, it is overwritten without warning.

KEEP Keyword

The KEEP keyword lists variables to be copied from the active dataset to the file or dataset specified on the OUTFILE keyword. KEEP has no bearing on the active dataset.

- At least one variable must be specified.
- Variables not listed are not copied.
- An error occurs if a specified variable does not exist in the active dataset.
- Variables are copied in the order in which they are listed.

DROP Keyword

The DROP keyword excludes variables from the file or dataset specified on the OUTFILE keyword. DROP has no bearing on the active dataset.

- At least one variable must be specified.
- Variables not listed are copied.
- The ALL keyword can be used to drop all variables.
- An error occurs if a specified variable does not exist in the active dataset.

JOINTPROB Subcommand

First-stage joint inclusion probabilities are automatically saved to an external SPSS-format data file when the plan file specifies a PPS without-replacement sampling method. By default, the joint probabilities file is given the same name as the plan file (with a different extension), and it is written to the same location. JOINTPROB is used to override the default name and location of the file.

- OUTFILE specifies the name of the file. In general, if the file exists, it is overwritten without warning.
- The joint probabilities file is generated only when the plan file specifies PPS_WOR, PPS_BREWER, PPS_SAMPFORD, or PPS_MURTHY as the sampling method. A warning is generated if JOINTPROB is used when any other sampling method is requested in the plan file.

Structure of the Joint Probabilities File

Complex Samples analysis procedures will expect the following variables in the joint probability file in the order listed below. If there are other variables beyond the joint probability variables, they will be silently ignored.

1. **Stratification variables.** These are the stratification variables used in the first stage of sampling. If there is no stratification in first stage, no stratification variables are included in the file.

2. **Cluster variables.** These are variables used to identify each primary sampling unit (PSU) within a stratum. At least one cluster variable is always included, since it is required for all selection methods that generate the joint probabilities as well as for the estimation method using them.

3. **System PSU id.** This variable labels PSU's within a stratum. The variable name used is *Unit_No_*.

4. **Joint probability variables.** These variables store the joint inclusion probabilities for each pair of units. The default names of these variables will have the form *Joint_Prob_n_*; for example, the joint inclusion probabilities of the 2nd and 3rd units will be the values located at case 2 of *Joint_Prob_3_* or case 3 of *Joint_Prob_2_*. Since the analysis procedures extract joint probabilities by location, it is safe to rename these variables at your convenience. Within each stratum, these joint inclusion probabilities will form a square symmetric matrix. Since the joint inclusion probabilities only vary for the off diagonal entries, the diagonal elements correspond to the first stage inclusion probabilities. The maximum number of joint inclusion probability variables will be equal to the maximum sample size across all strata.

Example

Figure 45-1
Joint probabilities file

	county	town	Unit_No_	Joint_Prob_1_	Joint_Prob_2_	Joint_Prob_3_	Joint_Prob_4_	Joint_Prob_5_
1	1	10	1	.31	.10	.11	.12	.
2	1	11	2	.10	.39	.15	.16	.
3	1	9	3	.11	.15	.44	.21	.
4	1	12	4	.12	.16	.21	.48	.
5	2	12	1	.22	.04	.07	.08	.
6	2	6	2	.04	.23	.07	.08	.
7	2	7	3	.07	.07	.41	.19	.
8	2	2	4	.08	.08	.19	.45	.
9	3	5	1	.58	.31	.32	.	.
10	3	3	2	.31	.61	.36	.	.
11	3	4	3	.32	.36	.63	.	.
12	4	14	1	.26	.06	.06	.07	.09
13	4	8	2	.06	.29	.07	.08	.10
14	4	4	3	.06	.07	.29	.08	.10
15	4	2	4	.07	.08	.08	.33	.12

Data View | Variable View

The file *poll_jointprob.sav* contains first-stage joint probabilities for selected townships within counties. *County* is a first-stage stratification variable, and *Township* is a cluster variable. Combinations of these variables identify all first-stage PSUs uniquely. *Unit_No_* labels PSUs within each stratum and is used to match up with *Joint_Prob_1_*, *Joint_Prob_2_*, *Joint_Prob_3_*, *Joint_Prob_4_*, and *Joint_Prob_5_*. The first two strata each have 4 PSUs; therefore, the joint inclusion probability matrices are 4×4 for these strata, and the *Joint_Prob_5_* column is left empty for these rows. Similarly, strata 3 and 5 have 3×3 joint inclusion probability matrices, and stratum 4 has a 5×5 joint inclusion probability matrix.

The need for a joint probabilities file is seen by perusing the values of the joint inclusion probability matrices. When the sampling method is not a PPS WOR method, the selection of a PSU is independent of the selection of another PSU, and their joint inclusion probability is simply the product of their inclusion probabilities. In contrast, the joint inclusion probability for Townships 9 and 10 of County 1 is approximately 0.11 (see the first case of *Joint_Prob_3_* or the third case of *Joint_Prob_1_*), or less than the product of their individual inclusion probabilities (the product of the first case of *Joint_Prob_1_* and the third case of *Joint_Prob_3_* is 0.31×0.44=0.1364).

SELECTRULE Subcommand

SELECTRULE generates a text file containing a rule that describes characteristics of selected units.

- The selection rule is not generated by default.

- `OUTFILE` specifies the name of the file. If the file exists, it is overwritten without warning.
- The selection rule is written in generic notation, for example—`(a EQ 1) AND (b EQ 2)'`. You can transform the selection rule into SQL code or command syntax that can be used to extract a subframe for the next stage of a multistage extraction.

PRINT Subcommand

`PRINT` controls output display.

SELECTION	*Summarizes the distribution of selected cases across strata*. The information is reported per design stage. The table is shown by default.
CPS	*Displays a case processing summary.*

CSTABULATE

CSTABULATE is available in the Complex Samples option.

```
CSTABULATE

/PLAN FILE = file

[/JOINTPROB FILE = file]

/TABLES VARIABLES = varlist [BY varname]

[/CELLS [POPSIZE] [ROWPCT] [COLPCT] [TABLEPCT]]

[/STATISTICS [SE] [CV] [DEFF] [DEFFSQRT] [CIN [({95** })]] [COUNT]
                                           {value}

             --- options for one-way frequency tables ---

             [CUMULATIVE]

             --- options for two-way crosstabulations ---

             [EXPECTED] [RESID] [ASRESID]]

[/TEST       --- options for one-way frequency tables ---

             [HOMOGENEITY]

             --- options for two-way crosstabulations ---

             [INDEPENDENCE]

             --- options for two-by-two crosstabulations ---

             [ODDSRATIO] [RELRISK] [RISKDIFF]]

[/SUBPOP TABLE = varname [BY varname [BY ...]] [DISPLAY = {LAYERED  }]]
                                                          {SEPARATE }

[/MISSING [SCOPE = {TABLE   }] [CLASSMISSING = {EXCLUDE }]]
                   {LISTWISE}                  {INCLUDE }
```

** Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
CSTABULATE
  /PLAN FILE = '/survey/myfile.xml'
  /TABLES VARIABLES = a.
```

Overview

CSTABULATE displays one-way frequency tables or two-way crosstabulations, and associated standard errors, design effects, confidence intervals, and hypothesis tests, for samples drawn by complex sampling methods. The procedure estimates variances by taking into account the sample design used to select the sample, including equal probability and probability proportional to

size (PPS) methods, and with-replacement (WR) and without-replacement (WOR) sampling procedures. Optionally, CSTABULATE creates tables for subpopulations.

Basic Specification

- The basic specification is a PLAN subcommand and the name of a complex sample analysis specification file, which may be generated by CSPLAN, and a TABLES subcommand with at least one variable specified.
- This specification displays a population size estimate and its standard error for each cell in the defined table, as well as for all marginals.

Operations

- CSTABULATE computes table statistics for sampling designs supported by CSPLAN and CSSELECT.
- The input dataset must contain the variables to be analyzed and variables related to the sampling design.
- The complex sample analysis specification file provides an analysis plan based on the sampling design.
- For each cell and marginal in the defined table, the default output is the population size estimate and its standard error.
- WEIGHT and SPLIT FILE settings are ignored by CSTABULATE.

Syntax Rules

- The PLAN and TABLES subcommands are required. All other subcommands are optional.
- Each subcommand may be specified only once.
- Subcommands can be specified in any order.
- All subcommand names and keywords must be spelled in full.
- Equals signs (=) shown in the syntax chart are required.
- Empty subcommands are not allowed.

Examples

Example: Frequency tables

```
* Complex Samples Frequencies.
CSTABULATE
 /PLAN FILE = 'samplesDirectory\nhis2000_subset.csaplan'
 /TABLES VARIABLES = VITANY
 /CELLS  POPSIZE TABLEPCT
 /STATISTICS  SE CIN(95)
 /SUBPOP TABLE = AGE_CAT
 /MISSING SCOPE = TABLE CLASSMISSING = EXCLUDE.
```

- The procedure will compute estimates based on the complex sample analysis specification given in *nhis2000_subset.csaplan*.

- One-way frequency tables are produced for variable *VITANY*. Estimates, standard errors, and 95% confidence intervals are displayed for the population size and table percent for each category.
- In addition, a separate table is produced for these statistics by levels of *AGE_CAT*.
- All other options are set to their default values.

Example: Crosstabulation table

```
* Complex Samples Crosstabs.
CSTABULATE
 /PLAN FILE = 'samplesDirectory\demo.csplan'
 /TABLES VARIABLES = news BY response
 /SUBPOP TABLE = inccat  DISPLAY=LAYERED
 /CELLS  ROWPCT
 /STATISTICS  SE
 /TEST  ODDSRATIO RELRISK
 /MISSING SCOPE = LISTWISE CLASSMISSING = INCLUDE.
```

- The procedure will compute estimates based on the complex sampling plan in *demo.csplan*.
- The crosstabulation of *news* by *response* is produced overall and again by levels of *inccat*.
- The estimates and standard errors of the row percentages are reported in the cells of the crosstabulation tables.
- In addition, the odds ratio and relative risk for *news* by *response* is computed for the overall population and separately for levels of *inccat*.
- All other options are set to their default values.

PLAN Subcommand

The PLAN subcommand specifies the name of an XML file containing analysis design specifications. This file is written by CSPLAN.

- The PLAN subcommand is required.

FILE *Specifies the name of an external file.*

JOINTPROB Subcommand

The JOINTPROB subcommand is used to specify the file or dataset containing the first stage joint inclusion probabilities for the UNEQUAL_WOR estimation. CSSELECT writes this file in the same location and with the same name (but different extension) as the plan file. When the UNEQUAL_WOR estimation is specified, CSTABULATE will use the default location and name of the file unless the JOINTPROB subcommand is used to override them.

FILE *Specifies the name of the file or dataset containing the joint inclusion probabilities.*

TABLES Subcommand

The TABLES subcommand specifies the tabulation variables.

- If a single variable list is specified, then a one-way frequency table is displayed for each variable in the list.
- If the variable list is followed by the BY keyword and a variable, then two-way crosstabulations are displayed for each pair of variables. Pairs of variables are defined by crossing the variable list to the left of the BY keyword with the variable to the right. Each variable on the left defines the row dimension in a two-way crosstabulation, and the variable to the right defines the column dimension. For example, TABLES VARIABLES = A B BY C displays two tables: *A* by *C* and *B* by *C*.
- Numeric or string variables may be specified.
- Plan file and subpopulation variables may not be specified on the TABLES subcommand.
- Within the variable list, all specified variables must be unique. Also, if a variable is specified after the BY keyword, then it must be different from all variables preceding the BY keyword.

VARIABLES *Specifies the tabulation variables.*

CELLS Subcommand

The CELLS subcommand requests various summary value estimates associated with the table cells.

If the CELLS subcommand is not specified, then CSTABULATE displays the population size estimate for each cell in the defined table(s), as well as for all marginals. However, if the CELLS subcommand is specified, then only those summary values that are requested are displayed.

POPSIZE *The population size estimate for each cell and marginal in a table.* This is the default output if the CELLS subcommand is not specified.

ROWPCT *Row percentages.* The population size estimate in each cell in a row is expressed as a percentage of the population size estimate for that row. Available for two-way crosstabulations. For one-way frequency tables, specifying this keyword gives the same output as the TABLEPCT keyword.

COLPCT *Column percentages.* The population size estimate in each cell in a column is expressed as a percentage of the population size estimate for that column. Available for two-way crosstabulations. For one-way frequency tables, specifying this keyword gives the same output as the TABLEPCT keyword.

TABLEPCT *Table percentages.* The population size estimate in each cell of a table is expressed as a percentage of the population size estimate for that table.

STATISTICS Subcommand

The STATISTICS subcommand requests various statistics associated with the summary value estimates in the table cells.

If the STATISTICS subcommand is not specified, then CSTABULATE displays the standard error for each summary value estimate in the defined table(s) cells. However, if the STATISTICS subcommand is specified, then only those statistics that are requested are displayed.

SE	*The standard error for each summary value estimate.* This is the default output if the STATISTICS subcommand is not specified.
CV	*Coefficient of variation.*
DEFF	*Design effects.*
DEFFSQRT	*Square root of the design effects.*
CIN [(value)]	*Confidence interval.* If the CIN keyword is specified alone, then the default 95% confidence interval is computed. Optionally, CIN may be followed by a value in parentheses, where $0 \leq$ value < 100.
COUNT	*Unweighted counts.* The number of valid observations in the dataset for each summary value estimate.
CUMULATIVE	*Cumulative summary value estimates.* Available for one-way frequency tables only.
EXPECTED	*Expected summary value estimates.* The summary value estimate in each cell if the two variables in a crosstabulation are statistically independent. Available for two-way crosstabulations only and displayed only if the TABLEPCT keyword is specified on the CELLS subcommand.
RESID	*Residuals.* The difference between the observed and expected summary value estimates in each cell. Available for two-way crosstabulations only and displayed only if the TABLEPCT keyword is specified on the CELLS subcommand.
ASRESID	*Adjusted Pearson residuals.* Available for two-way crosstabulations only and displayed only if the TABLEPCT keyword is specified on the CELLS subcommand.

TEST Subcommand

The TEST subcommand requests statistics or tests for summarizing the entire table.

Furthermore, if subpopulations are defined on the SUBPOP subcommand using only first-stage stratification variables (or a subset of them), then tests are performed for each subpopulation also.

HOMOGENEITY	*Test of homogeneous proportions.* Available for one-way frequency tables only.
INDEPENDENCE	*Test of independence.* Available for two-way crosstabulations only.
ODDSRATIO	*Odds ratio.* Available for two-by-two crosstabulations only.
RELRISK	*Relative risk.* Available for two-by-two crosstabulations only.
RISKDIFF	*Risk difference.* Available for two-by-two crosstabulations only.

SUBPOP Subcommand

The SUBPOP subcommand specifies subpopulations for which analyses are to be performed.

- The set of subpopulations is defined by specifying a single categorical variable, or two or more categorical variables, separated by the BY keyword, whose values are crossed.
- For example, /SUBPOP TABLE = A defines subpopulations based on the levels of variable *A*.

- For example, `/SUBPOP TABLE = A BY B` defines subpopulations based on crossing the levels of variables *A* and *B*.
- A maximum of 16 variables may be specified.
- Numeric or string variables may be specified.
- All specified variables must be unique.
- Stratification or cluster variables may be specified, but no other plan file variables are allowed on the `SUBPOP` subcommand.
- Tabulation variables may not be specified on the `SUBPOP` subcommand.
- The `BY` keyword is used to separate variables.

The `DISPLAY` keyword specifies the layout of results for subpopulations.

LAYERED	*Results for all subpopulations are displayed in the same table.* This is the default.
SEPARATE	*Results for different subpopulations are displayed in different tables.*

MISSING Subcommand

The `MISSING` subcommand specifies how missing values are handled.

- All design variables must have valid data. Cases with invalid data for any design variable are deleted from the analysis.

The `SCOPE` keyword specifies which cases are used in the analyses. This specification is applied to tabulation variables but not design variables.

TABLE	*Each table is based on all valid data for the tabulation variable(s) used in creating the table.* Tables for different variables may be based on different sample sizes. This is the default.
LISTWISE	*Only cases with valid data for all tabulation variables are used in creating the tables.* Tables for different variables are always based on the same sample size.

The `CLASSMISSING` keyword specifies whether user-missing values are treated as valid. This specification is applied to tabulation variables and categorical design variables (that is, strata, cluster, and subpopulation variables).

EXCLUDE	*Exclude user-missing values.* This is the default.
INCLUDE	*Include user-missing values.* Treat user-missing values as valid data.

CTABLES

CTABLES is available in the Tables option.

Note: Square brackets that are used in the CTABLES syntax chart are required parts of the syntax and are not used to indicate optional elements. All subcommands except /TABLE are optional.

```
CTABLES

 /FORMAT MINCOLWIDTH={DEFAULT}  MAXCOLWIDTH={DEFAULT}
                     {value  }              {value  }

         UNITS={POINTS}   EMPTY= {ZERO   }   MISSING= {'.'    }
               {INCHES}          {BLANK  }            {'chars'}
               {CM    }          {'chars'}

 /VLABELS VARIABLES= varlist

           {LISTWISE}

 /TABLE  rows BY columns BY layers

 /SLABELS POSITION= {COLUMN}  VISIBLE= {YES}
                    {ROW   }          {NO }
                    {LAYER }

 /CLABELS {AUTO                   }
          {ROWLABELS= {OPPOSITE} }
                      {LAYER   }
          {COLLABELS= {OPPOSITE} }
                      {LAYER   }

 /CATEGORIES  VARIABLES= varlist

    { [value, value, value...]                                  }
    { ORDER= {A} KEY= {VALUE           } MISSING= {EXCLUDE} }
             {D}      {LABEL           }          {INCLUDE}
                      {summary(varname)}

     TOTAL= {NO  }  LABEL= "label" POSITION= {AFTER } EMPTY= {INCLUDE}
            {YES }                           {BEFORE}        {EXCLUDE}

   Explicit value lists can include SUBTOTAL='label', HSUBTOTAL='label', MISSING, OTHERNM.

 /TITLES  CAPTION= ['text' 'text'...]
          CORNER=  ['text' 'text'...]
          TITLE=   ['text' 'text'...]
          Text can contain the symbols )DATE  )TIME  )TABLE

 /SIGTEST TYPE= CHISQUARE  ALPHA= {0.05              }
                                  {significance level}

          INCLUDEMRSETS={YES**}
                        {NO   }

          CATEGORIES={ALLVISIBLE**}
                     {SUBTOTALS   }
```

```
/COMPARETEST TYPE= {PROP}  ALPHA= {0.05              }
                   {MEAN}         {significance level}

          ADJUST= {BONFERRONI}  ORIGIN=COLUMN
                  {NONE      }

          INCLUDEMRSETS={YES**}  MEANSVARIANCE={ALLCATS   }
                        {NO   }                {TESTEDCATS}

          CATEGORIES={ALLVISIBLE**}
                     {SUBTOTALS   }
```

Row, column, and layer elements each have the general form

```
varname {[C]} [summary 'label' format...] {+}  varname ...
        {[S]}                             {>}
```

When nesting (>) and concatenation (+) are combined, as in `a + b > c`, nesting occurs before concatenation; parentheses can be used to change precedence, as in `(a + b) > c`.

Summary functions available for all variables: `COUNT ROWPCT.COUNT COLPCT.COUNT TABLEPCT.COUNT SUBTABLEPCT.COUNT LAYERPCT.COUNT LAYERROWPCT.COUNT LAYERCOLPCT.COUNT ROWPCT.VALIDN COLPCT.VALIDN TABLEPCT.VALIDN SUBTABLEPCT.VALIDN LAYERPCT.VALIDN LAYERROWPCT.VALIDN LAYERCOLPCT.VALIDN ROWPCT.TOTALN COLPCT.TOTALN TABLEPCT.TOTALN SUBTABLEPCT.TOTALN LAYERPCT.TOTALN LAYERROWPCT.TOTALN LAYERCOLPCT.TOTALN`

Summary functions available for scale variables and for totals and subtotals of numeric variables: `MAXIMUM MEAN MEDIAN MINIMUM MISSING MODE PTILE RANGE SEMEAN STDDEV SUM TOTALN VALIDN VARIANCE ROWPCT.SUM COLPCT.SUM TABLEPCT.SUM SUBTABLEPCT.SUM LAYERPCT.SUM LAYERROWPCT.SUM LAYERCOLPCT.SUM`

Summary functions available for multiple response variables and their totals: `RESPONSES ROWPCT.RESPONSES COLPCT.RESPONSES TABLEPCT.RESPONSES SUBTABLEPCT.RESPONSES LAYERPCT.RESPONSES LAYERROWPCT.RESPONSES LAYERCOLPCT.RESPONSES ROWPCT.RESPONSES.COUNT COLPCT.RESPONSES.COUNT TABLEPCT.RESPONSES.COUNT SUBTABLEPCT.RESPONSES.COUNT LAYERPCT.RESPONSES.COUNT LAYERROWPCT.RESPONSES.COUNT LAYERCOLPCT.RESPONSES.COUNT ROWPCT.COUNT.RESPONSES COLPCT.COUNT.RESPONSES TABLEPCT.COUNT.RESPONSES SUBTABLEPCT.COUNT.RESPONSES LAYERPCT.COUNT.RESPONSES LAYERROWPCT.COUNT.RESPONSES LAYERCOLPCT.COUNT.RESPONSES`

For unweighted summaries, prefix `U` to a function name, as in `UCOUNT`.

Formats for summaries: `COMMAw.d DOLLARw.d Fw.d NEGPARENw.d NEQUALw.d PARENw.d PCTw.d PCTPARENw.d DOTw.d CCA...CCEw.d Nw.d Ew.d` and all `DATE` formats

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Release History

Release 13.0

- HSUBTOTAL keyword introduced on the CATEGORIES subcommand.

Release 14.0

- INCLUDEMRSETS keyword introduced on the SIGTEST and COMPARETEST subcommands.
- CATEGORIES keyword introduced on the SIGTEST and COMPARETEST subcommands.
- MEANSVARIANCE keyword introduced on the COMPARETEST subcommand.

Examples

```
CTABLES /TABLE POLVIEWS [COLPCT] BY AGECAT.

CTABLES /TABLE $MLTNEWS [COUNT COLPCT] BY SEX
  /SLABELS VISIBLE=NO
  /CATEGORIES VARIABLES=SEX TOTAL=YES.

CTABLES /TABLE (CONFINAN + CONBUS + CONBUS + CONEDUC
  + CONPRESS + CONMEDIC)[COUNT ROWPCT]
  /CLABELS ROWLABELS=OPPOSITE.
```

Overview

The Custom Tables procedure produces tables in one, two, or three dimensions and provides a great deal of flexibility for organizing and displaying the contents.

- In each dimension (row, column, and layer), you can stack multiple variables to concatenate tables and nest variables to create subtables. See the TABLE subcommand.
- You can let Custom Tables determine summary statistics according to the measurement level in the dictionary, or you can assign one or more summaries to specific variables and override the measurement level without altering the dictionary. See the TABLE subcommand.
- You can create multiple response sets with the MRSETS command and use them like ordinary categorical variables in a table expression. You can control the percentage base by choosing an appropriate summary function, and you can control with the MRSETS subcommand whether duplicate responses from a single respondent are counted.
- You can assign totals to categorical variables at different nesting levels to create subtable and table totals, and you can assign subtotals across subsets of the values of a variable. See the CATEGORIES subcommand.
- You can determine, on a per-variable basis, which categories to display in the table, including whether to display missing values and empty categories for which variable labels exist. You can also sort categories by name, label, or the value of a summary function. See the CATEGORIES subcommand.
- You can specify whether to show or hide summary and category labels and where to position the labels. For variable labels, you can specify whether to show labels, names, both, or neither. See the SLABELS, CLABELS, and VLABELS subcommands.

- You can request chi-square tests and pairwise comparisons of column proportions and means. See the SIGTEST and COMPARETEST subcommands.
- You can assign custom titles and captions (see the TITLES subcommand) and control what is displayed for empty cells and those for which a summary function cannot be computed. See the FORMAT subcommand.
- CTABLES ignores SPLIT FILE requests if layered splits (compare groups in the graphical user interface) are requested. You can compare groups by using the split variables at the highest nesting level for row variables. See the TABLE subcommand for nesting variables.

Syntax Conventions

- The basic specification is a TABLE subcommand with at least one variable in one dimension. Multiple TABLE subcommands can be included in one CTABLES command.
- The global subcommands FORMAT, VLABELS, MRSETS, and SMISSING must precede the first TABLE subcommand and can be named in any order.
- The local subcommands SLABELS, CLABELS, CATEGORIES, TITLES, SIGTEST, and COMPARETEST follow the TABLE subcommand in any order and refer to the immediately preceding table expression.
- In general, if subcommands are repeated, their specifications are merged. The last value of each specified attribute is honored.
- Equals signs that are shown in the syntax charts are required.
- Square brackets that are shown in the syntax charts are required.
- All keywords except summary function names, attribute values, and explicit category list keywords can be truncated to as few as three characters. Function names must be spelled in full.
- The slash before all subcommands, including the first subcommand, is required.

Examples

Example: Column Percentages

```
CTABLES /TABLE POLVIEWS [COLPCT] BY AGECAT.
```

Figure 47-1

		Age category					
		Less than 25	25 to 34	35 to 44	45 to 54	55 to 64	65 or older
		Column N %	Column N %	Column N %	Column N %	Column N %	Column N %
Think of self as liberal or conservative	Extremely liberal	4.5%	2.5%	2.1%	2.4%	1.3%	2.2%
	Liberal	18.8%	15.7%	14.6%	11.3%	10.5%	9.4%
	Slightly liberal	13.5%	14.2%	13.2%	15.4%	10.5%	10.5%
	Moderate	36.8%	37.1%	32.7%	37.2%	39.3%	38.8%
	Slightly conservative	14.3%	14.9%	19.3%	15.0%	18.4%	13.4%
	Conservative	11.7%	13.0%	14.6%	15.4%	16.4%	21.2%
	Extremely conservative	.4%	2.7%	3.5%	3.3%	3.6%	4.5%

- *POLVIEWS* defines the rows, and *AGECAT* defines the columns. Column percentages are requested, overriding the default COUNT function.

Example: Using a Multiple Response Set

```
CTABLES  /TABLE $MLTNEWS [COUNT COLPCT] BY SEX
  /SLABELS VISIBLE=NO
  /CATEGORIES VARIABLES=SEX TOTAL=YES.
```

Figure 47-2

		Gender					
		Male		Female		Total	
News sources	Get news from newspapers	375	41.9%	430	36.3%	805	38.7%
	Get news from news magazines	121	13.5%	173	14.6%	294	14.1%
	Get news from television	451	50.3%	626	52.8%	1077	51.8%
	Get news from radio	233	26.0%	318	26.8%	551	26.5%
	Get news from internet	359	40.1%	508	42.9%	867	41.7%

- *$MLTNEWS* is a multiple response set.
- The COLPCT function uses the number of respondents as the percentage base, so each cell shows the percentage of males or females who gave each response, and the sum of percentage for each column is greater than 100.
- Summary labels are hidden.
- The CATEGORIES subcommand creates a total for both sexes.

Example: Concatenation

```
CTABLES /TABLE (CONFINAN + CONBUS + CONBUS + CONEDUC
  + CONPRESS + CONMEDIC)[COUNT ROWPCT]
  /CLABELS ROWLABELS=OPPOSITE.
```

Figure 47-3

	A great deal		Only some		Hardly any	
	Count	Row N %	Count	Row N %	Count	Row N %
Confidence in banks & financial institutions	490	26.3%	1068	57.3%	306	16.4%
Confidence in major companies	500	27.5%	1078	59.2%	243	13.3%
Confidence in major companies	500	27.5%	1078	59.2%	243	13.3%
Confidence in education	511	27.2%	1055	56.1%	315	16.7%
Confidence in press	176	9.5%	878	47.2%	808	43.4%
Confidence in medicine	844	45.0%	864	46.1%	167	8.9%

- The six confidence variables all have the same categories with the same value labels for each category.
- The CLABELS subcommand moves the category labels to the columns.

TABLE Subcommand

The TABLE subcommand specifies the structure of the table, including the variables and summary functions that define each dimension. The TABLE subcommand has the general form

```
/TABLE  rows BY columns BY layers
```

The minimum specification for a row, column, or layer is a variable name. You can specify one or more dimensions.

Variable Types

The variables that are used in a table expression can be category variables, scale variables, or multiple response sets. Multiple response sets are defined by the MRSETS command and always begin with a $. Custom Tables uses the measurement level in the dictionary for the active data file to identify category and scale variables. You can override the default variable type for numeric variables by placing [C] or [S] after the variable name. Thus, to treat the category variable *HAPPY* as a scale variable and obtain a mean, you would specify

```
/TABLE HAPPY [S].
```

Category Variables and Multiple Response Sets

Category variables define one cell per value. See the CATEGORIES subcommand for ways of controlling how categories are displayed. Multiple response sets also define one cell per value.

Example

```
CTABLES /TABLE HAPPY.
```

Figure 47-4

		Count
General happiness	Very happy	891
	Pretty happy	1575
	Not too happy	340

- The counts for *HAPPY* are in the rows.

Example

```
CTABLES /TABLE BY HAPPY.
```

Figure 47-5

General happiness		
Very happy	Pretty happy	Not too happy
Count	Count	Count
891	1575	340

- The counts for *HAPPY* are in the columns.

Example

```
CTABLES /TABLE BY BY HAPPY
```

Figure 47-6

General happiness Very happy

Count
891

- The counts for *HAPPY* are in layers.

Stacking and Nesting

Stacking (or concatenating) variables creates multiple logical tables within a single table structure.

Example

```
CTABLES /TABLE HAPPY + HAPMAR BY CHILDCAT.
```

Figure 47-7

		Number of children (grouped categories)			
		None	1-2	3-4	5 or more
		Count	Count	Count	Count
General happiness	Very happy	197	412	221	59
	Pretty happy	499	662	314	97
	Not too happy	98	136	79	27
Happiness of marriage	Very happy	111	462	232	49
	Pretty happy	51	238	133	22
	Not too happy	5	18	10	4

- The output contains two tables: one table for general happiness by number of children and one table for happiness in marriage by number of children. Except for missing values, all of the cases in the data appear in both tables.

Nesting variables creates hierarchical tables.

Example

```
CTABLES /TABLE SEX > HAPMAR BY CHILDCAT.
```

Figure 47-8

				Number of children (grouped categories)			
				None	1-2	3-4	5 or more
				Count	Count	Count	Count
Gender	Male	Happiness of marriage	Very happy	48	216	102	30
			Pretty happy	25	110	58	11
			Not too happy	3	7	4	1
	Female	Happiness of marriage	Very happy	63	246	130	19
			Pretty happy	26	128	75	11
			Not too happy	2	11	6	3

- The output contains one table with a subtable for each value of *SEX*. The same subtables would result from the table expression `HAPMAR BY CHILDCAT BY SEX`, but the subtables would appear in separate layers.

Stacking and nesting can be combined. When they are combined, by default, nesting takes precedence over stacking. You can use parentheses to alter the order of operations.

Example

```
CTABLES /TABLE (HAPPY + HAPMAR) > SEX.
```

Figure 47-9

				Count
General happiness	Very happy	Gender	Male	373
			Female	518
	Pretty happy	Gender	Male	712
			Female	863
	Not too happy	Gender	Male	133
			Female	207
Happiness of marriage	Very happy	Gender	Male	396
			Female	459
	Pretty happy	Gender	Male	205
			Female	240
	Not too happy	Gender	Male	15
			Female	22

- The output contains two tables. Without the parentheses, the first table, for general happiness, would not have separate rows for male and female.

Scale Variables

Scale variables, such as *age in years* or *population of towns*, do not define multiple cells within a table. The table expression `/TABLE AGE` creates a table with one cell containing the mean of *AGE* across all cases in the data. You can use nesting and/or dimensions to display summary statistics for scale variables within categories. The nature of scale variables prevents their being arranged hierarchically. Therefore:

- A scale variable cannot be nested under another scale variable.
- Scale variables can be used in only one dimension.

Example

```
CTABLES /TABLE AGE > HAPPY BY SEX.
```

Figure 47-10

			Gender	
			Male	Female
			Mean	Mean
Age of respondent	General happiness	Very happy	47	47
		Pretty happy	44	45
		Not too happy	43	47

Specifying Summaries

You can specify one or more summary functions for variables in any one dimension. For category variables, summaries can be specified only for the variables at the lowest nesting level. Thus, in the table expression

```
/TABLE SEX > (HAPPY + HAPMAR) BY AGECAT
```

you can assign summaries to *HAPPY* and *HAPMAR* or to *AGECAT*, but not to both and not to *SEX*.

If a scale variable appears in a dimension, that dimension becomes the statistics dimension, and all statistics must be specified for that dimension. A scale variable need not be at the lowest level of nesting. Thus, the following is a valid specification:

```
CTABLES /TABLE AGE [MINIMUM, MAXIMUM, MEAN] > SEX > HAPPY.
```

A multiple response variable also need not be at the lowest level of nesting. The following specification is a valid specification:

```
CTABLES /TABLE $MLTCARS [COUNT, RESPONSES] > SEX.
```

However, if two multiple response variables are nested, as in `$MULTCARS > $MULTNEWS`, summaries can be requested only for the variable at the innermost nesting level (in this case, *$MULTNEWS*).

The general form for a summary specification is

```
[summary 'label' format, ..., summary 'label' format]
```

- The specification follows the variable name in the table expression. You can apply a summary specification to multiple variables by enclosing the variables in parentheses. The following specifications are equivalent:

```
/TABLE SEX [COUNT] + HAPPY [COUNT, COLPCT]
/TABLE (SEX + HAPPY [COLPCT])[COUNT]
```

- The brackets are required even if only one summary is specified.
- Commas are optional.
- Label and format are both optional; defaults are used if label and format are not specified.
- If totals or subtotals are defined for a variable (on the `CATEGORIES` subcommand), by default, the same functions that are specified for the variable are used for the totals. You can use the keyword `TOTALS` within the summary specification to specify different summary functions for the totals and subtotals. The specification then has the form `[summary 'label' format ... TOTALS [summary 'label' format...]]`. You must still specify `TOTAL=YES` on the `CATEGORIES` subcommand to see the totals.
- Summaries that are available for category variables are also available for scale variables and multiple response sets. Functions that are specific to scale variables and to multiple response sets are also available.
- If case weighting is in effect, summaries are calculated taking into account the current `WEIGHT` value. To obtain unweighted summaries, prefix a `U` to the function name, as in `UCOUNT`. Unweighted functions are not available where weighting would not apply, as in the `MINIMUM` and `MAXIMUM` functions.

Example

```
CTABLES /TABLE SEX > HAPMAR [COLPCT] BY CHILDCAT.
```

Figure 47-11

				Number of children (grouped categories)			
				None	1-2	3-4	5 or more
				Column N %	Column N %	Column N %	Column N %
Gender	Male	Happiness of marriage	Very happy	63.2%	64.9%	62.2%	71.4%
			Pretty happy	32.9%	33.0%	35.4%	26.2%
			Not too happy	3.9%	2.1%	2.4%	2.4%
	Female	Happiness of marriage	Very happy	69.2%	63.9%	61.6%	57.6%
			Pretty happy	28.6%	33.2%	35.5%	33.3%
			Not too happy	2.2%	2.9%	2.8%	9.1%

Example

```
CTABLES /TABLE AGECAT > TVHOURS [MEAN F5.2,
   STDDEV 'Standard Deviation' F5.2, PTILE 90 '90th Percentile'].
```

Figure 47-12

			Mean	Standard Deviation	90th Percentile
Age category	Less than 25	Hours per day watching TV	2.85	2.03	5
	25 to 34	Hours per day watching TV	2.78	2.37	5
	35 to 44	Hours per day watching TV	2.56	2.11	5
	45 to 54	Hours per day watching TV	2.58	1.97	5
	55 to 64	Hours per day watching TV	3.02	2.22	6
	65 or older	Hours per day watching TV	3.58	2.50	6

- Each summary function for the row variable appears by default in a column.
- Labels for standard deviation and the 90th percentile override the defaults.
- Because *TVHOURS* is recorded in whole hours and has an integer print format, the default general print formats for mean and standard deviation would also be integer, so overrides are specified.

Table 47-1
Summary functions: all variables

Function	**Description**	**Default Label***	**Default Format**
COUNT	Number of cases in each category. This is the default for categorical and multiple response variables.	Count	Count
ROWPCT.COUNT	Row percentage based on cell counts. Computed within subtable.	Row %	Percent
COLPCT.COUNT	Column percentage based on cell counts. Computed within subtable.	Column %	Percent
TABLEPCT.COUNT	Table percentage based on cell counts.	Table %	Percent
SUBTABLEPCT.COUNT	Subtable percentage based on cell counts.	Subtable %	Percent
LAYERPCT.COUNT	Layer percentage based on cell counts. Same as table percentage if no layers are defined.	Layer %	Percent
LAYERROWPCT.COUNT	Row percentage based on cell counts. Percentages sum to 100% across the entire row (that is, across subtables).	Layer Row %	Percent

Function	Description	Default Label*	Default Format
LAYERCOLPCT.COUNT	Column percentage based on cell counts. Percentages sum to 100% across the entire column (that is, across subtables).	Layer Column %	Percent
ROWPCT.VALIDN	Row percentage based on valid count.	Row Valid N %	Percent
COLPCT.VALIDN	Column percentage based on valid count.	Column Valid N %	Percent
TABLEPCT.VALIDN	Table percentage based on valid count.	Table Valid N %	Percent
SUBTABLEPCT.VALIDN	Subtable percentage based on valid count.	Subtable Valid N %	Percent
LAYERPCT.VALIDN	Layer percentage based on valid count.	Layer Valid N %	Percent
LAYERROWPCT.VALIDN	Row percentage based on valid count. Percentages sum to 100% across the entire row.	Layer Row Valid N %	Percent
LAYERCOLPCT.VALIDN	Column percentage based on valid count. Percentages sum to 100% across the entire column.	Layer Column Valid N %	Percent
ROWPCT.TOTALN	Row percentage based on total count, including user-missing and system-missing values.	Row Total N %	Percent
COLPCT.TOTALN	Column percentage based on total count, including user-missing and system-missing values.	Column Total N %	Percent
TABLEPCT.TOTALN	Table percentage based on total count, including user-missing and system-missing values.	Table Total N %	Percent
SUBTABLEPCT.TOTALN	Subtable percentage based on total count, including user-missing and system-missing values.	Subtable Total N %	Percent
LAYERPCT.TOTALN	Layer percentage based on total count, including user-missing and system-missing values.	Layer Total N %	Percent
LAYERROWPCT.TOTALN	Row percentage based on total count, including user-missing and system-missing values. Percentages sum to 100% across the entire row.	Layer Row Total N %	Percent
LAYERCOLPCT.TOTALN	Column percentage based on total count, including user-missing and system-missing values. Percentages sum to 100% across the entire column.	Layer Column Total N %	Percent

* This is the default on a U.S.-English system.

The .COUNT suffix can be omitted from percentages that are based on cell counts. Thus, ROWPCT is equivalent to ROWPCT.COUNT.

Table 47-2
Summary functions: scale variables, totals, and subtotals

Function	Description	Default Label	Default Format
MAXIMUM	Largest value.	Maximum	General
MEAN	Arithmetic mean. The default for scale variables.	Mean	General
MEDIAN	50th percentile.	Median	General
MINIMUM	Smallest value.	Minimum	General
MISSING	Count of missing values (both user-missing and system-missing).	Missing	General
MODE	Most frequent value. If there is a tie, the smallest value is shown.	Mode	General
PTILE	Percentile. Takes a numeric value between 0 and 100 as a required parameter. PTILE is computed the same way as APTILE in the Tables add-on module. Note that in the Tables module, the default percentile method was HPTILE.	Percentile ####.##	General
RANGE	Difference between maximum and minimum values.	Range	General
SEMEAN	Standard error of the mean.	Std Error of Mean	General
STDDEV	Standard deviation.	Std Deviation	General
SUM	Sum of values.	Sum	General
TOTALN	Count of nonmissing, user-missing, and system-missing values. The count excludes valid values hidden via the CATEGORIES subcommand.	Total N	Count
VALIDN	Count of nonmissing values.	Valid N	Count
VARIANCE	Variance.	Variance	General
ROWPCT.SUM	Row percentage based on sums.	Row Sum %	Percent
COLPCT.SUM	Column percentage based on sums.	Column Sum %	Percent
TABLEPCT.SUM	Table percentage based on sums.	Table Sum %	Percent
SUBTABLEPCT.SUM	Subtable percentage based on sums.	Subtable Sum %	Percent
LAYERPCT.SUM	Layer percentage based on sums.	Layer Sum %	Percent
LAYERROWPCT.SUM	Row percentage based on sums. Percentages sum to 100% across the entire row.	Layer Row Sum %	Percent
LAYERCOLPCT.SUM	Column percentage based on sums. Percentages sum to 100% across the entire column.	Layer Column Sum %	Percent

Table 47-3
Summary functions: multiple response sets

Function	Description	Default Label	Default Format
RESPONSES	Count of responses.	Responses	Count
ROWPCT.RESPONSES	Row percentage based on responses. Total number of responses is the denominator.	Row Responses %	Percent
COLPCT.RESPONSES	Column percentage based on responses. Total number of responses is the denominator.	Column Responses %	Percent
TABLEPCT.RESPONSES	Table percentage based on responses. Total number of responses is the denominator.	Table Responses %	Percent
SUBTABLEPCT.RESPONSES	Subtable percentage based on responses. Total number of responses is the denominator.	Subtable Responses %	Percent
LAYERPCT.RESPONSES	Layer percentage based on responses. Total number of responses is the denominator.	Layer Responses %	Percent
LAYERROWPCT.RESPONSES	Row percentage based on responses. Total number of responses is the denominator. Percentages sum to 100% across the entire row (that is, across subtables).	Layer Row Responses %	Percent
LAYERCOLPCT.RESPONSES	Column percentage based on responses. Total number of responses is the denominator. Percentages sum to 100% across the entire column (that is, across subtables).	Layer Column Responses %	Percent
ROWPCT.RESPONSES.COUNT	Row percentage: Responses are the numerator, and total count is the denominator.	Row Responses % (Base: Count)	Percent
COLPCT.RESPONSES.COUNT	Column percentage: Responses are the numerator, and total count is the denominator.	Column Responses % (Base: Count)	Percent
TABLEPCT.RESPONSES.COUNT	Table percentage: Responses are the numerator, and total count is the denominator.	Table Responses % (Base: Count)	Percent
SUBTABLEPCT.RESPONSES.COUNT	Subtable percentage: Responses are the numerator, and total count is the denominator.	Subtable Responses % (Base: Count)	Percent
LAYERPCT.RESPONSES.COUNT	Layer percentage: Responses are the numerator, and total count is the denominator.	Layer Responses % (Base: Count)	Percent
LAYERROWPCT.RESPONSES.COUNT	Row percentage: Responses are the numerator, and total count is the denominator. Percentages sum to 100% across the entire row (that is, across subtables).	Layer Row Responses % (Base: Count)	Percent

Function	Description	Default Label	Default Format
LAYERCOLPCT.RESPONSES.COUNT	Column percentage: Responses are the numerator, and total count is the denominator. Percentages sum to 100% across the entire column (that is, across subtables).	Layer Column Responses % (Base: Count)	Percent
ROWPCT.COUNT.RESPONSES	Row percentage: Count is the numerator, and total responses are the denominator.	Row Count % (Base: Responses)	Percent
COLPCT.COUNT.RESPONSES	Column percentage: Count is the numerator, and total responses are the denominator.	Column Count % (Base: Responses)	Percent
TABLEPCT.COUNT.RESPONSES	Table percentage: Count is the numerator, and total responses are the denominator.	Table Count % (Base: Responses)	Percent
SUBTABLEPCT.COUNT.RESPONSES	Subtable percentage: Count is the numerator, and total responses are the denominator.	Subtable Count % (Base: Responses)	Percent
LAYERPCT.COUNT. RESPONSES	Layer percentage: Count is the numerator, and total responses are the denominator.	Layer Count % (Base: Responses)	Percent
LAYERROWPCT.COUNT.RESPONSES	Row percentage: Count is the numerator, and total responses are the denominator. Percentages sum to 100% across the entire row (that is, across subtables).	Layer Row Count % (Base: Responses)	Percent
LAYERCOLPCT.COUNT.RESPONSES	Row percentage: Count is the numerator, and total responses are the denominator. Percentages sum to 100% across the entire column (that is, across subtables).	Layer Column Count % (Base: Responses)	Percent

Formats for Summaries

A default format is assigned to each summary function:

Count	The value is expressed in F (standard numeric) format with 0 decimal places. If you have fractional weights and want a count that reflects those weights, use F format with appropriate decimal places.
Percent	The value is expressed with one decimal place and a percent symbol.
General	The value is expressed in the variable's print format.

These default formats are internal to CTABLES and cannot be used in table expressions. To override the default formats, use any of the print formats that are available in the Base system except Z, PBHEX, and HEX, or use the additional formats that are described in the following table.

Table 47-4
Additional formats for summaries

Format	Description	Example
NEGPARENw.d	Parentheses appear around negative numbers.	–1234.567 formatted as NEGPAREN9.2 yields (1234.57).
NEQUALw.d	"N=" precedes the number.	1234.567 formatted as NEQUAL9.2 yields N=1234.57.
PARENw.d	The number is parenthesized.	1234.567 formatted as PAREN8.2 yields (1234.57).
PCTPARENw.d	A percent symbol follows the parenthesized value.	1234.567 formatted as PCTPAREN10.2 yields (1234.57%).

Missing Values in Summaries

The following table presents the rules for including cases in a table for VALIDN, COUNT, and TOTALN functions when values are included or excluded explicitly through an explicit category list or implicitly through inclusion or exclusion of user-missing values.

Table 47-5
Inclusion/exclusion of values in summaries

Variable and Value Type	VALIDN	COUNT	TOTALN
Categorical Variable: shown valid value Multiple Dichotomy Set: at least one "true" value Multiple Category Set: at least one shown valid value Scale Variable: valid value	Include	Include	Include
Categorical Variable: included user-missing value Multiple Category Set: all values are included user-missing Scale Variable: user-missing or system-missing	Exclude	Include	Include
Categorical Variable: excluded user-missing or system-missing value Multiple Dichotomy Set: all values are "false" Multiple Category Set: all values are excluded user-missing, system-missing, or excluded valid, but at least one value is not excluded valid	Exclude	Exclude	Include
Categorical Variable: excluded valid value Multiple Dichotomy Set: all values are excluded valid values	Exclude	Exclude	Exclude

SLABELS Subcommand

The SLABELS subcommand controls the position of summary statistics in the table and controls whether summary labels are shown.

```
/SLABELS POSITION= {COLUMN}  VISIBLE= {YES}
                   {ROW   }          {NO }
                   {LAYER }
```

By default, summaries appear in the columns and labels are visible.

Example: Summary Label Positioning

```
CTABLES /TABLE NEWS [COUNT COLPCT].
```

Figure 47-13

		Count	Column N %
How often does respondent read newspaper	Every day	805	43.0%
	Few times a week	420	22.5%
	Once a week	294	15.7%
	Less than once a week	202	10.8%
	Never	149	8.0%

```
CTABLES /TABLE NEWS [COUNT COLPCT]
  /SLABELS POSITION=ROW VISIBLE=NO.
```

Figure 47-14

How often does respondent read newspaper	Every day	805
		43.0%
	Few times a week	420
		22.5%
	Once a week	294
		15.7%
	Less than once a week	202
		10.8%
	Never	149
		8.0%

CLABELS Subcommand

The CLABELS subcommand controls the location of category labels.

```
/CLABELS {AUTO                    }
         {ROWLABELS= {OPPOSITE} }
                     {LAYER    }
         {COLLABELS= {OPPOSITE} }
                     {LAYER    }
```

By default, category labels are nested under the variables to which they belong. Category labels for row and column variables can be moved to the opposite dimension or to the layers. If labels exist in both dimensions, only one dimension, row labels or column labels, can be moved; they cannot be swapped.

Example

```
CTABLES
  /TABLE (CONFINAN + CONEDUC + CONBUS + CONMEDIC + CONPRESS + CONTV )
```

Figure 47-15

		Count
Confidence in banks & financial institutions	A great deal	490
	Only some	1068
	Hardly any	306
Confidence in education	A great deal	511
	Only some	1055
	Hardly any	315
Confidence in major companies	A great deal	500
	Only some	1078
	Hardly any	243
Confidence in medicine	A great deal	844
	Only some	864
	Hardly any	167
Confidence in press	A great deal	176
	Only some	878
	Hardly any	808
Confidence in television	A great deal	196
	Only some	936
	Hardly any	744

- Six variables are stacked in the rows, and their category labels are stacked under them.

```
CTABLES
  /TABLE (CONFINAN + CONEDUC + CONBUS + CONMEDIC + CONPRESS + CONTV )
  /SLABELS VISIBLE=NO   /CLABELS ROWLABELS=OPPOSITE
```

Figure 47-16

	A great	Only some	Hardly any
Confidence in banks & financial institutions	490	1068	306
Confidence in education	511	1055	315
Confidence in major companies	500	1078	243
Confidence in medicine	844	864	167
Confidence in press	176	878	808
Confidence in television	196	936	744

- The category labels are moved to the columns. Where variables are stacked, as in this example, the value labels for all of the variables must be exactly the same to allow for this format. Additionally, all must have the same category specifications, and data-dependent sorting is not allowed.

CATEGORIES Subcommand

The CATEGORIES subcommand controls the order of categories in the rows and columns of the table, controls the showing and hiding of ordinary and user-missing values, and controls the computation of totals and subtotals.

```
/CATEGORIES  VARIABLES= varlist

    { [value, value, value...]                                  }
    { ORDER= {A} KEY= {VALUE           } MISSING= {EXCLUDE} }
             {D}      {LABEL           }          {INCLUDE}
                      {summary(varname)}

     TOTAL= {NO  }  LABEL= "label" POSITION= {AFTER } EMPTY= {INCLUDE}
            {YES }                           {BEFORE}        {EXCLUDE}
```

The minimum specification is a variable list and one of the following specifications: a category specification, TOTAL specification, or EMPTY specification. The variable list can be a list of variables or the keyword ALL, which refers to all category variables in the table expression. ALL cannot be used with the explicit category list.

Explicit Category Specification

The explicit category specification is a bracketed list of data values or value ranges in the order in which they are to be displayed in the table. Values not included in the list are excluded from the table. This form allows for subtotals and showing or hiding of specific values (both ordinary and user-missing).

- The list can include both ordinary and user-missing values but not the system-missing value (.).
- Values are optionally separated by commas.
- String and date values must be quoted. Date values must be consistent with the variable's print format.
- The LO, THRU, and HI keywords can be used in the value list to refer to a range of categories. LO and HI can be used only as part of a range specification.
- The MISSING keyword can be used to refer to all user-missing values.
- The OTHERNM keyword can be used to refer to all nonmissing values that are not explicitly named in the list. The keyword can be placed anywhere within the list. The values to which it refers appear in ascending order.
- If a value is repeated in the list, the last instance is honored. Thus, for a variable *RATING* with integer values 1 through 5, the following specifications are equal:

```
/CATEGORIES VARIABLES = RATING [1,2,4,5,3]
/CATEGORIES VARIABLES = RATING [1 THRU 5,3]
/CATEGORIES VARIABLES = RATING [OTHERNM,3]
```

- For a multiple dichotomy set, you can order the variables in the set by using the names of the variables in the set. The variable names are not enclosed in quotation marks.
- The SUBTOTAL keyword is used within a category list to request subtotals for a variable. The position of a subtotal within the list determines where it will appear in the table and the categories to which it applies. By default, a subtotal applies to all values that precede it up to the next subtotal. If POSITION=BEFORE is specified (For more information, see Totals on p. 486.), subtotals apply to the categories that follow them in the list. Hierarchical and overlapping subtotals are not supported. You can specify a label for a subtotal by placing the label in quotation marks immediately following the SUBTOTAL keyword and an equals sign, as illustrated in the following example:

Example

```
CTABLES  /TABLE AGECAT
   /CATEGORIES VARIABLES=AGECAT [1, 2, 3, SUBTOTAL='Subtotal < 45',
   4, 5, 6, SUBTOTAL='Subtotal 45+'].
```

Figure 47-17

		Count
Age category	Less than 25	242
	25 to 34	627
	35 to 44	679
	Subtotal < 45	1548
	45 to 54	481
	55 to 64	320
	65 or older	479
	Subtotal 45+	1280

- The HSUBTOTAL keyword functions just like the SUBTOTAL keyword, except that only the subtotal is displayed in the table; the categories that define the subtotal are not included in the table. So you can use HSUBTOTAL to collapse categories in a table without recoding the original variables.

Example

```
CTABLES  /TABLE AGECAT
   /CATEGORIES VARIABLES=AGECAT [1, 2, 3, HSUBTOTAL='Under 45',
       4, 5, 6, HSUBTOTAL='45 or older']..
```

Figure 47-18

		Count
Age category	Under 45	1548
	45 or older	1280

Implicit Category Specification

The implicit list allows you to sort the categories and to show or hide user-missing values without having to enumerate the values. The implicit list also provides for data-dependent sorting. If you do not supply an explicit value list, you can use the following keywords:

ORDER	*The sorting order.* You can select A (the default) for ascending order, or D for descending order.
KEY	*The sort key.* You can specify VALUE (the default) to sort by the values or LABEL to sort by the value labels. When values are sorted by label, any unlabeled values appear after the labeled values in the table. You can also specify a summary function for data-dependent sorting.
MISSING	*Whether user-missing values are included.* You can specify EXCLUDE (the default) or INCLUDE. System-missing values are never included.

Data-Dependent Sorting. The following conventions and limitations apply to sorting by using a summary function as the key:

- The sort function must be a summary function that is supported in CTABLES.
- The sort function must be used in the table. The exception to this rule is COUNT. You can sort by COUNT even if counts do not appear in the table.
- Data-dependent sorting is not available if category labels are repositioned by using the CLABELS subcommand.

- Summary functions that are available only for scale variables require that you give the variable name in parentheses, as in `MEAN(age)`. For percentiles, the variable name must be followed by a comma and an integer value between 0 and 100, as in `PTILE(age, 75)`. Other functions, such as `COUNT`, do not require a variable name, but you can supply a variable name to restrict the sort.
- When a variable name is given, and multiple logical tables are created through stacking, the entire table is sorted based on the first logical table that includes the categorical variable that is being sorted and the variable that is specified in the key.
- When a table contains more than one dimension, the sort is based on the distribution of the key within the categories of the sorted variable, without regard to the contents of the other dimensions. Thus, given the table

```
CTABLES /TABLE A BY B + C /CAT VAR=A ORDER=A KEY=COUNT(A),
```

the rows are sorted according to the counts for the categories of *A*, without regard to the values of *B* and *C*. If there are no missing values in the other dimension, the result is the same as sorting on the totals for that dimension (in this case, *B* or *C*). If the other dimension has an unbalanced pattern of missing values, the sorting may give unexpected results; however, the result is unaffected by differences in the pattern for *B* and *C*.

- If the sort variable is crossed with stacked category variables, the first table in the stack determines the sort order.
- To ensure that the categories are sorted the same way in each layer of the pivot table, layer variables are ignored for the purpose of sorting.

Example

```
CTABLES
  /TABLE CAR1 BY AGECAT
  /CATEGORIES VARIABLES=AGECAT TOTAL=YES
  /CATEGORIES VARIABLES=CAR1 ORDER=D KEY=COUNT.
```

Figure 47-19

		Age category						
		Less than 25	25 to 34	35 to 44	45 to 54	55 to 64	65 or older	Total
		Count	Count	Count	Count	Count	Count	Count
Car maker, most recent car	American	99	267	293	214	140	215	1228
	Japanese	73	136	140	107	66	104	626
	German	18	91	69	63	36	61	338
	Korean	23	77	88	45	35	50	318
	Swedish	18	32	46	20	24	25	165
	Other	11	24	43	32	19	24	153

- The first `CATEGORIES` subcommand requests a total across all age categories.
- The second `CATEGORIES` subcommand requests a sort of the categories of *CAR1* in descending order (using `COUNT` as the key). The categories of *CAR1* are sorted according to the total counts.

Example

```
CTABLES
  /TABLE AGE [MEAN F5.1] > CAR1 BY SEX
```

```
/CATEGORIES VARIABLES=SEX TOTAL=YES
/CATEGORIES VARIABLES=CAR1 KEY=MEAN(AGE).
```

Figure 47-20

			Gender		
			Male	Female	Total
			Mean	Mean	Mean
Age of respondent	Car maker, most recent car	Swedish	42.6	45.6	44.3
		Japanese	43.5	45.5	44.7
		Korean	43.4	46.2	45.0
		American	45.3	46.5	45.9
		German	44.3	47.6	46.2
		Other	48.6	46.4	47.3

- The first `CATEGORIES` subcommand requests a total across the values of *SEX*.
- The second `CATEGORIES` subcommand requests that the categories of *CAR1* be sorted according to the mean of *AGE*. The categories are sorted according to the total means for both sexes, and that would be the case if the totals were not shown in the table.

Totals

A total can be specified for any category variable regardless of its level of nesting within a dimension. Totals can be requested in more than one dimension. The following options are available:

TOTAL *Whether to display a total for a variable.* You can specify `TOTAL=NO` (the default) or `TOTAL=YES`.

LABEL *The label for the total.* The specification is a quoted string.

POSITION *Whether a total comes after or before the categories of the variable being totaled.* You can specify `AFTER` (the default) or `BEFORE`. `POSITION` also determines whether subtotals that are specified in an explicit list of categories apply to the categories that precede them (`AFTER`) or follow them (`BEFORE`).

Scale variables cannot be totaled directly. To obtain a total or subtotals for a scale variable, request the total or subtotals for the category variable within whose categories the summaries for the scale variable appear.

Example

```
CTABLES /TABLE AGECAT
  /CATEGORIES VARIABLES=AGECAT TOTAL=YES LABEL='Total Respondents'.
```

Figure 47-21

		Count
Age category	Less than 25	242
	25 to 34	627
	35 to 44	679
	45 to 54	481
	55 to 64	320
	65 or older	479
	Total Respondents	2828

Example

```
CTABLES /TABLE AGE [MEAN 'Average' F5.1] > SEX
  /CATEGORIES VARIABLES=SEX TOTAL=YES LABEL='Combined'.
```

Figure 47-22

			Average
Age of respondent	Gender	Male	44.6
		Female	46.3
		Combined	45.6

- The summary function for *AGE* appears in cells that are determined by the values of *SEX*. The total is requested for *SEX* to obtain the average age across both sexes.

Empty Categories

Empty categories are those categories for which no cases appear in the data. For an explicit category list, this includes all explicitly named values and all labeled values that are implied by THRU, OTHERNM, or MISSING. For an implicit category list, this includes all values for which value labels exist.

EMPTY *Whether to show categories whose count is zero*. You can specify EMPTY=INCLUDE (the default) or EMPTY=EXCLUDE.

TITLES Subcommand: Titles, Captions, and Corner Text

The TITLES subcommand specifies table annotations. If the subcommand is used, a title, caption, or corner text must be specified. No caption, title, or corner text is displayed by default.

```
/TITLES  CAPTION= ['text' 'text'...]
         CORNER=  ['text' 'text'...]
         TITLE=   ['text' 'text'...]
```

CAPTION *Caption lines.* The caption appears below the table. Multiple lines can be specified. Each line must be quoted.

CORNER *Corner text.* Corner text appears in the corner cell of the table, above row titles and next to column titles. Multiple lines can be specified. Each line must be quoted.

Pivot tables show all corner text that fits in the corner cell. The specified text is ignored if the table has no corner cell.

The system default TableLook uses the corner area for display of row dimension labels. To display CTABLES corner text, the Row Dimension Labels setting in Table Properties should be set to Nested. This choice can be preset in the default TableLook.

TITLE *Title text.* The title appears above the table. Multiple lines can be specified. Each line must be quoted.

The following symbols can be used within any caption, corner text, or title line. Each symbol must be specified by using an opening right parenthesis and all uppercase letters.

)DATE *Current date.* Displays a locale-appropriate date stamp that includes the year, month, and day.

)TIME *Current time.* Displays a locale-appropriate time stamp.

)TABLE *Table description.* Inserts a description of the table, which consists of the table expression stripped of measurement levels, statistics specifications, and `/TABLE`. If variable labels are available, they are used instead of variable names in the table expression.

Example

```
CTABLES /VLABELS VARIABLES=SEX HAPMAR DISPLAY=NONE
  /TABLE SEX > HAPMAR BY CHILDCAT [COLPCT]
  /SLABELS VISIBLE=NO
  /TITLE TITLE = 'Marital Happiness for Men and Women '+
              'by Number of Children'
         CAPTION= 'Report created at )TIME on )DATE' ')TABLE'.
```

Figure 47-23

Marital Happiness for Men and Women by Number of Children

		Number of children (grouped categories)			
		None	1-2	3-4	5 or more
Male	Very happy	63.2%	64.9%	62.2%	71.4%
	Pretty happy	32.9%	33.0%	35.4%	26.2%
	Not too happy	3.9%	2.1%	2.4%	2.4%
Female	Very happy	69.2%	63.9%	61.6%	57.6%
	Pretty happy	28.6%	33.2%	35.5%	33.3%
	Not too happy	2.2%	2.9%	2.8%	9.1%

Report created at 8:48:27 AM on 11/22/2004
Gender > Happiness of marriage BY Number of children (grouped categories)

- The `VLABELS` subcommand suppresses the display of variable labels for *SEX* and *HAPMAR*.
- The `SLABELS` subcommand suppresses the default label for the summary function.
- The `TITLE` specification on the `TITLE` subcommand uses the standard SPSS convention to break a single string across input lines.
- The `CAPTION` specification uses the `)DATE`, `)TIME`, and `)TABLE` keywords to print the date, time, and a description of the table structure.

Significance Testing

Custom Tables can perform the chi-square test of independence and pairwise comparisons of column proportions for tables that contain at least one category variable in both the rows and the columns. Custom Tables can perform pairwise comparisons of column means for tables that contain at least one summary variable in the rows and one category variable in the columns.

Chi-Square Tests: SIGTEST Subcommand

```
/SIGTEST TYPE= CHISQUARE  ALPHA= {0.05              }
                                 {significance level}

         INCLUDEMRSETS={YES**}
```

```
                    {NO    }

CATEGORIES={ALLVISIBLE**}
           {SUBTOTALS    }
```

The SIGTEST subcommand has the following specifications:

TYPE *Type of significance test*. The specification is required. The only current choice is CHISQUARE.

ALPHA *Significance level for the test*. The specification must be greater than 0 and less than 1. The default is 0.05.

INCLUDEMRSETS *Include multiple response variables in tests*. If there are no multiple response sets, this keyword is ignored. If INCLUDEMRSETS=YES and COUNTDUPLICATES=YES on the MRSETS subcommand, multiple response sets are suppressed with a warning.

CATEGORIES *Replacing categories with subtotals for testing*. If SUBTOTALS is specified, each subtotal replaces its categories for significance testing. If ALLVISIBLE is specified, only subtotals that are specified by using the HSUBTOTAL keyword replace their categories for testing.

Example

```
CTABLES /TABLE AGECAT BY MARITAL
  /CATEGORIES VARIABLES=AGECAT MARITAL TOTAL=YES
  /SIGTEST TYPE=CHISQUARE.
```

Figure 47-24

		Marital status					
		Married	Widowed	Divorced	Separated	Never married	Total
		Count	Count	Count	Count	Count	Count
Age category	Less than 25	37	1	5	5	194	242
	25 to 34	271	13	63	16	263	626
	35 to 44	379	11	129	44	116	679
	45 to 54	275	18	123	13	52	481
	55 to 64	186	31	76	7	20	320
	65 or older	197	209	48	8	17	479
	Total	1345	283	444	93	662	2827

Figure 47-25

Pearson Chi-Square Tests

		Marital status
Age category	Chi-square	1473.381
	df	20
	Sig.	.000*

Results are based on nonempty rows and columns in each innermost subtable.

*. The Chi-square statistic is significant at the 0.05 level.

Pairwise Comparisons of Proportions and Means: COMPARETEST Subcommand

```
/COMPARETEST TYPE= {PROP}  ALPHA= {0.05              }
                  {MEAN}         {significance level}

         ADJUST= {BONFERRONI}  ORIGIN=COLUMN
                 {NONE      }

         INCLUDEMRSETS={YES**}  MEANSVARIANCE={ALLCATS   }
```

```
                        {NO    }                {TESTEDCATS}

      CATEGORIES={ALLVISIBLE**}
                 {SUBTOTALS   }
```

The COMPARETEST subcommand has the following specifications:

TYPE *The type of pairwise comparison.* The specification is required. To compare proportions when the test variable in the rows is categorical, choose PROP. To compare means when the test variable in the rows is scale, choose MEAN.

ALPHA *The significance level for the test.* The specification must be greater than 0 and less than 1. The default is 0.05.

ADJUST *The method for adjusting p values for multiple comparisons.* Valid options are NONE and BONFERRONI. If ADJUST is not specified, the Bonferroni correction is used.

ORIGIN *The direction of the comparison.* This specification will determine whether column means (proportions) or row means (proportions) are being compared. Currently, only COLUMN is supported.

INCLUDEMRSETS *Include multiple response variables in tests.* If there are no multiple response sets, this keyword is ignored. If INCLUDEMRSETS=YES and COUNTDUPLICATES=YES on the MRSETS subcommand, multiple response sets are suppressed with a warning.

MEANSVARIANCE *Computation of variance for means test.* The variance for the means test is always based on the categories that are compared for multiple response tests, but for ordinary categorical variables, the variance can be estimated from just the categories that are compared or all categories. This keyword is ignored unless TYPE=MEAN.

CATEGORIES *Replacing categories with subtotals for testing.* If SUBTOTALS is specified, each subtotal replaces its categories for significance testing. If ALLVISIBLE is specified, only subtotals that are specified by using the HSUBTOTAL keyword replace their categories for testing.

Example

```
CTABLES /TABLE AGECAT BY MARITAL
  /CATEGORIES VARIABLES=AGECAT MARITAL TOTAL=YES
  /COMPARETEST TYPE=PROP ALPHA=.01.
```

Figure 47-26

Comparisons of Column Proportions[a]

		Marital status				
		Married	Widowed	Divorced	Separated	Never married
		(A)	(B)	(C)	(D)	(E)
Age category	Less than 25				B	A B C D
	25 to 34	B		B	B	A B C D
	35 to 44	B E		B E	A B C E	B
	45 to 54	B E		B E		
	55 to 64	E	E	E		
	65 or older	E	A C D E	E		

Results are based on two-sided tests with significance level .01. For each significant pair, the key of the category with the smaller column proportion appears under the category with the larger column proportion.

a. Tests are adjusted for all pairwise comparisons within a row of each innermost subtable using the Bonferroni correction.

- The table of counts is identical to that shown in the example for chi-square above.
- The comparison output shows a number of predictable pairs for marital status among different age groups that are significant at the 0.01 level that is specified with ALPHA in the command.

Example

```
CTABLES /TABLE AGE > SEX BY MARITAL
  /CATEGORIES VARIABLES=SEX TOTAL=YES
  /COMPARETEST TYPE=MEAN.
```

Figure 47-27

			Marital status				
			Married	Widowed	Divorced	Separated	Never married
			Mean	Mean	Mean	Mean	Mean
Age of respondent	Gender	Male	49	66	48	44	32
		Female	45	70	48	41	32
		Total	47	70	48	42	32

Figure 47-28

Comparisons of Column Means[a]

			Marital status				
			Married	Widowed	Divorced	Separated	Never married
			(A)	(B)	(C)	(D)	(E)
Age of respondent	Gender	Male	E	A C D E	E	E	
		Female	E	A C D E	D E	E	

Results are based on two-sided tests assuming equal variances with significance level 0.05. For each significant pair, the key of the smaller category appears under the category with larger mean.

a. Tests are adjusted for all pairwise comparisons within a row of each innermost subtable using the Bonferroni correction.

FORMAT Subcommand

```
/FORMAT MINCOLWIDTH={DEFAULT}  MAXCOLWIDTH={DEFAULT}
                    {value   }              {value   }

        UNITS={POINTS}   EMPTY= {ZERO   }   MISSING= {'.'     }
              {INCHES}          {BLANK  }            {'chars'}
              {CM    }          {'chars'}
```

The FORMAT subcommand controls the appearance of the table. At least one of the following attributes must be specified: MINCOLWIDTH, MAXCOLWIDTH, UNITS, EMPTY, or MISSING.

MINCOLWIDTH *The minimum width of columns in the table.* This setting includes the main tables as well as any tables of significance tests. DEFAULT honors the column labels setting in the current TableLook. The value must be less than or equal to the setting for MAXCOLWIDTH.

MAXCOLWIDTH *The maximum width of columns in the table.* This setting includes the main tables as well as any tables of significance tests. DEFAULT honors the column labels setting in the current TableLook. The value must be greater than or equal to the setting for MINCOLWIDTH.

UNITS *The measurement system for column width values.* The default is POINTS. You can also specify INCHES or CM (centimeters). UNITS is ignored unless MINCOLWIDTH or MAXCOLWIDTH is specified.

EMPTY *Fill characters used when a count or percentage is zero.* ZERO (the default) displays a 0 using the format for the cell statistic. BLANK leaves the statistic blank. You can also specify a quoted character string. If the string is too wide for the cell, the text is truncated.

If FORMAT EMPTY=BLANK, there will be no visible difference between cells that have a count of 0 and cells for which no statistics are defined.

MISSING *Fill characters used when a cell statistic cannot be computed.* This specification applies to non-empty cells for which a statistic, such as standard deviation, cannot be computed. The default is a period (.). You can specify a quoted string. If the string is too wide for the cell, the text is truncated.

VLABELS Subcommand

```
/VLABELS VARIABLES=varlist

        DISPLAY={DEFAULT}
                {NAME   }
                {LABEL  }
                {BOTH   }
                {NONE   }
```

By default, the display of variable labels is controlled by the TVARS specification on the SET command in the Base system. The VLABELS subcommand allows you to show a name, label, or both for each table variable. The minimum specification is a variable list and a DISPLAY specification. To give different specifications for different variables, use multiple VLABELS subcommands.

VARIABLES *The variables to which the subcommand applies.* You can use ALL or *VARNAME* TO *VARNAME,* which refers to the order of variables in the current active data file. If a specified variable does not appear in a table, VLABELS is ignored for that variable.

DISPLAY *Whether the variable's name, label, both, or neither is shown in the table.* DEFAULT honors the SET TVARS setting. NAME shows the variable name only. LABEL shows the variable label only. BOTH shows the variable name and label. NONE hides the name and label.

SMISSING Subcommand

```
/SMISSING {VARIABLE}
          {LISTWISE}
```

If more than one scale variable is included in a table, you can control whether cases that are missing on one variable are included in summaries for which they have valid values.

VARIABLE *Exclude cases variable by variable.* A case is included in summaries for each scale variable for which the case has a valid value regardless of whether the case has missing values for other scale variables in the table.

LISTWISE *Exclude cases that are missing on any scale variable in the table.* This process ensures that summaries for all scale variables in the table are based on the same set of cases.

Listwise deletion applies on a per-table basis. Thus, given the specification

```
/TABLE (AGE [MEAN,COUNT]>SEX) + (AGE+CHILDS)[MEAN,COUNT] > HAPPY
```

all cases with valid values for *AGE* will be used in the AGE > SEX table, regardless of whether they have missing values for *CHILDS* (assuming that they also have valid values for *SEX*).

MRSETS Subcommand

```
/MRSETS COUNTDUPLICATES= {NO }
                         {YES}
```

For multiple response sets that combine multiple category variables, a respondent can select the same response for more than one of the variables. Typically, only one response is desired. For example, *$MAGS* can combine *MAG1* to *MAG5* to record which magazines a respondent reads regularly. If a respondent indicated the same magazine for *MAG1* and *MAG2*, you would not want to count that magazine twice. However, if *$CARS* combines *CAR1* to *CAR5* to indicate which cars a respondent owns now, and a respondent owns two cars of the same make, you might want to count both responses. The MRSETS subcommand allows you to specify whether duplicates are counted. By default, duplicates are not counted.

The MRSETS specification applies only to RESPONSES and percentages based on RESPONSES. MRSETS does not affect counts, which always ignore duplicates.

CURVEFIT

```
CURVEFIT VARIABLES= varname [WITH varname]

 [/MODEL= [LINEAR**] [LOGARITHMIC] [INVERSE]

          [QUADRATIC] [CUBIC] [COMPOUND]

          [POWER] [S] [GROWTH] [EXPONENTIAL]

          [LGSTIC] [ALL]]

 [/CIN={95** }]
       {value}

 [/UPPERBOUND={NO**}]
              {n   }

 [/{CONSTANT† }
   {NOCONSTANT}

 [/PLOT={FIT**}]
        {NONE }

 [/ID = varname]

 [/PRINT=ANOVA]

 [/SAVE=[PRED] [RESID] [CIN]]

 [/APPLY [='model name'] [{SPECIFICATIONS}]]
                          {FIT           }
```

**Default if the subcommand is omitted.

†Default if the subcommand is omitted and there is no corresponding specification on the TSET command.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
CURVEFIT VARIABLES = VARY
  /MODEL=CUBIC.
```

Overview

CURVEFIT fits selected curves to a line plot, allowing you to examine the relationship between one or more dependent variables and one independent variable. CURVEFIT also fits curves to time series and produces forecasts, forecast errors, lower confidence limits, and upper confidence limits. You can choose curves from a variety of regression models.

Options

Model Specification. There are 11 regression models available on the MODEL subcommand. You can fit any or all of these to the data. The keyword ALL is available to fit all 11 models. You can control whether the regression equation includes a constant term using the CONSTANT or NOCONSTANT subcommand.

Upperbound Value. You can specify the upperbound value for the logistic model using the UPPERBOUND subcommand.

Output. You can produce an analysis-of-variance summary table using the PRINT subcommand. You can suppress the display of the curve-fitting plot using the PLOT subcommand.

New Variables. To evaluate the regression statistics without saving predicted and residual variables, specify TSET NEWVAR=NONE prior to CURVEFIT. To save the new variables and replace the variables saved earlier, use TSET NEWVAR=CURRENT (the default). To save the new variables without erasing variables saved earlier, use TSET NEWVAR=ALL or the SAVE subcommand on CURVEFIT.

Forecasting. When used with the PREDICT command, CURVEFIT can produce forecasts and confidence limits beyond the end of the series. For more information, see PREDICT on p. 1425.

Basic Specification

The basic specification is one or more dependent variables. If the variables are not time series, you must also specify the keyword WITH and an independent variable.

- By default, the LINEAR model is fit.
- A 95% confidence interval is used unless it is changed by a TSET CIN command prior to the procedure.
- CURVEFIT produces a plot of the curve, a regression summary table displaying the type of curve used, the R^2 coefficient, degrees of freedom, overall F test and significance level, and the regression coefficients.
- For each variable and model combination, CURVEFIT creates four variables: fit/forecast values, residuals, lower confidence limits, and upper confidence limits. These variables are automatically labeled and added to the active dataset unless TSET NEWVAR=NONE is specified prior to CURVEFIT. For more information, see SAVE Subcommand on p. 499.

Subcommand Order

- Subcommands can be specified in any order.

Syntax Rules

- VARIABLES can be specified only once.
- Other subcommands can be specified more than once, but only the last specification of each one is executed.

Operations

- When CURVEFIT is used with the PREDICT command to forecast values beyond the end of a time series, the original and residual series are assigned the system-missing value after the last case in the original series.
- If a model requiring a log transformation (COMPOUND, POWER, S, GROWTH, EXPONENTIAL, or LGSTIC) is requested and there are values in the dependent variable(s) less than or equal to 0, the model cannot be fit because nonpositive values cannot be log-transformed.
- CURVEFIT uses listwise deletion of missing values. Whenever one dependent variable is missing a value for a particular case or observation, that case or observation will not be included in any computations.
- For the models QUADRATIC and CUBIC, a message is issued if the tolerance criterion is not met. (See TSET for information on changing the tolerance criterion.)
- Since CURVEFIT automatically generates four variables for each dependent variable and model combination, the ALL specification after MODEL should be used cautiously to avoid creating and adding to the active dataset many more variables than are necessary.
- The residual variable is always reported in the original metric. To compute the logged residual (which should be used for diagnostic checks) for the models COMPOUND, POWER, S, GROWTH, and EXPONENTIAL, specify

  ```
  COMPUTE NEWVAR = LN(VAR) - LN(FIT#n).
  ```

  where *NEWVAR* is the logged residual, *VAR* is the name of the dependent variable or observed series, and *FIT#n* is the name of the fitted variable generated by CURVEFIT.

  For the LGSTIC (logistic) model, the logged residual can be obtained by

  ```
  COMPUTE NEWERR = LN(VAR) - LN(1/FIT#n).
  ```

  or, if upperbound value *u* is specified on the UPPERBOUND subcommand, by

  ```
  COMPUTE NEWVAR = LN(1/VAR - 1/u) - LN(1/FIT#n).
  ```

- CURVEFIT obeys the WEIGHT command when there is an independent variable. The WEIGHT specification is ignored if no independent variable is specified.

Limitations

- A maximum of 1 VARIABLES subcommand. There is no limit on the number of dependent variables or series named on the subcommand.
- A maximum of 1 independent variable can be specified after the keyword WITH.

Example

```
CURVEFIT VARIABLES = VARY
  /MODEL=CUBIC.
```

- This example fits a cubic curve to the series *VARY*.

VARIABLES Subcommand

VARIABLES specifies the variables and is the only required subcommand.

- If the dependent variables specified are not time series, you must also specify the keyword WITH and an independent variable.

MODEL Subcommand

MODEL specifies the model or models to be fit to the data. The default model is LINEAR.

- You can fit any or all of the 11 available models.
- Model name keywords can be abbreviated to the first three characters.
- You can use the keyword ALL to fit all models.
- When the LGSTIC model is specified, the upperbound value is included in the output.

The following table lists the available models and their regression equations. The linear transformations for the last six models are also shown.

Keyword	Equation	Linear equation
LINEAR	$Y = b_0 + b_1 t$	
LOGARITHMIC	$Y = b_0 + b_1 \ln(t)$	
INVERSE	$Y = b_0 + b_1 / t$	
QUADRATIC	$Y = b_0 + b_1 t + b_2 t^2$	
CUBIC	$Y = b_0 + b_1 t + b_2 t^2 + b_3 t^3$	
COMPOUND	$Y = b_0 {b_1}^t$	$\ln(Y) = \ln(b_0) + t\ \ln(b_1)$
POWER	$Y = b_0 t^{b_1}$	$\ln(Y) = \ln(b_0) + b_1\ \ln(t)$
S	$Y = e^{b_0 + b_1/t}$	$\ln(Y) = b_0 + b_1/t$
GROWTH	$Y = e^{b_0 + b_1 t}$	$\ln(Y) = b_0 + b_1 t$
EXPONENTIAL	$Y = b_0 e^{b_1 t}$	$\ln(Y) = \ln(b_0) + b_1 t$
LGSTIC (logistic)	$Y = \left(1/u + b_0 {b_1}^t\right)_{-1}$	$\ln(1/Y - 1/u) = \ln(b_0) + t\ \ln(b_1)$

where

b_0 = a constant

b_n = regression coefficient

t = independent variable or time value

ln = the natural logarithm

u = upperbound value for LGSTIC

Example

```
CURVEFIT VARIABLES = VARX.
```

- This command fits a curve to *VARX* using the linear regression model (the default).

Example

```
CURVEFIT VARIABLES = VARY
  /MODEL=GROWTH EXPONENTIAL.
```

- This command fits two curves to *VARY*, one using the growth model and the other using the exponential model.

UPPERBOUND Subcommand

UPPERBOUND is used with the logistic model (keyword LGSTIC) to specify an upper boundary value to be used in the regression equation.

- The specification on UPPERBOUND must be a positive number and must be greater than the largest data value in any of the specified dependent variables.
- The default UPPERBOUND value is infinity, so that $1/u = 0$ and is dropped from the equation.
- You can specify UPPERBOUND NO to reset the value to infinity when applying a previous model.
- If you specify UPPERBOUND without LGSTIC, it is ignored.
- Note that UPPERBOUND is a subcommand and cannot be used within a MODEL subcommand. For example, the following specification is *not* valid:

```
/MODEL=CUBIC LGSTIC   /UPPER=99 LINEAR
```

The correct specification is:

```
/MODEL=CUBIC LGSTIC LINEAR
/UPPER=99
```

CONSTANT and NOCONSTANT Subcommands

CONSTANT and NOCONSTANT indicate whether a constant term should be estimated in the regression equation. The specification overrides the corresponding setting on the TSET command.

- CONSTANT indicates that a constant should be estimated. It is the default unless changed by TSET NOCONSTANT prior to the current procedure.
- NOCONSTANT eliminates the constant term from the model.

Example

```
CURVEFIT VARIABLES = Y1
  /MODEL=COMPOUND
  /NOCONSTANT.
```

- In this example, a compound curve is fit to *Y1* with no constant term in the model.

CIN Subcommand

CIN controls the size of the confidence interval.

- The specification on CIN must be greater than 0 and less than 100.
- The default confidence interval is 95.
- The CIN subcommand overrides the TSET CIN setting.

PLOT Subcommand

PLOT specifies whether the curve-fitting plot is displayed. If PLOT is not specified, the default is FIT. The curve-fitting plot is displayed. PLOT=FIT is generally used with an APPLY subcommand to turn off a PLOT=NONE specification in the applied model.

FIT	*Display the curve-fitting plot.*
NONE	*Do not display the plot.*

ID Subcommand

ID specifies an identification variable. When in point selection mode, you can click on an individual chart point to display the value of the ID variable for the selected case.

SAVE Subcommand

SAVE saves the values of predicted, residual, and/or confidence interval variables generated during the current session in the active dataset.

- SAVE saves the specified variables with default names: *FIT_n* for predicted values, *ERR_n* for residuals, *LCL_n* for the lower confidence limit, and *UCL_n* for the upper confidence limit, where *n* increments each time any variable is saved for a model.
- SAVE overrides the CURRENT or NONE setting on TSET NEWVARS (see TSET).

PRED	*Predicted variable.*
RESID	*Residual variable.*
CIN	*Confidence interval.*

PRINT Subcommand

PRINT is used to produce an additional analysis-of-variance table for each model and variable.

- The only specification on PRINT is the keyword ANOVA.

APPLY Subcommand

APPLY allows you to use a previously defined CURVEFIT model without having to repeat the specifications.

- The specifications on APPLY can include the name of a previous model in quotes and one of two keywords. All of these specifications are optional.
- If a model name is not specified, the model specified on the previous CURVEFIT command is used.
- To change one or more of the specifications of the model, specify the subcommands of only those portions you want to change after the subcommand APPLY.
- If no variables or series are specified on the CURVEFIT command, the dependent variables that were originally specified with the model being reapplied are used.
- To change the dependent variables used with the model, enter new variable names before or after the APPLY subcommand.

The keywords available for APPLY on CURVEFIT are:

SPECIFICATIONS	*Use only the specifications from the original model.* This is the default.
FIT	*Use the coefficients estimated for the original model in the equation.*

Example

```
CURVEFIT VARIABLES = X1
  /MODEL=QUADRATIC.
CURVEFIT VARIABLES = Z1
  /APPLY.
```

- The first command fits a quadratic curve to *X1*.
- The second command fits the same type of curve to *Z1*.

Example

```
CURVEFIT VARIABLES = X1 Y1 Z1
  /MODEL=QUADRATIC.
CURVEFIT APPLY
  /MODEL=CUBIC.
```

- The first command fits quadratic curves to *X1*, *Y1*, and *Z1*.
- The second command fits curves to the same three series using the cubic model.

DATA LIST

```
DATA LIST [FILE='file'] [ENCODING='encoding specification']

[{FIXED}]
  {FREE }  [{("delimiter", "delimiter",..., TAB)}]
  {LIST }

[RECORDS={1}] [SKIP={n}] [{TABLE   }]
         {n}             {NOTABLE}

 /{1    } varname {col location [(format)]} [varname ...]
  {rec #}         {(FORTRAN-like format)  }

 [/{2    } ...] [/ ...]
   {rec #}
```

Numeric and string input formats:

Type	Column-style format	FORTRAN-like format
Numeric (default)	`d` or `F,d`	`Fw.d`
Restricted numeric	`N,d`	`Nw.d`
Scientific notation	`E,d`	`Ew.d`
Numeric with commas	`COMMA,d`	`COMMAw.d`
Numeric with dots	`DOT,d`	`DOTw.d`
Numeric with commas and dollar sign	`DOLLAR,d`	`DOLLARw.d`
Numeric with percent sign	`PCT,d`	`PCTw.d`
Zoned decimal	`Z,d`	`Zw.d`
String	`A`	`Aw`

Format elements to skip columns:

Type	Column-style format	FORTRAN-like format
Tab to column *n*		`Tn`
Skip *n* columns		`nX`

Date and time input formats:

Type	Data input	Format	FORTRAN-like format
International date	dd-mmm-yyyy	`DATE`	`DATEw`
American date	mm/dd/yyyy	`ADATE`	`ADATEw`
European date	dd/mm/yy	`EDATE`	`EDATEw`
Julian date	yyddd	`JDATE`	`JDATEw`
Sorted date	yy/mm/dd	`SDATE`	`SDATEw`
Quarter and year	qQyyyy	`QYR`	`QYRw`
Month and year	mm/yyyy	`MOYR`	`MOYRw`
Week and year	wkWKyyyy	`WKYR`	`WKYRw`

Type	Data input	Format	FORTRAN-like format
Date and time	dd-mmm-yyyy hh:mm:ss.ss	DATETIME	DATETIMEw.d
Time	hh:mm:ss.ss	TIME	TIMEw.d
Days and time	ddd hh:mm:ss.ss	DTIME	DTIMEw.d
Day of the week	string	WKDAY	WKDAYw
Month	string	MONTH	MONTHw

Note: For default numeric (F) format and scientific notation (E) format, the decimal indicator of the input data must match the SPSS locale decimal indicator (period or comma). Use SHOW DECIMAL to display the current decimal indicator and SET DECIMAL to set the decimal indicator. (Comma and Dollar formats only recognize a period as the decimal indicator, and Dot format only recognizes the comma as the decimal indicator.)

Release History

Release 16.0

- ENCODING subcommand added for Unicode support.

Example

```
DATA LIST /ID 1-3 SEX 5 (A) AGE 7-8 OPINION1 TO OPINION5 10-14.
```

Overview

DATA LIST defines a raw data file (a raw data file contains numbers and other alphanumeric characters) by assigning names and formats to each variable in the file. Raw data can be inline (entered with your commands between BEGIN DATA and END DATA) or stored in an external file. They can be in fixed format (values for the same variable are always entered in the same location on the same record for each case) or in freefield format (values for consecutive variables are not in particular columns but are entered one after the other, separated by blanks or commas).

For information on defining matrix materials, see MATRIX DATA. For information on defining complex data files that cannot be defined with DATA LIST, see FILE TYPE and REPEATING DATA. For information on reading SPSS-format data files and portable files, see GET and IMPORT.

The program can also read data files created by other software applications. Commands that read these files include GET CAPTURE and GET TRANSLATE.

Options

Data Source. You can use inline data or data from an external file.

Data Formats. You can define numeric (with or without decimal places) and string variables using an array of input formats (percent, dollar, date and time, and so forth). You can also specify column binary and unaligned positive integer binary formats (available only if used with the MODE=MULTIPUNCH setting on the FILE HANDLE command).

Data Organization. You can define data that are in fixed format (values in the same location on the same record for each case), in freefield format with multiple cases per record, or in freefield format with one case on each record using the FIXED, FREE, and LIST keywords.

Multiple Records. For fixed-format data, you can indicate the number of records per case on the RECORDS subcommand. You can specify which records to read in the variable definition portion of DATA LIST.

Summary Table. For fixed-format data, you can display a table that summarizes the variable definitions using the TABLE subcommand. You can suppress this table using NOTABLE.

Value Delimiter. For freefield-format data (keywords FREE and LIST), you can specify the character(s) that separate data values, or you can use the keyword TAB to specify the tab character as the delimiter. Any delimiter other than the TAB keyword must be enclosed in quotation marks, and the specification must be enclosed in parentheses, as in DATA LIST FREE(",").

End-of-File Processing. You can specify a logical variable that indicates the end of the data using the END subcommand. This logical variable can be used to invoke special processing after all the cases from the data file have been read.

Basic Specification

- The basic specification is the FIXED, LIST, or FREE keyword followed by a slash that signals the beginning of variable definition.
- FIXED is the default.
- If the data are in an external file, the FILE subcommand must be used.
- If the data are inline, the FILE subcommand is omitted and the data are specified between the BEGIN DATA and END DATA commands.
- Variable definition for fixed-format data includes a variable name, a column location, and a format (unless the default numeric format is used). The column location is not specified if FORTRAN-like formats are used, since these formats include the variable width.
- Variable definition for freefield data includes a variable name and, optionally, a delimiter specification and a FORTRAN-like format specification. If format specifications include a width and number of decimal positions (for example, F8.2), the width and decimal specifications are not used to read the data but are assigned as print and write formats for the variables.

Subcommand Order

Subcommands can be named in any order. However, all subcommands must precede the first slash, which signals the beginning of variable definition.

Syntax Rules

Subcommands on DATA LIST are separated by spaces or commas, not by slashes.

Examples

```
* Column-style format specifications.
```

```
DATA LIST /ID 1-3 SEX 5 (A) AGE 7-8 OPINION1 TO OPINION5 10-14.
BEGIN DATA
001 m 28 12212
002 f 29 21212
003 f 45 32145
 ...
128 m 17 11194
END DATA.
```

- The data are inline between the BEGIN DATA and END DATA commands, so the FILE subcommand is not specified. The data are in fixed format. The keyword FIXED is not specified because it is the default.
- Variable definition begins after the slash. Variable *ID* is in columns 1 through 3. Because no format is specified, numeric format is assumed. Variable *ID* is therefore a numeric variable that is three digits wide.
- Variable *SEX* is a short string variable in column 5. Variable *SEX* is one byte wide.
- *AGE* is a two-column numeric variable in columns 7 and 8.
- Variables *OPINION1*, *OPINION2*, *OPINION3*, *OPINION4*, and *OPINION5* are named using the TO keyword. Each is a one-column numeric variable, with *OPINION1* located in column 10 and *OPINION5* located in column 14.
- The BEGIN DATA and END DATA commands enclose the inline data. Note that the values of *SEX* are lowercase letters and must be specified as such on subsequent commands.

Operations

- DATA LIST creates a new active dataset.
- Variable names are stored in the active dataset dictionary.
- Formats are stored in the active dataset dictionary and are used to display and write the values. To change output formats of numeric variables defined on DATA LIST, use the FORMATS command.
- For default numeric (F) format and scientific notation (E) format, the decimal indicator of the input data must match the SPSS locale decimal indicator (period or comma). Use SHOW DECIMAL to display the current decimal indicator and SET DECIMAL to set the decimal indicator. (Comma and Dollar formats only recognize a period as the decimal indicator, and Dot format only recognizes the comma as the decimal indicator.)

Fixed-Format Data

- The order of the variables in the active dataset dictionary is the order in which they are defined on DATA LIST, not their sequence in the input data file. This order is important if you later use the TO keyword to refer to variables on subsequent commands.
- In numeric format, blanks to the left or right of a number are ignored; embedded blanks are invalid. When the program encounters a field that contains one or more blanks interspersed among the numbers, it issues a warning message and assigns the system-missing value to that case.
- Alphabetical and special characters, except the decimal point and leading plus and minus signs, are not valid in numeric variables and are set to system-missing if encountered in the data.

- For string variables, “column” specifications represent bytes, not characters. Many string characters that only take one byte in code page format take two or more bytes in Unicode format. For example, é is one byte in code page format but is two bytes in Unicode format; so *résumé* is six bytes in a code page file and eight bytes in a Unicode file.
- The system-missing value is assigned to a completely blank field for numeric variables. The value assigned to blanks can be changed using the BLANKS specification on the SET command.
- The program ignores data contained in columns and records that are not specified in the variable definition.

Freefield Data

FREE can read freefield data with multiple cases recorded on one record or with one case recorded on more than one record. LIST can read freefield data with one case on each record.

- Line endings are read as delimiters between values.
- If you use FORTRAN-like format specifications (for example, DOLLAR12.2), width and decimal specifications are not used to read the data but are assigned as print and write formats for the variable.

For freefield data *without* explicitly specified value delimiters:

- Commas and blanks are interpreted as delimiters between values.
- Extra blanks are ignored.
- Multiple commas with or without blank space between them can be used to specify missing data.
- If a valid value contains commas or blank spaces, enclose the values in quotes.

For data with explicitly specified value delimiters (for example, DATA LIST FREE (",")):

- Multiple delimiters without any intervening space can be used to specify missing data.
- The specified delimiters cannot occur within a data value, even if you enclose the value in quotes.

Note: Freefield format with specified value delimiters is typically used to read data in text format written by a computer program, not for data manually entered in a text editor.

FILE Subcommand

FILE specifies the raw data file. FILE is required when data are stored in an external data file. FILE must not be used when the data are stored in a file that is included with the INCLUDE command or when the data are inline (see INCLUDE and BEGIN DATA–END DATA).

- FILE must be separated from other DATA LIST subcommands by at least one blank or comma.
- FILE must precede the first slash, which signals the beginning of variable definition.

ENCODING Subcommand

ENCODING specifies the encoding format of the file. The keyword is followed by an equals sign and a quoted encoding specification.

- In Unicode mode, the default is UTF8. For more information, see SET command, UNICODE subcommand.
- In code page mode, the default is the current locale setting. For more information, see SET command, LOCALE subcommand.
- The quoted encoding value can be: Locale (the current locale setting), UTF8, UTF16, UTF16BE (big endian), UTF16LE (little endian), a numeric Windows code page value (for example, '1252'), or an IANA code page value (for example, 'iso8859-1' or cp1252).
- In Unicode mode, the defined width of string variables is tripled for code page and UTF-16 text data files. Use ALTER TYPE to automatically adjust the defined width of string variables.
- If there is no FILE subcommand, the ENCODING subcommand is ignored.

FIXED, FREE, and LIST Keywords

FIXED, FREE, or LIST indicates the format of the data. Only one of these keywords can be used on each DATA LIST. The default is FIXED.

FIXED	*Fixed-format data.* Each variable is recorded in the same column location on the same record for each case in the data. FIXED is the default.
FREE	*Freefield data.* The variables are recorded in the same order for each case but not necessarily in the same column locations. More than one case can be entered on the same record. By default, values are separated by blanks or commas. You can also specify different value delimiters.
LIST	*Freefield data with one case on each record.* The variables are recorded in freefield format as described for the keyword FREE except that the variables for each case must be recorded on one record.

- FIXED, FREE, or LIST must be separated from other DATA LIST subcommands by at least one blank or comma.
- FIXED, FREE, or LIST must precede the first slash, which signals the beginning of data definition.
- For fixed-format data, you can use column-style or FORTRAN-like formats, or a combination of both. For freefield data, you can use only FORTRAN-like formats.
- For fixed-format data, the program reads values according to the column locations specified or implied by the FORTRAN-like format. Values in the data do *not* have to be in the same order as the variables named on DATA LIST and do *not* have to be separated by a space or column.
- For freefield data, the program reads values sequentially in the order in which the variables are named on DATA LIST. Values in the data *must* be in the order in which the variables are named on DATA LIST and *must* be separated by at least one valid delimiter.
- For freefield data, multiple blank spaces can be used to indicate missing information only if a blank space is explicitly specified as the delimiter. In general, it is better to use multiple nonblank delimiters (for example, two commas with no intervening space) to specify missing data.

- In freefield format, a value cannot be split across records.

Example

```
* Data in fixed format.

DATA LIST FILE="/data/hubdata.txt" FIXED RECORDS=3
  /1 YRHIRED 14-15 DEPT 19 SEX 20.
```

- FIXED indicates explicitly that the *hubdata.txt* file is in fixed format. Because FIXED is the default, the keyword FIXED could have been omitted.
- Variable definition begins after the slash. Column locations are specified after each variable. Since formats are not specified, the default numeric format is used. Variable widths are determined by the column specifications: *YRHIRED* is two digits wide, and *DEPT* and *SEX* are each one digit wide.

Example

```
* Data in freefield format.

DATA LIST FREE / POSTPOS NWINS.
BEGIN DATA
2, 19, 7, 5, 10, 25, 5, 17, 8, 11, 3,, 6, 8, 1, 29
END DATA.
```

- Data are inline, so FILE is omitted. The keyword FREE is used because data are in freefield format with multiple cases on a single record. Two variables, *POSTPOS* and *NWINS*, are defined. Since formats are not specified, both variables receive the default F8.2 format.
- All of the data are recorded on one record. The first two values build the first case in the active dataset. For the first case, *POSTPOS* has value 2 and *NWINS* has value 19. For the second case, *POSTPOS* has value 7 and *NWINS* has value 5, and so on. The active dataset will contain eight cases.
- The two commas without intervening space after the data value 3 indicate a missing data value.

Example

```
* Data in list format.

DATA LIST LIST (",")/ POSTPOS NWINS.
BEGIN DATA
2,19
7,5
10,25
5,17
8,11
3,
6,8
1,29
END DATA.
```

- This example defines the same data as the previous example, but LIST is used because each case is recorded on a separate record. FREE could also be used. However, LIST is less prone to errors in data entry. If you leave out a value in the data with FREE format, all values after the missing value are assigned to the wrong variable. Since LIST format reads a case from each record, a missing value will affect only one case.

- A comma is specified as the delimiter between values.
- Since line endings are interpreted as delimiters between values, the second comma after the value 3 (in the sixth line of data) is not necessary to indicate that the value of *NWINS* is missing for that case.

TABLE and NOTABLE Subcommands

TABLE displays a table summarizing the variable definitions supplied on DATA LIST. NOTABLE suppresses the summary table. TABLE is the default.

- TABLE and NOTABLE can be used only for fixed-format data.
- TABLE and NOTABLE must be separated from other DATA LIST subcommands by at least one blank or comma.
- TABLE and NOTABLE must precede the first slash, which signals the beginning of variable definition.

RECORDS Subcommand

RECORDS indicates the number of records per case for fixed-format data. In the variable definition portion of DATA LIST, each record is preceded by a slash. By default, DATA LIST reads one record per case.

- The only specification on RECORDS is a single integer indicating the *total* number of records for each case (even if the DATA LIST command does not define all the records).
- RECORDS can be used only for fixed-format data and must be separated from other DATA LIST subcommands by at least one blank or comma. RECORDS must precede the first slash, which signals the beginning of variable definition.
- Each slash in the variable definition portion of DATA LIST indicates the beginning of a new record. The first slash indicates the first (or only) record. The second and any subsequent slashes tell the program to go to a new record.
- To skip a record, specify a slash without any variables for that record.
- The number of slashes in the variable definition cannot exceed the value of the integer specified on RECORDS.
- The sequence number of the record being defined can be specified after each slash. DATA LIST reads the number to determine which record to read. If the sequence number is used, you *do not* have to use a slash for any skipped records. However, the records to be read must be in their sequential order.
- The slashes for the second and subsequent records can be specified within the variable list, or they can be specified on a format list following the variable list (see the example below).
- All variables to be read from one record should be defined before you proceed to the next record.
- Since RECORDS can be used only with fixed format, it is not necessary to define all the variables on a given record or to follow their order in the input data file.

Example

```
DATA LIST FILE="/data/hubdata.txt" RECORDS=3
 /2 YRHIRED 14-15 DEPT 19 SEX 20.
```

- DATA LIST defines fixed-format data. RECORDS can be used only for fixed-format data.
- RECORDS indicates that there are three records per case in the data. Only one record per case is defined in the data definition.
- The sequence number (2) before the first variable definition indicates that the variables being defined are on the second record. Because the sequence number is provided, a slash is not required for the first record, which is skipped.
- The variables *YRHIRED*, *DEPT*, and *SEX* are defined and will be included in the active dataset. Any other variables on the second record or on the other records are not defined and are not included in the active dataset.

Example

```
DATA LIST FILE="/data/hubdata.txt" RECORDS=3
  / /YRHIRED 14-15 DEPT 19 SEX 20.
```

- This command is equivalent to the one in the previous example. Because the record sequence number is omitted, a slash is required to skip the first record.

Example

```
DATA LIST FILE="/data/hubdata.txt" RECORDS=3
  /YRHIRED (T14,F2.0) /  /NAME (T25,A24).
```

- RECORDS indicates there are three records for each case in the data.
- *YRHIRED* is the only variable defined on the first record. The FORTRAN-like format specification T14 means tab over 14 columns. Thus, *YRHIRED* begins in column 14 and has format F2.0.
- The second record is skipped. Because the record sequence numbers are not specified, a slash must be used to skip the second record.
- *NAME* is the only variable defined for the third record. *NAME* begins in column 25 and is a string variable with a width of 24 bytes (format A24).

Example

```
DATA LIST FILE="/data/hubdata.txt" RECORDS=3
  /YRHIRED NAME (T14,F2.0 /  / T25,A24).
```

- This command is equivalent to the one in the previous example. *YRHIRED* is located on the first record, and *NAME* is located on the third record.
- The slashes that indicate the second and third records are specified within the format specifications. The format specifications follow the complete variable list.

SKIP Subcommand

SKIP skips the first *n* records of the data file.

Example

```
DATA LIST LIST SKIP=2 /numvar.
BEGIN DATA
Some text describing the file
followed by some more text
1
2
3
END DATA.
```

END Subcommand

END provides control of end-of-file processing by specifying a variable that is set to a value of 0 until the end of the data file is encountered, at which point the variable is set to 1. The values of all variables named on DATA LIST are left unchanged. The logical variable created with END can then be used on DO IF and LOOP commands to invoke special processing after all of the cases from a particular input file have been built.

- DATA LIST and the entire set of commands used to define the cases must be enclosed within an INPUT PROGRAM—END INPUT PROGRAM structure. The END FILE command must also be used to signal the end of case generation.
- END can be used only with fixed-format data. An error is generated if the END subcommand is used with FREE or LIST.

Example

```
INPUT PROGRAM.
NUMERIC         TINCOME (DOLLAR8.0).                  /* Total income
LEAVE           TINCOME.
DO IF           $CASENUM EQ 1.
+  PRINT        EJECT.
+  PRINT        / 'Name        Income'.
END IF
DATA LIST     FILE=INCOME END=#EOF NOTABLE / NAME 1-10(A)
                                             INCOME 16-20(F).
DO IF           #EOF.
+  PRINT        / 'TOTAL     ', TINCOME.
+  END FILE.
ELSE.
+  PRINT        / NAME, INCOME (A10,COMMA8).
+  COMPUTE      TINCOME = TINCOME+INCOME.  /* Accumulate total income
END IF.
END INPUT PROGRAM.

EXECUTE.
```

- The data definition commands are enclosed within an INPUT PROGRAM—END INPUT PROGRAM structure.
- NUMERIC indicates that a new numeric variable, *TINCOME*, will be created.

- LEAVE tells the program to leave variable *TINCOME* at its value for the previous case as each new case is read, so that it can be used to accumulate totals across cases.
- The first DO IF structure, enclosing the PRINT EJECT and PRINT commands, tells the program to display the headings *Name* and *Income* at the top of the display (when *$CASENUM* equals 1).
- DATA LIST defines variables *NAME* and *INCOME*, and it specifies the scratch variable *#EOF* on the END subcommand.
- The second DO IF prints the values for *NAME* and *INCOME* and accumulates the variable *INCOME* into *TINCOME* by passing control to ELSE as long as *#EOF* is not equal to 1. At the end of the file, *#EOF* equals 1, and the expression on DO IF is true. The label *TOTAL* and the value for *TINCOME* are displayed, and control is passed to END FILE.

Example

```
* Concatenate three raw data files.

INPUT PROGRAM.
NUMERIC #EOF1 TO #EOF3.  /*These will be used as the END variables.

DO IF #EOF1 & #EOF2 & #EOF3.
+   END FILE.
ELSE IF #EOF1 & #EOF2.
+    DATA LIST  FILE=THREE END=#EOF3 NOTABLE / NAME 1-20(A)
             AGE 25-26 SEX 29(A).
+    DO IF NOT #EOF3.
+       END CASE.
+    END IF.
ELSE IF #EOF1.
+    DATA LIST  FILE=TWO END=#EOF2 NOTABLE / NAME 1-20(A)
             AGE 21-22 SEX 24(A).
+    DO IF NOT #EOF2.
+       END CASE.
+    END IF.
ELSE.
+    DATA LIST  FILE=ONE END=#EOF1 NOTABLE /1 NAME 1-20(A)
             AGE 21-22 SEX 24 (A).
+    DO IF NOT #EOF1.
+       END CASE.
+    END IF.
END IF.
END INPUT PROGRAM.

REPORT FORMAT AUTOMATIC LIST /VARS=NAME AGE SEX.
```

- The input program contains a DO IF–ELSE IF–END IF structure.
- Scratch variables are used on each END subcommand so the value will not be reinitialized to the system-missing value after each case is built.
- Three data files are read, two of which contain data in the same format. The third requires a slightly different format for the data items. All three DATA LIST commands are placed within the DO IF structure.

- END CASE builds cases from each record of the three files. END FILE is used to trigger end-of-file processing once all data records have been read.
- This application can also be handled by creating three separate SPSS-format data files and using ADD FILES to put them together. The advantage of using the input program is that additional files are not required to store the separate data files prior to performing ADD FILES.

Variable Definition

The variable definition portion of DATA LIST assigns names and formats to the variables in the data. Depending on the format of the file, you may also need to specify record and column location. The following sections describe variable names, location, and formats.

Variable Names

- Variable names must conform to variable-naming rules. System variables (beginning with a $) cannot be defined on DATA LIST. For more information, see Variable Names on p. 43.
- The keyword TO can be used to generate names for consecutive variables in the data. Leading zeros in the number are preserved in the name. *X1* TO *X100* and *X001* TO *X100* both generate 100 variable names, but the first 99 names are not the same in the two lists. *X01* TO *X9* is not a valid specification.
- The order in which variables are named on DATA LIST determines their order in the active dataset. If the active dataset is saved as an SPSS-format data file, the variables are saved in this order unless they are explicitly reordered on the SAVE or XSAVE command.

Example

```
DATA LIST FREE / ID SALARY #V1 TO #V4.
```

- The FREE keyword indicates that the data are in freefield format. Six variables are defined: *ID*, *SALARY*, *#V1*, *#V2*, *#V3*, and *#V4*. *#V1* to *#V4* are scratch variables that are not stored in the active dataset. Their values can be used in transformations but not in procedure commands.

Variable Location

For fixed-format data, variable locations are specified either explicitly using column locations or implicitly using FORTRAN-like formats. For freefield data, variable locations are not specified. Values are read sequentially in the order in which variables are named on the variable list.

Fixed-Format Data

- If column-style formats are used, you must specify the column location of each variable after the variable name. If the variable is one column wide, specify the column number. Otherwise, specify the first column number followed by a dash (–) and the last column number.
- If several adjacent variables on the same record have the same width and format type, you can use one column specification after the last variable name. Specify the beginning column location of the first variable, a dash, and the ending column location of the last variable. The

program divides the total number of columns specified equally among the variables. If the number of columns does not divide equally, an error message is issued.

- The same column locations can be used to define multiple variables.
- For FORTRAN-like formats, column locations are implied by the width specified on the formats. For more information, see Variable Formats on p. 514. To skip columns, use the `Tn` or `nX` format specifications.
- With fixed format, column-style and FORTRAN-like specifications can be mixed on the same `DATA LIST` command.
- Record location is indicated by a slash or a slash and record number before the names of the variables on that record. For more information, see RECORDS Subcommand on p. 508.
- The program ignores data in columns and on records that are not specified on `DATA LIST`.
- In the data, values do not have to be separated by a space or comma.

Example

```
DATA LIST  FILE="/data/hubdata.txt" RECORDS=3
  /1 YRHIRED 14-15 DEPT 19 SEX 20
  /2 SALARY 21-25.
```

- The data are in fixed format (the default) and are read from the file *HUBDATA*.
- Three variables, *YRHIRED*, *DEPT*, and *SEX*, are defined on the first record of the *HUBDATA* file. One variable, *SALARY*, is read from columns 21 through 25 on the second record. The total number of records per case is specified as 3 even though no variables are defined on the third record. The third record is simply skipped in data definition.

Example

```
DATA LIST  FILE="/data/hubdata.txt" RECORDS=3
  /1 DEPT 19 SEX 20 YRHIRED 14-15 MOHIRED 12-13 HIRED 12-15
  /2 SALARY 21-25.
```

- The first two defined variables are *DEPT* and *SEX*, located in columns 19 and 20 on record 1. The next three variables, *YRHIRED*, *MOHIRED*, and *HIRED*, are also located on the first record.
- *YRHIRED* is read from columns 14 and 15, *MOHIRED* from columns 12 and 13, and *HIRED* from columns 12 through 15. The variable *HIRED* is a four-column variable with the first two columns representing the month when an employee was hired (the same as *MOHIRED*) and the last two columns representing the year of employment (the same as *YRHIRED*).
- The order of the variables in the dictionary is the order in which they are defined on `DATA LIST`, not their sequence in the *HUBDATA* file.

Example

```
DATA LIST  FILE="/data/hubdata.txt" RECORDS=3
  /1 DEPT 19 SEX 20 MOHIRED YRHIRED 12-15
  /2 SALARY 21-25.
```

- A single column specification follows *MOHIRED* and *YRHIRED*. DATA LIST divides the total number of columns specified equally between the two variables. Thus, each variable has a width of two columns.

Example

```
* Mixing column-style and FORTRAN-like format specifications.

DATA LIST FILE=PRSNL / LNAME M_INIT STREET (A20,A1,1X,A10)
    AGE 35-36.
```

- FORTRAN-like format specifications are used for string variables *LNAME*, *M_INIT*, and *STREET*. These variables must be adjacent in the data file. *LNAME* is 20 bytes wide and is located in columns 1–20. *M_INIT* is one byte wide and is located in column 21. The 1X specification defines a blank column between *M_INIT* and *STREET*. *STREET* is 10 bytes wide and is located in columns 23–32.
- A column-style format is used for the variable *AGE*. *AGE* begins in column 35, ends in column 36, and by default has numeric format.

Freefield Data

- In freefield data, column location is irrelevant since values are not in fixed column positions. Instead, values are simply separated from each other by blanks, commas, or a specified delimiter. Any number of consecutive blanks are interpreted as one delimiter unless a blank space is explicitly specified as the value delimiter. A value cannot be split across records.
- If there are not enough values to complete the last case, a warning is issued and the incomplete case is dropped.
- The specified delimiter can only be used within data values if the value is enclosed in quotes.
- To include a single quote (apostrophe) in a string value, enclose the value in double quotes. To include double quotes in a string value, enclose the value in single quotes. For more information, see String Values in Command Specifications on p. 35.

Variable Formats

Two types of format specifications are available: column-style and FORTRAN-like. With each type, you can specify both numeric and string formats. The difference between the two types is that FORTRAN-like formats include the width of the variable and column-style formats do not.

- Column-style formats are available only for fixed-format data.
- Column-style and FORTRAN-like formats can be mixed on the same DATA LIST to define fixed-format data.
- A value that cannot be read according to the format type specified is assigned the system-missing value and a warning message is issued.

The following sections discuss the rules for specifying column-style and FORTRAN-like formats, followed by additional considerations for numeric and string formats.

Column-Style Format Specifications

The following rules apply to column-style formats:

- Data must be in a fixed format.
- Column locations must be specified after variable names. The width of a variable is determined by the number of specified columns. For more information, see Fixed-Format Data on p. 512.
- Following the column location, specify the format type in parentheses. The format type applies only to the variable or the list of variables associated with the column location specification immediately before it. If no format type is specified, numeric (F) format is used.
- To include decimal positions in the format, specify the format type followed by a comma and the number of decimal positions. For example, `(DOLLAR)` specifies only whole dollar amounts, and `(DOLLAR,2)` specifies `DOLLAR` format with two decimal positions.
- Since column positions are explicitly specified, the variables can be named in any order.

FORTRAN-like Format Specifications

The following rules apply to FORTRAN-like formats:

- Data can be in either fixed or freefield format.
- Column locations cannot be specified. The width of a variable is determined by the width portion (`w`) of the format specification. The width must specify the number of bytes in the widest value.
- One format specification applies to only one variable. The format is specified in parentheses after the variable to which it applies. Alternatively, a variable list can be followed by an equal number of format specifications contained in one set of parentheses. When a number of consecutive variables have the same format, the number can be used as a multiplying factor preceding the format. For example, `(3F5.2)` assigns the format `F5.2` to three consecutive variables.
- For fixed data, the number of formats specified (either explicitly or implied by the multiplication factor) must be the same as the number of variables. Otherwise, the program issues an error message. If no formats are specified, all variables have the default format `F8.2`.
- For freefield data, variables with no specified formats take the default `F8.2` format. However, an asterisk (*) must be used to indicate where the default format stops. Otherwise, the program tries to apply the next specified format to every variable before it and issues an error message if the number of formats specified is less than the number of variables.
- For freefield data, width and decimal specifications are not used to read the data but are assigned as print and write formats for the variable.
- For fixed data, `Tn` can be used before a format to indicate that the variable begins at the *n*th column, and `nX` can be used to skip *n* columns before reading the variable. When `Tn` is specified, variables named do not have to follow the order of the variables in the data.
- For freefield data, variables are located according to the sequence in which they are named on `DATA LIST`. The order of variables on `DATA LIST` must correspond to the order of variables in the data.

- To include decimal positions in the format for fixed-format data, specify the total width followed by a decimal point and the number of decimal positions. For example, `(DOLLAR5)` specifies a five-column `DOLLAR` format without decimal positions, and `(DOLLAR5.2)` specifies a five-column `DOLLAR` format, two columns of which are decimal positions.

Numeric Formats

- Format specifications on `DATA LIST` are input formats. Based on the width specification and format type, the program generates output (print and write) formats for each variable. The program automatically expands the output format to accommodate punctuation characters such as decimal points, commas, dollar signs, or date and time delimiters. (The program does not automatically expand the output formats you assign on the `FORMATS`, `PRINT FORMATS`, and `WRITE FORMATS` commands. For information on assigning output formats, refer to these commands.)
- Scientific notation is accepted in input data with `F`, `COMMA`, `DOLLAR`, `DOT`, and `PCT` formats. The same rules apply to these formats as to `E` format. The values 1.234E3, 1.234+3, and 1.234E 3 are all legitimate. The last value (with a blank space) will cause freefield data to be misread and therefore should be avoided when `LIST` or `FREE` is specified.

Implied Decimal Positions

- For fixed-format data, decimal positions can be coded in the data or implied by the format. If decimal positions are implied but are not entered in the data, the program interprets the rightmost digits in each value as the decimal digits. A coded decimal point in a value overrides the number of implied decimal places. For example, `(DOLLAR,2)` specifies two decimal positions. The value 123 is interpreted as 1.23; however, the value 12.3 is interpreted as 12.3 because the coded decimal position overrides the number of implied decimal positions.
- For freefield data, decimal positions cannot be implied but must be coded in the data. If decimal positions are specified in the format but a data value does not include a decimal point, the program fills the decimal places with zeros. For example, with `F3.1` format (three columns with one decimal place), the value 22 is displayed as 22.0. If a value in the data has more decimal digits than are specified in the format, the additional decimals are truncated in displayed output (but not in calculations). For example, with `F3.1` format, the value 2.22 is displayed as 2.2 even though in calculations it remains 2.22.

The table below compares how values are interpreted for fixed and freefield formats. Values in the table are for a four-column numeric variable.

Table 49-1
Interpretation of values in fixed and freefield format

	Fixed		Freefield	
Values	**Default**	**Two defined decimal places**	**Default**	**Two defined decimal places**
2001	2001	20.01	2001.00	2001.00
201	201	2.01	201.00	201.00
–201	–201	–2.01	–201.00	–201.00
2	2	.02	2.00	2.00

	Fixed		Freefield	
Values	**Default**	**Two defined decimal places**	**Default**	**Two defined decimal places**
20	20	.20	20.00	20.00
2.2	2.2	2.2	2.20	2.20
.201	.201	.201	.201	.201
2 01	Undefined	Undefined	Two values	Two values

Example

```
DATA LIST
  /MODEL 1 RATE 2-6(PCT,2) COST 7-11(DOLLAR) READY 12-21(ADATE).
BEGIN DATA
1935  7878811-07-1988
2 16754654606-08-1989
3 17684783612-09-1989
END DATA.
```

- Data are inline and in fixed format (the default).
- Each variable is followed by its column location. After the column location, a column-style format is specified in parentheses.
- *MODEL* begins in column 1, is one column wide, and receives the default numeric `F` format.
- *RATE* begins in column 2 and ends in column 6. The `PCT` format is specified with two decimal places. A comma is used to separate the format type from the number of decimal places. Decimal points are not coded in the data. Thus, the program reads the rightmost digits of each value as decimal digits. The value 935 for the first case in the data is interpreted as 9.35. Note that it does not matter where numbers are entered within the column width.
- *COST* begins in column 7 and ends in column 11. `DOLLAR` format is specified.
- *READY* begins in column 12 and ends in column 21. `ADATE` format is specified.

Example

```
DATA LIST FILE="/data/data1.txt"
  /MODEL (F1) RATE (PCT5.2) COST (DOLLAR5) READY (ADATE10).
```

- In this example, the `FILE` subcommand is used because the data are in an external file.
- The variable definition is the same as in the preceding example except that FORTRAN-like format specifications are used rather than column-style. Column locations are not specified. Instead, the format specifications include a width for each format type.
- The width (`w`) portion of each format must specify the total number of bytes in the widest value. `DOLLAR5` format for *COST* accepts the five-digit value 78788, which displays as $78,788. Thus, the specified input format `DOLLAR5` generates an output format `DOLLAR7`. The program automatically expands the width of the output format to accommodate the dollar sign and comma in displayed output.

String Formats

String (alphanumeric) variables can contain any numbers, letters, or characters, including special characters and embedded blanks. Numbers entered as values for string variables cannot be used in calculations unless you convert them to numeric format (see RECODE). On DATA LIST, a string variable is defined with an A format if data are in standard character form or an AHEX format if data are in hexadecimal form.

- For fixed-format data, the width of a string variable is either implied by the column location specification or specified by the *w* on the FORTRAN-like format. For freefield data, the width must be specified on the FORTRAN-like format.
- For string variables, "column" and width specifications represent bytes, not characters. Many string characters that only take one byte in code page format take two or more bytes in Unicode format. For example, é is one byte in code page format but is two bytes in Unicode format; so *resumé* is six bytes in a code page file and seven bytes in a Unicode file.
- AHEX format is available only for fixed-format data. Since each set of two hexadecimal characters represents one standard character, the width specification must be an even number. The output format for a variable in AHEX format is A format with half the specified width.
- If a string in the data is longer than its specified width, the string is truncated and a warning message is displayed. If the string in the data is shorter, it is right-padded with blanks and no warning message is displayed.
- For fixed-format data, all characters within the specified or implied columns, including leading, trailing, and embedded blanks and punctuation marks, are read as the value of the string.
- For freefield data without a specified delimiter, string values in the data must be enclosed in quotes if the string contains a blank or a comma. Otherwise, the blank or comma is treated as a delimiter between values. For more information, see String Values in Command Specifications on p. 35.

Example

```
DATA LIST FILE="/data/wins.txt" FREE /POSTPOS NWINS * POSNAME (A24).
```

- *POSNAME* is specified as a 24-byte string. The asterisk preceding *POSNAME* indicates that *POSTPOS* and *NWINS* are read with the default format. If the asterisk was not specified, the program would apply the A24 format to *POSNAME* and then issue an error message indicating that there are more variables than specified formats.

Example

```
DATA LIST FILE="/data/wins.txt" FREE /POSTPOS * NWINS (A5) POSWINS.
```

- Both *POSTPOS* and *POSWINS* receive the default numeric format F8.2.
- *NWINS* receives the specified format of A5.

DATAFILE ATTRIBUTE

```
DATAFILE ATTRIBUTE
         ATTRIBUTE=name('value') name('value')...
                   arrayname[1]('value') arrayname[2]('value')...
         DELETE=name name...
                arrayname[n] arrayname...
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Release History

Release 14.0

- Command introduced.

Example

```
DATAFILE ATTRIBUTE
  ATTRIBUTE=OriginalVersion ('1').
```

Overview

DATAFILE ATTRIBUTE provides the ability for you to define your own data file attributes and assign attribute values to the active dataset.

- User-defined data file attributes are saved with the data file in the data dictionary.
- The DATAFILE ATTRIBUTE command takes effect immediately, updating the data dictionary without requiring a data pass.
- You can display a list of data file and variable attributes with DISPLAY ATTRIBUTES. For more information, see DISPLAY on p. 598.

Basic Specification

The basic specification is:

- ATTRIBUTE keyword followed by an equals sign (=) and one or more attribute names that follow variable naming rules, with each attribute name followed by a quoted attribute value, enclosed in parentheses.

or

- DELETE keyword followed by an equals sign (=) and a list of defined attribute names or attribute arrays.

Syntax Rules

- The keywords ATTRIBUTE and DELETE must each be followed by an equals sign (=).

- Each ATTRIBUTE keyword must be followed by a name that follows variable naming rules and a single, quoted attribute value, enclosed in parentheses. For more information, see Variable Names on p. 43.
- Attribute names that begin with @ are not displayed by DISPLAY DICTIONARY or DISPLAY ATTRIBUTES. They can only be displayed with DISPLAY @ATTRIBUTES.
- Attribute names that begin with a dollar sign ($) are reserved for internal use.
- All attribute values must be quoted (single or double quotes), even if the values are numbers.
- Attribute values can be up to 32,767 bytes in length.

Example

```
DATAFILE ATTRIBUTE
  ATTRIBUTE=OriginalVersion ('1')
            CreationDate('10/28/2004')
            RevisionDate('10/29/2004').
```

Attribute Arrays

If you append an integer enclosed in square brackets to the end of an attribute name, the attribute is interpreted as an array of attributes. For example:

```
DATAFILE ATTRIBUTE
  ATTRIBUTE=FileAttribute[99]('not quite 100').
```

will create 99 attributes—*FileAttribute[01]* through *FileAttribute[99]*—and will assign the value "not quite 100" to the last one.

- Array subscripts (the value enclosed in square brackets) must be integers greater than 0. (Array subscript numbering starts with 1, not 0.)
- If the root name of an attribute array is the same as an existing attribute name, the attribute array replaces the existing attribute. If no value is assigned to the first element in the array (subscript [1]), the original attribute value is used for that element value.

With the DELETE keyword, the following rules apply to attribute arrays:

- If you specify DELETE followed by an array root name and no value in square brackets, all attributes in the array are deleted.
- If you specify DELETE with an array name followed by an integer value in square brackets, the specified array element is deleted and the integer values for all subsequent attributes in the array (in numeric order) are changed to reflect the new order of array elements.

Example

```
DATAFILE ATTRIBUTE
  ATTRIBUTE=RevisionDate('10/29/2004').
 DATAFILE ATTRIBUTE
   ATTRIBUTE=RevisionDate[2] ('10/21/2005').
DATAFILE ATTRIBUTE
  DELETE=RevisionDate[1].
DATAFILE ATTRIBUTE
  DELETE=RevisionDate.
```

- The first `DATAFILE ATTRIBUTE` command creates the attribute *RevisionDate* with a value of 10/29/2004.
- The second `DATAFILE ATTRIBUTE` command creates an array attribute named *RevisionDate*, which replaces the original attribute of the same name. Two array elements are created: *RevisionDate[1]* retains the original value of *RevisionDate*, and *RevisionDate[2]* has a value of 10/21/2005.
- The third `DATAFILE ATTRIBUTE` command deletes *RevisionDate[1]*, and the array element formerly known as *RevisionDate[2]* becomes the new *RevisionDate[1]* (with a value of 10/21/2005).
- The last `DATAFILE ATTRIBUTE` command deletes all attributes in the *RevisionDate* array, since it specifies the array root name without an integer value in brackets.

DATASET ACTIVATE

```
DATASET ACTIVATE name
        [WINDOW={ASIS }]
                {FRONT}
```

Release History

Release 14.0

- Command introduced.

Example

```
GET FILE='/data/mydata.sav'.
DATASET NAME file1.
COMPUTE AvgIncome=income/famsize.
GET DATA /TYPE=XLS
  /FILE='/data/exceldata.xls'.
COMPUTE TotIncome=SUM(income1, income2, income3).
DATASET NAME file2.
DATASET ACTIVATE file1.
```

Overview

The DATASET commands (DATASET NAME, DATASET ACTIVATE, DATASET DECLARE, DATASET COPY, DATASET CLOSE) provide the ability to have multiple data sources open at the same time and control which open data source is active at any point in the session. Using defined dataset names, you can then:

- Merge data (for example, MATCH FILES, ADD FILES, UPDATE) from multiple different source types (for example, text data, database, spreadsheet) without saving each one as an SPSS data file first.
- Create new datasets that are subsets of open data sources (for example, males in one subset, females in another, people under a certain age in another, or original data in one set and transformed/computed values in another subset).
- Copy and paste variables, cases, and/or variable properties between two or more open data sources in the Data Editor.

The DATASET ACTIVATE command makes the named dataset the active dataset in the session.

- If the previous active dataset does not have a defined dataset name, it is no longer available in the session.
- If the previous active dataset has a defined dataset name, it remains available for subsequent use in its current state.
- If the named dataset does not exist, an error occurs, and the command is not executed.
- DATASET ACTIVATE cannot be used within transformation structures such as DO IF, DO REPEAT, or LOOP.

Basic Specification

The basic specification for DATASET ACTIVATE is the command name followed by a name of a previously defined dataset. For more information, see DATASET NAME on p. 533.

WINDOW keyword

The WINDOW keyword controls the state of the Data Editor window associated with the dataset.

ASIS	The Data Editor window containing the dataset is not affected. This is the default.
FRONT	The Data Editor window containing the dataset is brought to the front and the dataset becomes the active dataset for dialog boxes.

Operations

- Commands operate on the active dataset. The **active** dataset is the data source most recently opened (for example, by commands such as GET DATA, GET SAS, GET STATA, GET TRANSLATE) or most recently activated by a DATASET ACTIVATE command. (*Note*: the active dataset can also be changed by clicking anywhere in the Data Editor window of an open data source or selecting a dataset from the list of available datasets in a syntax window toolbar.)
- Variables from one dataset are not available when another dataset is the active dataset.
- Transformations to the active dataset—before or after defining a dataset name—are preserved with the named dataset during the session, and any pending transformations to the active dataset are automatically executed whenever a different data source becomes the active dataset.
- Dataset names can be used in most commands that can contain a reference to an SPSS data file.
- Wherever a dataset name, file handle (defined by the FILE HANDLE command), or filename can be used to refer to an SPSS data file, defined dataset names take precedence over file handles, which take precedence over filenames. For example, if *file1* exists as both a dataset name and a file handle, FILE=file1 in the MATCH FILES command will be interpreted as referring to the dataset named *file1*, not the file handle.

Example

```
GET FILE='/data/mydata.sav'.
DATASET NAME file1.
COMPUTE AvgIncome=income/famsize.
GET DATA /TYPE=XLS
  /FILE='/data/exceldata.xls'.
COMPUTE TotIncome=SUM(income1, income2, income3).
DATASET NAME file2.
DATASET ACTIVATE file1.
```

- Reading a new data source automatically changes the active dataset; so the GET DATA command changes the active dataset to the data read from the Excel worksheet.

- Since the previous active dataset has a defined dataset name associated with it, it is preserved in its current state for subsequent use in the session. The "current state" includes the new variable *AvgIncome* generated by the `COMPUTE` command, since pending transformations are automatically executed before the Excel worksheet become the active dataset.
- When the dataset *file1* is activated again, any pending transformations associated with dataset *file2* are automatically executed; so the new variable *TotIncome* is preserved with the dataset.

DATASET CLOSE

```
DATASET CLOSE {name}
              {*   }
              {ALL }
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Release History

Release 14.0

- Command introduced.

Example

```
DATASET CLOSE file1.
```

Overview

The DATASET commands (DATASET NAME, DATASET ACTIVATE, DATASET DECLARE, DATASET COPY, DATASET CLOSE) provide the ability to have multiple data sources open at the same time and control which open data source is active at any point in the session. Using defined dataset names, you can then:

- Merge data (for example, MATCH FILES, ADD FILES, UPDATE) from multiple different source types (for example, text data, database, spreadsheet) without saving each one as an SPSS data file first.
- Create new datasets that are subsets of open data sources (for example, males in one subset, females in another, people under a certain age in another, or original data in one set and transformed/computed values in another subset).
- Copy and paste variables, cases, and/or variable properties between two or more open data sources in the Data Editor.

The DATASET CLOSE command closes the named dataset.

- If the dataset name specified is not the active dataset, that dataset is closed and no longer available in the session.
- If the dataset name specified is the active dataset or if an asterisk (*) is specified and the active dataset has a name, the association with that name is broken. The active dataset remains active but has no name.
- If ALL is specified, all associations with datasets are broken. All the datasets except the active dataset and their data windows are closed and no longer available in the session. The active dataset remains active but has no name.

Basic Specification

The only specification for DATASET CLOSE is the command name followed by a dataset name, an asterisk (*), or the keyword ALL.

DATASET COPY

```
DATASET COPY name
        [WINDOW={MINIMIZED}]
                {HIDDEN   }
                {FRONT    }
```

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Release History

Release 14.0

- Command introduced.

Example

```
DATASET NAME original.
DATASET COPY males.
DATASET ACTIVATE males.
SELECT IF gender=0.
DATASET ACTIVATE original.
DATASET COPY females.
DATASET ACTIVATE females.
SELECT IF gender=1.
```

Overview

The DATASET commands (DATASET NAME, DATASET ACTIVATE, DATASET DECLARE, DATASET COPY, DATASET CLOSE) provide the ability to have multiple data sources open at the same time and control which open data source is active at any point in the session. Using defined dataset names, you can then:

- Merge data (for example, MATCH FILES, ADD FILES, UPDATE) from multiple different source types (for example, text data, database, spreadsheet) without saving each one as an SPSS data file first.
- Create new datasets that are subsets of open data sources (for example, males in one subset, females in another, people under a certain age in another, or original data in one set and transformed/computed values in another subset).
- Copy and paste variables, cases, and/or variable properties between two or more open data sources in the Data Editor.

The DATASET COPY command creates a new dataset that captures the current state of the active dataset. This is particularly useful for creating multiple subsets of data from the same original data source.

- If the active dataset has a defined dataset name, its name remains associated with subsequent changes.

- If this command occurs when there are transformations pending, those transformations are executed, as if EXECUTE had been run prior to making the copy; so the transformations appear in both the original and the copy. The command is illegal where EXECUTE would be illegal. If no transformations are pending, the data are not passed.
- If the specified dataset name is already associated with a dataset, a warning is issued, the old dataset is destroyed, and the specified name becomes associated with the current state of the active dataset.
- If the specified name is associated with the active dataset, it becomes associated with the current state and the active dataset becomes unnamed.

Basic Specification

The basic specification for DATASET COPY is the command name followed by a new dataset name that conforms to variable naming rules. For more information, see Variable Names on p. 43.

WINDOW Keyword

The WINDOW keyword controls the state of the Data Editor window associated with the dataset.

MINIMIZED	The Data Editor window associated with the new dataset is opened in a minimized state. This is the default.
HIDDEN	The Data Editor window associated with the new dataset is not displayed.
FRONT	The Data Editor window containing the dataset is brought to the front and the dataset becomes the active dataset for dialog boxes.

Operations

- Commands operate on the active dataset. The **active** dataset is the data source most recently opened (for example, by commands such as GET DATA, GET SAS, GET STATA, GET TRANSLATE) or most recently activated by a DATASET ACTIVATE command. (*Note*: the active dataset can also be changed by clicking anywhere in the Data Editor window of an open data source or selecting a dataset from the list of available datasets in a syntax window toolbar.)
- Variables from one dataset are not available when another dataset is the active dataset.
- Transformations to the active dataset—before or after defining a dataset name—are preserved with the named dataset during the session, and any pending transformations to the active dataset are automatically executed whenever a different data source becomes the active dataset.
- Dataset names can be used in most commands that can contain a reference to an SPSS data file.
- Wherever a dataset name, file handle (defined by the FILE HANDLE command), or filename can be used to refer to an SPSS data file, defined dataset names take precedence over file handles, which take precedence over filenames. For example, if *file1* exists as both a dataset name and a file handle, FILE=file1 in the MATCH FILES command will be interpreted as referring to the dataset named *file1*, not the file handle.

Limitations

Because each window requires a minimum amount of memory, there is a limit to the number of windows, SPSS or otherwise, that can be concurrently open on a given system. The particular number depends on the specifications of your system and may be independent of total memory due to OS constraints.

Example

```
DATASET NAME original.
DATASET COPY males.
DATASET ACTIVATE males.
SELECT IF gender=0.
DATASET ACTIVATE original.
DATASET COPY females.
DATASET ACTIVATE females.
SELECT IF gender=1.
```

- The first `DATASET COPY` command creates a new dataset, *males*, that represents the state of the active dataset at the time it was copied.
- The *males* dataset is activated and a subset of males is created.
- The original dataset is activated, restoring the cases deleted from the *males* subset.
- The second `DATASET COPY` command creates a second copy of the original dataset with the name *females*, which is then activated and a subset of females is created.
- Three different versions of the initial data file are now available in the session: the original version, a version containing only data for males, and a version containing only data for females.

DATASET DECLARE

```
DATASET DECLARE name
        [WINDOW={MINIMIZED}]
                {HIDDEN   }
                {FRONT    }
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Release History

Release 14.0

- Command introduced.

Example

```
DATASET DECLARE corrmatrix.
REGRESSION
  /DEPENDENT=var1
  /METHOD=ENTER= var2 to var10
  /OUTFILE=CORB(corrmatrix).
DATASET ACTIVATE corrmatrix.
```

Overview

The DATASET commands (DATASET NAME, DATASET ACTIVATE, DATASET DECLARE, DATASET COPY, DATASET CLOSE) provide the ability to have multiple data sources open at the same time and control which open data source is active at any point in the session. Using defined dataset names, you can then:

- Merge data (for example, MATCH FILES, ADD FILES, UPDATE) from multiple different source types (for example, text data, database, spreadsheet) without saving each one as an SPSS data file first.
- Create new datasets that are subsets of open data sources (for example, males in one subset, females in another, people under a certain age in another, or original data in one set and transformed/computed values in another subset).
- Copy and paste variables, cases, and/or variable properties between two or more open data sources in the Data Editor.

The DATASET DECLARE command creates a new dataset name that is not associated with any open dataset. It can become associated with a dataset if it is used in a command that writes an SPSS data file. This is particularly useful if you need to create temporary SPSS-format data files as an intermediate step in a program.

Basic Specification

The basic specification for DATASET DECLARE is the command name followed by a new dataset name that conforms to variable naming rules. For more information, see Variable Names on p. 43.

WINDOW Keyword

The WINDOW keyword controls the state of the Data Editor window associated with the dataset.

MINIMIZED	The Data Editor window associated with the new dataset is opened in a minimized state. This is the default.
HIDDEN	The Data Editor window associated with the new dataset is not displayed.
FRONT	The Data Editor window containing the dataset is brought to the front and the dataset becomes the active dataset for dialog boxes.

Example

```
DATASET DECLARE corrmatrix.
REGRESSION
  /DEPENDENT=var1
  /METHOD=ENTER= var2 to var10
  /OUTFILE=CORB(corrmatrix).
```

- The DATASET DECLARE command creates a new dataset name, *corrmatrix*, that is initially not assigned to any data source.
- The REGRESSION command writes a correlation matrix to an SPSS-format data file.
- Instead of specifying an external data file, the OUTFILE subcommand specifies the dataset name *corrmatrix*, which is now available for subsequent use in the session. If not explicitly saved (for example, with the SAVE command), this dataset will be automatically deleted at the end of the session.

DATASET DISPLAY

```
DATASET DISPLAY
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Release History

Release 14.0

- Command introduced.

Example

```
DATASET DISPLAY.
```

Overview

The DATASET commands (DATASET NAME, DATASET ACTIVATE, DATASET DECLARE, DATASET COPY, DATASET CLOSE) provide the ability to have multiple data sources open at the same time and control which open data source is active at any point in the session. Using defined dataset names, you can then:

- Merge data (for example, MATCH FILES, ADD FILES, UPDATE) from multiple different source types (for example, text data, database, spreadsheet) without saving each one as an SPSS data file first.
- Create new datasets that are subsets of open data sources (for example, males in one subset, females in another, people under a certain age in another, or original data in one set and transformed/computed values in another subset).
- Copy and paste variables, cases, and/or variable properties between two or more open data sources in the Data Editor.

The DATASET DISPLAY command displays a list of currently available datasets. The only specification is the command name DATASET DISPLAY.

DATASET NAME

```
DATASET NAME name
        [WINDOW={ASIS }]
                {FRONT}
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Release History

Release 14.0

- Command introduced.

Example

```
GET FILE='/data/mydata.sav'.
DATASET NAME file1.
SORT CASES BY ID.
GET FILE '/data/moredata.sav'
SORT CASES BY ID.
DATASET NAME file2.
GET DATA  /TYPE=XLS
  /FILE='/data/exceldata.xls'.
SORT CASES BY ID.
MATCH FILES FILE=*
  /FILE=file1
  /FILE=file2
  /BY ID.
SAVE OUTFILE='/data/mergedata.sav'.
```

Overview

The DATASET commands (DATASET NAME, DATASET ACTIVATE, DATASET DECLARE, DATASET COPY, DATASET CLOSE) provide the ability to have multiple data sources open at the same time and control which open data source is active at any point in the session. Using defined dataset names, you can then:

- Merge data (for example, MATCH FILES, ADD FILES, UPDATE) from multiple different source types (for example, text data, database, spreadsheet) without saving each one as an SPSS data file first.
- Create new datasets that are subsets of open data sources (for example, males in one subset, females in another, people under a certain age in another, or original data in one set and transformed/computed values in another subset).
- Copy and paste variables, cases, and/or variable properties between two or more open data sources in the Data Editor.

The DATASET NAME command:

- Assigns a unique name to the active dataset, which can be used in subsequent file access commands and subsequent DATASET commands.
- Makes the current data file available even after other data sources have been opened/activated.

The following general rules apply:

- If the active dataset already has a defined dataset name, the existing association is broken, and the new name is associated with the active file.
- If the name is already associated with another dataset, that association is broken, and the new association is created. The dataset previously associated with that name is closed and is no longer available.

Basic Specification

The basic specification for DATASET NAME is the command name followed by a name that conforms to variable naming rules. For more information, see Variable Names on p. 43.

WINDOW Keyword

The WINDOW keyword controls the state of the Data Editor window associated with the dataset.

ASIS	The Data Editor window containing the dataset is not affected. This is the default.
FRONT	The Data Editor window containing the dataset is brought to the front and the dataset becomes the active dataset for dialog boxes.

Operations

- Commands operate on the active dataset. The **active** dataset is the data source most recently opened (for example, by commands such as GET DATA, GET SAS, GET STATA, GET TRANSLATE) or most recently activated by a DATASET ACTIVATE command. (*Note*: the active dataset can also be changed by clicking anywhere in the Data Editor window of an open data source or selecting a dataset from the list of available datasets in a syntax window toolbar.)
- Variables from one dataset are not available when another dataset is the active dataset.
- Transformations to the active dataset—before or after defining a dataset name—are preserved with the named dataset during the session, and any pending transformations to the active dataset are automatically executed whenever a different data source becomes the active dataset.
- Dataset names can be used in most commands that can contain a reference to an SPSS data file.
- Wherever a dataset name, file handle (defined by the FILE HANDLE command), or filename can be used to refer to an SPSS data file, defined dataset names take precedence over file handles, which take precedence over filenames. For example, if *file1* exists as both a dataset name and a file handle, FILE=file1 in the MATCH FILES command will be interpreted as referring to the dataset named *file1*, not the file handle.

Example

```
GET FILE='/examples/data/mydata.sav'.
SORT CASES BY ID.
DATASET NAME mydata.
GET DATA /TYPE=XLS
  /FILE='/examples/data/excelfile.xls'.
SORT CASES BY ID.
DATASET NAME excelfile.
GET DATA /TYPE=ODBC /CONNECT=
 'DSN=MS Access Database;DBQ=/examples/data/dm_demo.mdb;'+
 'DriverId=25;FIL=MS Access;MaxBufferSize=2048;PageTimeout=5;'
 /SQL='SELECT * FROM main'.
SORT CASES BY ID.
MATCH FILES
 /FILE='mydata'
 /FILE='excelfile'
 /FILE=*
 /BY ID.
```

- An SPSS data file is read and assigned the dataset name *mydata*. Since it has been assigned a dataset name, it remains available for subsequent use even after other data sources have been opened.
- An Excel file is then read and assigned the dataset name *exceldata*. Like the SPSS data file, since it has been assigned a dataset name, it remains available after other data sources have been opened.
- Then a table from a database is read. Since it is the most recently opened or activated dataset, it is the active dataset.
- The three datasets are then merged together with `MATCH FILES` command, using the dataset names on the `FILE` subcommands instead of file names.
- An asterisk (*) is used to specify the active dataset, which is the database table in this example.
- The files are merged together based on the value of the key variable *ID*, specified on the `BY` subcommand.
- Since all the files being merged need to be sorted in the same order of the key variable(s), `SORT CASES` is performed on each dataset.

DATE

```
DATE  keyword [starting value [periodicity]]
      [keyword [starting value [periodicity]]]
      [BY increment]
```

Keywords for long time periods:

Keyword	Abbreviation	Default starting value	Default periodicity
YEAR	Y	1	none
QUARTER	Q	1	4
MONTH	M	1	12

Keywords for short time periods:

Keyword	Abbreviation	Default starting value	Default periodicity
WEEK	W	1	none
DAY	D	1	7
HOUR	H	0	24
MINUTE	MI	0	60
SECOND	S	0	60

Keywords for any time periods:

Keyword	Abbreviation	Default starting value	Default periodicity
CYCLE	C	1	none
OBS	O	none	none

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
DATE Y 1960 M.
```

Overview

DATE generates date identification variables. You can use these variables to label plots and other output, establish periodicity, and distinguish between historical, validation, and forecasting periods.

Options

You can specify the starting value and periodicity. You can also specify an increment for the lowest-order keyword specified.

Basic Specification

The basic specification on DATE is a single keyword.

- For each keyword specified, DATE creates a numeric variable whose name is the keyword with an underscore as a suffix. Values for this variable are assigned to observations sequentially, beginning with the specified starting value. DATE also creates a string variable named *DATE_*, which combines the information from the numeric date variables and is used for labeling.
- If no starting value is specified, either the default is used or the value is inferred from the starting value of another DATE keyword.
- All variables created by DATE are automatically assigned variable labels that describe periodicity and associated formats. DATE produces a list of the names of the variables it creates and their variable labels.

Subcommand Order

- Keywords can be specified in any order.

Operations

- DATE creates a numeric variable for every keyword specified, plus a string variable *DATE_*, which combines information from all the specified keywords.
- DATE automatically creates variable labels for each keyword specified indicating the variable name and its periodicity. For the *DATE_* variable, the label indicates the variable name and format.
- If the highest-order DATE variable specified has a periodicity, the *CYCLE_* variable will automatically be created. *CYCLE_* cannot have a periodicity. For more information, see Example 3 on p. 540.
- Default periodicities are not used for the highest-order keyword specified. The exception is QUARTER, which will always have a default periodicity.
- The periodicity of the lowest-order variable is the default periodicity used by the procedures when periodicity is not defined either within the procedure or by the TSET command.
- The keyword name with an underscore is always used as the new variable name, even if keyword abbreviations are used in the specifications.
- Each time the DATE command is used, any DATE variables already in the active dataset are deleted.
- The DATE command invalidates any previous USE and PREDICT commands specified. The USE and PREDICT periods must be respecified after DATE.

Limitations

- There is no limit on the number of keywords on the DATE command. However, keywords that describe long time periods (YEAR, QUARTER, MONTH) cannot be used on the same command with keywords that describe short time periods (WEEK, DAY, HOUR, MINUTE, SECOND).
- User-defined variable names must not conflict with DATE variable names.

Syntax Rules

- You can specify more than one keyword per command.
- If a keyword is specified more than once, only the last one is executed.
- Keywords that describe long time periods (YEAR, QUARTER, MONTH) cannot be used on the same command with keywords that describe short time periods (WEEK, DAY, HOUR, MINUTE, SECOND).
- Keywords CYCLE and OBS can be used with any other keyword.
- The lowest-order keyword specified should correspond to the level at which observations occur. For example, if observations are daily, the lowest-order keyword should be DAY.
- Keywords (except MINUTE) can be abbreviated down to the first character. MINUTE must have at least two characters (MI) to distinguish it from keyword MONTH.
- Keywords and additional specifications are separated by commas or spaces.

Starting Value and Periodicity

- A starting value and periodicity can be entered for any keyword except CYCLE. CYCLE can have only a starting value.
- Starting value and periodicity *must* be specified for keyword OBS.
- The starting value is specified first, followed by the periodicity, if any.
- You cannot specify a periodicity without first specifying a starting value.
- Starting values for HOUR, MINUTE, and SECOND can range from 0 to the periodicity minus 1 (for example, 0 to 59). For all other keywords, the range is 1 to the periodicity.
- If both MONTH and QUARTER are specified, DATE can infer the starting value of one from the other. For more information, see Example 5 on p. 542.
- Specifying conflicting starting values for MONTH and QUARTER, such as `Q 1 M 4`, results in an error.
- For keyword YEAR, the starting value can be specified as the last two digits (93) instead of the whole year (1993) when the series and any forecasting are all within the same century. The same format (2 digits or 4 digits) must be used in all other commands that use year values.
- If you specify keywords that describe short time periods and skip over a level of measurement (for example, if you specify HOUR and SECOND but not MINUTE), you must specify the starting value and periodicity of the keyword after the skipped keywords. Otherwise, inappropriate periodicities will be generated. For more information, see Example 7 on p. 543.

BY Keyword

- Keyword `BY` and a positive integer can be specified after the lowest-order keyword on the command to indicate an increment value. This value indicates how much to increment values of the lowest-order date variable as they are assigned to observations. For more information, see Example 4 on p. 541.
- The increment value must divide evenly into the periodicity of the lowest-order `DATE` variable specified.

Example 1

```
DATE Y 1960 M.
```

- This command generates variables *DATE_*, *YEAR_*, and *MONTH_*.
- *YEAR_* has a starting value of 1960. *MONTH_* starts at the default value of 1.
- By default, *YEAR_* has no periodicity, and *MONTH_* has a periodicity of 12.

`DATE` reports the following:

```
  Name         Label

  YEAR_        YEAR, not periodic
  MONTH_       MONTH, period 12
  DATE_        DATE.  FORMAT:  "MMM YYYY"
```

The following is a partial listing of the new variables:

```
   YEAR_ MONTH_ DATE_

    1960    1   JAN 1960
    1960    2   FEB 1960
    1960    3   MAR 1960
    1960    4   APR 1960
     ...
    1960   10   OCT 1960
    1960   11   NOV 1960
    1960   12   DEC 1960
    1961    1   JAN 1961
    1961    2   FEB 1961
     ...
    1999    4   APR 1999
    1999    5   MAY 1999
    1999    6   JUN 1999
```

Example 2

```
DATE WEEK DAY 1 5 HOUR 1 8.
```

- This command creates four variables (*DATE_*, *WEEK_*, *DAY_*, and *HOUR_*) in a file where observations occur hourly in a 5-day, 40-hour week.
- For *WEEK,* the default starting value is 1 and the default periodicity is none.

- For *DAY_,* the starting value has to be specified, even though it is the same as the default, because a periodicity is specified. The periodicity of 5 means that observations are measured in a 5-day week.
- For *HOUR_,* a starting value of 1 is specified. The periodicity of 8 means that observations occur in an 8-hour day.

DATE reports the following:

```
Name         Label

WEEK_        WEEK, not periodic
DAY_         DAY, period 5
HOUR_        HOUR, period 24
DATE_        DATE.  FORMAT:  "WWW D HH"
```

The following is a partial listing of the new variables:

```
 WEEK_ DAY_ HOUR_ DATE_

     1   1     1    1 1  1
     1   1     2    1 1  2
     1   1     3    1 1  3
     1   1     4    1 1  4
     1   1     5    1 1  5
     ...
     1   1    22    1 1 22
     1   1    23    1 1 23
     1   2     0    1 2  0
     1   2     1    1 2  1
     1   2     2    1 2  2
     ...
     4   5    16    4 5 16
     4   5    17    4 5 17
     4   5    18    4 5 18
```

Example 3

```
DATE DAY 1 5 HOUR 3 8.
```

- This command creates four variables (*DATE_*, *CYCLE_*, *DAY_*, and *HOUR_*) in a file where observations occur hourly.
- For *HOUR_,* the starting value is 3 and the periodicity is 8.
- For *DAY_,* the starting value is 1 and the periodicity is 5. Since *DAY_* is the highest-order variable and it has a periodicity assigned, variable *CYCLE_* is automatically created.

DATE reports the following:

```
Name         Label

CYCLE_       CYCLE, not periodic
DAY_         DAY, period 5
HOUR_        HOUR, period 8
DATE_        DATE.  FORMAT:  "CCCC D H"
```

The following is a partial listing of the new variables:

```
CYCLE_ DAY_ HOUR_ DATE_

     1   1    3       1 1 3
     1   1    4       1 1 4
     1   1    5       1 1 5
     1   1    6       1 1 6
     1   1    7       1 1 7
     1   2    0       1 2 0
     1   2    1       1 2 1
    ...
    12   4    6      12 4 6
    12   4    7      12 4 7
    12   5    0      12 5 0
    12   5    1      12 5 1
    12   5    2      12 5 2
    12   5    3      12 5 3
    12   5    4      12 5 4
```

Example 4

```
DATE DAY HOUR 1 24 BY 2.
```

- This command creates three variables (*DATE_*, *DAY_*, and *HOUR_*) in a file where observations occur every two hours in a 24-hour day.
- *DAY_* uses the default starting value of 1. It has no periodicity, since none is specified, and it is the highest-order keyword on the command.
- *HOUR_* starts with a value of 1 and has a periodicity of 24.
- Keyword `BY` specifies an increment of 2 to use in assigning hour values.

`DATE` reports the following:

```
Name         Label

DAY_         DAY, not periodic
HOUR_        HOUR, period 24 by 2
DATE_        DATE.  FORMAT:  "DDDD HH"
```

The following is a partial listing of the new variables:

```
  DAY_ HOUR_ DATE_

     1    1     1  1
     1    3     1  3
     1    5     1  5
   ...
    39   17    39 17
    39   19    39 19
    39   21    39 21
    39   23    39 23
    40    1    40  1
    40    3    40  3
    40    5    40  5
    40    7    40  7
    40    9    40  9
    40   11    40 11
```

Example 5

```
DATE Y 1950 Q 2 M.
```

- This example creates four variables (*DATE_*, *YEAR_*, *QUARTER_,* and *MONTH_*) in a file where observations are quarterly, starting with April 1950.
- The starting value for *MONTH_* is inferred from *QUARTER_*.
- This specification is equivalent to `DATE Y 1950 Q M 4`. Here, the starting value for *QUARTER_* (2) would be inferred from `MONTH`.

`DATE` reports the following:

```
  Name         Label

  YEAR_        YEAR, not periodic
  QUARTER_     QUARTER, period 4
  MONTH_       MONTH, period 12
  DATE_        DATE.  FORMAT:  "MMM YYYY"
```

The following is a partial listing of the new variables:

```
   YEAR_ QUARTER_ MONTH_ DATE_

    1950     2       4   APR 1950
    1950     2       5   MAY 1950
    1950     2       6   JUN 1950
    1950     3       7   JUL 1950
    1950     3       8   AUG 1950
     ...
    1988     4      11   NOV 1988
    1988     4      12   DEC 1988
    1989     1       1   JAN 1989
    1989     1       2   FEB 1989
    1989     1       3   MAR 1989
    1989     2       4   APR 1989
    1989     2       5   MAY 1989
    1989     2       6   JUN 1989
    1989     3       7   JUL 1989
    1989     3       8   AUG 1989
    1989     3       9   SEP 1989
```

Example 6

```
DATE OBS 9 17.
```

- This command creates variables *DATE_*, *CYCLE_*, and *OBS_* and assigns values to observations sequentially, starting with value 9. The periodicity is 17.

`DATE` reports the following:

```
  Name         Label

  CYCLE_       CYCLE, not periodic
  OBS_         OBS, period 17
  DATE_        DATE.  FORMAT:  "CCCC OO"
```

The following is a partial listing of the new variables:

```
CYCLE_ OBS_ DATE_

      1   9     1  9
      1  10     1 10
      1  11     1 11
      1  12     1 12
      1  13     1 13
      1  14     1 14
      1  15     1 15
      1  16     1 16
      1  17     1 17
      2   1     2  1
      2   2     2  2
     ...
     28  15    28 15
     28  16    28 16
     28  17    28 17
     29   1    29  1
     29   2    29  2
     29   3    29  3
     29   4    29  4
     29   5    29  5
     29   6    29  6
```

Example 7

```
DATE W H 1 168
```

- This example creates three variables (*DATE_*, *WEEK_*, and *HOUR_*) in a file where observations occur hourly.
- Since the `DAY` keyword is not specified, a periodicity must be specified for `HOUR`. The value 168 indicates that there are 168 hours in a week.
- The starting value of `HOUR` is specified as 1.

`DATE` reports the following:

```
  Name         Label

  WEEK_        WEEK, not periodic
  HOUR_        HOUR, period 168
  DATE_        DATE.  FORMAT:  "WWWW HHH"
```

The following is a partial listing of the new variables:

```
   WEEK_ HOUR_ DATE_

      1    1     1   1
      1    2     1   2
      1    3     1   3
      1    4     1   4
      1    5     1   5
      1    6     1   6
    ...
      1  161     1 161
      1  162     1 162
      1  163     1 163
      1  164     1 164
      1  165     1 165
```

```
 1  166      1 166
 1  167      1 167

```

Release History

Release 14.0

- For syntax processed in interactive mode, modifications to the macro facility may affect macro calls occurring at the end of a command. For more information, see Overview on p. 546.

Example

```
DEFINE sesvars ()
  age sex educ religion
!ENDDEFINE.
```

Overview

DEFINE—!ENDDEFINE defines a program macro, which can then be used within a command sequence. A macro can be useful in several different contexts. For example, it can be used to:

- Issue a series of the same or similar commands repeatedly, using looping constructs rather than redundant specifications.
- Specify a set of variables.
- Produce output from several program procedures with a single command.
- Create complex input programs, procedure specifications, or whole sessions that can then be executed.

A macro is defined by specifying any part of a valid command and giving it a macro name. This name is then specified in a macro call within a command sequence. When the program encounters the macro name, it expands the macro.

In the examples of macro definition throughout this reference, the macro name, body, and arguments are shown in lowercase for readability. Macro keywords, which are always preceded by an exclamation point (!), are shown in uppercase.

Options

Macro Arguments. You can declare and use arguments in the macro definition and then assign specific values to these arguments in the macro call. You can define defaults for the arguments and indicate whether an argument should be expanded when the macro is called. For more information, see Macro Arguments on p. 550.

Macro Directives. You can turn macro expansion on and off. For more information, see Macro Directives on p. 557.

String Manipulation Functions. You can process one or more character strings and produce either a new character string or a character representation of a numeric result. For more information, see String Manipulation Functions on p. 557.

Conditional Processing. You can build conditional and looping constructs. For more information, see Conditional Processing on p. 560.

Macro Variables. You can directly assign values to macro variables For more information, see Direct Assignment of Macro Variables on p. 563.

Basic Specification

All macros must start with DEFINE and end with !ENDDEFINE. These commands identify the beginning and end of a macro definition and are used to separate the macro definition from the rest of the command sequence.

- Immediately after DEFINE, specify the **macro name**. All macros must have a name. The name is used in the macro call to refer to the macro. Macro names can begin with an exclamation point (!), but other than this, follow the usual naming conventions. Starting a name with an ! ensures that it will not conflict with the other text or variables in the session.
- Immediately after the macro name, specify an optional **argument** definition in parentheses. This specification indicates the arguments that will be read when the macro is called. If you do not want to include arguments, specify just the parentheses; *the parentheses are required, whether or not they enclose an argument.*
- Next specify the body of the macro. The **macro body** can include commands, parts of commands, or macro statements (macro directives, string manipulation statements, and looping and conditional processing statements).
- At the end of the macro body, specify !ENDDEFINE.

To invoke the macro, issue a **macro call** in the command sequence. To call a macro, specify the macro name and any necessary arguments. If there are no arguments, only the macro name is required.

Operations

- When the program reads the macro definition, it translates into uppercase all text (except arguments) not enclosed in quotation marks. Arguments are read in upper- and lowercase.
- The macro facility does not build and execute commands; rather, it expands strings in a process called **macro expansion**. A macro call initiates macro expansion. After the strings are expanded, the commands (or parts of commands) that contain the expanded strings are executed as part of the command sequence.
- Any elements on the macro call that are not used in the macro expansion are read and combined with the expanded strings.
- The expanded strings and the remaining elements from the macro call, if any, must conform to the syntax rules for the program. If not, the program generates either a warning or an error message, depending on the nature of the syntax problem.

Syntax Rules

Just like other commands, expanded macros must adhere to the rules of the processing mode under which they are run. While it is desirable to create macro syntax that will run in both interactive and batch modes, this may sometimes add a layer of complexity that you may want to avoid. So we recommend that you write macro syntax that adheres to interactive syntax rules and structure your jobs to execute macro syntax under interactive syntax rules.

- The macro !ENDDEFINE statement should end with a period. A period as the last character on a line is interpreted as a command terminator in interactive mode.

- Other macro statements (for example, !IF, !LOOP, !LET) should not end with a period.
- Text within the body of the macro that represent commands that will be generated when the macro is expanded should include the period at the end of each command, and each command should start on a new line.

Example

```
DEFINE !macro1(type = !DEFAULT(1) !TOKENS(1)
                                /varlist=!CMDEND)
!IF (!type = 1)!THEN
frequencies variables=!varlist.
!ELSE
descriptives variables=!varlist.
!IFEND
!ENDDEFINE.
```

- The macro statements DEFINE, !IF, !ELSE, and !IFEND do not end with a period.
- !ENDDEFINE ends with a period.
- The FREQUENCIES and DESCRIPTIVES commands generated by the macro each start on a new line and end with a period.

To structure your command syntax jobs so that interactive processing rules are always used instead of batch processing rules:

- Use INSERT instead of INCLUDE to combine command files containing macros with other command files. For more information, see INSERT on p. 917.
- In Production Facility jobs, select Interactive for the Syntax Input Format.
- In the SPSS Batch Facility (available only with SPSS Server), use the -i switch to use interactive processing rules.

Compatibility

Improvements to the macro facility may cause errors in jobs that previously ran without errors. Specifically, for syntax that is processed with interactive rules, if a macro call occurs at the end of a command, and there is no command terminator (either a period or a blank line), the next command after the macro expansion will be interpreted as a continuation line instead of a new command, as in:

```
DEFINE !macro1()
var1 var2 var3
!ENDDEFINE.
FREQUENCIES VARIABLES = !macro1
DESCRIPTIVES VARIABLES = !macro1.
```

In interactive mode, the DESCRIPTIVES command will be interpreted as a continuation of the FREQUENCIES command, and neither command will run.

Limitations

- The BEGIN DATA–END DATA commands are not allowed within a macro.
- BEGIN PROGRAM-END PROGRAM commands are not supported within a macro.
- The DEFINE command is not allowed within a macro.

Examples

Example

```
* Macro without arguments: Specify a group of variables.

DEFINE sesvars ()
   age sex educ religion
!ENDDEFINE.

FREQUENCIES VARIABLES=sesvars.
```

- The macro name is `sesvars`. Because the parentheses are empty, `sesvars` has no arguments. The macro body defines four variables: *age*, *sex*, *educ*, and *religion*.
- The macro call is specified on `FREQUENCIES`. When the call is executed, `sesvars` is expanded into the variables *age*, *sex*, *educ*, and *religion*.
- After the macro expansion, `FREQUENCIES` is executed.

Example

```
* Macro without arguments: Repeat a sequence of commands.

DATA LIST FILE = MAC4D /GROUP 1   REACTIME 3-5 ACCURACY 7-9.
VALUE LABELS GROUP    1'normal'
                      2'learning disabled'.
* Macro definition.
DEFINE check ()
split file by group.
frequencies variables = reactime accuracy
  /histogram.
descriptives reactime accuracy.
list.
split file off.
regression variables = group reactime accuracy
  /dependent = accuracy
  /enter
  /scatterplot (reactime, accuracy).
!ENDDEFINE.

check.                        /* First call of defined macro check

COMPUTE REACTIME = SQRT (REACTIME).
COMPUTE ACCURACY = SQRT (ACCURACY).

check.                        /* Second call of defined macro check

COMPUTE REACTIME = lg10 (REACTIME * REACTIME).
COMPUTE ACCURACY = lg10 (ACCURACY * ACCURACY).

check.                        /* Third call of defined macro check
```

- The name of the macro is `check`. The empty parentheses indicate that there are no arguments to the macro.
- The macro definition (between `DEFINE` and `!ENDDEFINE`) contains the command sequence to be repeated: `SPLIT FILE`, `FREQUENCIES`, `DESCRIPTIVES`, `LIST`, `SPLIT FILE`, and `REGRESSION`.

- The macro is called three times. Every time `check` is encountered, it is replaced with the command sequence `SPLIT FILE`, `FREQUENCIES`, `DESCRIPTIVES`, `LIST`, `SPLIT FILE OFF`, and `REGRESSION`. The command sequence using the macro facility is identical to the command sequence in which the specified commands are explicitly stated three separate times.

Example

```
* Macro with an argument.

DEFINE myfreq (vars = !CHAREND('/'))
frequencies variables = !vars
  /format = notable
  /statistics = default skewness kurtosis.
!ENDDEFINE.

myfreq vars = age sex educ religion /.
```

- The macro definition defines `vars` as the macro argument. In the macro call, four variables are specified as the argument to the macro `myfreq`. When the program expands the `myfreq` macro, it substitutes the argument, `age`, `sex`, `educ`, and `religion`, for `!vars` and executes the resulting commands.

Macro Arguments

The macro definition can include macro arguments, which can be assigned specific values in the macro call. There are two types of arguments: keyword and positional. Keyword arguments are assigned names in the macro definition; in the macro call, they are identified by name. Positional arguments are defined after the keyword `!POSITIONAL` in the macro definition; in the macro call, they are identified by their relative position within the macro definition.

- There is no limit to the number of arguments that can be specified in a macro.
- All arguments are specified in parentheses and must be separated by slashes.
- If both keyword and positional arguments are defined in the same definition, the positional arguments must be defined, used in the macro body, and invoked in the macro call before the keyword arguments.

Example

```
* A keyword argument.

DEFINE macname (arg1 = !TOKENS(1))
frequencies variables = !arg1.
!ENDDEFINE.

macname arg1 = V1.
```

- The macro definition defines `macname` as the macro name and `arg1` as the argument. The argument `arg1` has one token and can be assigned any value in the macro call.
- The macro call expands the `macname` macro. The argument is identified by its name, `arg1`, and is assigned the value `V1`. `V1` is substituted wherever `!arg1` appears in the macro body. The macro body in this example is the `FREQUENCIES` command.

Example

```
* A positional argument.

DEFINE macname (!POSITIONAL !TOKENS(1)
               /!POSITIONAL !TOKENS(2))
frequencies variables = !1 !2.
!ENDDEFINE.

macname V1 V2 V3.
```

- The macro definition defines `macname` as the macro name with two positional arguments. The first argument has one token and the second argument has two tokens. The tokens can be assigned any values in the macro call.
- The macro call expands the `macname` macro. The arguments are identified by their positions. `V1` is substituted for `!1` wherever `!1` appears in the macro body. `V2` and `V3` are substituted for `!2` wherever `!2` appears in the macro body. The macro body in this example is the `FREQUENCIES` command.

Keyword Arguments

Keyword arguments are called with user-defined keywords that can be specified in any order. In the macro body, the argument name is preceded by an exclamation point. On the macro call, the argument is specified without the exclamation point.

- Keyword argument definitions contain the argument name, an equals sign, and the `!TOKENS`, `!ENCLOSE`, `!CHAREND`, or `!CMDEND` keyword. For more information, see Assigning Tokens to Arguments on p. 553.
- Argument names are limited to seven characters and cannot match the character portion of a macro keyword, such as `DEFINE`, `TOKENS`, `CHAREND`, and so forth.
- The keyword `!POSITIONAL` cannot be used in keyword argument definitions.
- Keyword arguments do not have to be called in the order they were defined.

Example

```
DATA LIST FILE=MAC / V1 1-2 V2 4-5 V3 7-8.

* Macro definition.
DEFINE macdef2 (arg1 = !TOKENS(1)
               /arg2 = !TOKENS(1)
               /arg3 = !TOKENS(1))
frequencies  variables = !arg1 !arg2 !arg3.
!ENDDEFINE.

* Macro call.
macdef2 arg1=V1  arg2=V2  arg3=V3.
macdef2 arg3=V3  arg1=V1  arg2=V2.
```

- Three arguments are defined: `arg1`, `arg2`, and `arg3`, each with one token. In the first macro call, `arg1` is assigned the value `V1`, `arg2` is assigned the value `V2`, and `arg3` is assigned the value `V3`. `V1`, `V2`, and `V3` are then used as the variables in the `FREQUENCIES` command.
- The second macro call yields the same results as the first one. With keyword arguments, you do not need to call the arguments in the order in which they were defined.

Positional Arguments

Positional arguments must be defined in the order in which they will be specified on the macro call. In the macro body, the first positional argument is referred to by `!1`, the second positional argument defined is referred to by `!2`, and so on. Similarly, the value of the first argument in the macro call is assigned to `!1`, the value of the second argument is assigned to `!2`, and so on.

- Positional arguments can be collectively referred to in the macro body by specifying `!*`. The `!*` specification concatenates arguments, separating individual arguments with a blank.

Example

```
DATA LIST FILE='/data/mac.txt' / V1 1-2 V2 4-5 V3 7-8.

* Macro definition.
DEFINE macdef (!POS !TOKENS(1)
               /!POS !TOKENS(1)
               /!POS !TOKENS(1))
frequencies variables = !1 !2 !3.
!ENDDEFINE.

* Macro call.
macdef  V1    V2   V3.
macdef  V3    V1   V2.
```

- Three positional arguments with one token each are defined. The first positional argument is referred to by `!1` on the `FREQUENCIES` command, the second by `!2`, and the third by `!3`.
- When the first call expands the macro, the first positional argument (`!1`) is assigned the value `V1`, the second positional argument (`!2`) is assigned the value `V2`, and the third positional argument (`!3`) is assigned the value `V3`.
- In the second call, the first positional argument is assigned the value `V3`, the second positional argument is assigned the value `V1`, and the third positional argument is assigned the value `V2`.

Example

```
DEFINE macdef (!POS !TOKENS(3))
frequencies variables = !1.
!ENDDEFINE.

macdef  V1    V2   V3.
```

- This example is the same as the previous one, except that it assigns three tokens to one argument instead of assigning one token to each of three arguments. The result is the same.

Example

```
DEFINE macdef (!POS !TOKENS(1)
               /!POS !TOKENS(1)
               /!POS !TOKENS(1)
frequencies variables = !*.
!ENDDEFINE.
```

```
macdef  V1    V2   V3.
```

- This is a third alternative for achieving the macro expansion shown in the previous two examples. It specifies three arguments but then joins them all together on one FREQUENCIES command using the symbol !*.

Assigning Tokens to Arguments

A **token** is a character or group of characters that has a predefined function in a specified context. The argument definition must include a keyword that indicates which tokens following the macro name are associated with each argument.

- Any program keyword, variable name, or delimiter (a slash, comma, and so on) is a valid token.
- The arguments for a given macro can use a combination of the token keywords.

!TOKENS (n)	*Assign the next* n *tokens to the argument.* The value *n* can be any positive integer and must be enclosed in parentheses. !TOKENS allows you to specify exactly how many tokens are desired.
!CHAREND ('char')	*Assign all tokens up to the specified character to the argument.* The character must be a one-character string specified in apostrophes and enclosed in parentheses. !CHAREND specifies the character that ends the argument assignment. This is useful when the number of assigned tokens is arbitrary or not known in advance.
!ENCLOSE ('char','char')	*Assign all tokens between the indicated characters to the argument.* The starting and ending characters can be any one-character strings, and they do not need to be the same. The characters are each enclosed in apostrophes and separated by a comma. The entire specification is enclosed in parentheses. !ENCLOSE allows you to group multiple tokens within a specified pair of symbols. This is useful when the number of tokens to be assigned to an argument is indeterminate, or when the use of an ending character is not sufficient.
!CMDEND	*Assign to the argument all of the remaining text on the macro call, up to the start of the next command.* !CMDEND is useful for changing the defaults on an existing command. Since !CMDEND reads up to the next command, only the last argument on the argument list can be specified with !CMDEND. If !CMDEND is not the final argument, the arguments following !CMDEND are read as text.

Example

```
* Keyword !TOKENS.

DEFINE macname (!POSITIONAL !TOKENS (3)
frequencies variables = !1.
!ENDDEFINE.

macname ABC DEFG HI.
```

- The three tokens following macname (ABC, DEFG, and HI) are assigned to the positional argument !1, and FREQUENCIES is then executed.

Example

```
* Keyword !TOKENS.

* Macro definition.
```

```
DEFINE earnrep (varrep = !TOKENS (1))
sort cases by !varrep.
report variables = earnings
  /break = !varrep
  /summary = mean.
!ENDDEFINE.

* Call the macro three times.
earnrep varrep= SALESMAN.  /*First macro call
earnrep varrep = REGION.   /*Second macro call
earnrep varrep = MONTH.    /*Third macro call
```

- This macro runs a REPORT command three times, each time with a different break variable.
- The macro name is earnrep, and there is one keyword argument, varrep, which has one token.
- In the first macro call, the token SALESMAN is substituted for !varrep when the macro is expanded. REGION and MONTH are substituted for !varrep when the macro is expanded in the second and third calls.

Example

```
* Keyword !CHAREND'.

DEFINE macname (!POSITIONAL !CHAREND ('/')
               /!POSITIONAL !TOKENS(2))
frequencies variables = !1.
correlations variables= !2.
!ENDDEFINE.

macname A B C D / E F.
```

- When the macro is called, all tokens up to the slash (A, B, C, and D) are assigned to the positional argument !1. E and F are assigned to the positional argument !2.

Example

```
* Keyword !CHAREND.

DEFINE macname (!POSITIONAL !CHAREND ('/'))
frequencies variables = !1.
!ENDDEFINE.

macname A B C D / E F.
```

- Although E and F are not part of the positional argument and are not used in the macro expansion, the program still reads them as text and interprets them in relation to where the macro definition ends. In this example, macro definition ends after the expanded variable list (D). E and F are names of variables. Thus, E and F are added to the variable list and FREQUENCIES is executed with six variables: *A*, *B*, *C*, *D*, *E*, and *F*.

Example

```
* Keyword !ENCLOSE.

DEFINE macname (!POSITIONAL !ENCLOSE('(',')'))
frequencies variables = !1
  /statistics = default skewness.
```

```
!ENDDEFINE.

macname (A B C) D E.
```

- When the macro is called, the three tokens enclosed in parentheses—A, B, and C—are assigned to the positional argument !1 in the macro body.
- After macro expansion is complete, the program reads the remaining characters on the macro call as text. In this instance, the macro definition ends with keyword SKEWNESS on the STATISTICS subcommand. Adding variable names to the STATISTICS subcommand is not valid syntax. The program generates a warning message but is still able to execute the frequencies command. Frequency tables and the specified statistics are generated for the variables *A*, *B*, and *C*.

Example

```
* Keyword !CMDEND'.

DEFINE macname (!POSITIONAL !TOKENS(2)
               /!POSITIONAL !CMDEND)
frequencies variables = !1.
correlations variables= !2.
!ENDDEFINE.

macname A B C D E.
```

- When the macro is called, the first two tokens following macname (A and B) are assigned to the positional argument !1. C, D, and E are assigned to the positional argument !2. Thus, the variables used for FREQUENCIES are *A* and *B*, and the variables used for CORRELATION are *C*, *D*, and *E*.

Example

```
* Incorrect order for !CMDEND.

DEFINE macname  (!POSITIONAL !CMDEND
                /!POSITIONAL !tokens(2))
frequencies variables = !1.
correlations variables= !2.
!ENDDEFINE.

macname  A B C D E.
```

- When the macro is called, all five tokens, A, B, C, D, and E, are assigned to the first positional argument. No variables are included on the variable list for CORRELATIONS, causing the program to generate an error message. The previous example declares the arguments in the correct order.

Example

```
* Using !CMDEND.
SUBTITLE 'CHANGING DEFAULTS ON A COMMAND'.

DEFINE myfreq (!POSITIONAL !CMDEND)
frequencies !1
  /statistics=default skewness  /* Modify default statistics.
!ENDDEFINE.
```

```
myfreq VARIABLES = A B /HIST.
```

- The macro `myfreq` contains options for the `FREQUENCIES` command. When the macro is called, `myfreq` is expanded to perform a `FREQUENCIES` analysis on the variables *A* and *B*. The analysis produces default statistics and the skewness statistic, plus a histogram, as requested on the macro call.

Example

```
* Keyword arguments: Using a combination of token keywords.

DATA LIST FREE / A B C D E.
DEFINE macdef3 (arg1 = !TOKENS(1)
               /arg2 = !ENCLOSE ('(',')')
               /arg3 = !CHAREND('%'))
frequencies variables = !arg1  !arg2 !arg3.
!ENDDEFINE.
macdef arg1 = A  arg2=(B C)  arg3=D E %.
```

- Because `arg1` is defined with the `!TOKENS` keyword, the value for `arg1` is simply specified as `A`. The value for `arg2` is specified in parentheses, as indicated by `!ENCLOSE`. The value for `arg3` is followed by a percentage sign, as indicated by `!CHAREND`.

Defining Defaults

The optional `!DEFAULT` keyword in the macro definition establishes default settings for arguments.

!DEFAULT *Default argument.* After `!DEFAULT`, specify the value you want to use as a default for that argument. A default can be specified for each argument.

Example

```
DEFINE macdef (arg1 = !DEFAULT (V1) !TOKENS(1)
              /arg2 = !TOKENS(1)
              /arg3 = !TOKENS(1))
frequencies variables = !arg1 !arg2 !arg3.
!ENDDEFINE.

macdef arg2=V2  arg3=V3.
```

- `V1` is defined as the default value for argument `arg1`. Since `arg1` is not specified on the macro call, it is set to `V1`.
- If `!DEFAULT (V1)` were not specified, the value of `arg1` would be set to a null string.

Controlling Expansion

`!NOEXPAND` indicates that an argument should not be expanded when the macro is called.

!NOEXPAND *Do not expand the specified argument.* `!NOEXPAND` applies to a single argument and is useful only when a macro calls another macro (embedded macros).

Macro Directives

!ONEXPAND and !OFFEXPAND determine whether macro expansion is on or off. !ONEXPAND activates macro expansion and !OFFEXPAND stops macro expansion. All symbols between !OFFEXPAND and !ONEXPAND in the macro definition will not be expanded when the macro is called.

!ONEXPAND	*Turn macro expansion on.*
!OFFEXPAND	*Turn macro expansion off.* !OFFEXPAND is effective only when SETMEXPAND is ON (the default).

Macro Expansion in Comments

When macro expansion is on, a macro is expanded when its name is specified in a comment line beginning with *. To use a macro name in a comment, specify the comment within slashes and asterisks (/*...*/) to avoid unwanted macro expansion. (See COMMENT.)

String Manipulation Functions

String manipulation functions process one or more character strings and produce either a new character string or a character representation of a numeric result.

- The result of any string manipulation function is treated as a character string.
- The arguments to string manipulation functions can be strings, variables, or even other macros. A macro argument or another function can be used in place of a string.
- The strings within string manipulation functions must be either single tokens, such as ABC, or delimited by apostrophes or quotation marks, as in 'A B C'.

Table 58-1
Expressions and results

Expression	Result
!UPCASE(abc)	ABC
!UPCASE('abc')	ABC
!UPCASE(a b c)	error
!UPCASE('a b c')	A B C
!UPCASE(a/b/c)	error
!UPCASE('a/b/c')	A/B/C
!UPCASE(!CONCAT(a,b,c))	ABC
!UPCASE(!CONCAT('a','b','c'))	ABC
!UPCASE(!CONCAT(a, b, c))	ABC
!UPCASE(!CONCAT('a ','b ','c '))	A B C
!UPCASE(!CONCAT('a,b,c'))	A,B,C
!QUOTE(abc)	'ABC'
!QUOTE('abc')	abc
!QUOTE('Bill"s')	'Bill"s'

Expression	Result
!QUOTE(“Bill’s”)	“Bill’s”
!QUOTE(Bill’s)	error
!QUOTE(!UNQUOTE(‘Bill”s’))	‘Bill”s’

!LENGTH (str) *Return the length of the specified string.* The result is a character representation of the string length. `!LENGTH(abcdef)` returns 6. If the string is specified with apostrophes around it, each apostrophe adds 1 to the length. `!LENGTH ('abcdef')` returns 8. If an argument is used in place of a string and it is set to null, this function will return 0.

!CONCAT (str1,str2 . . .) *Return a string that is the concatenation of the strings.* For example, `!CONCAT (abc,def)` returns abcdef.

!SUBSTR (str,from,[length]) *Return a substring of the specified string.* The substring starts at the *from* position and continues for the specified *length*. If the length is not specified, the substring ends at the end of the input string. For example, `!SUBSTR (abcdef, 3, 2)` returns cd.

!INDEX (haystack,needle) *Return the position of the first occurrence of the needle in the haystack.* If the needle is not found in the haystack, the function returns 0. `!INDEX (abcdef,def)` returns 4.

!HEAD (str) *Return the first token within a string.* The input string is not changed. `!HEAD ('a b c')` returns a.

!TAIL (str) *Return all tokens except the head token.* The input string is not changed. `!TAIL('a b c')` returns b c.

!QUOTE (str) *Put apostrophes around the argument.* `!QUOTE` replicates any embedded apostrophe. `!QUOTE(abc)` returns ‘abc’. If `!1` equals Bill’s, `!QUOTE(!1)` returns ‘Bill”s’.

!UNQUOTE (str) *Remove quotation marks and apostrophes from the enclosed string.* If `!1` equals ‘abc’, `!UNQUOTE(!1)` is abc. Internal paired quotation marks are unpaired; if `!1` equals ‘Bill”s’, `!UNQUOTE(!1)` is Bill’s. The specification `!UNQUOTE(!QUOTE(Bill))` returns Bill.

!UPCASE (str) *Convert all lowercase characters in the argument to uppercase.* `!UPCASE('abc def')` returns ABC DEF.

!BLANKS (n) *Generate a string containing the specified number of blanks.* The *n* specification must be a positive integer. `!BLANKS(5)` returns a string of five blank spaces. Unless the blanks are quoted, they cannot be processed, since the macro facility compresses blanks.

!NULL *Generate a string of length 0.* This can help determine whether an argument was ever assigned a value, as in `!IF (!1 !EQ !NULL) !THEN. . . .`

!EVAL (str) *Scan the argument for macro calls.* During macro definition, an argument to a function or an operand in an expression is not scanned for possible macro calls unless the `!EVAL` function is used. It returns a string that is the expansion of its argument. For example, if mac1 is a macro, then `!EVAL(mac1)` returns the expansion of mac1. If mac1 is not a macro, `!EVAL(mac1)` returns mac1.

SET Subcommands for Use with Macro

Four subcommands on the SET command were designed for use with the macro facility.

MPRINT	*Display a list of commands after macro expansion.* The specification on MPRINT is YES or NO (alias ON or OFF). By default, the output does not include a list of commands after macro expansion (MPRINT NO). The MPRINT subcommand on SET is independent of the PRINTBACK command.
MEXPAND	*Macro expansion.* The specification on MEXPAND is YES or NO (alias ON or OFF). By default, MEXPAND is on. SET MEXPAND OFF prevents macro expansion. Specifying SET MEXPAND ON reestablishes macro expansion.
MNEST	*Maximum nesting level for macros.* The default number of levels that can be nested is 50. The maximum number of levels depends on storage capacity.
MITERATE	*Maximum loop iterations permitted in macro expansions.* The default number of iterations is 1000.

Restoring SET Specifications

The PRESERVE and RESTORE commands bring more flexibility and control over SET. PRESERVE and RESTORE are available generally within the program but are especially useful with macros.

- The settings of all SET subcommands—those set explicitly and those set by default (except MEXPAND)—are saved with PRESERVE. PRESERVE has no further specifications.
- With RESTORE, all SET subcommands are changed to what they were when the PRESERVE command was executed. RESTORE has no further specifications.
- PRESERVE...RESTORE sequences can be nested up to five levels.

PRESERVE	*Store the SET specifications that are in effect at this point in the session.*
RESTORE	*Restore the SET specifications to what they were when PRESERVE was specified.*

Example

```
* Two nested levels of preserve and restore'.

DEFINE macdef ()
preserve.
set format F5.3.
descriptives v1 v2.
+ preserve.
set format F3.0 blanks=999.
descriptives v3 v4.
+ restore.
descriptives v5 v6.
restore.
!ENDDEFINE.
```

- The first PRESERVE command saves all of the current SET conditions. If none have been specified, the default settings are saved.
- Next, the format is set to F5.3 and descriptive statistics for *V1* and *V2* are obtained.
- The second PRESERVE command saves the F5.3 format setting and all other settings in effect.
- The second SET command changes the format to F3.0 and sets BLANKS to 999 (the default is SYSMIS). Descriptive statistics are then obtained for *V3* and *V4*.

- The first RESTORE command restores the format to F5.3 and BLANKS to the default, the setting in effect at the second PRESERVE. Descriptive statistics are then obtained for *V5* and *V6*.
- The last RESTORE restores the settings in effect when the first PRESERVE was specified.

Conditional Processing

The !IF construct specifies conditions for processing. The syntax is as follows:

```
!IF (expression) !THEN statements
                [!ELSE statements]
!IFEND
```

- !IF, !THEN, and !IFEND are all required. !ELSE is optional.
- If the result of the expression is true, the statements following !THEN are executed. If the result of the expression is false and !ELSE is specified, the statements following !ELSE are executed. Otherwise, the program continues.
- Valid operators for the expressions include !EQ, !NE, !GT, !LT, !GE, !LE, !OR, !NOT, and !AND, or =, ~= (¬=), >, <, >=, <=, |, ~ (¬), and &.
- When a macro is expanded, conditional processing constructs are interpreted after arguments are substituted and functions are executed.
- !IF statements can be nested whenever necessary. Parentheses can be used to specify the order of evaluation. The default order is the same as for transformations: !NOT has precedence over !AND, which has precedence over !OR.

Example

```
DEFINE mymacro(type = !DEFAULT(1) !TOKENS(1))
!IF (!type = 1)!then
frequencies variables=varone.
!ELSE
descriptives variables=vartwo.
!IFEND
!ENDDEFINE.
```

Unquoted String Constants in Conditional !IF Statements

Prior to version 12.0, under certain circumstances unquoted string constants in conditional !IF statements were not case sensitive. Starting with version 12.0, unquoted string constants are case sensitive. For backward compatibility, always use quoted string constants.

Example

```
DEFINE noquote(type = !DEFAULT(a) !TOKENS(1))
!IF (!type = A)!THEN
frequencies variables=varone.
!ELSE
descriptives variables=vartwo.
!IFEND
!ENDDEFINE.
DEFINE yesquote(type = !DEFAULT('a') !TOKENS(1)).
!IF (!type = 'A')!THEN
FREQUENCIES varone.
```

```
!ELSE
DESCRIPTIVES vartwo.
!IFEND.
!ENDDEFINE.
```

- In the first macro, `!IF(!type = A)` is evaluated as false if the value of the unquoted string constant is lowercase ‘a’—and is therefore evaluated as false in this example.
- Prior to version 12.0, `!IF (!type = A)` was evaluated as true if the value of the unquoted string constant was lowercase ‘a’ or uppercase ‘A’—and was therefore evaluated as true in this example.
- In the second macro, `!IF (!type = 'A')` is always evaluated as false if the value of the string constant is lowercase ‘a.’

Looping Constructs

Looping constructs accomplish repetitive tasks. Loops can be nested to whatever depth is required, but loops cannot be crossed. The macro facility has two looping constructs: the index loop (`DO` loop) and the list-processing loop (`DO IN` loop).

- When a macro is expanded, looping constructs are interpreted after arguments are substituted and functions are executed.

Index Loop

The syntax of an index loop is as follows:

```
!DO !var = start !TO finish [ !BY step ]
    statements
!BREAK
!DOEND
```

- The indexing variable is *!var* and must begin with an exclamation point.
- The start, finish, and step values must be numbers or expressions that evaluate to numbers.
- The loop begins at the start value and continues until it reaches the finish value (unless a `!BREAK` statement is encountered). The step value is optional and can be used to specify a subset of iterations. If start is set to 1, finish to 10, and step to 3, the loop will be executed four times with the index variable assigned values 1, 4, 7, and 10.
- The statements can be any valid commands or macro keywords. `!DOEND` specifies the end of the loop.
- `!BREAK` is an optional specification. It can be used in conjunction with conditional processing to exit the loop.

Example

```
DEFINE macdef (arg1 = !TOKENS(1)
              /arg2 = !TOKENS(1))
!DO !i = !arg1 !TO !arg2.
frequencies variables = !CONCAT(var,!i).
!DOEND
!ENDDEFINE.
macdef arg1 = 1 arg2 = 3.
```

- The variable *!i* is initially assigned the value 1 (`arg1`) and is incremented until it equals 3 (`arg2`), at which point the loop ends.
- The first loop concatenates `var` and the value for *!I*, which is 1 in the first loop. The second loop concatenates `var` and 2, and the third concatenates `var` and 3. The result is that `FREQUENCIES` is executed three times, with variables *VAR1*, *VAR2*, and *VAR3*, respectively.

List-Processing Loop

The syntax of a list-processing loop is as follows:

```
!DO !var !IN (list)
    statements
!BREAK
!DOEND
```

- The `!DO` and `!DOEND` statements begin and end the loop. `!BREAK` is used to exit the loop.
- The `!IN` function requires one argument, which must be a list of items. The number of items on the list determines the number of iterations. At each iteration, the index variable *!var* is set to each item on the list.
- The list can be any expression, although it is usually a string. Only one list can be specified in each list-processing loop.

Example

```
DEFINE macdef (!POS !CHAREND('/'))
!DO !i !IN (!1)
frequencies variables = !i.
!DOEND
!ENDDEFINE.
macdef VAR1 VAR2 VAR3  /.
```

- The macro call assigns three variables, *VAR1*, *VAR2*, and *VAR3*, to the positional argument !1. Thus, the loop completes three iterations.
- In the first iteration, *!i* is set to value *VAR1*. In the second and third iterations, *!I* is set to *VAR2* and *VAR3*, respectively. Thus, `FREQUENCIES` is executed three times, respectively with *VAR1*, *VAR2*, and *VAR3*.

Example

```
DEFINE macdef (!POS !CHAREND('/'))
!DO !i !IN (!1)
sort cases by !i.
report var = earnings
  /break = !i
  /summary = mean.
!DOEND
!ENDDEFINE.

macdef SALESMAN REGION MONTH /.
```

- The positional argument !1 is assigned the three variables *SALESMAN*, *REGION*, and *MONTH*. The loop is executed three times and the index variable *!i* is set to each of the variables in succession. The macro creates three reports.

Direct Assignment of Macro Variables

The macro command `!LET` assigns values to macro variables. The syntax is as follows:

```
!LET !var = expression
```

- The expression must be either a single token or enclosed in parentheses.
- The macro variable *!var* cannot be a macro keyword, and it cannot be the name of one of the arguments within the macro definition. Thus, `!LET` cannot be used to change the value of an argument.
- The macro variable *!var* can be a new variable or one previously assigned by a `!DO` command or another `!LET` command.

Example

```
!LET !a = 1
!LET !b = !CONCAT(ABC,!SUBSTR(!1,3,1),DEF)
!LET !c = (!2 ~= !NULL)
```

- The first `!LET` sets *!a* equal to 1.
- The second `!LET` sets *!b* equal to ABC followed by 1 character taken from the third position of `!1` followed by DEF.
- The last `!LET` sets *!c* equal to 0 (false) if `!2` is a null string or to 1 (true) if `!2` is not a null string.

DELETE VARIABLES

```
DELETE VARIABLES  varlist.
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Example

```
DElETE VARIABLES varX varY thisVar TO thatVar.
```

Overview

DELETE VARIABLES deletes the specified variables from the active dataset.

Basic Specification

- The basic specification is one or more variable names.

Syntax Rules

- The variables must exist in the active dataset.
- The keyword TO can be used to specify consecutive variable in the active dataset.
- This command cannot be executed when there are pending transformations. For example, DELETE VARIABLES cannot be immediately preceded by transformation commands such as COMPUTE or RECODE.
- DELETE VARIABLES cannot be used with TEMPORARY.
- You cannot use this command to delete all variables in the active dataset. If the variable list includes all variables in the active dataset, an error results and the command is not executed. Use NEW FILE to delete all variables.

DESCRIPTIVES

```
DESCRIPTIVES VARIABLES= varname[(zname)] [varname...]

 [/MISSING={VARIABLE**}  [INCLUDE]]
           {LISTWISE  }

 [/SAVE]

 [/STATISTICS=[DEFAULT**]  [MEAN**]  [MIN**]  [SKEWNESS]]
              [STDDEV** ]  [SEMEAN]  [MAX**]  [KURTOSIS]
              [VARIANCE ]  [SUM   ]  [RANGE]  [ALL]

 [/SORT=[{MEAN    }] [{(A)}]]
         {SMEAN   }   {(D)}
         {STDDEV  }
         {VARIANCE}
         {KURTOSIS}
         {SKEWNESS}
         {RANGE   }
         {MIN     }
         {MAX     }
         {SUM     }
         {NAME    }
```

**Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
DESCRIPTIVES VARIABLES=FOOD RENT, APPL TO COOK
```

Overview

DESCRIPTIVES computes univariate statistics—including the mean, standard deviation, minimum, and maximum—for numeric variables. Because it does not sort values into a frequency table, DESCRIPTIVES is an efficient means of computing descriptive statistics for continuous variables. Other procedures that display descriptive statistics include FREQUENCIES, MEANS, and EXAMINE.

Options

Z Scores. You can create new variables that contain *z* scores (standardized deviation scores from the mean) and add them to the active dataset by specifying *z*-score names on the VARIABLES subcommand or by using the SAVE subcommand.

Statistical Display. Optional statistics available with the STATISTICS subcommand include the standard error of the mean, variance, kurtosis, skewness, range, and sum. DESCRIPTIVES does not compute the median or mode (see FREQUENCIES or EXAMINE).

Display Order. You can list variables in ascending or descending alphabetical order or by the numerical value of any of the available statistics using the SORT subcommand.

Basic Specification

The basic specification is the VARIABLES subcommand with a list of variables. All cases with valid values for a variable are included in the calculation of statistics for that variable. Statistics include the mean, standard deviation, minimum, maximum, and number of cases with valid values.

Subcommand Order

- Subcommands can be used in any order.

Operations

- If a string variable is specified on the variable list, no statistics are displayed for that variable.
- If there is insufficient memory available to calculate statistics for all variables requested, DESCRIPTIVES truncates the variable list.

Examples

Example Description

```
DESCRIPTIVES VARIABLES=FOOD RENT, APPL TO COOK, TELLER, TEACHER
 /STATISTICS=VARIANCE DEFAULT
 /MISSING=LISTWISE.
```

- DESCRIPTIVES requests statistics for the variables *FOOD*, *RENT*, *TELLER*, *TEACHER*, and all of the variables between and including *APPL* and *COOK* in the active dataset.
- STATISTICS requests the variance and the default statistics: mean, standard deviation, minimum, and maximum.
- MISSING specifies that cases with missing values for any variable on the variable list will be omitted from the calculation of statistics for all variables.

Example Description

```
DESCRIPTIVES VARS=ALL.
```

- DESCRIPTIVES requests statistics for all variables in the active dataset.
- Because no STATISTICS subcommand is included, only the mean, standard deviation, minimum, and maximum are displayed.

VARIABLES Subcommand

VARIABLES names the variables for which you want to compute statistics.

- The keyword ALL can be used to refer to all user-defined variables in the active dataset.
- Only one variable list can be specified.

Z Scores

The *z*-score transformation standardizes variables to the same scale, producing new variables with a mean of 0 and a standard deviation of 1. These variables are added to the active dataset.

- To obtain *z* scores for all specified variables, use the SAVE subcommand.
- To obtain *z* scores for a subset of variables, name the new variable in parentheses following the source variable on the VARIABLES subcommand and do not use the SAVE subcommand.
- Specify new names individually; a list in parentheses is not recognized.
- The new variable name can be any acceptable variable name that is not already part of the active dataset. For information on variable naming rules, see "Variable Names" on p. 36.

Example

```
DESCRIPTIVES VARIABLES=NTCSAL NTCPUR (PURCHZ) NTCPRI (PRICEZ).
```

- DESCRIPTIVES creates *z*-score variables named *PURCHZ* and *PRICEZ* for *NTCPUR* and *NTCPRI*, respectively. No *z*-score variable is created for *NTCSAL*.

SAVE Subcommand

SAVE creates a *z*-score variable for each variable specified on the VARIABLES subcommand. The new variables are added to the active dataset.

- When DESCRIPTIVES creates new *z*-score variables, it displays the source variable names, the new variable names, and their labels in the Notes table.
- DESCRIPTIVES automatically supplies variable names for the new variables. The new variable name is created by prefixing the letter *Z* to the source variable name. For example, *ZNTCPRI* is the *z*-score variable for *NTCPRI*.
- If the default naming convention duplicates variable names in the active dataset, DESCRIPTIVES uses an alternative naming convention: first *ZSC001* through *ZSC099*, then *STDZ01* through *STDZ09*, then *ZZZZ01* through *ZZZZ09*, and then *ZQZQ01* through *ZQZQ09*.
- Variable labels are created by prefixing *ZSCORE* to the source variable label. If the alternative naming convention is used, DESCRIPTIVES prefixes *ZSCORE(varname)* to the label. If the source variable does not have a label, DESCRIPTIVES uses *ZSCORE(varname)* for the label.
- If you specify new names on the VARIABLES subcommand *and* use the SAVE subcommand, DESCRIPTIVES creates one new variable for each variable on the VARIABLES subcommand, using default names for variables not assigned names on VARIABLES.
- If at any time you want to change any of the variable names, whether those DESCRIPTIVES created or those you previously assigned, you can do so with the RENAME VARIABLES command.

Example

```
DESCRIPTIVES VARIABLES=ALL
  /SAVE.
```

- SAVE creates a *z*-score variable for all variables in the active dataset. All *z*-score variables receive the default name.

Example

```
DESCRIPTIVES VARIABLES=NTCSAL NTCPUR (PURCHZ) NTCPRI (PRICEZ)
  /SAVE.
```

- DESCRIPTIVES creates three *z*-score variables named *ZNTCSAL* (the default name), *PURCHZ*, and *PRICEZ*.

STATISTICS Subcommand

By default, DESCRIPTIVES displays the mean, standard deviation, minimum, and maximum. Use the STATISTICS subcommand to request other statistics.

- When you use STATISTICS, DESCRIPTIVES displays *only* those statistics you request.
- The keyword ALL obtains all statistics.
- You can specify the keyword DEFAULT to obtain the default statistics without having to name MEAN, STDDEV, MIN, and MAX.
- The median and mode, which are available in FREQUENCIES and EXAMINE, are not available in DESCRIPTIVES. These statistics require that values be sorted, and DESCRIPTIVES does not sort values (the SORT subcommand does not sort values, it simply lists variables in the order you request).
- If you request a statistic that is not available, DESCRIPTIVES issues an error message and the command is not executed.

MEAN	*Mean*.
SEMEAN	*Standard error of the mean*.
STDDEV	*Standard deviation*.
VARIANCE	*Variance*.
KURTOSIS	*Kurtosis and standard error of kurtosis.*
SKEWNESS	*Skewness and standard error of skewness.*
RANGE	*Range*.
MIN	*Minimum observed value.*
MAX	*Maximum observed value.*
SUM	*Sum*.
DEFAULT	*Mean, standard deviation, minimum, and maximum*. These are the default statistics.
ALL	*All statistics available in DESCRIPTIVES.*

SORT Subcommand

By default, DESCRIPTIVES lists variables in the order in which they are specified on VARIABLES. Use SORT to list variables in ascending or descending alphabetical order of variable name or in ascending or descending order of numeric value of any of the statistics.

- If you specify SORT without any keywords, variables are sorted in ascending order of the mean.
- SORT can sort variables by the value of any of the statistics available with DESCRIPTIVES, but only those statistics specified on STATISTICS (or the default statistics) are displayed.

Only one of the following keywords can be specified on SORT:

MEAN	*Sort by mean.* This is the default when SORT is specified without a keyword.
SEMEAN	*Sort by standard error of the mean.*
STDDEV	*Sort by standard deviation.*
VARIANCE	*Sort by variance.*
KURTOSIS	*Sort by kurtosis.*
SKEWNESS	*Sort by skewness.*
RANGE	*Sort by range.*
MIN	*Sort by minimum observed value.*
MAX	*Sort by maximum observed value.*
SUM	*Sort by sum.*
NAME	*Sort by variable name.*

Sort order can be specified in parentheses following the specified keyword:

A	*Sort in ascending order.* This is the default when SORT is specified without keywords.
D	*Sort in descending order.*

Example

```
DESCRIPTIVES VARIABLES=A B C
 /STATISTICS=DEFAULT RANGE
 /SORT=RANGE (D).
```

- DESCRIPTIVES sorts variables *A*, *B*, and *C* in descending order of range and displays the mean, standard deviation, minimum and maximum values, range, and the number of valid cases.

MISSING Subcommand

MISSING controls missing values.

- By default, DESCRIPTIVES deletes cases with missing values on a variable-by-variable basis. A case with a missing value for a variable will not be included in the summary statistics for that variable, but the case *will* be included for variables where it is not missing.

- The VARIABLE and LISTWISE keywords are alternatives; however, each can be specified with INCLUDE.
- When either the keyword VARIABLE or the default missing-value treatment is used, DESCRIPTIVES reports the number of valid cases for each variable. It always displays the number of cases that would be available if listwise deletion of missing values had been selected.

VARIABLE *Exclude cases with missing values on a variable-by-variable basis.* This is the default.

LISTWISE *Exclude cases with missing values listwise.* Cases with missing values for any variable named are excluded from the computation of statistics for all variables.

INCLUDE *Include user-missing values.*

DETECTANOMALY

DETECTANOMALY is available in the Data Preparation option.

```
DETECTANOMALY

[/VARIABLES [CATEGORICAL=varlist]
            [SCALE=varlist]
            [ID=variable]
            [EXCEPT=varlist]]

[/HANDLEMISSING [APPLY={NO**}]
                       {YES }
                [CREATEMISPROPVAR={NO**}]]
                                  {YES }

[/CRITERIA [MINNUMPEERS={1**    }]
                        {integer}
           [MAXNUMPEERS={15**   }]
                        {integer}
           [MLWEIGHT={6**   }]
                     {number}
           [NUMREASONS={1**    }]
                       {integer}
           [PCTANOMALOUSCASES={5**   }]

           [NUMANOMALOUSCASES={integer}]
           [ANOMALYCUTPOINT={2**   }
                            {number}
                            {NONE  }]]

[/SAVE [ANOMALY[(varname)]]
       [PEERID[(varname)]]
       [PEERSIZE[(varname)]]
       [PEERPCTSIZE[(varname)]]
       [REASONVAR[(rootname)]]
       [REASONMEASURE[(rootname)]]
       [REASONVALUE[(rootname)]]
       [REASONNORM[(rootname)]]]

[/OUTFILE [MODEL=filespec]]

[/PRINT [CPS]  [ANOMALYLIST**]  [NORMS]
        [ANOMALYSUMMARY]  [REASONSUMMARY]
        [NONE]]
```

** Default if the subcommand or keyword is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Release History

Release 14.0

- Command introduced.

Example

```
DETECTANOMALY.
```

Overview

The Anomaly Detection procedure searches for unusual cases based on deviations from the norms of their cluster groups. The procedure is designed to quickly detect unusual cases for data-auditing purposes in the exploratory data analysis step, prior to any inferential data analysis. This algorithm is designed for generic anomaly detection; that is, the definition of an anomalous case is not specific to any particular application, such as detection of unusual payment patterns in the healthcare industry or detection of money laundering in the finance industry, in which the definition of an anomaly can be well-defined.

Options

Methods. The DETECTANOMALY procedure clusters cases into peer groups based on the similarities of a set of input variables. An anomaly index is assigned to each case to reflect the unusualness of a case with respect to its peer group. All cases are sorted by the values of the anomaly index, and the top portion of the cases is identified as the set of anomalies. For each variable, an impact measure is assigned to each case that reflects the contribution of the variable to the deviation of the case from its peer group. For each case, the variables are sorted by the values of the variable impact measure, and the top portion of variables is identified as the set of reasons why the case is anomalous.

Data File. The DETECTANOMALY procedure assumes that the input data is a flat file in which each row represents a distinct case and each column represents a distinct variable. Moreover, it is assumed that all input variables are non-constant and that no case has missing values for all of the input variables.

Missing Values. The DETECTANOMALY procedure allows missing values. By default, missing values of continuous variables are substituted by their corresponding grand means, and missing categories of categorical variables are grouped and treated as a valid category. Moreover, an additional variable called the *Missing Proportion Variable*, which represents the proportion of missing variables in each case, is created. The processed variables are used to detect the anomalies in the data. You can turn off either of the options. If the first is turned off, cases with missing values are excluded from the analysis. In this situation, the second option is turned off automatically.

ID Variable. A variable that is the unique identifier of the cases in the data can optionally be specified in the ID keyword. If this keyword is not specified, the case sequence number of the active dataset is assumed to be the ID.

Weights. The DETECTANOMALY procedure ignores specification on the WEIGHT command.

Output. The DETECTANOMALY procedure displays an anomaly list in pivot table output, or offers an option for suppressing it. The procedure can also save the anomaly information to the active dataset as additional variables. Anomaly information can be grouped into three sets of variables: anomaly, peer, and reason. The anomaly set consists of the anomaly index of each case. The peer set consists of the peer group ID of each case, the size, and the percentage size of the peer group. The reason set consists of a number of reasons. Each reason consists of information such as the variable impact, the variable name for this reason, the value of the variable, and the corresponding norm value of the peer group.

Basic Specification

The basic specification is the DETECTANOMALY command. By default, all variables in the active dataset are used in the procedure, with the dictionary setting of each variable in the dataset determining its measurement level.

Syntax Rules

- All subcommands are optional.
- Only a single instance of each subcommand is allowed.
- An error occurs if an attribute or keyword is specified more than once within a subcommand.
- Parentheses, slashes, and equals signs shown in the syntax chart are required.
- Subcommand names and keywords must be spelled in full.
- Empty subcommands are not honored.

Operations

The DETECTANOMALY procedure begins by applying the missing value handling option and the create missing proportion variable option to the data.

Then the procedure groups cases into their peer groups based on the similarities of the processed variables. An anomaly index is assigned to each case to measure the overall deviation of the case from its peer group. All cases are sorted by the values of the anomaly index, and the top portion of the cases is identified as the anomaly list.

For each anomalous case, the variables are sorted by their corresponding variable impact values. The top variables, their values, and the corresponding norm values are presented as the reasons why a case is identified as an anomaly.

By default, the anomaly list is presented in a pivot table. Optionally, the anomaly information can be added to the active dataset as additional variable. The anomaly detection model may be written to an XML model file.

Limitations

WEIGHT and SPLIT FILE settings are ignored with a warning by the DETECTANOMALY procedure.

Examples

```
DETECTANOMALY
  /VARIABLES CATEGORICAL=A B C SCALE=D E
  /SAVE ANOMALY REASON.
```

- DETECTANOMALY treats variables *A*, *B*, and *C* as categorical variables and *D* and *F* as continuous variables.
- All of the processed variables are then used in the analysis to generate the anomaly list. Since no ID option is specified, the case number is used as the case identity variable. The size of the list is the number of cases with an anomaly index of at least 2.0 and is not more than 5% of the size of the working file. The anomaly list consists of the ID variable, the anomaly index, the peer group ID and size, and the reason. By default, there is one reason for each anomaly.

Each reason consists of information such as the variable impact measure, the variable name for this reason, the value of the variable, and the value of the corresponding peer group. The anomaly list is presented in the pivot table output.

- Since the keywords ANOMALY and REASON are specified in the SAVE subcommand, the additional variables for the anomaly index and the anomaly reason are added to the active dataset.

Specifying a Case ID Variable and Excepted Variables

```
DETECTANOMALY
  /VARIABLES ID=CaseID EXCEPT=GeoID DemoID AddressID.
```

- DETECTANOMALY uses all variables in the active dataset in the analysis, except the variables *GeoID*, *DemoID*, and *AddressID*, which are excluded. Moreover, it treats the variable *CaseID* as the ID variable in the procedure. The processed variables are used in the analysis to generate the anomaly list.

VARIABLES Subcommand

The VARIABLES subcommand specifies the variables to be used in the procedure. If the CATEGORICAL option or the SCALE option are specified, then variables that are listed in these options are used in the analysis. If neither the CATEGORICAL option nor the SCALE option is specified, then all variables in the active dataset are used, except the variable specified in the ID option and those in the EXCEPT option, if any. In the latter situation, the dictionary setting of each variable determines its measurement level. The procedure treats ordinal and nominal variables equivalently as categorical.

CATEGORICAL=varlist *List of categorical variables.* If this option is specified, at least one variable must be listed. Variables in the list can be numeric or string. They are treated as categorical variables and are used in the analysis. If duplicate variables are specified in the list, the duplicates are ignored. After the EXCEPT option (if specified) is applied, if there are variables also specified in either the continuous list or as an ID variable, an error is issued. TO and ALL keywords may be used.

SCALE=varlist *List of continuous variables.* If this option is specified, at least one variable must be listed. Variables in the list must be numeric and are used in the analysis. If duplicate variables are specified in the list, the duplicates are ignored. After the EXCEPT option (if specified) is applied, if there are variables also specified in either the categorical list or as an ID variable, an error is issued. TO and ALL keywords may be used.

ID=variable *Case ID variable.* If this option is specified, one variable must be listed. The variable can be numeric or string. It is used as a unique identifier for the cases in the data file and is not used in the analysis. If this option is not specified, the case number of the active dataset is used as the identifier variable. If the identifier variable is specified in either the categorical list or continuous list, an error is issued.

EXCEPT=varlist *List of variables that are excluded from the analysis.* If this option is specified, at least one variable must be listed. Variables in the list are not used in the analysis, even if they are specified in the continuous or categorical lists. This option ignores duplicate variables and variables that are not specified on the continuous or categorical list. Specifying the ALL keyword causes an error. The TO keyword may be used.

This option can be useful if the categorical list or continuous list contains a large number of variables but there are a few variables that should be excluded.

HANDLEMISSING Subcommand

The HANDLEMISSING subcommand specifies the methods of handling missing values in this procedure.

APPLY=optionvalue *Apply missing value handling.* Valid option values are YES or NO. If YES, the missing values of continuous variables are substituted by their corresponding grand means, and missing categories of categorical variables are grouped and treated as a valid category. The processed variables are used in the analysis. If NO, cases with missing values are excluded from the analysis. The default value is NO.

CREATEMISPROPVAR=optionvalue *Create an additional Missing Proportion Variable and use it in the analysis.* Valid option values are YES or NO. If YES, an additional variable called the *Missing Proportion Variable* that represents the proportion of missing variables in each case is created, and this variable is used in the analysis. If NO, the *Missing Proportion Variable* is not created. The default value is NO.

CRITERIA Subcommand

The CRITERIA subcommand specifies settings for the DETECTANOMALY procedure.

MINNUMPEERS=integer *Minimum number of peer groups.* The procedure will search for the best number of peer groups between the specified value and the value in the MAXNUMPEERS keyword. The specified value must be a positive integer less than or equal to the value in the MAXNUMPEERS keyword. When the specified value is equal to the value in the MAXNUMPEERS keyword, the procedure assumes a fixed number of peer groups. The default value is 1.

Note: Depending on the amount of variation in your data, there may be situations in which the number of peer groups that the data can support is less than the number specified in the MINNUMPEERS option. In such a situation, the procedure may produce a smaller number of peer groups.

MAXNUMPEERS=integer *Maxim number of peer groups.* The procedure will search for the best number of peer groups between the value in the MINNUMPEERS keyword and the specified value. The specified value must be a positive integer greater than or equal to the value in the MINNUMPEERS keyword. When the specified value is equal to the value in the MINNUMPEERS keyword, the procedure assumes a fixed number of peer groups. The default value is 15.

MLWEIGHT=number *An adjustment weight on the measurement level.* This parameter is used to balance the influences between continuous and categorical variables during the calculation of the indices. A large value increases the influence of a continuous variable. Specify a positive number. The default value is 6.

NUMREASONS=integer *Number of reasons in the anomaly list.* A reason consists of information such as the variable impact measure, the variable name for this reason, the value of the variable, and the value of the corresponding peer group. Specify a non-negative integer less than or equal to the number of processed variables used in the analysis. The specified option value will be adjusted downward to the maximum number of variables used in the analysis if it is set larger than the number of variables. The default value is 1.

PCTANOMALOUSCASES=number *Percentage of cases considered as anomalies and included in the anomaly list.* Specify a non-negative number less than or equal to 100. The default value is 5.

NUMANOMALOUSCASES=integer *Number of cases considered as anomalies and included in the anomaly list.* Specify a non-negative integer less than or equal to the total number of cases in the active dataset and used in the analysis. If this option is specified, an option value must be listed. The specified option value will be adjusted downward to the maximum available if it is set larger than the number of cases used in the analysis. This option, if specified, overrides the PCTANOMALOUSCASES option.

ANOMALYCUTPOINT=number *Cut point of the anomaly index to determine whether a case is considered as an anomaly.* Specify a non-negative number. A case is considered anomalous if its anomaly index value is larger than or equal to the specified cut point. This option can be used together with the PCTANOMALOUSCASES and NUMANOMALOUSCASES options. For example, if NUMANOMALOUSCASES=50 and ANOMALYCUTPOINT=2 are specified, the anomaly list will consist of at most 50 cases each with an anomaly index value larger than or equal to 2. The default value is 2. If NONE is specified, the option is suppressed and no cut point is set.

SAVE Subcommand

The SAVE subcommand specifies the additional variables to save to the active dataset.

- One or more keywords should be specified, each followed by an optional variable name or rootname in parentheses.
- The variable name or the rootname, if specified, must be a valid variable name.
- If no variable name or rootname is specified, a default varname or rootname is used. If the default varname or rootname is used and it conflicts with that of an existing variable, a suffix is added to make the name unique.

- The values of the additional variables are assigned to all cases included in the analysis, even if the cases are not in the anomaly list.
- This subcommand is not affected by the specifications on the PCTANOMALOUSCASES, NUMANOMALOUSCASES, or ANOMALYCUTPOINT keywords in the CRITERIA subcommand.

ANOMALY(varname) *The anomaly index.* If an optional varname is not specified, the default varname is *AnomalyIndex*, which is the anomaly index. If an optional varname is specified, the specified varname is used to replace the default varname. For example, if ANOMALY(MyAnomaly) is specified, the variable name will be *MyAnomaly*.

PEERID(varname) *Peer group ID.* If an optional varname is not specified, the default varname *PeerId* is used. If an optional varname is specified, the specified name is used.

PEERSIZE(varname) *Peer group size.* If an optional varname is not specified, the default variable name *PeerSize* is used. If an optional varname is specified, the specified name is used.

PEERPCTSIZE(varname) *Peer group size in percentage.* If an optional varname is not specified, the default varname *PeerPctSize* is used. If an optional varname is specified, the specified name is used.

REASONVAR(rootname) *The variable associated with a reason.* The number of REASONVAR variables created depends on the number of reasons specified on the CRITERIA subcommand NUMREASONS option. If an optional rootname is not specified, the default rootname *ReasonVar* is used to automatically generate one or more varnames, *ReasonVar_k*, where *k* is the *k*th reason. If an optional rootname is specified, the specified name is used. If NUMREASONS=0 is specified, this option is ignored and a warning is issued.

REASONMEASURE(rootname) *The variable impact measure associated with a reason.* The number of REASONMEASURE variables created depends on the number of reasons specified on the CRITERIA subcommand NUMREASONS option. If an optional rootname is not specified, the default rootname *ReasonMeasure* is used to automatically generate one or more varnames, *ReasonMeasure_k*, where *k* is the *k*th reason. If an optional rootname is specified, the specified name is used. If NUMREASONS=0 is specified, this option is ignored and a warning is issued.

REASONVALUE(rootname) *The variable value associated with a reason.* The number of REASONVALUE variables created depends on the number of reasons specified on the CRITERIA subcommand NUMREASONS option. If an optional rootname is not specified, the default rootname *ReasonValue* is used to automatically generate one or more varnames, *ReasonValue_k*, where *k* is the *k*th reason. If an optional rootname is specified, the specified name is used. If NUMREASONS=0 is specified, this option is ignored and a warning is issued.

REASONNORM(rootname) *The norm value associated with a reason.* The number of REASONNORM variables created depends on the number of reasons specified on the CRITERIA subcommand NUMREASONS option. If an optional rootname is not specified, the default rootname *ReasonNorm* is used to automatically generate one or more varnames, *ReasonNorm_k*, where *k* is the *k*th reason. If an optional rootname is specified, the specified name is used. If NUMREASONS=0 is specified, this option is ignored and a warning is issued.

OUTFILE Subcommand

The OUTFILE subcommand directs the DETECTANOMALY procedure to write its model to the specified filename as XML.

MODEL=filespec *File specification to which the model is written.*

PRINT Subcommand

The PRINT subcommand controls the display of the output results.

- If the PRINT subcommand is not specified, the default output is the anomaly list. If the PRINT subcommand is specified, DETECTANOMALY displays output only for the keywords that are specified.

CPS *Display a case processing summary.* The case processing summary displays the counts and count percentages for all cases in the active dataset, the cases included and excluded in the analysis, and the cases in each peer.

ANOMALYLIST *Display the anomaly index list, the anomaly peer ID list, and the anomaly reason list.* The anomaly index list displays the case number and its corresponding anomaly index value. The anomaly peer ID list displays the case number, its corresponding peer group ID, peer size, and size in percent. The anomaly reason list displays the case number, the reason variable, the variable impact value, the value of the variable, and the norm of the variable for each reason. All tables are sorted by anomaly index in descending order. Moreover, the IDs of the cases are displayed if the case identifier variable is specified in the ID option of the VARIABLES subcommand. This is the default output.

NORMS *Display the continuous variable norms table if any continuous variable is used in the analysis, and display the categorical variable norms table if any categorical variable is used in the analysis.* In the continuous variable norms table, the mean and standard deviation of each continuous variable for each peer group is displayed. In the categorical variable norms table, the mode (most popular category), its frequency, and frequency percent of each categorical variable for each peer group is displayed. The mean of a continuous variable and the mode of a categorical variable are used as the norm values in the analysis.

ANOMALYSUMMARY *Display the anomaly index summary.* The anomaly index summary displays descriptive statistics for the anomaly index of the cases identified as the most unusual.

REASONSUMMARY *Display the reason summary table for each reason.* For each reason, the table displays the frequency and frequency percent of each variable's occurrence as a reason. It also reports the descriptive statistics of the impact of each variable. If `NUMREASONS=0` is specified on the `CRITERIA` subcommand, this option is ignored and a warning is issued.

NONE *Suppress all displayed output except the notes table and any warnings.* If `NONE` is specified with one or more other keywords, the other keywords override `NONE`.

DISCRIMINANT

Example

```
DISCRIMINANT GROUPS=OUTCOME (1,4)
```

```
/VARIABLES=V1 TO V7.
```

Overview

DISCRIMINANT performs linear discriminant analysis for two or more groups. The goal of discriminant analysis is to classify cases into one of several mutually exclusive groups based on their values for a set of predictor variables. In the analysis phase, a classification rule is developed using cases for which group membership is known. In the classification phase, the rule is used to classify cases for which group membership is not known. The grouping variable must be categorical, and the independent (predictor) variables must be interval or dichotomous, since they will be used in a regression-type equation.

Options

Variable Selection Method. In addition to the direct-entry method, you can specify any of several stepwise methods for entering variables into the discriminant analysis using the METHOD subcommand. You can set the values for the statistical criteria used to enter variables into the equation using the TOLERANCE, FIN, PIN, FOUT, POUT, and VIN subcommands, and you can specify inclusion levels on the ANALYSIS subcommand. You can also specify the maximum number of steps in a stepwise analysis using the MAXSTEPS subcommand.

Case Selection. You can select a subset of cases for the analysis phase using the SELECT subcommand.

Prior Probabilities. You can specify prior probabilities for membership in a group using the PRIORS subcommand. Prior probabilities are used in classifying cases.

New Variables. You can add new variables to the active dataset containing the predicted group membership, the probability of membership in each group, and discriminant function scores using the SAVE subcommand.

Classification Options. With the CLASSIFY subcommand, you can classify only those cases that were not selected for inclusion in the discriminant analysis, or only those cases whose value for the grouping variable was missing or fell outside the range analyzed. In addition, you can classify cases based on the separate-group covariance matrices of the functions instead of the pooled within-groups covariance matrix.

Statistical Display. You can request any of a variety of statistics on the STATISTICS subcommand. You can rotate the pattern or structure matrices using the ROTATE subcommand. You can compare actual with predicted group membership using a classification results table requested with the STATISTICS subcommand or compare any of several types of plots or histograms using the PLOT subcommand.

Basic Specification

The basic specification requires two subcommands:

- GROUPS specifies the variable used to group cases.
- VARIABLES specifies the predictor variables.

By default, DISCRIMINANT enters all variables simultaneously into the discriminant equation (the DIRECT method), provided that they are not so highly correlated that multicollinearity problems arise. Default output includes analysis case processing summary, valid numbers of cases in group statistics, variables failing tolerance test, a summary of canonical discriminant functions, standardized canonical discriminant function coefficients, a structure matrix showing pooled within-groups correlations between the discriminant functions and the predictor variables, and functions at group centroids.

Subcommand Order

- The GROUPS, VARIABLES, and SELECT subcommands must precede all other subcommands and may be entered in any order.
- The analysis block follows, which may include ANALYSIS, METHOD, TOLERANCE, MAXSTEPS, FIN, FOUT, PIN, POUT, VIN, FUNCTIONS, PRIORS, SAVE, and OUTFILE. Each analysis block performs a single analysis. To do multiple analyses, specify multiple analysis blocks.
- The keyword ANALYSIS is optional for the first analysis block. Each new analysis block must begin with an ANALYSIS subcommand. Remaining subcommands in the block may be used in any order and apply only to the analysis defined within the same block.
- No analysis block subcommands can be specified after any of the global subcommands, which apply to all analysis blocks. The global subcommands are MISSING, MATRIX, HISTORY, ROTATE, CLASSIFY, STATISTICS, and PLOT. If an analysis block subcommand appears after a global subcommand, the program displays a warning and ignores it.

Syntax Rules

- Only one GROUPS, one SELECT, and one VARIABLES subcommand can be specified per DISCRIMINANT command.

Operations

- DISCRIMINANT first estimates one or more discriminant functions that best distinguish among the groups.
- Using these functions, DISCRIMINANT then classifies cases into groups (if classification output is requested).
- If more than one analysis block is specified, the above steps are repeated for each block.

Limitations

- Pairwise deletion of missing data is not available.

Example

```
DISCRIMINANT GROUPS=OUTCOME (1,4)
  /VARIABLES=V1 TO V7
  /SAVE CLASS=PREDOUT
  /STATISTICS=COV GCOV TCOV.
```

- Only cases with values 1, 2, 3, or 4 for the grouping variable *GROUPS* will be used in computing the discriminant functions.

- The variables in the active dataset between and including *V1* and *V7* will be used to compute the discriminant functions and to classify cases.
- Predicted group membership will be saved in the variable *PREDOUT*.
- In addition to the default output, the STATISTICS subcommand requests the pooled within-groups covariance matrix and the group and total covariance matrices.
- Since SAVE is specified, DISCRIMINANT also displays a classification processing summary table and a priori probabilities for groups table.

GROUPS Subcommand

GROUPS specifies the name of the grouping variable, which defines the categories or groups, and a range of categories.

- GROUPS is required and can be specified only once.
- The specification consists of a variable name followed by a range of values in parentheses.
- Only one grouping variable may be specified; its values must be integers. To use a string variable as the grouping variable, first use AUTORECODE to convert the string values to integers and then specify the recoded variable as the grouping variable.
- Empty groups are ignored and do not affect calculations. For example, if there are no cases in group 2, the value range (1, 5) will define only four groups.
- Cases with values outside the value range or missing are ignored during the analysis phase but are classified during the classification phase.

VARIABLES Subcommand

VARIABLES identifies the predictor variables, which are used to classify cases into the groups defined on the GROUPS subcommand. The list of variables follows the usual conventions for variable lists.

- VARIABLES is required and can be specified only once. Use the ANALYSIS subcommand to obtain multiple analyses.
- Only numeric variables can be used.
- Variables should be suitable for use in a regression-type equation, either measured at the interval level or dichotomous.

SELECT Subcommand

SELECT limits cases used in the analysis phase to those with a specified value for any one variable.

- Only one SELECT subcommand is allowed. It can follow the GROUPS and VARIABLES subcommands but must precede all other subcommands.
- The specification is a variable name and a single integer value in parentheses. Multiple variables or values are not permitted.
- The selection variable does not have to be specified on the VARIABLES subcommand.
- Only cases with the specified value for the selection variable are used in the analysis phase.

- All cases, whether selected or not, are classified by default. Use CLASSIFY=UNSELECTED to classify only the unselected cases.
- When SELECT is used, classification statistics are reported separately for selected and unselected cases, unless CLASSIFY=UNSELECTED is used to restrict classification.

Example

```
DISCRIMINANT GROUPS=APPROVAL(1,5)
  /VARS=Q1 TO Q10
  /SELECT=COMPLETE(1)
  /CLASSIFY=UNSELECTED.
```

- Using only cases with the value 1 for the variable *COMPLETE*, DISCRIMINANT estimates a function of *Q1* to *Q10* that discriminates between the categories 1 to 5 of the grouping variable *APPROVAL*.
- Because CLASSIFY=UNSELECTED is specified, the discriminant function will be used to classify only the unselected cases (cases for which *COMPLETE* does not equal 1).

ANALYSIS Subcommand

ANALYSIS is used to request several different discriminant analyses using the same grouping variable, or to control the order in which variables are entered into a stepwise analysis.

- ANALYSIS is optional for the first analysis block. By default, all variables specified on the VARIABLES subcommand are included in the analysis.
- The variables named on ANALYSIS must first be specified on the VARIABLES subcommand.
- The keyword ALL includes all variables on the VARIABLES subcommand.
- If the keyword TO is used to specify a list of variables on an ANALYSIS subcommand, it refers to the order of variables on the VARIABLES subcommand, which is not necessarily the order of variables in the active dataset.

Example

```
DISCRIMINANT GROUPS=SUCCESS(0,1)
  /VARIABLES=V10 TO V15, AGE, V5
  /ANALYSIS=V15 TO V5
  /ANALYSIS=ALL.
```

- The first analysis will use the variables *V15*, *AGE*, and *V5* to discriminate between cases where *SUCCESS* equals 0 and *SUCCESS* equals 1.
- The second analysis will use all variables named on the VARIABLES subcommand.

Inclusion Levels

When you specify a stepwise method on the METHOD subcommand (any method other than the default direct-entry method), you can control the order in which variables are considered for entry or removal by specifying inclusion levels on the ANALYSIS subcommand. By default, all variables in the analysis are entered according to the criterion requested on the METHOD subcommand.

- An **inclusion level** is an integer between 0 and 99, specified in parentheses after a variable or list of variables on the ANALYSIS subcommand.
- The default inclusion level is 1.
- Variables with higher inclusion levels are considered for entry before variables with lower inclusion levels.
- Variables with even inclusion levels are entered as a group.
- Variables with odd inclusion levels are entered individually, according to the stepwise method specified on the METHOD subcommand.
- Only variables with an inclusion level of 1 are considered for removal. To make a variable with a higher inclusion level eligible for removal, name it twice on the ANALYSIS subcommand, first specifying the desired inclusion level and then an inclusion level of 1.
- Variables with an inclusion level of 0 are never entered. However, the statistical criterion for entry is computed and displayed.
- Variables that fail the tolerance criterion are not entered regardless of their inclusion level.

The following are some common methods of entering variables and the inclusion levels that could be used to achieve them. These examples assume that one of the stepwise methods is specified on the METHOD subcommand (otherwise, inclusion levels have no effect).

Direct. ANALYSIS=ALL(2) forces all variables into the equation. (This is the default and can be requested with METHOD=DIRECT or simply by omitting the METHOD subcommand.)

Stepwise. ANALYSIS=ALL(1) yields a stepwise solution in which variables are entered and removed in stepwise fashion. (This is the default when anything other than DIRECT is specified on the METHOD subcommand.)

Forward. ANALYSIS=ALL(3) enters variables into the equation stepwise but does not remove variables.

Backward. ANALYSIS=ALL(2) ALL(1) forces all variables into the equation and then allows them to be removed stepwise if they satisfy the criterion for removal.

Inclusion Levels Used With a Stepwise Method

```
DISCRIMINANT GROUPS=SUCCESS(0,1)
  /VARIABLES=A, B, C, D, E
  /ANALYSIS=A TO C (2) D, E (1)
  /METHOD=WILKS.
```

- *A*, *B*, and *C* are entered into the analysis first, assuming that they pass the tolerance criterion. Since their inclusion level is even, they are entered together.
- *D* and *E* are then entered stepwise. The one that minimizes the overall value of Wilks' lambda is entered first.
- After entering *D* and *E*, the program checks whether the partial *F* for either one justifies removal from the equation (see the FOUT and POUT subcommands).

Inclusion Levels Without a Stepwise Method

```
DISCRIMINANT GROUPS=SUCCESS(0,1)
```

```
/VARIABLES=A, B, C, D, E
/ANALYSIS=A TO C (2) D, E (1).
```

- Since no stepwise method is specified, inclusion levels have no effect and all variables are entered into the model at once.

METHOD Subcommand

METHOD is used to select a method for entering variables into an analysis.

- A variable will never be entered into the analysis if it does not pass the tolerance criterion specified on the TOLERANCE subcommand (or the default).
- A METHOD subcommand applies only to the *preceding* ANALYSIS subcommand, or to an analysis using all predictor variables if no ANALYSIS subcommand has been specified before it.
- If more than one METHOD subcommand is specified within one analysis block, the last is used.

Any one of the following methods can be specified on the METHOD subcommand:

DIRECT	*All variables passing the tolerance criteria are entered simultaneously.* This is the default method.
WILKS	*At each step, the variable that minimizes the overall Wilks' lambda is entered.*
MAHAL	*At each step, the variable that maximizes the Mahalanobis distance between the two closest groups is entered.*
MAXMINF	*At each step, the variable that maximizes the smallest* F *ratio between pairs of groups is entered.*
MINRESID	*At each step, the variable that minimizes the sum of the unexplained variation for all pairs of groups is entered.*
RAO	*At each step, the variable that produces the largest increase in Rao's* V *is entered.*

OUTFILE Subcommand

Exports model information to the specified file in XML (PMML) format. *SmartScore* and SPSS Server (a separate product) can use this model file to apply the model information to other data files for scoring purposes.

- The minimum specification is the keyword MODEL and a file name enclosed in parentheses.
- The OUTFILE subcommand cannot be used if split file processing is on (SPLIT FILE command).

TOLERANCE Subcommand

TOLERANCE specifies the minimum tolerance a variable can have and still be entered into the analysis. The tolerance of a variable that is a candidate for inclusion in the analysis is the proportion of its within-groups variance not accounted for by other variables in the analysis. A variable with very low tolerance is nearly a linear function of the other variables; its inclusion in the analysis would make the calculations unstable.

- The default tolerance is 0.001.
- You can specify any decimal value between 0 and 1 as the minimum tolerance.

PIN and POUT Subcommands

PIN specifies the minimum probability of *F* that a variable can have to enter the analysis and POUT specifies the maximum probability of *F* that a variable can have and not be removed from the model.

- PIN and POUT take precedence over FIN and FOUT. That is, if all are specified, PIN and POUT values are used.
- If PIN and POUT are omitted, FIN and FOUT are used by default.
- You can set PIN and POUT to any decimal value between 0 and 1. However, POUT should be greater than PIN if PIN is also specified.
- PIN and POUT apply only to the stepwise methods and are ignored if the METHOD subcommand is omitted or if DIRECT is specified on METHOD.

FIN and FOUT Subcommands

FIN specifies the minimum partial *F* value that a variable must have to enter the analysis. As additional variables are entered into the analysis, the partial *F* for variables already in the equation changes. FOUT specifies the smallest partial *F* that a variable can have and not be removed from the model.

- PIN and POUT take precedence over FIN and FOUT. That is, if all are specified, PIN and POUT values are used.
- If PIN and POUT are omitted, FIN and FOUT are used by default. If FOUT is specified but FIN is omitted, the default value for FIN is 3.84. If FIN is specified, the default value for FOUT is 2.71.
- You can set FIN and FOUT to any non-negative number. However, FOUT should be less than FIN if FIN is also specified.
- FIN and FOUT apply only to the stepwise methods and are ignored if the METHOD subcommand is omitted or if DIRECT is specified on METHOD.

VIN Subcommand

VIN specifies the minimum Rao's *V* that a variable must have to enter the analysis. When you use METHOD=RAO, variables satisfying one of the other criteria for entering the equation may actually cause a decrease in Rao's *V* for the equation. The default VIN prevents this but does not prevent the addition of variables that provide no additional separation between groups.

- You can specify any value for VIN. The default is 0.
- VIN should be used only when you have specified METHOD=RAO. Otherwise, it is ignored.

MAXSTEPS Subcommand

MAXSTEPS is used to decrease the maximum number of steps allowed. By default, the maximum number of steps allowed in a stepwise analysis is the number of variables with inclusion levels greater than 1 plus twice the number of variables with inclusion levels equal to 1. This is the maximum number of steps possible without producing a loop in which a variable is repeatedly cycled in and out.

- MAXSTEPS applies only to the stepwise methods (all except DIRECT).
- MAXSTEPS applies only to the preceding METHOD subcommand.
- The format is MAX=*n,* where *n* is the maximum number of steps desired.
- If multiple MAXSTEPS subcommands are specified, the last is used.

FUNCTIONS Subcommand

By default, DISCRIMINANT computes all possible functions. This is either the number of groups minus 1 or the number of predictor variables, whichever is less. Use FUNCTIONS to set more restrictive criteria for the extraction of functions.

FUNCTIONS has three parameters:

- *Maximum number of functions*. The default is the number of groups minus 1 or the number of predictor variables, whichever is less.
- *Cumulative percentage of the sum of the eigenvalues*. The default is 100.
- *Significance level of function*. The default is 1.0.

- The parameters must always be specified in sequential order (n_1, n_2, n_3). To specify n_2, you must explicitly specify the default for n_1. Similarly, to specify n_3, you must specify the defaults for n_1 and n_2.
- If more than one restriction is specified, the program stops extracting functions when any one of the restrictions is met.
- When multiple FUNCTIONS subcommands are specified, the program uses the last; however, if n_2 or n_3 are omitted on the last FUNCTIONS subcommand, the corresponding specifications on the previous FUNCTIONS subcommands will remain in effect.

Example

```
DISCRIMINANT  GROUPS=CLASS(1,5)
  /VARIABLES = SCORE1 TO SCORE20
  /FUNCTIONS=4,100,.80.
```

- The first two parameters on the FUNCTIONS subcommand are defaults: the default for n_1 is 4 (the number of groups minus 1), and the default for n_2 is 100.
- The third parameter tells DISCRIMINANT to use fewer than four discriminant functions if the significance level of a function is greater than 0.80.

PRIORS Subcommand

By default, DISCRIMINANT assumes equal prior probabilities for groups when classifying cases. You can provide different prior probabilities with the PRIORS subcommand.

- Prior probabilities are used only during classification.
- If you provide unequal prior probabilities, DISCRIMINANT adjusts the classification coefficients to reflect this.
- If adjacent groups have the same prior probability, you can use the notation *n*c* on the value list to indicate that *n* adjacent groups have the same prior probability *c*.
- You can specify a prior probability of 0. No cases are classified into such a group.
- If the sum of the prior probabilities is not 1, the program rescales the probabilities to sum to 1 and issues a warning.

EQUAL	*Equal prior probabilities*. This is the default.
SIZE	*Proportion of the cases analyzed that fall into each group.* If 50% of the cases included in the analysis fall into the first group, 25% in the second, and 25% in the third, the prior probabilities are 0.5, 0.25, and 0.25, respectively. Group size is determined after cases with missing values for the predictor variables are deleted.
Value list	*User-specified prior probabilities*. The list of probabilities must sum to 1.0. The number of prior probabilities named or implied must equal the number of groups.

Example

```
DISCRIMINANT  GROUPS=TYPE(1,5)
  /VARIABLES=A TO H
  /PRIORS = 4*.15,.4.
```

- The PRIORS subcommand establishes prior probabilities of 0.15 for the first four groups and 0.4 for the fifth group.

SAVE Subcommand

SAVE allows you to save casewise information as new variables in the active dataset.

- SAVE applies only to the current analysis block. To save casewise results from more than one analysis, specify a SAVE subcommand in each analysis block.
- You can specify a variable name for CLASS and rootnames for SCORES and PROBS to obtain descriptive names for the new variables.
- If you do not specify a variable name for CLASS, the program forms variable names using the formula *DSC_m*, where *m* increments to distinguish group membership variables saved on different SAVE subcommands for different analysis blocks.
- If you do not specify a rootname for SCORES or PROBS, the program forms new variable names using the formula *DSCn_m*, where *m* increments to create unique rootnames and *n* increments to create unique variable names. For example, the first set of default names assigned to discriminant scores or probabilities are *DSC1_1*, *DSC2_1*, *DSC3_1*, and so on. The next set of default names assigned will be *DSC1_2*, *DSC2_2*, *DSC3_2*, and so on,

regardless of whether discriminant scores or probabilities are being saved or whether they are saved by the same SAVE subcommand.

- The keywords CLASS, SCORES, and PROBS can be used in any order, but the new variables are always added to the end of the active dataset in the following order: first the predicted group, then the discriminant scores, and finally probabilities of group membership.
- Appropriate variable labels are automatically generated. The labels describe whether the variables contain predictor group membership, discriminant scores, or probabilities, and for which analysis they are generated.
- The CLASS variable will use the value labels (if any) from the grouping variable specified for the analysis.
- When SAVE is specified with any keyword, DISCRIMINANT displays a classification processing summary table and a prior probabilities for groups table.
- You cannot use the SAVE subcommand if you are replacing the active dataset with matrix materials (see Matrix Output on p. 595).

CLASS [(varname)]	*Predicted group membership.*
SCORES [(rootname)]	*Discriminant scores.* One score is saved for each discriminant function derived. If a rootname is specified, DISCRIMINANT will append a sequential number to the name to form new variable names for the discriminant scores.
PROBS [(rootname)]	*For each case, the probabilities of membership in each group.* As many variables are added to each case as there are groups. If a rootname is specified, DISCRIMINANT will append a sequential number to the name to form new variable names.

Example

```
DISCRIMINANT GROUPS=WORLD(1,3)
 /VARIABLES=FOOD TO FSALES
 /SAVE CLASS=PRDCLASS SCORES=SCORE PROBS=PRB
 /ANALYSIS=FOOD SERVICE COOK MANAGER FSALES
 /SAVE CLASS SCORES PROBS.
```

- Two analyses are specified. The first uses all variables named on the VARIABLES subcommand and the second narrows down to five variables. For each analysis, a SAVE subcommand is specified.
- For each analysis, DISCRIMINANT displays a classification processing summary table and a prior probabilities for groups table.
- On the first SAVE subcommand, a variable name and two rootnames are provided. With three groups, the following variables are added to each case:

Name	Variable label	Description
PRDCLASS	Predicted group for analysis 1	Predicted group membership
SCORE1	Function 1 for analysis 1	Discriminant score for function 1
SCORE2	Function 2 for analysis 1	Discriminant score for function 2
PRB1	Probability 1 for analysis 1	Probability of being in group 1

Name	Variable label	Description
PRB2	Probability 2 for analysis 1	Probability of being in group 2
PRB3	Probability 3 for analysis 1	Probability of being in group 3

- Since no variable name or rootnames are provided on the second SAVE subcommand, DISCRIMINANT uses default names. Note that *m* serves only to distinguish variables saved as a set and does not correspond to the sequential number of an analysis. To find out what information a new variable holds, read the variable label, as shown in the following table:

Name	Variable label	Description
DSC_1	Predicted group for analysis 2	Predicted group membership
DSC1_1	Function 1 for analysis 2	Discriminant score for function 1
DSC2_1	Function 2 for analysis 2	Discriminant score for function 2
DSC1_2	Probability 1 for analysis 2	Probability of being in group 1
DSC2_2	Probability 2 for analysis 2	Probability of being in group 2
DSC3_2	Probability 3 for analysis 2	Probability of being in group 3

STATISTICS Subcommand

By default, DISCRIMINANT produces the following statistics for each analysis: analysis case processing summary, valid numbers of cases in group statistics, variables failing tolerance test, a summary of canonical discriminant functions, standardized canonical discriminant function coefficients, a structure matrix showing pooled within-groups correlations between the discriminant functions and the predictor variables, and functions at group centroids.

- *Group statistics.* Only valid number of cases is reported.
- *Summary of canonical discriminant functions.* Displayed in two tables: an eigenvalues table with percentage of variance, cumulative percentage of variance, and canonical correlations and a Wilks' lambda table with Wilks' lambda, chi-square, degrees of freedom, and significance.
- *Stepwise statistics.* Wilks' lambda, equivalent *F*, degrees of freedom, significance of *F* and number of variables are reported for each step. Tolerance, *F*-to-remove, and the value of the statistic used for variable selection are reported for each variable in the equation. Tolerance, minimum tolerance, *F*-to-enter, and the value of the statistic used for variable selection are reported for each variable not in the equation. (These statistics can be suppressed with HISTORY=NONE.)
- *Final statistics.* Standardized canonical discriminant function coefficients, the structure matrix of discriminant functions and all variables named in the analysis (whether they were entered into the equation or not), and functions evaluated at group means are reported following the last step.

In addition, you can request optional statistics on the STATISTICS subcommand. STATISTICS can be specified by itself or with one or more keywords.

- STATISTICS without keywords displays MEAN, STDDEV, and UNIVF. If you include a keyword or keywords on STATISTICS, only the statistics you request are displayed.

MEAN	*Means*. Total and group means for all variables named on the ANALYSIS subcommand are displayed.
STDDEV	*Standard deviations*. Total and group standard deviations for all variables named on the ANALYSIS subcommand are displayed.
UNIVF	*Univariate* F *ratios*. The analysis-of-variance *F* statistic for equality of group means for each predictor variable is displayed. This is a one-way analysis-of-variance test for equality of group means on a single discriminating variable.
COV	*Pooled within-groups covariance matrix*.
CORR	*Pooled within-groups correlation matrix*.
FPAIR	*Matrix of pairwise* F *ratios*. The *F* ratio for each pair of groups is displayed. This *F* is the significance test for the Mahalanobis distance between groups. This statistic is available only with stepwise methods.
BOXM	*Box's* M *test*. This is a test for equality of group covariance matrices.
GCOV	*Group covariance matrices*.
TCOV	*Total covariance matrix*.
RAW	*Unstandardized canonical discriminant functions*.
COEFF	*Classification function coefficients*. Although DISCRIMINANT does not directly use these coefficients to classify cases, you can use them to classify other samples (see the CLASSIFY subcommand).
TABLE	*Classification results*. If both selected and unselected cases are classified, the results are reported separately. To obtain cross-validated results for selected cases, specify CROSSVALID.
CROSSVALID	*Cross-validated classification results.* The cross-validation is done by treating *n*–1 out of *n* observations as the training dataset to determine the discrimination rule and using the rule to classify the one observation left out. The results are displayed only for selected cases.
ALL	*All optional statistics.*

ROTATE Subcommand

The coefficient and correlation matrices can be rotated to facilitate interpretation of results. To control varimax rotation, use the ROTATE subcommand.

- Neither COEFF nor STRUCTURE affects the classification of cases.

COEFF	*Rotate pattern matrix.* DISCRIMINANT displays a varimax transformation matrix, a rotated standardized canonical discriminant function coefficients table, and a correlations between variables and rotated functions table.
STRUCTURE	*Rotate structure matrix.* DISCRIMINANT displays a varimax transformation matrix, a rotated structure matrix, and a rotated standardized canonical discriminant function coefficients table.
NONE	*Do not rotate.* This is the default.

HISTORY Subcommand

HISTORY controls the display of stepwise and summary output.

- By default, HISTORY displays both the step-by-step output and the summary table (keyword STEP, alias END).

STEP *Display step-by-step and summary output*. Alias END. This is the default. See *Stepwise statistics* in STATISTICS Subcommand on p. 591.

NONE *Suppress the step-by-step and summary table*. Alias NOSTEP, NOEND.

CLASSIFY Subcommand

CLASSIFY determines how cases are handled during classification.

- By default, all cases with nonmissing values for all predictors are classified, and the pooled within-groups covariance matrix is used to classify cases.
- The default keywords for CLASSIFY are NONMISSING and POOLED.

NONMISSING *Classify all cases that do not have missing values on any predictor variables.* Two sets of classification results are produced, one for selected cases (those specified on the SELECT subcommand) and one for unselected cases. This is the default.

UNSELECTED *Classify only unselected cases*. The classification phase is suppressed for cases selected via the SELECT subcommand. If all cases are selected (when the SELECT subcommand is omitted), the classification phase is suppressed for all cases and no classification results are produced.

UNCLASSIFIED *Classify only unclassified cases*. The classification phase is suppressed for cases that fall within the range specified on the GROUPS subcommand.

POOLED *Use the pooled within-groups covariance matrix to classify cases.* This is the default.

SEPARATE *Use separate-groups covariance matrices of the discriminant functions for classification.* DISCRIMINANT displays the group covariances of canonical discriminant functions and Box's test of equality of covariance matrices of canonical discriminant functions. Since classification is based on the discriminant functions and not the original variables, this option is not necessarily equivalent to quadratic discrimination.

MEANSUB *Substitute means for missing predictor values during classification*. During classification, means are substituted for missing values and cases with missing values are classified. Cases with missing values are not used during analysis.

PLOT Subcommand

PLOT requests additional output to help you examine the effectiveness of the discriminant analysis.

- If PLOT is specified without keywords, the default is COMBINED and CASES.

- If any keywords are requested on PLOT, only the requested plots are displayed.
- If PLOT is specified with any keyword except MAP, DISCRIMINANT displays a classification processing summary table and a prior probabilities for groups table.

COMBINED *All-groups plot*. For each case, the first two function values are plotted.

CASES(n) *Casewise statistics*. For each case, classification information, squared Mahalanobis distance to centroid for the highest and second highest groups, and discriminant scores of all functions are plotted. Validated statistics are displayed for selected cases if CROSSVALID is specified on STATISTICS. If *n* is specified, DISCRIMINANT displays the first *n* cases only.

MAP *Territorial map*. A plot of group centroids and boundaries used for classifying groups.

SEPARATE *Separate-groups plots*. These are the same types of plots produced by the keyword COMBINED, except that a separate plot is produced for each group. If only one function is used, a histogram is displayed.

ALL *All available plots.*

MISSING Subcommand

MISSING controls the treatment of cases with missing values in the analysis phase. By default, cases with missing values for any variable named on the VARIABLES subcommand are not used in the analysis phase but are used in classification.

- The keyword INCLUDE includes cases with user-missing values in the analysis phase.
- Cases with missing or out-of-range values for the grouping variable are always excluded.

EXCLUDE *Exclude all cases with missing values*. Cases with user or system-missing values are excluded from the analysis. This is the default.

INCLUDE *Include cases with user-missing values*. User-missing values are treated as valid values. Only the system-missing value is treated as missing.

MATRIX Subcommand

MATRIX reads and writes SPSS-format matrix data files.

- Either IN or OUT and the matrix file in parentheses are required. When both IN and OUT are used in the same DISCRIMINANT procedure, they can be specified on separate MATRIX subcommands or on the same subcommand.

OUT ('savfile'|'dataset') *Write a matrix data file.* Specify either a quoted file specification, a previously declared dataset name (DATASET DECLARE command) or an asterisk (*), enclosed in parentheses. If you specify an asterisk (*), the matrix data file replaces the active dataset .

IN ('savfile'|'dataset') *Read a matrix data file.* Specify either a quoted file specification, a previously declared dataset name (DATASET DECLARE command) or an asterisk (*), enclosed in parentheses. An asterisk indicates the active dataset. A matrix file read from an a file or dataset does not replace the active dataset.

Matrix Output

- In addition to Pearson correlation coefficients, the matrix materials written by DISCRIMINANT include weighted and unweighted numbers of cases, means, and standard deviations. (See Format of the Matrix Data File on p. 595 for a description of the file.) These materials can be used in subsequent DISCRIMINANT procedures.
- Any documents contained in the active dataset are not transferred to the matrix file.
- If BOXM or GCOV is specified on the STATISTICS subcommand or SEPARATE is specified on the CLASSIFY subcommand when a matrix file is written, the *STDDEV* and *CORR* records in the matrix materials represent within-cell data, and separate covariance matrices are written to the file. When the matrix file is used as input for a subsequent DISCRIMINANT procedure, at least one of these specifications must be used on that DISCRIMINANT command.

Matrix Input

- DISCRIMINANT can read correlation matrices written by a previous DISCRIMINANT command or by other procedures. Matrix materials read by DISCRIMINANT must contain records with *ROWTYPE_* values *MEAN*, *N* or *COUNT* (or both), *STDDEV*, and *CORR*.
- If the data do not include records with *ROWTYPE_* value *COUNT* (unweighted number of cases), DISCRIMINANT uses information from records with *ROWTYPE_* value *N* (weighted number of cases). Conversely, if the data do not have *N* values, DISCRIMINANT uses the *COUNT* values. These records can appear in any order in the matrix input file with the following exceptions: the order of split-file groups cannot be violated and all *CORR* vectors must appear consecutively within each split-file group.
- If you want to use a covariance-type matrix as input to DISCRIMINANT, you must first use the MCONVERT command to change the covariance matrix to a correlation matrix.
- DISCRIMINANT can use a matrix from a previous dataset to classify data in the active dataset. The program checks to make sure that the grouping variable (specified on GROUPS) and the predictor variables (specified on VARIABLES) are the same in the active dataset as in the matrix file. If they are not, the program displays an error message and the classification will not be executed.
- MATRIX=IN cannot be used unless a active dataset has already been defined. To read an existing matrix data file at the beginning of a session, first use GET to retrieve the matrix file and then specify IN(*) on MATRIX.

Format of the Matrix Data File

- The matrix data file has two special variables created by the program: *ROWTYPE_* and *VARNAME_*. Variable *ROWTYPE_* is a short string variable having values *N*, *COUNT*, *MEAN*, *STDDEV*, and *CORR* (for Pearson correlation coefficient). The variable *VARNAME_* is a short string variable whose values are the names of the variables used to form the correlation matrix.
- When *ROWTYPE_* is *CORR*, *VARNAME_* gives the variable associated with that row of the correlation matrix.
- Between *ROWTYPE_* and *VARNAME_* is the grouping variable, which is specified on the GROUPS subcommand of DISCRIMINANT.
- The remaining variables are the variables used to form the correlation matrix.

Split Files

- When split-file processing is in effect, the first variables in the matrix data file will be split variables, followed by *ROWTYPE_*, the grouping variable, *VARNAME_*, and then the variables used to form the correlation matrix.
- A full set of matrix materials is written for each subgroup defined by the split variables.
- A split variable cannot have the same variable name as any other variable written to the matrix data file.
- If split-file processing is in effect when a matrix is written, the same split file must be in effect when that matrix is read by another procedure.

STDDEV and CORR Records

Records written with *ROWTYPE_* values *STDDEV* and *CORR* are influenced by specifications on the STATISTICS and CLASSIFY subcommands.

- If BOXM or GCOV is specified on STATISTICS or SEPARATE is specified on CLASSIFY, the *STDDEV* and *CORR* records represent within-cell data and receive values for the grouping variable.
- If none of the above specifications is in effect, the *STDDEV* and *CORR* records represent pooled values. The *STDDEV* vector contains the square root of the mean square error for each variable, and *STDDEV* and *CORR* records receive the system-missing value for the grouping variable.

Missing Values

Missing-value treatment affects the values written to a matrix data file. When reading a matrix data file, be sure to specify a missing-value treatment on DISCRIMINANT that is compatible with the treatment that was in effect when the matrix materials were generated.

Examples

Writing Output to a Matrix Data File

```
GET FILE=UNIONBK /KEEP WORLD FOOD SERVICE BUS MECHANIC
                  CONSTRUC COOK MANAGER FSALES APPL RENT.
DISCRIMINANT  GROUPS=WORLD(1,3)
 /VARIABLES=FOOD SERVICE BUS MECHANIC CONSTRUC COOK MANAGER FSALES
 /METHOD=WILKS
 /PRIORS=SIZE
 /MATRIX=OUT(DISCMTX).
```

- DISCRIMINANT reads data from the SPSS-format data file *UNIONBK* and writes one set of matrix materials to the file *DISCMTX*.
- The active dataset is still *UNIONBK*. Subsequent commands are executed on this file.

Using Matrix Output to Classify Data in a Different File

```
GET FILE=UB2 /KEEP WORLD FOOD SERVICE BUS MECHANIC
```

```
              CONSTRUC COOK MANAGER FSALES APPL RENT.
DISCRIMINANT  GROUPS=WORLD(1,3)
 /VARIABLES=FOOD SERVICE BUS MECHANIC CONSTRUC COOK MANAGER FSALES
 /METHOD=WILKS
 /PRIORS=SIZE
 /MATRIX=IN(DISCMTX).
```

- The matrix data file created in the previous example is used to classify data from the file *UB2*.

Replacing the Active Dataset with Matrix Data Output

```
GET FILE=UNIONBK /KEEP WORLD FOOD SERVICE BUS MECHANIC
                  CONSTRUC COOK MANAGER FSALES APPL RENT.
DISCRIMINANT  GROUPS=WORLD(1,3)
 /VARIABLES=FOOD SERVICE BUS MECHANIC CONSTRUC COOK MANAGER FSALES
 /METHOD=WILKS
 /PRIORS=SIZE
 /MATRIX=OUT(*).
LIST.
```

- DISCRIMINANT writes the same matrix as in the first example. However, the matrix data file replaces the active dataset.
- The LIST command is executed on the matrix file, not on the *UNIONBK* file.

Using the Active Dataset as Matrix Input

```
GET FILE=DISCMTX.
DISCRIMINANT  GROUPS=WORLD(1,3)
 /VARIABLES=FOOD SERVICE BUS MECHANIC CONSTRUC COOK MANAGER FSALES
 /METHOD=RAO
 /MATRIX=IN(*).
```

- This example assumes that you are starting a new session and want to read an existing matrix data file. GET retrieves the matrix data file *DISCMTX*.
- MATRIX=IN specifies an asterisk because the matrix data file is the active dataset. If MATRIX=IN(DISCMTX) is specified, the program issues an error message.
- If the GET command is omitted, the program issues an error message.

Using Matrix Output as Matrix Input in the Active Dataset

```
GET FILE=UNIONBK /KEEP WORLD FOOD SERVICE BUS MECHANIC
                  CONSTRUC COOK MANAGER FSALES APPL RENT.
DISCRIMINANT  GROUPS=WORLD(1,3)
 /VARIABLES=FOOD SERVICE BUS MECHANIC CONSTRUC COOK MANAGER FSALES
 /CLASSIFY=SEPARATE
 /MATRIX=OUT(*).
DISCRIMINANT  GROUPS=WORLD(1,3)
 /VARIABLES=FOOD SERVICE BUS MECHANIC CONSTRUC COOK MANAGER FSALES
 /STATISTICS=BOXM
 /MATRIX=IN(*).
```

- The first DISCRIMINANT command creates a matrix with CLASSIFY=SEPARATE in effect. To read this matrix, the second DISCRIMINANT command must specify either BOXM or GCOV on STATISTICS or SEPARATE on CLASSIFY. STATISTICS=BOXM is used.

DISPLAY

```
DISPLAY [SORTED] [{NAMES**   }] [/VARIABLES=varlist]
                  {INDEX     }
                  {VARIABLES }
                  {LABELS    }
                  {DICTIONARY}
                  {ATTRIBUTES}
                  {@ATTRIBUTES}

        {[SCRATCH]  }
        {[VECTOR]   }
        {[MACROS]   }
        {[DOCUMENTS]}
```

***Default if the subcommand is omitted.*

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Release History

Release 14.0

- ATTRIBUTES keyword introduced.

Release 15.0

- @ATTRIBUTES keyword introduced.

Example

```
DISPLAY SORTED DICTIONARY /VARIABLES=DEPT SALARY SEX TO JOBCAT.
```

Overview

DISPLAY exhibits information from the dictionary of the active dataset. The information can be sorted, and it can be limited to selected variables.

Basic Specification

The basic specification is simply the command keyword, which displays an unsorted list of the variables in the active dataset.

Syntax Rules

DISPLAY can be specified by itself or with one of the keywords defined below. NAMES is the default. To specify two or more keywords, use multiple DISPLAY commands.

NAMES	*Variable names.* A list of the variables in the active dataset is displayed.
DOCUMENTS	*Documentary text.* Documentary text is provided on the DOCUMENT and ADD DOCUMENT commands. No error message is issued if there is no documentary information in the active dataset.
DICTIONARY	*Complete dictionary information for variables.* Information includes variable names, labels, sequential position of each variable in the file, print and write formats, missing values, and value labels.
ATTRIBUTES	*Variable and data file attributes, except attributes with names that begin with "@" or "$@".* Custom attributes defined by the VARIABLE ATTRIBUTE and DATAFILE ATTRIBUTE commands.
@ATTRIBUTES	*All variable and data file attributes, including those with names that begin with "@" or "$@".*
INDEX	*Variable names and positions.*
VARIABLES	*Variable names, positions, print and write formats, and missing values.*
LABELS	*Variable names, positions, and variable labels.*
SCRATCH	*Scratch variable names.*
VECTOR	*Vector names.*
MACROS	*Currently defined macros.* The macro names are always sorted.

Operations

- DISPLAY directs information to the output.
- If SORTED is not specified, information is displayed according to the order of variables in the active dataset.
- DISPLAY is executed as soon as it is encountered in the command sequence, as long as a dictionary has been defined.

Examples

```
GET FILE="/data/hub.sav".
DISPLAY DOCUMENTS.
DISPLAY DICTIONARY.
```

- Each DISPLAY command specifies only one keyword. The first requests documentary text and the second requests complete dictionary information for the *hub.sav* file.

SORTED Keyword

SORTED alphabetizes the display by variable name. SORTED can precede the keywords NAMES, DICTIONARY, INDEX, VARIABLES, LABELS, SCRATCH, or VECTOR.

Example

```
DISPLAY SORTED DICTIONARY.
```

- This command displays complete dictionary information for variables in the active dataset, sorted alphabetically by variable name.

VARIABLES Subcommand

VARIABLES (alias NAMES) limits the displayed information to a set of specified variables. VARIABLES must be the last specification on DISPLAY and can follow any specification that requests information about variables (all except VECTOR, SCRATCH, DOCUMENTS, and MACROS).

- The only specification is a slash followed by a list of variables. The slash is optional.
- If the keyword SORTED is not specified, information is displayed in the order in which variables are stored in the active dataset, regardless of the order in which variables are named on VARIABLES.

Example

```
DISPLAY SORTED DICTIONARY
 /VARIABLES=DEPT, SALARY, SEX TO JOBCAT.
```

- DISPLAY exhibits dictionary information only for the variables named and implied by the keyword TO on the VARIABLES subcommand, sorted alphabetically by variable name.

DO IF

```
DO IF [(]logical expression[)]

transformation commands

[ELSE IF [(]logical expression[)]]

transformation commands

[ELSE IF [(]logical expression[)]]
  .
  .
  .
[ELSE]

transformation commands

END IF
```

This command does not read the active dataset. It is stored, pending execution with the next command that reads the dataset. For more information, see Command Order on p. 36.

The following relational operators can be used in logical expressions:

Symbol	Definition
EQ or =	Equal to
NE or ~= or ¬ = or <>	Not equal to
LT or <	Less than
LE or <=	Less than or equal to
GT or >	Greater than
GE or >=	Greater than or equal to

The following logical operators can be used in logical expressions:

Symbol	Definition
AND or &	Both relations must be true
OR or |	Either relation can be true
NOT	Reverses the outcome of an expression

Example

```
DO IF (YearHired GT 87).
COMPUTE             Bonus = 0.
ELSE IF (Dept87 EQ 3).
COMPUTE             Bonus = .1*Salary87.
ELSE IF (Dept87 EQ 1).
COMPUTE             Bonus = .12*Salary87.
ELSE IF (Dept87 EQ 4).
COMPUTE             Bonus = .08*Salary87.
ELSE IF (Dept87 EQ 2).
COMPUTE             Bonus = .14*Salary87.
END IF.
```

Overview

The DO IF–END IF structure conditionally executes one or more transformations on subsets of cases based on one or more logical expressions. The ELSE command can be used within the structure to execute one or more transformations when the logical expression on DO IF is not true. The ELSE IF command within the structure provides further control.

The DO IF–END IF structure is best used for conditionally executing multiple transformation commands, such as COMPUTE, RECODE, and COUNT. DO IF–END IF transforms data for subsets of cases defined by logical expressions. To perform repeated transformations on the same case, use LOOP–END LOOP.

A DO IF–END IF structure can be used within an input program to define complex files that cannot be handled by standard file definition facilities. For more information, see Complex File Structures on p. 609.

See END FILE for information on using DO IF–END IF to instruct the program to stop reading data before it encounters the end of the file or to signal the end of the file when creating data.

Basic Specification

The basic specification is DO IF followed by a logical expression, a transformation command, and the END IF command, which has no specifications.

Examples

Simple, One-Condition Example

```
DO IF (YearHired LT 87).
RECODE Ethnicity(1=5)(2=4)(4=2)(5=1).
END IF.
```

- The RECODE command recodes *Ethnicity* for those individuals hired before 1987 (*YearHired* is less than 87). The *Ethnicity* variable is not recoded for individuals hired in 1987 or later.
- The RECODE command is skipped for any case with a missing value for *YearHired*.

Conditional Execution Based on a Logical Expression

```
DATA LIST       FREE / X(F1).
NUMERIC         #QINIT.
DO IF           NOT #QINIT.
+  PRINT EJECT.
+  COMPUTE         #QINIT = 1.
END IF.
PRINT           / X.

BEGIN DATA
1 2 3 4 5
END DATA.
EXECUTE.
```

- This example shows how to execute a command only once.
- The NUMERIC command creates scratch variable *#QINIT*, which is initialized to 0.

- The NOT logical operator on DO IF reverses the outcome of a logical expression. In this example, the logical expression is a numeric variable that takes only 0 (false) or 1 (true) as its values. The PRINT EJECT command is executed only once, when the value of scratch variable *#QINIT* equals 0. After the COMPUTE command sets *#QINIT* to 1, the DO IF structure is skipped for all subsequent cases. A scratch variable is used because it is initialized to 0 and is not reinitialized after each case.

Syntax Rules

- The ELSE IF command is optional and can be repeated as many times as needed.
- The ELSE command is optional. It can be used only once and must follow any ELSE IF commands.
- The END IF command must follow any ELSE IF and ELSE commands.
- A logical expression must be specified on the DO IF and ELSE IF commands. Logical expressions are not used on the ELSE and END IF commands.
- String values used in expressions must be specified in quotation marks and must include any leading or trailing blanks. Lowercase letters are distinguished from uppercase letters.
- To create a new string variable within a DO IF–END IF structure, you must first declare the variable on the STRING command.
- DO IF–END IF structures can be nested to any level permitted by available memory. They can be nested within LOOP–END LOOP structures, and loop structures can be nested within DO IF structures.

Example

```
DATA LIST FREE /var1.
BEGIN DATA
1 2 3 4 5
END DATA.
DO IF (var1 > 2) & (var1 < 5).
- COMPUTE var2=1.
ELSE IF (var1=2).
- COMPUTE var2=2.
ELSE.
- COMPUTE var2=3.
END IF.
```

var1	var2
1	3
2	2
3	1
4	1
5	3

Example

```
INPUT PROGRAM.
+ STRING odd (A3).
```

```
+ LOOP numvar=1 TO 5.
+  DO IF MOD(numvar, 2)=0.
+   COMPUTE odd='No'.
+  ELSE.
+   COMPUTE odd='Yes'.
+  END IF.
+  END CASE.
+ END LOOP.
+ END FILE.
END INPUT PROGRAM.
```

numvar	odd
1	Yes
2	No
3	Yes
4	No
5	Yes

Logical Expressions

- Logical expressions can be simple logical variables or relations, or they can be complex logical tests involving variables, constants, functions, relational operators, and logical operators. Logical expressions can use any of the numeric or string functions allowed in COMPUTE transformations (see COMPUTE).
- Parentheses can be used to enclose the logical expression itself and to specify the order of operations within a logical expression. Extra blanks or parentheses can be used to make the expression easier to read.
- Blanks (*not* commas) are used to separate relational operators from expressions.
- A relation can include variables, constants, or more complicated arithmetic expressions. Relations cannot be abbreviated. For example, the first relation below is valid; the second is not:

  Valid: (A EQ 2 OR A EQ 5) *Not valid:* (A EQ 2 OR 5)
- A relation cannot compare a string variable to a numeric value or variable, or vice versa. A relation cannot compare the result of a logical function (SYSMIS, MISSING, ANY, or RANGE) to a number.

Operations

- DO IF marks the beginning of the control structure and END IF marks the end. Control for a case is passed out of the structure as soon as a logical condition is met on a DO IF, ELSE IF, or ELSE command.
- A logical expression is evaluated as true, false, or missing. A transformation specified for a logical expression is executed only if the expression is true.
- Logical expressions are evaluated in the following order: functions, exponentiation, arithmetic operations, relations, and finally, logical operators. (For strings, the order is functions, relations, and then logical operators.) When more than one logical operator is used, NOT is

evaluated first, followed by AND, and then OR. You can change the order of operations using parentheses.

- Numeric variables created within a DO IF structure are initially set to the system-missing value. By default, they are assigned an F8.2 format.
- New string variables created within a DO IF structure are initially set to a blank value and are assigned the format specified on the STRING command that creates them.
- If the transformed value of a string variable exceeds the variable's defined format, the value is truncated. If the value is shorter than the format, the value is right-padded with blanks.
- If WEIGHT is specified within a DO IF structure, it takes effect unconditionally.
- Commands like SET, DISPLAY, SHOW, and so forth specified within a DO IF structure are executed when they are encountered in the command file.
- The DO IF–END IF structure (like LOOP–END LOOP) can include commands such as DATA LIST, END CASE, END FILE, and REREAD, which define complex file structures.

Flow of Control

- If the logical expression on DO IF is true, the commands immediately following DO IF are executed up to the next ELSE IF, ELSE, or END IF command. Control then passes to the first statement following END IF.
- If the expression on DO IF is false, control passes to the following ELSE IF command. Multiple ELSE IF commands are evaluated in the order in which they are specified until the logical expression on one of them is true. Commands following that ELSE IF command are executed up to the ELSE or END IF command, and control passes to the first statement following END IF.
- If none of the expressions are true on the DO IF or any of the ELSE IF commands, the commands following ELSE are executed and control passes out of the structure. If there is no ELSE command, a case goes through the entire structure with no change.
- Missing values returned by the logical expression on DO IF or on any ELSE IF cause control to pass to the END IF command at that point.

Missing Values and Logical Operators

When two or more relations are joined by logical operators AND and OR, the program always returns missing if all of the relations in the expression are missing. However, if any one of the relations can be determined, the program tries to return true or false according to the logical outcomes shown in the following table. The asterisk indicates situations where the program can evaluate the outcome with incomplete information.

Table 64-1
Logical outcomes

Expression	Outcome	Expression	Outcome
true AND true	= true	true OR true	= true
true AND false	= false	true OR false	= true
false AND false	= false	false OR false	= false

Expression	Outcome	Expression	Outcome
true AND missing	= missing	true OR missing	= true*
missing AND missing	= missing	missing OR missing	= missing
false AND missing	= false*	false OR missing	= missing

ELSE Command

ELSE executes one or more transformations when none of the logical expressions on DO IF or any ELSE IF commands is true.

- Only one ELSE command is allowed within a DO IF–END IF structure.
- ELSE must follow all ELSE IF commands (if any) in the structure.
- If the logical expression on DO IF or any ELSE IF command is true, the program ignores the commands following ELSE.

Example

```
DO IF (X EQ 0).
COMPUTE Y=1.
ELSE.
COMPUTE Y=2.
END IF.
```

- *Y* is set to 1 for all cases with value 0 for *X*, and *Y* is 2 for all cases with any other valid value for *X*.
- The value of *Y* is not changed by this structure if *X* is missing.

Example

```
DO IF (YearHired GT 87).
COMPUTE            Bonus = 0.
ELSE.
IF (Dept87 EQ 1) Bonus = .12*Salary87.
IF (Dept87 EQ 2) Bonus = .14*Salary87.
IF (Dept87 EQ 3) Bonus = .1*Salary87.
IF (Dept87 EQ 4) Bonus = .08*Salary87.
END IF.
```

- If an individual was hired after 1987 (*YearHired* is greater than 87), *Bonus* is set to 0 and control passes out of the structure. Otherwise, control passes to the IF commands following ELSE.
- Each IF command evaluates every case. The value of *Bonus* is transformed only when the case meets the criteria specified on IF. Compare this structure with the second example for the ELSE IF command, which performs the same task more efficiently.

Example

```
* Test for listwise deletion of missing values.

DATA LIST / V1 TO V6 1-6.
BEGIN DATA
123456
```

```
    56
1 3456
123456
123456
END DATA.

DO IF NMISS(V1 TO V6)=0.
+  COMPUTE SELECT='V'.
ELSE
+  COMPUTE SELECT='M'.
END IF.

FREQUENCIES VAR=SELECT.
```

- If there are no missing values for any of the variables *V1* to *V6*, COMPUTE sets the value of *SELECT* equal to V (for valid). Otherwise, COMPUTE sets the value of *SELECT* equal to M (for missing).
- FREQUENCIES generates a frequency table for *SELECT*. The table gives a count of how many cases have missing values for one or more variables, and how many cases have valid values for all variables. Commands in this example can be used to determine how many cases are dropped from an analysis that uses listwise deletion of missing values.

ELSE IF Command

ELSE IF executes one or more transformations when the logical expression on DO IF is not true.

- Multiple ELSE IF commands are allowed within the DO IF–END IF structure.
- If the logical expression on DO IF is true, the program executes the commands immediately following DO IF up to the first ELSE IF. Then control passes to the command following the END IF command.
- If the result of the logical expression on DO IF is false, control passes to ELSE IF.

Example

```
STRING Stock(A9).
DO IF (ITEM EQ 0).
COMPUTE Stock='New'.
ELSE IF (ITEM LE 9).
COMPUTE Stock='Old'.
ELSE.
COMPUTE Stock='Cancelled'.
END IF.
```

- STRING declares string variable *Stock* and assigns it a width of nine characters.
- The first COMPUTE is executed for cases with value 0 for *ITEM*, and then control passes out of the structure. Such cases are not reevaluated by ELSE IF, even though 0 is less than 9.
- When the logical expression on DO IF is false, control passes to the ELSE IF command, where the second COMPUTE is executed only for cases with *ITEM* less than or equal to 9. Then control passes out of the structure.
- If the logical expressions on both the DO IF and ELSE IF commands are false, control passes to ELSE, where the third COMPUTE is executed.

- The DO IF–END IF structure sets *Stock* equal to New when *ITEM* equals 0, to Old when *ITEM* is less than or equal to 9 but not equal to 0 (including negative numbers if they are valid), and to Cancelled for all valid values of *ITEM* greater than 9. The value of *Stock* remains blank if *ITEM* is missing.

Example

```
DO IF (YearHired GT 87).
COMPUTE            Bonus = 0.
ELSE IF (Dept87 EQ 3).
COMPUTE            Bonus = .1*Salary87.
ELSE IF (Dept87 EQ 1).
COMPUTE            Bonus = .12*Salary87.
ELSE IF (Dept87 EQ 4).
COMPUTE            Bonus = .08*Salary87.
ELSE IF (Dept87 EQ 2).
COMPUTE            Bonus = .14*Salary87.
END IF.
```

- For cases hired after 1987, *Bonus* is set to 0 and control passes out of the structure. For a case that was hired before 1987 with value 3 for *Dept87*, *Bonus* equals 10% of salary. Control then passes out of the structure. The other three ELSE IF commands are not evaluated for that case. This differs from the second example for the ELSE command, where the IF command is evaluated for every case. The DO IF–ELSE IF structure shown here is more efficient.
- If Department 3 is the largest, Department 1 the next largest, and so forth, control passes out of the structure quickly for many cases. For a large number of cases or a command file that will be executed frequently, these efficiency considerations can be important.

Nested DO IF Structures

To perform transformations involving logical tests on two variables, you can use nested DO IF–END IF structures.

- There must be an END IF command for every DO IF command in the structure.

Example

```
DO IF (Ethnicity EQ 5).          /*Do whites
+  DO IF (Gender EQ 2).        /*White female
+  COMPUTE Gender_Ethnicity=3.
+  ELSE.                       /*White male
+  COMPUTE Gender_Ethnicity=1.
+  END IF.                     /*Whites done
ELSE IF (Gender EQ 2).           /*Nonwhite female
COMPUTE Gender_Ethnicity=4.
ELSE.                          /*Nonwhite male
COMPUTE Gender_Ethnicity=2.
END IF.                        /*Nonwhites done
```

- This structure creates variable *Gender_Ethnicity*, which indicates both the sex and minority status of an individual.
- An optional plus sign, minus sign, or period in the first column allows you to indent commands so you can easily see the nested structures.

Complex File Structures

Some complex file structures may require you to embed more than one DATA LIST command inside a DO IF–END IF structure. For example, consider a data file that has been collected from various sources. The information from each source is basically the same, but it is in different places on the records:

```
111295100FORD      CHAPMAN AUTO SALES
121199005VW    MIDWEST VOLKSWAGEN SALES
11 395025FORD      BETTER USED CARS
11       CHEVY 195005        HUFFMAN SALES & SERVICE
11       VW    595020        MIDWEST VOLKSWAGEN SALES
11       CHEVY 295015        SAM'S AUTO REPAIR
12       CHEVY 210 20        LONGFELLOW CHEVROLET
 9555032 VW                  HYDE PARK IMPORTS
```

In the above file, an automobile part number always appears in columns 1 and 2, and the automobile manufacturer always appears in columns 10 through 14. The location of other information, such as price and quantity, depends on both the part number and the type of automobile. The DO IF–END IF structure in the following example reads records for part type 11.

Example

```
INPUT PROGRAM.
DATA LIST FILE="/data/carparts.txt"
  /PARTNO 1-2 KIND 10-14 (A).

DO IF (PARTNO EQ 11 AND KIND EQ 'FORD').
+ REREAD.
+ DATA LIST /PRICE 3-6 (2) QUANTITY 7-9 BUYER 20-43 (A).
+ END CASE.

ELSE IF (PARTNO EQ 11 AND (KIND EQ 'CHEVY' OR KIND EQ 'VW')).
+ REREAD.
+ DATA LIST /PRICE 15-18 (2) QUANTITY 19-21 BUYER 30-53 (A).
+ END CASE.
END IF.
END INPUT PROGRAM.

PRINT FORMATS PRICE (DOLLAR6.2).
PRINT /PARTNO TO BUYER.
WEIGHT BY QUANTITY.
DESCRIPTIVES PRICE.
```

- The first DATA LIST extracts the part number and the type of automobile.
- Depending on the information from the first DATA LIST, the records are reread, pulling the price, quantity, and buyer from different places.
- The two END CASE commands limit the working file to only those cases with a part number of 11 and automobile type of Ford, Chevrolet, or Volkswagen. Without the END CASE commands, cases would be created in the working file for other part numbers and automobile types with missing values for price, quantity, and buyer.
- The results of the PRINT command are shown below.

Figure 64-1
Printed information for part 11

```
11 FORD $12.95 100 CHAPMAN AUTO SALES
```

```
11 FORD  $3.95 25  BETTER USED CARS
11 CHEVY $1.95 5   HUFFMAN SALES & SERVICE
11 VW    $5.95 20  MIDWEST VOLKSWAGEN SALES
11 CHEVY $2.95 15  SAM'S AUTO REPAIR
```

DO REPEAT-END REPEAT

```
DO REPEAT stand-in var={varlist  | ALL  } [/stand-in var=...]
                       {value list}

transformation commands

END REPEAT [PRINT]
```

Release History

Release 14.0

- ALL keyword introduced.

Example

```
DO REPEAT var=var1 to var5
         /value=1 to 5.
COMPUTE var=value.
END REPEAT.
```

This command does not read the active dataset. It is stored, pending execution with the next command that reads the dataset. For more information, see Command Order on p. 36.

Overview

The DO REPEAT—END REPEAT structure repeats the same transformations on a specified set of variables, reducing the number of commands you must enter to accomplish a task. This utility does not reduce the number of commands the program executes, just the number of commands you enter. To display the expanded set of commands the program generates, specify PRINT on END REPEAT.

DO REPEAT uses a **stand-in variable** to represent a **replacement list** of variables or values. The stand-in variable is specified as a placeholder on one or more transformation commands within the structure. When the program repeats the transformation commands, the stand-in variable is replaced, in turn, by each variable or value specified on the replacement list.

The following commands can be used within a DO REPEAT—END REPEAT structure:

- Data transformations: COMPUTE, RECODE, IF, COUNT, and SELECT IF
- Data declarations: VECTOR, STRING, NUMERIC, and LEAVE
- Data definition: DATA LIST, MISSING VALUES (but not VARIABLE LABELS or VALUE LABELS)
- Loop structure commands: LOOP, END LOOP, and BREAK
- Do-if structure commands: DO IF, ELSE IF, ELSE, and END IF
- Print and write commands: PRINT, PRINT EJECT, PRINT SPACE, and WRITE
- Format commands: PRINT FORMATS, WRITE FORMATS, and FORMATS

Basic Specification

The basic specification is DO REPEAT, a stand-in variable followed by a required equals sign and a replacement list of variables or values, and at least one transformation command. The structure must end with the END REPEAT command. On the transformation commands, a single stand-in variable represents every variable or value specified on the replacement list.

Syntax Rules

- Multiple stand-in variables can be specified on a DO REPEAT command. Each stand-in variable must have its own equals sign and associated variable or value list and must be separated from other stand-in variables by a slash. All lists must name or generate the same number of items.
- Stand-in variables can be assigned any valid variable names: permanent, temporary, scratch, system, and so forth. A stand-in variable does not exist outside the DO REPEAT–END REPEAT structure and has no effect on variables with the same name that exist outside the structure. However, two stand-in variables cannot have the same name within the same DO REPEAT structure.
- A replacement variable list can include either new or existing variables. You cannot mix new and existing variables in the same replacement list.
- Keyword TO can be used to name consecutive existing variables and to create a set of new variables, and keyword ALL can be used to specify all variables.
- New string variables must be declared on the STRING command either before DO REPEAT or within the DO REPEAT structure.

▶ All replacement variable and value lists must have the same number of items.

- A replacement value list can be a list of strings or numeric values, or it can be of the form n_1 TO n_2, where n_1 is less than n_2 and both are integers. (Note that the keyword is TO, not THRU.)

Operations

- DO REPEAT marks the beginning of the control structure and END REPEAT marks the end. Once control passes out of the structure, all stand-in variables defined within the structure cease to exist.
- The program repeats the commands between DO REPEAT and END REPEAT once for each variable or value on the replacement list.
- Numeric variables created within the structure are initially set to the system-missing value. By default, they are assigned an F8.2 format.
- New string variables declared within the structure are initially set to a blank value and are assigned the format specified on the STRING command that creates them.
- If DO REPEAT is used to create new variables, the order in which they are created depends on how the transformation commands are specified. Variables created by specifying the TO keyword (for example, *V1* TO *V5*) are not necessarily consecutive in the active dataset. For more information, see PRINT Subcommand on p. 614.
- Multiple replacement lists are stepped through in parallel, not in a nested fashion, and all replacement lists must name or generate the same number of items.

Examples

Creating Multiple New Variables with the Same Value

```
DO REPEAT R=REGION1 TO REGION5.
COMPUTE R=0.
END REPEAT.
```

- `DO REPEAT` defines the stand-in variable *R*, which represents five new numeric variables: *REGION1, REGION2*, *REGION3, REGION4*, and *REGION5*.
- The five variables are initialized to 0 by a single `COMPUTE` specification that is repeated for each variable on the replacement list. Thus, the program generates five `COMPUTE` commands from the one specified.
- Stand-in variable *R* ceases to exist once control passes out of the `DO REPEAT` structure.

Multiple Replacement Lists

```
DO REPEAT existVar=firstVar TO var5
         /newVar=new1 TO new5
         /value=1 TO 5.
COMPUTE newVar=existVar*value.
END REPEAT PRINT.

****generated COMPUTE commands****
  57 +COMPUTE        new1=firstVar*1
  58 +COMPUTE        new2=secondVar*2
  59 +COMPUTE        new3=var3*3
  60 +COMPUTE        new4=fourthVar*4
  61 +COMPUTE        new5=var5*5.
```

- `existVar=firstVar to var5` includes all existing variables from *firstVar* to *var5*, in file order.
- `newVar=new1 TO new5` specifies five new variables: *var1*, *var2*, *var3*, *var4*, and *var5*.
- `value=1 to 5` specifies a list of five consecutive values: 1, 2, 3, 4, 5.
- All three replacement lists contain five items, and five `COMPUTE` commands are generated.

Generating Data with DO REPEAT, LOOP, and INPUT PROGRAM

```
* This example shows a typical application of INPUT PROGRAM, LOOP,
   and DO REPEAT. A data file containing random numbers is generated.

INPUT PROGRAM.
+  LOOP #I = 1 TO 1000.
+     DO REPEAT RESPONSE = R1 TO R400.
+          COMPUTE RESPONSE = UNIFORM(1) > 0.5.
+     END REPEAT.
+     COMPUTE AVG = MEAN(R1 TO R400).
+     END CASE.
+   END LOOP.
+   END FILE.
END INPUT PROGRAM.

FREQUENCIES VARIABLE=AVG
 /FORMAT=CONDENSE
 /HISTOGRAM
 /STATISTICS=MEAN MEDIAN MODE STDDEV MIN MAX.
```

- The INPUT PROGRAM—END INPUT PROGRAM structure encloses an input program that builds cases from transformation commands.
- The indexing variable (*#I*) on LOOP—END LOOP indicates that the loop should be executed 1000 times.
- The DO REPEAT—END REPEAT structure generates 400 variables, each with a 50% chance of being 0 and a 50% chance of being 1. This is accomplished by specifying a logical expression on COMPUTE that compares the values returned by UNIFORM(1) to the value 0.5. (UNIFORM(1) generates random numbers between 0 and 1.) Logical expressions are evaluated as false (0), true (1), or missing. Thus, each random number returned by UNIFORM that is 0.5 or less is evaluated as false and assigned the value 0, and each random number returned by UNIFORM that is greater than 0.5 is evaluated as true and assigned the value 1.
- The second COMPUTE creates variable *AVG*, which is the mean of *R1* to *R400* for each case.
- END CASE builds a case with the variables created within each loop. Thus, the loop structure creates 1000 cases, each with 401 variables (*R1* to *R400*, and *AVG)*.
- END FILE signals the end of the data file generated by the input program. If END FILE were not specified in this example, the input program would go into an infinite loop. No dataset would be built, and the program would display an error message for every procedure that follows the input program.
- FREQUENCIES produces a condensed frequency table, histogram, and statistics for *AVG*. The histogram for *AVG* shows a normal distribution.

PRINT Subcommand

The PRINT subcommand on END REPEAT displays the commands generated by the DO REPEAT—END REPEAT structure. PRINT can be used to verify the order in which commands are executed.

Example

```
DO REPEAT Q=Q1 TO Q5/ R=R1 TO R5.
COMPUTE Q=0.
COMPUTE R=1.
END REPEAT PRINT.
```

- The DO REPEAT—END REPEAT structure initializes one set of variables to 0 and another set to 1.
- The output from the PRINT subcommand is shown below. The generated commands are preceded by plus signs.
- The COMPUTE commands are generated in such a way that variables are created in alternating order: *Q1*, *R1*, *Q2*, *R2*, and so forth. If you plan to use the TO keyword to refer to *Q1* to *Q5* later, you should use two separate DO REPEAT utilities; otherwise, *Q1* to *Q5* will include four of the five *R* variables. Alternatively, use the NUMERIC command to predetermine the order in which variables are added to the active dataset, or specify the replacement value lists as shown in the next example.

Figure 65-1
Output from the PRINT subcommand

```
  2      0          DO REPEAT Q=Q1 TO Q5/ R=R1 TO R5
  3      0          COMPUTE Q=0
  4      0          COMPUTE R=1
  5      0          END REPEAT PRINT

  6      0         +COMPUTE Q1=0
  7      0         +COMPUTE R1=1
  8      0         +COMPUTE Q2=0
  9      0         +COMPUTE R2=1
 10      0         +COMPUTE Q3=0
 11      0         +COMPUTE R3=1
 12      0         +COMPUTE Q4=0
 13      0         +COMPUTE R4=1
 14      0         +COMPUTE Q5=0
 15      0         +COMPUTE R5=1
```

Example

```
DO REPEAT Q=Q1 TO Q5,R1 TO R5/ N=0,0,0,0,0,1,1,1,1,1.
COMPUTE Q=N.
END REPEAT PRINT.
```

- In this example, a series of constants is specified as a stand-in value list for *N*. All the *Q* variables are initialized first, and then all the *R* variables, as shown below.

Figure 65-2
Output from the PRINT subcommand

```
  2      0              DO REPEAT Q=Q1 TO Q5,R1 TO R5/ N=0,0,0,0,0,1,1,1,1,1
  3      0              COMPUTE Q=N
  4      0              END REPEAT PRINT

  5      0             +COMPUTE Q1=0
  6      0             +COMPUTE Q2=0
  7      0             +COMPUTE Q3=0
  8      0             +COMPUTE Q4=0
  9      0             +COMPUTE Q5=0
 10      0             +COMPUTE R1=1
 11      0             +COMPUTE R2=1
 12      0             +COMPUTE R3=1
 13      0             +COMPUTE R4=1
 14      0             +COMPUTE R5=1
```

Example

```
DO REPEAT R=REGION1 TO REGION5/ X=1 TO 5.
COMPUTE R=REGION EQ X.
END REPEAT PRINT.
```

- In this example, stand-in variable *R* represents the variable list *REGION1* to *REGION5*. Stand-in variable *X* represents the value list 1 to 5.
- The `DO REPEAT–END REPEAT` structure creates dummy variables *REGION1* to *REGION5* that equal 0 or 1 for each of 5 regions, depending on whether variable *REGION* equals the current value of stand-in variable *X*.
- `PRINT` on `END REPEAT` causes the program to display the commands generated by the structure, as shown below.

Figure 65-3
Commands generated by DO REPEAT

```

```

DOCUMENT

```
DOCUMENT text
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Example

```
DOCUMENT    This file contains a subset of variables from the
            General Social Survey data.  For each case it records
            only the age, sex, education level, marital status,
            number of children, and type of medical insurance
            coverage.
```

Overview

DOCUMENT saves a block of text of any length in an SPSS-format data file. The documentation can be displayed with the DISPLAY command. (See also ADD DOCUMENT.)

When GET retrieves a data file, or when ADD FILES, MATCH FILES, or UPDATE is used to combine data files, all documents from each specified file are copied into the active dataset. DROP DOCUMENTS can be used to drop those documents from the active dataset. Whether or not DROP DOCUMENTS is used, new documents can be added to the active dataset with the DOCUMENT command.

Basic Specification

The basic specification is DOCUMENT followed by any length of text. The text is stored in the file dictionary when the data are saved in an SPSS-format data file.

Syntax Rules

- The text can be entered on as many lines as needed.
- Blank lines can be used to separate paragraphs.
- A period at the end of a line terminates the command, so you should not place a period at the end of any line but the last.
- Multiple DOCUMENT commands can be used within the command sequence. However, the DISPLAY command cannot be used to exhibit the text from a particular DOCUMENT command. DISPLAY shows all existing documentation.

Operations

- The documentation and the date it was entered are saved in the data file's dictionary. New documentation is saved along with any documentation already in the active dataset.

- If a DROP DOCUMENTS command *follows* a DOCUMENT command anywhere in the command sequence, the documentation added by that DOCUMENT command is dropped from the active dataset along with all other documentation.

Examples

Adding Descriptive Text to a Data File

```
GET FILE="/data/gensoc.sav" /KEEP=AGE SEX EDUC MARITAL CHILDRN MED_INS.
FILE LABEL  General Social Survey subset.

DOCUMENT    This file contains a subset of variables from the
            General Social Survey data.  For each case it records
            only the age, sex, education level, marital status,
            number of children, and type of medical insurance
            coverage.

SAVE OUTFILE="/data/subsoc.sav".
```

- GET keeps only a subset of variables from the file *gensoc.sav*. All documentation from the file *GENSOC* is copied into the active dataset.
- FILE LABEL creates a label for the new active dataset.
- DOCUMENT specifies the new document text. Both existing documents from the file *GENSOC* and the new document text are saved in the file *subsoc.sav*.

Replacing Existing DOCUMENT Text

```
GET FILE="/data/gensoc.sav" /KEEP=AGE SEX EDUC MARITAL CHILDRN MED_INS.

DROP DOCUMENTS.

FILE LABEL  General Social Survey subset.

DOCUMENT    This file contains a subset of variables from the
            General Social Survey data.  For each case it records
            only the age, sex, education level, marital status,
            number of children, and type of medical insurance
            coverage.

SAVE OUTFILE="/data/subsoc.sav".
```

- DROP DOCUMENTS drops the documentation from the file *gensoc.sav* as data are copied into the active dataset. Only the new documentation specified on DOCUMENT is saved in the file *subsoc.sav*.

DROP DOCUMENTS

```
DROP DOCUMENTS
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Overview

When GET retrieves an SPSS-format data file, or when ADD FILES, MATCH FILES, or UPDATE are used to combine SPSS-format data files, all documents from each specified file are copied into the active dataset. DROP DOCUMENTS is used to drop these or any documents added with the DOCUMENT command from the active dataset. Whether or not DROP DOCUMENTS is used, new documents can be added to the active dataset with the DOCUMENT command.

Basic Specification

The only specification is DROP DOCUMENTS. There are no additional specifications.

Operations

- Documents are dropped from the active dataset only. The original data file is unchanged, unless it is resaved.
- DROP DOCUMENTS drops all documentation, including documentation added by any DOCUMENT commands specified prior to the DROP DOCUMENTS command.

Examples

```
GET FILE="/data/gensoc.sav"
  /KEEP=AGE SEX EDUC MARITAL CHILDRN MED_INS.

DROP DOCUMENTS.

FILE LABEL  General Social Survey Subset.
DOCUMENT    This file contains a subset of variables from the
            General Social Survey data.  For each case it records
            only the age, sex, education level, marital status,
            number of children, and type of medical insurance
            coverage.

SAVE OUTFILE="/data/subsoc.sav".
```

- DROP DOCUMENTS drops the documentation text from data file. Only the new documentation added with the DOCUMENT command is saved in file *subsoc.sav*.
- The original file *gensoc.sav* is unchanged.

ECHO

```
ECHO "text".
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Example

```
ECHO "Hey! Look at this!".
```

Overview

ECHO displays the quoted text string as text output.

Basic Specification

The basic specification is the command name ECHO followed by a quoted text string.

Syntax Rules

The text string must be enclosed in single or double quotes, following the standard rules for quoted strings.

- The text string can be continued on multiple lines by enclosing each line in quotes and using the plus sign (+) to combine the strings; the string will be displayed on a single line in output.

END CASE

```
END CASE
```

Example

```
* Restructure a data file to make each data item into a single case.

INPUT PROGRAM.
DATA LIST /#X1 TO #X3 (3(F1,1X)).

VECTOR V=#X1 TO #X3.

LOOP #I=1 TO 3.
- COMPUTE X=V(#I).
- END CASE.
END LOOP.
END INPUT PROGRAM.
```

Overview

END CASE is used in an INPUT PROGRAM—END INPUT PROGRAM structure to signal that a case is complete. Control then passes to the commands immediately following the input program. After these commands are executed for the newly created case, the program returns to the input program and continues building cases by processing the commands immediately after the last END CASE command that was executed. For more information about the flow control in an input program, see INPUT PROGRAM—END INPUT PROGRAM.

END CASE is especially useful for restructuring files, either building a single case from several cases or building several cases from a single case. It can also be used to generate data without any data input (see DO REPEAT for an example).

Basic Specification

The basic specification is simply END CASE. There are no additional specifications.

Syntax Rules

- END CASE is available only within an input program and is generally specified within a loop.
- Multiple END CASE commands can be used within an input program. Each builds a case from the transformation and data definition commands executed since the last END CASE command.
- If no END CASE is explicitly specified, an END CASE command is implied immediately before END INPUT PROGRAM and the input program loops until an end-of-file is encountered or specified (see END FILE).

Operations

- When an END CASE command is encountered, the program suspends execution of the rest of the commands before the END INPUT PROGRAM command and passes control to the commands after the input program. After these commands are executed for the new case,

control returns to the input program. The program continues building cases by processing the commands immediately after the most recent END CASE command. Use a loop to build cases from the same set of transformation and data definition commands.

- When multiple END CASE commands are specified, the program follows the flow of the input program and builds a case whenever it encounters an END CASE command, using the set of commands executed since the last END CASE.
- Unless LEAVE is specified, all variables are reinitialized each time the input program is resumed.
- When transformations such as COMPUTE, definitions such as VARIABLE LABELS, and utilities such as PRINT are specified between the last END CASE command and END INPUT PROGRAM, they are executed while a case is being initialized, not when it is complete. This may produce undesirable results.

Examples

Restructuring a data file to make each data item a single case

```
INPUT PROGRAM.
DATA LIST /#X1 TO #X3 (3(F1,1X)).

VECTOR V=#X1 TO #X3.

LOOP #I=1 TO 3.
- COMPUTE X=V(#I).
- END CASE.
END LOOP.
END INPUT PROGRAM.

BEGIN DATA
2 1 1
3 5 1
END DATA.
FORMAT X(F1.0).
PRINT / X.
EXECUTE.
```

- The input program encloses the commands that build cases from the input file. An input program is required because END CASE is used to create multiple cases from single input records.
- DATA LIST defines three variables. In the format specification, the number 3 is a repetition factor that repeats the format in parentheses three times, once for each variable. The specified format is F1 and the 1X specification skips one column.
- VECTOR creates the vector *V* with the original scratch variables as its three elements. The indexing expression on the LOOP command increments the variable *#I* three times to control the number of iterations per input case and to provide the index for the vector *V*.
- COMPUTE sets *X* equal to each of the scratch variables. END CASE tells the program to build a case. Thus, the first loop (for the first case) sets *X* equal to the first element of vector *V*. Since *V(1)* references *#X1*, and *#X1* is 2, the value of *X* is 2. Variable *X* is then formatted and printed before control returns to the command END LOOP. The loop continues, since indexing is not complete. Thus, the program then sets *X* to *#X2*, which is 1, builds the second case, and passes it to the FORMAT and PRINT commands. After the third iteration, which sets *X* equal to

1, the program formats and prints the case and terminates the loop. Since the end of the file has not been encountered, `END INPUT PROGRAM` passes control to the first command in the input program, `DATA LIST`, to read the next input case. After the second loop, however, the program encounters `END DATA` and completes building the active dataset.

- The six new cases are shown below.

Figure 69-1
Outcome for multiple cases read from a single case

```

```

Restructuring a data file to create a separate case for each book order

```
INPUT PROGRAM.
DATA LIST  /ORDER 1-4 #X1 TO #X22 (1X,11(F3.0,F2.0,1X)).

LEAVE ORDER.
VECTOR BOOKS=#X1 TO #X22.

LOOP #I=1 TO 21 BY 2 IF NOT SYSMIS(BOOKS(#I)).
- COMPUTE ISBN=BOOKS(#I).
- COMPUTE QUANTITY=BOOKS(#I+1).
- END CASE.
END LOOP.
END INPUT PROGRAM.
BEGIN DATA
1045 182 2 155 1 134 1 153 5
1046 155 3 153 5 163 1
1047 161 5 182 2 163 4 186 6
1048 186 2
1049 155 2 163 2 153 2 074 1 161 1
END DATA.

SORT CASES ISBN.
DO IF $CASENUM EQ 1.
- PRINT EJECT /'Order ISBN Quantity'.
- PRINT SPACE.
END IF.

FORMATS ISBN (F3)/ QUANTITY (F2).
PRINT /' ' ORDER ' ' ISBN '  ' QUANTITY.

EXECUTE.
```

- Data are extracted from a file whose records store values for an invoice number and a series of book codes and quantities ordered. For example, invoice 1045 is for four different titles and a total of nine books: two copies of book 182, one copy each of 155 and 134, and five copies of book 153. The task is to break each individual book order into a record, preserving the order number on each new case.
- The input program encloses the commands that build cases from the input file. They are required because the `END CASE` command is used to create multiple cases from single input records.

- DATA LIST specifies *ORDER* as a permanent variable and defines 22 scratch variables to hold the book numbers and quantities (this is the maximum number of numbers and quantities that will fit in 72 columns). In the format specification, the first element skips one space after the value for the variable *ORDER*. The number 11 repeats the formats that follow it 11 times: once for each book number and quantity pair. The specified format is F3.0 for book numbers and F2.0 for quantities. The 1X specification skips one column after each quantity value.
- LEAVE preserves the value of the variable *ORDER* across the new cases to be generated.
- VECTOR sets up the vector *BOOKS* with the 22 scratch variables as its elements. The first element is *#X1*, the second is *#X2*, and so on.
- If the element for the vector *BOOKS* is not system-missing, LOOP initiates the loop structure that moves through the vector *BOOKS*, picking off the book numbers and quantities. The indexing clause initiates the indexing variable *#I* at 1, to be increased by 2 to a maximum of 21.
- The first COMPUTE command sets the variable *ISBN* equal to the element in the vector *BOOKS* indexed by *#I*, which is the current book number. The second COMPUTE sets the variable *QUANTITY* equal to the next element in the vector *BOOKS*, *#I* +1, which is the quantity associated with the book number in *BOOKS(#I)*.
- END CASE tells the program to write out a case with the current values of the three variables: *ORDER*, *ISBN*, and *QUANTITY*.
- END LOOP terminates the loop structure and control is returned to the LOOP command, where *#I* is increased by 2 and looping continues until the entire input case is read or until *#I* exceeds the maximum value of 21.
- SORT CASES sorts the new cases by book number.
- The DO IF structure encloses a PRINT EJECT command and a PRINT SPACE command to set up titles for the output.
- FORMATS establishes dictionary formats for the new variables *ISBN* and *QUANTITY*. PRINT displays the new cases.
- EXECUTE runs the commands. The output is shown below.

Figure 69-2
PRINT output showing new cases

```
Order ISBN Quantity
 1049   74    1
 1045  134    1
 1045  153    5
 1046  153    5
 1049  153    2
 1045  155    1
 1046  155    3
 1049  155    2
 1047  161    5
 1049  161    1
 1046  163    1
 1047  163    4
 1049  163    2
 1045  182    2
 1047  182    2
 1047  186    6
 1048  186    2
```

Create variable that approximates a log-normal distribution

```
SET FORMAT=F8.0.

INPUT PROGRAM.
LOOP I=1 TO 1000.
+ COMPUTE SCORE=EXP(NORMAL(1)).
+ END CASE.
END LOOP.
END FILE.
END INPUT PROGRAM.

FREQUENCIES VARIABLES=SCORE /FORMAT=NOTABLE /HISTOGRAM
 /PERCENTILES=1 10 20 30 40 50 60 70 80 90 99
 /STATISTICS=ALL.
```

- The input program creates 1,000 cases with a single variable *SCORE*. Values for *SCORE* approximate a log-normal distribution.

Restructure a data file to create a separate case for each individual

```
INPUT PROGRAM.
DATA LIST  /#RECS 1 HEAD1 HEAD2 3-4(A).     /*Read header info
LEAVE  HEAD1 HEAD2.

LOOP  #I=1 TO #RECS.
DATA LIST  /INDIV 1-2(1).                   /*Read individual info
PRINT  /#RECS HEAD1 HEAD2 INDIV.
END CASE.                                   /*Create combined case
END LOOP.
END INPUT PROGRAM.
BEGIN DATA
1 AC
91
2 CC
35
43
0 XX
1 BA
34
3 BB
42
96
37
END DATA.
LIST.
```

- Data are in a file with header records that indicate the type of record and the number of individual records that follow. The number of records following each header record varies. For example, the 1 in the first column of the first header record (AC) says that only one individual record (91) follows. The 2 in the first column of the second header record (CC) says that two individual records (35 and 43) follow. The next header record has no individual records, indicated by the 0 in column 1, and so on.
- The first `DATA LIST` reads the expected number of individual records for each header record into temporary variable *#RECS*. *#RECS* is then used as the terminal value in the indexing variable to read the correct number of individual records using the second `DATA LIST`.
- The variables *HEAD1* and *HEAD2* contain the information in columns 3 and 4, respectively, in the header records. The `LEAVE` command retains *HEAD1* and *HEAD2* so that this information can be spread to the individual records.

- The variable *INDIV* is the information from the individual record. *INDIV* is combined with *#RECS*, *HEAD1*, and *HEAD2* to create the new case. Notice in the output from the `PRINT` command below that no case is created for the header record with 0 for *#RECS*.
- `END CASE` passes each case out of the input program to the `LIST` command. Without `END CASE`, the `PRINT` command would still display the cases because it is inside the loop. However, only one (the last) case per header record would pass out of the input program. The outcome for `LIST` will be quite different.

Figure 69-3

B     A      3.4
B     B      3.7
```

END FILE

```
END FILE
```

Example

```
INPUT PROGRAM.
DATA LIST FILE=PRICES /YEAR 1-4 QUARTER 6 PRICE 8-12(2).
DO IF (YEAR GE 1881).  /*Stop reading before 1881
END FILE.
END IF.
END INPUT PROGRAM.
```

Overview

END FILE is used in an INPUT PROGRAM—END INPUT PROGRAM structure to tell the program to stop reading data before it actually encounters the end of the file. END FILE can be used with END CASE to concatenate raw data files by causing the program to delay end-of-file processing until it has read multiple data files. END FILE can also be used with LOOP and END CASE to generate data without any data input.

Basic Specification

The basic specification is simply END FILE. There are no additional specifications. The end of file is defined according to the conditions specified for END FILE in the input program.

Syntax Rules

- END FILE is available only within an INPUT PROGRAM structure.
- Only one END FILE command can be executed per input program. However, multiple END FILE commands can be specified within a conditional structure in the input program.

Operations

- When END FILE is encountered, the program stops reading data and puts an end of file in the active dataset it was building. The case that causes the execution of END FILE is not read. To include this case, use the END CASE command before END FILE (see the examples below).
- END FILE has the same effect as the end of the input data file. It terminates the input program (see INPUT PROGRAM—END INPUT PROGRAM).

Examples

Stop reading a file based on a data value

```
*Select cases.

INPUT PROGRAM.
DATA LIST FILE=PRICES /YEAR 1-4 QUARTER 6 PRICE 8-12(2).
```

```
DO IF (YEAR GE 1881).  /*Stop reading before 1881
END FILE.
END IF.

END INPUT PROGRAM.

LIST.
```

- This example assumes that data records are entered chronologically by year. The DO IF—END IF structure specifies an end of file when the first case with a value of 1881 or later for *YEAR* is reached.
- LIST executes the input program and lists cases in the active dataset. The case that causes the end of the file is not included in the active dataset.
- As an alternative to an input program with END FILE, you can use N OF CASES to select cases if you know the exact number of cases. Another alternative is to use SELECT IF to select cases before 1881, but then the program would unnecessarily read the entire input file.

END FILE with END CASE

```
*Select cases but retain the case that causes end-of-file processing.

INPUT PROGRAM.
DATA LIST FILE=PRICES /YEAR 1-4 QUARTER 6 PRICE 8-12(2).

DO IF (YEAR GE 1881).   /*Stop reading before 1881 (or at end of file)
END CASE.              /*Create case 1881
END FILE.

ELSE.
END CASE.              /*Create all other cases
END IF.
END INPUT PROGRAM.

LIST.
```

- The first END CASE command forces the program to retain the case that causes end-of-file processing.
- The second END CASE indicates the end of case for all other cases and passes them out of the input program one at a time. It is required because the first END CASE command causes the program to abandon default end-of-case processing (see END CASE).

ERASE

```
ERASE FILE='file'
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Example

```
ERASE FILE='PRSNL.DAT'.
```

Overview

ERASE removes a file from a disk.

Basic Specification

The basic specification is the keyword FILE followed by a file specification enclosed in quotes. The specified file is erased from the disk. The file specification may vary from operating system to operating system.

Syntax Rules

- The keyword FILE is required, but the equals sign is optional.
- ERASE allows one file specification only and does not accept wildcard characters. To erase more than one file, specify multiple ERASE commands.
- The file to be erased must be specified in full. ERASE does not recognize any default file extension.

Operations

ERASE deletes the specified file regardless of its type. No message is displayed unless the command cannot be executed. Use ERASE with caution.

Examples

```
ERASE FILE 'PRSNL.DAT'.
```

- The file *PRSNL.SAV* is deleted from the current directory. Whether it is an SPSS-format data file or a file of any other type makes no difference.

EXAMINE

```
EXAMINE VARIABLES=varlist [[BY varlist] [varname BY varname]]

 [/COMPARE={GROUPS** }]
           {VARIABLES}

 [/{TOTAL**}]
   {NOTOTAL}

                                        {n}
              [{ALL }]
               {NONE}

 [/CINTERVAL {95**}]
             {n   }

 [/MESTIMATOR=[{NONE**}]]
               {ALL   }

              [HUBER({1.339})] [ANDREW({1.34}]
                     {c    }           {c    }

              [HAMPEL({1.7,3.4,8.5})]
                      {a  ,b  ,c  }

              [TUKEY({4.685})]
                     {c    }

[/MISSING=[{LISTWISE**}] [{EXCLUDE**}] [{NOREPORT**}]]
          {PAIRWISE  }   {INCLUDE  }   {REPORT    }
```

**Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Examples

```
EXAMINE VARIABLES=ENGSIZE,COST.

EXAMINE VARIABLES=MIPERGAL BY MODEL, MODEL BY CYLINDERS.
```

Overview

EXAMINE provides stem-and-leaf plots, histograms, boxplots, normal plots, robust estimates of location, tests of normality, and other descriptive statistics. Separate analyses can be obtained for subgroups of cases.

Options

Cells. You can subdivide cases into cells based on their values for grouping (factor) variables using the BY keyword on the VARIABLES subcommand.

Output. You can control the display of output using the COMPARE subcommand. You can specify the computational method and break points for percentiles with the PERCENTILES subcommand, and you can assign a variable to be used for labeling outliers on the ID subcommand.

Plots. You can request stem-and-leaf plots, histograms, vertical boxplots, spread-versus-level plots with Levene tests for homogeneity of variance, and normal and detrended probability plots with tests for normality. These plots are available through the PLOT subcommand.

Statistics. You can request univariate statistical output with the STATISTICS subcommand and maximum-likelihood estimators with the MESTIMATORS subcommand.

Basic Specification

- The basic specification is VARIABLES and at least one dependent variable.
- The default output includes a Descriptives table displaying univariate statistics (mean, median, standard deviation, standard error, variance, kurtosis, kurtosis standard error, skewness, skewness standard error, sum, interquartile range (IQR), range, minimum, maximum, and 5% trimmed mean), a vertical boxplot, and a stem-and-leaf plot. Outliers are labeled on the boxplot with the system variable *$CASENUM*.

Subcommand Order

Subcommands can be named in any order.

Limitations

- When string variables are used as factors, only the first eight characters are used to form cells. String variables cannot be specified as dependent variables.
- When more than eight crossed factors (for example, A, B, ... in the specification Y by A by B by ...) are specified, the command is not executed.

Examples

Example Description

```
EXAMINE VARIABLES=ENGSIZE,COST.
```

- *ENGSIZE* and *COST* are the dependent variables.

- EXAMINE produces univariate statistics for *ENGSIZE* and *COST* in the Descriptives table and a vertical boxplot and a stem-and-leaf plot for each variable.

Example Description

```
EXAMINE VARIABLES=MIPERGAL BY MODEL,MODEL BY CYLINDERS.
```

- *MIPERGAL* is the dependent variable. The cell specification follows the first BY keyword. Cases are subdivided based on values of *MODEL* and also based on the combination of values of *MODEL* and *CYLINDERS*.
- Assuming that there are three values for *MODEL* and two values for *CYLINDERS*, this example produces a Descriptives table, a stem-and-leaf plot, and a boxplot for the total sample, a Descriptives table and a boxplot for each factor defined by the first BY (*MIPERGAL* by *MODEL* and *MIPERGAL* by *MODEL* by *CYLINDERS*), and a stem-and-leaf plot for each of the nine cells (three defined by *MODEL* and six defined by *MODEL* and *CYLINDERS* together).

VARIABLES Subcommand

VARIABLES specifies the dependent variables and the cells. The dependent variables are specified first, followed by the keyword BY and the variables that define the cells. Repeated models on the same EXAMINE are discarded.

- To create cells defined by the combination of values of two or more factors, specify the factor names separated by the keyword BY.

Caution. Large amounts of output can be produced if many cells are specified. If there are many factors or if the factors have many values, EXAMINE will produce a large number of separate analyses.

Example

```
EXAMINE VARIABLES=SALARY,YRSEDUC BY RACE,SEX,DEPT,RACE BY SEX.
```

- *SALARY* and *YRSEDUC* are dependent variables.
- Cells are formed first for the values of *SALARY* and *YRSEDUC* individually, and then each by values for *RACE*, *SEX, DEPT,* and the combination of *RACE* and *SEX*.
- By default, EXAMINE produces Descriptives tables, stem-and-leaf plots, and boxplots.

COMPARE Subcommand

COMPARE controls how boxplots are displayed. This subcommand is most useful if there is more than one dependent variable and at least one factor in the design.

GROUPS *For each dependent variable, boxplots for all cells are displayed together.* With this display, comparisons across cells for a single dependent variable are easily made. This is the default.

VARIABLES *For each cell, boxplots for all dependent variables are displayed together.* With this display, comparisons of several dependent variables are easily made. This is useful in situations where the dependent variables are repeated measures of the same variable (see the following example) or have similar scales, or when the dependent variable has very different values for different cells, and plotting all cells on the same scale would cause information to be lost.

Example

```
EXAMINE VARIABLES=GPA1 GPA2 GPA3 GPA4 BY MAJOR   /COMPARE=VARIABLES.
```

- The four GPA variables are summarized for each value of *MAJOR*.
- COMPARE=VARIABLES groups the boxplots for the four GPA variables together for each value of *MAJOR*.

Example

```
EXAMINE VARIABLES=GPA1 GPA2 GPA3 GPA4 BY MAJOR /COMPARE=GROUPS.
```

- COMPARE=GROUPS groups the boxplots for *GPA1* for all majors together, followed by boxplots for *GPA2* for all majors, and so on.

TOTAL and NOTOTAL Subcommands

TOTAL and NOTOTAL control the amount of output produced by EXAMINE when factor variables are specified.

- TOTAL is the default. By default, or when TOTAL is specified, EXAMINE produces statistics and plots for each dependent variable overall and for each cell specified by the factor variables.
- NOTOTAL suppresses overall statistics and plots.
- TOTAL and NOTOTAL are alternatives.
- NOTOTAL is ignored when the VARIABLES subcommand does not specify factor variables.

ID Subcommand

ID assigns a variable from the active dataset to identify the cases in the output. By default the case number is used for labeling outliers and extreme cases in boxplots.

- The identification variable can be either string or numeric. If it is numeric, value labels are used to label cases. If no value labels exist, the values are used.
- Only one identification variable can be specified.

Example

```
EXAMINE VARIABLES=SALARY BY RACE BY SEX /ID=LASTNAME.
```

- ID displays the value of *LASTNAME* for outliers and extreme cases in the boxplots.

PERCENTILES Subcommand

PERCENTILES displays the Percentiles table. If PERCENTILES is omitted, no percentiles are produced. If PERCENTILES is specified without keywords, HAVERAGE is used with default break points of 5, 10, 25, 50, 75, 90, and 95.

- Values for break points are specified in parentheses following the subcommand. EXAMINE displays up to six decimal places for user-specified percentile values.
- The method keywords follow the specifications for break points.

For each of the following methods of percentile calculation, w is the sum of the weights for all nonmissing cases, p is the specified percentile divided by 100, and X_i is the value of the ith case (cases are assumed to be ranked in ascending order). For details on the specific formulas used, see the algorithms documentation included on the installation CD.

HAVERAGE	Weighted average at $X_{(w+1)p}$. The percentile value is the weighted average of X_i and X_{i+1}, where i is the integer part of $(w + 1)p$. This is the default if PERCENTILES is specified without a keyword.
WAVERAGE	Weighted average at Xwp. The percentile value is the weighted average of X_i and $X_{(i+1)}$, where i is the integer portion of wp.
ROUND	*Observation closest to* wp. The percentile value is X_i or X_{i+1}, depending upon whether i or $i + 1$ is "closer" to wp.
EMPIRICAL	*Empirical distribution function.* The percentile value is X_i, where i is equal to wp rounded up to the next integer.
AEMPIRICAL	*Empirical distribution with averaging.* This is equivalent to EMPIRICAL, except when $i=wp$, in which case the percentile value is the average of X_i and X_{i+1}.
NONE	*Suppress percentile output.* This is the default if PERCENTILES is omitted.

Example

```
EXAMINE VARIABLE=SALARY /PERCENTILES(10,50,90)=EMPIRICAL.
```

- PERCENTILES produces the 10th, 50th, and 90th percentiles for the dependent variable *SALARY* using the EMPIRICAL distribution function.

PLOT Subcommand

PLOT controls plot output. The default is a vertical boxplot and a stem-and-leaf plot for each dependent variable for each cell in the model.

- Spread-versus-level plots can be produced only if there is at least one factor variable on the VARIABLES subcommand. If you request a spread-versus-level plot and there are no factor variables, the program issues a warning and no spread-versus-level plot is produced.

- If you specify the PLOT subcommand, only those plots explicitly requested are produced.

BOXPLOT	*Vertical boxplot.* The boundaries of the box are Tukey's hinges. The median is identified by a line inside the box. The length of the box is the interquartile range (IQR) computed from Tukey's hinges. Values more than three IQR's from the end of a box are labeled as extreme, denoted with an asterisk (*). Values more than 1.5 IQR's but less than 3 IQR's from the end of the box are labeled as outliers (o).
STEMLEAF	*Stem-and-leaf plot.* In a stem-and-leaf plot, each observed value is divided into two components—leading digits (stem) and trailing digits (leaf).
HISTOGRAM	*Histogram.*
SPREADLEVEL(n)	*Spread-versus-level plot with the Test of Homogeneity of Variance table.* If the keyword appears alone, the natural logs of the interquartile ranges are plotted against the natural logs of the medians for all cells. If a power for transforming the data (*n*) is given, the IQR and median of the transformed data are plotted. If 0 is specified for *n*, a natural log transformation of the data is done. The slope of the regression line and Levene tests for homogeneity of variance are also displayed. The Levene tests are based on the original data if no transformation is specified and on the transformed data if a transformation is requested.
NPPLOT	*Normal and detrended Q-Q plots with the Tests of Normality table presenting Shapiro-Wilk's statistic and a Kolmogorov-Smirnov statistic with a Lilliefors significance level for testing normality.* If non-integer weights are specified, the Shapiro-Wilk's statistic is calculated when the weighted sample size lies between 3 and 50. For no weights or integer weights, the statistic is calculated when the weighted sample size lies between 3 and 5,000.
ALL	*All available plots.*
NONE	*No plots.*

Example

```
EXAMINE VARIABLES=CYCLE BY TREATMNT /PLOT=NPPLOT.
```

- PLOT produces normal and detrended Q-Q plots for each value of *TREATMNT* and a Tests of Normality table.

Example

```
EXAMINE VARIABLES=CYCLE BY TREATMNT /PLOT=SPREADLEVEL(.5).
```

- PLOT produces a spread-versus-level plot of the medians and interquartile ranges of the square root of *CYCLE*. Each point on the plot represents one of the *TREATMNT* groups.
- A Test of Homogeneity of Variance table displays Levene statistics.

Example

```
EXAMINE VARIABLES=CYCLE BY TREATMNT /PLOT=SPREADLEVEL(0).
```

- PLOT generates a spread-versus-level plot of the medians and interquartile ranges of the natural logs of *CYCLE* for each *TREATMENT* group.
- A Test of Homogeneity of Variance table displays Levene statistics.

Example

```
EXAMINE VARIABLES=CYCLE BY TREATMNT /PLOT=SPREADLEVEL.
```

- PLOT generates a spread-versus-level plot of the natural logs of the medians and interquartile ranges of *CYCLE* for each *TREATMNT* group.
- A Test of Homogeneity of Variance table displays Levene statistics.

STATISTICS Subcommand

STATISTICS requests univariate statistics and determines how many extreme values are displayed. DESCRIPTIVES is the default. If you specify keywords on STATISTICS, only the requested statistics are displayed.

DESCRIPTIVES	*Display the Descriptives table showing univariate statistics (the mean, median, 5% trimmed mean, standard error, variance, standard deviation, minimum, maximum, range, interquartile range, skewness, skewness standard error, kurtosis, and kurtosis standard error).* This is the default.
EXTREME(n)	*Display the Extreme Values table presenting cases with the* n *largest and* n *smallest values.* If *n* is omitted, the five largest and five smallest values are displayed. Extreme cases are labeled with their values for the identification variable if the ID subcommand is used or with their values for the system variable *$CASENUM* if ID is not specified.
ALL	*Display the Descriptives and Extreme Values tables.*
NONE	*Display neither the Descriptives nor the Extreme Values tables.*

Example

```
EXAMINE VARIABLE=FAILTIME /ID=BRAND
  /STATISTICS=EXTREME(10) /PLOT=NONE.
```

- STATISTICS identifies the cases with the 10 lowest and 10 highest values for *FAILTIME*. These cases are labeled with the first characters of their values for the variable *BRAND*. The Descriptives table is not displayed.

CINTERVAL Subcommand

CINTERVAL controls the confidence level when the default DESCRIPTIVES statistics is displayed. CINTERVAL has a default value of 95.

- You can specify a CINTERVAL value (*n)* between 50 and 99.99 inclusive. If the value you specify is out of range, the program issues a warning and uses the default 95% intervals.
- If you specify a keyword on STATISTICS subcommand that turns off the default DESCRIPTIVES, the CINTERVAL subcommand is ignored.
- The confidence interval appears in the output with the label *n% CI for Mean*, followed by the confidence interval in parentheses. For example, 95% CI for Mean (.0001,.00013)

The *n* in the label shows up to six decimal places. That is, input /CINTERVAL 95 displays as *95% CI* while input /CINTERVAL 95.975 displays as *95.975% CI*.

MESTIMATORS Subcommand

M-estimators are robust maximum-likelihood estimators of location. Four M-estimators are available for display in the M-Estimators table. They differ in the weights they apply to the cases. MESTIMATORS with no keywords produces Huber's M-estimator with c=1.339; Andrews' wave with c=1.34π; Hampel's M-estimator with a=1.7, b=3.4, and c=8.5; and Tukey's biweight with c=4.685.

HUBER(c)	*Huber's M-estimator.* The value of weighting constant c can be specified in parentheses following the keyword. The default is c=1.339.
ANDREW(c)	*Andrews' wave estimator.* The value of weighting constant c can be specified in parentheses following the keyword. Constants are multiplied by π. The default is 1.34π.
HAMPEL(a,b,c)	*Hampel's M-estimator.* The values of weighting constants a, b, and c can be specified in order in parentheses following the keyword. The default values are a=1.7, b=3.4, and c=8.5.
TUKEY(c)	*Tukey's biweight estimator.* The value of weighting constant c can be specified in parentheses following the keyword. The default is c=4.685.
ALL	*All four above M-estimators.* This is the default when MESTIMATORS is specified with no keyword. The default values for weighting constants are used.
NONE	*No M-estimators.* This is the default if MESTIMATORS is omitted.

Example

```
EXAMINE VARIABLE=CASTTEST /MESTIMATORS.
```

- MESTIMATORS generates all four M-estimators computed with the default constants.

Example

```
EXAMINE VARIABLE=CASTTEST /MESTIMATORS=HAMPELS(2,4,8).
```

- MESTIMATOR produces Hampel's M-estimator with weighting constants a=2, b=4, and c=8.

MISSING Subcommand

MISSING controls the processing of missing values in the analysis. The default is LISTWISE, EXCLUDE, and NOREPORT.

- LISTWISE and PAIRWISE are alternatives and apply to all variables. They are modified for dependent variables by INCLUDE/EXCLUDE and for factor variables by REPORT/NOREPORT.
- INCLUDE and EXCLUDE are alternatives; they apply only to dependent variables.
- REPORT and NOREPORT are alternatives; they determine if missing values for factor variables are treated as valid categories.

LISTWISE	*Delete cases with missing values listwise.* A case with missing values for any dependent variable or any factor in the model specification is excluded from statistics and plots unless modified by INCLUDE or REPORT. This is the default.
PAIRWISE	*Delete cases with missing values pairwise.* A case is deleted from the analysis only if it has a missing value for the dependent variable or factor being analyzed.

EXCLUDE	*Exclude user-missing values.* User-missing values and system-missing values for dependent variables are excluded. This is the default.
INCLUDE	*Include user-missing values.* Only system-missing values for dependent variables are excluded from the analysis.
NOREPORT	*Exclude user- and system-missing values for factor variables.* This is the default.
REPORT	*Include user- and system-missing values for factor variables.* User- and system-missing values for factors are treated as valid categories and are labeled as missing.

Example

```
EXAMINE VARIABLES=RAINFALL MEANTEMP BY REGION.
```

- `MISSING` is not specified and the default is used. Any case with a user- or system-missing value for *RAINFALL*, *MEANTEMP*, or *REGION* is excluded from the analysis and display.

Example

```
EXAMINE VARIABLES=RAINFALL MEANTEMP BY REGION
  /MISSING=PAIRWISE.
```

- Only cases with missing values for *RAINFALL* are excluded from the analysis of *RAINFALL*, and only cases with missing values for *MEANTEMP* are excluded from the analysis of *MEANTEMP*. Missing values for *REGION* are not used.

Example

```
EXAMINE VARIABLES=RAINFALL MEANTEMP BY REGION
  /MISSING=REPORT.
```

- Missing values for *REGION* are considered valid categories and are labeled as missing.

EXECUTE

```
EXECUTE.
```

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Overview

EXECUTE forces the data to be read and executes the transformations that precede it in the command sequence.

Basic Specification

The basic specification is simply the command keyword. EXECUTE has no additional specifications.

Operations

- EXECUTE causes the data to be read but has no other influence on the session.
- EXECUTE is designed for use with transformation commands and facilities such as ADD FILES, MATCH FILES, UPDATE, PRINT, and WRITE, which do not read data and are not executed unless followed by a data-reading procedure.

Examples

```
DATA LIST  FILE=RAWDATA / 1 LNAME 1-13 (A) FNAME 15-24 (A)
  MMAIDENL 40-55.
VAR LABELS  MMAIDENL 'MOTHER''S MAIDEN NAME'.
DO IF (MMAIDENL EQ 'Smith').
WRITE OUTFILE=SMITHS/LNAME FNAME.
END IF.
EXECUTE.
```

- This example writes the last and first names of all people whose mother's maiden name was Smith to the data file *SMITHS*.
- DO IF-END IF and WRITE do not read data and are executed only when data are read for a procedure. Because there is no procedure in this session, EXECUTE is used to read the data and execute all of the preceding transformation commands. Otherwise, the commands would not be executed.

EXPORT

```
EXPORT OUTFILE='file'

 [/TYPE={COMM**}]
        {TAPE  }

 [/UNSELECTED=[{RETAIN}]
              {DELETE}

 [/KEEP={ALL**  }] [/DROP=varlist]
        {varlist}

 [/RENAME=(old varnames=new varnames)...]

 [/MAP]

 [/DIGITS=n]
```

**Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
EXPORT OUTFILE="/data/newdata.por"
  /RENAME=(V1 TO V3=ID, SEX, AGE) /MAP.
```

Overview

EXPORT produces a portable data file. A portable data file is a data file created used to transport data between different types of computers and operating systems, or other software using the same portable file format. Like an SPSS-format data file, a portable file contains all of the data and dictionary information stored in the active dataset from which it was created. (To send data to a computer and operating system the same as your own, send an SPSS-format data file, which is easier and faster to process than a portable file.)

EXPORT is similar to the SAVE command. It can occur in the same position in the command sequence as the SAVE command and saves the active dataset. The file includes the results of all permanent transformations and any temporary transformations made just prior to the EXPORT command. The active dataset is unchanged after the EXPORT command.

- In most cases, saving data in portable format is no longer necessary, since SPSS-format data files should be platform/operating system independent.
- To export data in external data formats (e.g., Excel, SAS, Stata, CSV, tab-delimited), use SAVE TRANSLATE.

Options

Format. You can control the format of the portable file using the TYPE subcommand.

Variables. You can save a subset of variables from the active dataset and rename the variables using the DROP, KEEP, and RENAME subcommands. You can also produce a record of all variables and their names on the exported file with the MAP subcommand.

Precision. You can specify the number of decimal digits of precision for the values of all numeric variables on the DIGITS subcommand.

Basic Specification

The basic specification is the OUTFILE subcommand with a file specification. All variables from the active dataset are written to the portable file, with variable names, variable and value labels, missing-value flags, and print and write formats.

Subcommand Order

Subcommands can be named in any order.

Operations

- Portable files are written with 80-character record lengths.
- Portable files may contain some unprintable characters.
- The active dataset is still available for transformations and procedures after the portable file is created.
- The system variables *$CASENUM* and *$DATE* are assigned when the file is read by IMPORT.
- If the WEIGHT command is used before EXPORT, the weighting variable is included in the portable file.
- Variable names that exceed eight bytes are converted to unique eight-byte names—for example, *mylongrootname1*, *mylongrootname2*, and *mylongrootname3* would be converted to *mylongro*, *mylong_2*, and *mylong_3*, respectively.

Limitations

The EXPORT command is not supported in Unicode mode. For more information, see SET command, UNICODE subcommand.

Examples

```
EXPORT OUTFILE="/newdata.por"
  /RENAME=(V1 TO V3=ID,SEX,AGE) /MAP.
```

- The portable file is written to *newdata.por*.
- The variables *V1*, *V2*, and *V3* are renamed *ID*, *SEX*, and *AGE* in the portable file. Their names remain *V1*, *V2*, and *V3* in the active dataset. None of the other variables written to the portable file are renamed.
- MAP requests a display of the variables in the portable file.

Methods of Transporting Portable Files

Portable files can be transported on magnetic tape or by a communications program.

Magnetic Tape

Before transporting files on a magnetic tape, make sure the receiving computer can read the tape being sent. The following tape specifications must be known before you write the portable file on the tape:

- **Number of tracks.** Either 7 or 9.
- **Tape density.** 200, 556, 800, 1600, or 6250 bits per inch (BPI).
- **Parity.** Even or odd. This must be known only when writing a 7-track tape.
- **Tape labeling.** Labeled or unlabeled. Check whether the site can use tape labels. Also make sure that the site has the ability to read multivolume tape files if the file being written uses more than one tape.
- **Blocksize.** The maximum blocksize the receiving computer can accept.

A tape written with the following characteristics can be read by most computers: 9 track, 1600 BPI, unlabeled, and a blocksize of 3200 characters. However, there is no guarantee that a tape written with these characteristics can be read successfully. The best policy is to know the requirements of the receiving computer ahead of time.

The following advice may help ensure successful file transfers by magnetic tape:

- Unless you are certain that the receiving computer can read labels, prepare an unlabeled tape.
- Make sure the record length of 80 is not changed.
- Do not use a separate character translation program, especially ASCII/EBCDIC translations. `EXPORT/IMPORT` takes care of this for you.
- Make sure the same blocking factor is used when writing and reading the tape. A blocksize of 3200 is frequently a good choice.
- If possible, write the portable file directly to tape to avoid possible interference from copy programs. Read the file directly from the tape for the same reason.
- Use the `INFO LOCAL` command to find out about using the program on your particular computer and operating system. `INFO LOCAL` generally includes additional information about reading and writing portable files.

Communications Programs

Transmission of a portable file by a communications program may not be possible if the program misinterprets any characters in the file as control characters (for example, as a line feed, carriage return, or end of transmission). This can be prevented by specifying `TYPE=COMM` on `EXPORT`. This specification replaces each control character with the character 0. The affected control characters are in positions 0–60 of the `IMPORT/EXPORT` character set. For more information, see IMPORT/EXPORT Character Sets on p. 2017.

The line length that the communications program uses must be set to 80 to match the 80-character record length of portable files. A transmitted file must be checked for blank lines or special characters inserted by the communications program. These must be edited out prior to reading the file with the IMPORT command.

Character Translation

Portable files are character files, not binary files, and they have 80-character records so they can be transmitted over data links. A receiving computer may not use the same character set as the computer where the portable file was written. When it imports a portable file, the program translates characters in the file to the character set used by the receiving computer. Depending on the character set in use, some characters in labels and in string data may be lost in the translation. For example, if a file is transported from a computer using a seven-bit ASCII character set to a computer using a six-bit ASCII character set, some characters in the file may have no matching characters in six-bit ASCII. For a character that has no match, the program generates an appropriate nonprintable character (the null character in most cases).

For a table of the character-set translations available with IMPORT and EXPORT, refer to Appendix B. A blank in a column of the table means that there is no matching character for that character set and an appropriate nonprintable character will be generated when you import a file.

OUTFILE Subcommand

OUTFILE specifies the portable file. OUTFILE is the only required subcommand on EXPORT.

TYPE Subcommand

TYPE indicates whether the portable file should be formatted for magnetic tape or for a communications program. You can specify either COMM or TAPE. For more information, see Methods of Transporting Portable Files on p. 642.

COMM	*Transport portable files by a communications program.* When COMM is specified on TYPE, the program removes all control characters and replaces them with the character 0. This is the default.
TAPE	*Transport portable files on magnetic tape.*

Example

```
EXPORT TYPE=TAPE /OUTFILE=HUBOUT.
```

- File *HUBOUT* is saved as a tape-formatted portable file.

UNSELECTED Subcommand

UNSELECTED determines whether cases excluded on a previous FILTER or USE command are to be retained or deleted in the SPSS-format data file. The default is RETAIN. The UNSELECTED subcommand has no effect when the active dataset does not contain unselected cases.

RETAIN *Retain the unselected cases*. All cases in the active dataset are saved. This is the default when UNSELECTED is specified by itself.

DELETE *Delete the unselected cases*. Only cases that meet the FILTER or USE criteria are saved in the SPSS-format data file.

DROP and KEEP Subcommands

DROP and KEEP save a subset of variables in the portable file.

- DROP excludes a variable or list of variables from the portable file. All variables not named are included in the portable file.
- KEEP includes a variable or list of variables in the portable file. All variables not named are excluded.
- Variables can be specified on DROP and KEEP in any order. With the DROP subcommand, the order of variables in the portable file is the same as their order in the active dataset. With the KEEP subcommand, the order of variables in the portable file is the order in which they are named on KEEP. Thus, KEEP can be used to reorder variables in the portable file.
- Both DROP and KEEP can be used on the same EXPORT command; the effect is cumulative. If you specify a variable already named on a previous DROP or one not named on a previous KEEP, the variable is considered nonexistent and the program displays an error message. The command is aborted and no portable file is saved.

Example

```
EXPORT OUTFILE=NEWSUM /DROP=DEPT TO DIVISION.
```

- The portable file is written to file *NEWSUM*. Variables between and including *DEPT* and *DIVISION* in the active dataset are excluded from the portable file.
- All other variables are saved in the portable file.

RENAME Subcommand

RENAME renames variables being written to the portable file. The renamed variables retain their original variable and value labels, missing-value flags, and print formats. The names of the variables are not changed in the active dataset.

- To rename a variable, specify the name of the variable in the active dataset, an equals sign, and the new name.
- A variable list can be specified on both sides of the equals sign. The number of variables on both sides must be the same, and the entire specification must be enclosed in parentheses.
- The keyword TO can be used for both variable lists.

- If you specify a renamed variable on a subsequent DROP or KEEP subcommand, the new variable name must be used.

Example

```
EXPORT OUTFILE=NEWSUM /DROP=DEPT TO DIVISION
  /RENAME=(NAME,WAGE=LNAME,SALARY).
```

- RENAME renames *NAME* and *WAGE* to *LNAME* and *SALARY*.
- *LNAME* and *SALARY* retain the variable and value labels, missing-value flags, and print formats assigned to *NAME* and *WAGE*.

MAP Subcommand

MAP displays any changes that have been specified by the RENAME, DROP, or KEEP subcommands.

- MAP can be specified as often as desired.
- Each MAP subcommand maps the results of subcommands that precede it; results of subcommands that follow it are not mapped. When MAP is specified last, it also produces a description of the portable file.

Example

```
EXPORT OUTFILE=NEWSUM /DROP=DEPT TO DIVISION /MAP
  /RENAME NAME=LNAME WAGE=SALARY /MAP.
```

- The first MAP subcommand produces a listing of the variables in the file after DROP has dropped the specified variables.
- RENAME renames *NAME* and *WAGE*.
- The second MAP subcommand shows the variables in the file after renaming. Since this is the last subcommand, the listing will show the variables as they are written in the portable file.

DIGITS Subcommand

DIGITS specifies the degree of precision for all noninteger numeric values written to the portable file.

- DIGITS has the general form DIGITS=*n*, where *n* is the number of digits of precision.
- DIGITS applies to all numbers for which rounding is required.
- Different degrees of precision *cannot* be specified for different variables. Thus, DIGITS should be set according to the requirements of the variable that needs the most precision.
- Default precision methods used by EXPORT work perfectly for integers that are not too large and for fractions whose denominators are products of 2, 3, and 5 (all decimals, quarters, eighths, sixteenths, thirds, thirtieths, sixtieths, and so forth.) For other fractions and for integers too large to be represented exactly in the active dataset (usually more than 9 digits, often 15 or more), the representation used in the active dataset contains some error already, so no exact way of sending these numbers is possible. The program sends enough digits to get very close. The number of digits sent in these cases depends on the originating computer: on

mainframe IBM versions of the program, it is the equivalent of 13 decimal digits (integer and fractional parts combined). If many numbers on a file require this level of precision, the file can grow quite large. If you do not need the full default precision, you can save some space in the portable file by using the `DIGITS` subcommand.

Example

```
EXPORT OUTFILE=NEWSUM /DROP=DEPT TO DIVISION /MAP /DIGITS=4.
```

- `DIGITS` guarantees the accuracy of values to four significant digits. For example, 12.34567890876 will be rounded to 12.35.

EXTENSION

```
EXTENSION ACTION={ADD** }
                 {REMOVE}

  /SPECIFICATION COMMAND=file.
```

** Default if the subcommand or keyword is omitted.

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Release History

Release 16.0

- Command introduced.

Example

```
EXTENSION
  /SPECIFICATION COMMAND="c:\mypls.xml"
```

Overview

EXTENSION allows you to add user-created "extension" commands to the command table, enabling the use of "native" command syntax to drive functions written in an external programming language.

Basic Specification

The minimum specification is the SPECIFICATION subcommand with a COMMAND file specified.

ACTION Keyword

The ACTION keyword specifies the action to be taken on the command table.

ADD	*Add command name to command table.* This is the default. Note that ADD will replace an existing command of the same name, regardless of the languages in which the commands are written.
REMOVE	*Remove command name from command table.*

Examples

Adding a New Command

```
EXTENSION
```

```
  /SPECIFICATION COMMAND="<installdir>/extensions/plscommand.xml".
```

The SPECIFICATION subcommand specifies that the syntax diagram for the extension command is defined by *plscommand.xml* in the *\extensions* subdirectory of the main installation directory (replace <*installdir*> with the path to the installation directory on your system). The default action is for the command name provided in the XML file to be added to the command table or replace an existing command name.

Removing a Command

```
EXTENSION ACTION=REMOVE
  /SPECIFICATION COMMAND="<installdir>/extensions/plscommand.xml".
```

The ACTION keyword specifies that the command name provided in *plscommand.xml* should be removed from the command table.

SPECIFICATION Subcommand

The SPECIFICATION subcommand allows you to specify the location of the XML file that defines the syntax diagram for the extension command.

Note: The system processes all XML files in the *\extensions* subdirectory of the main installation directory on startup. EXTENSION is most useful when you have files in a different directory, or want to add a new extension command to an already-running session.

COMMAND Keyword

The COMMAND keyword specifies the location of the XML file that defines the syntax diagram for the extension command. This file provides the command name and is used by the universal parser to pass the correct arguments to the extension command.

FACTOR

```
FACTOR VARIABLES=varlist† [/MISSING=[{LISTWISE**}] [INCLUDE]]
                                    {PAIRWISE  }
                                    {MEANSUB   }

† Omit VARIABLES with matrix input.

**Default if subcommand or keyword is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
FACTOR VARIABLES=V1 TO V12.
```

Overview

FACTOR performs factor analysis based either on correlations or covariances and using one of the seven extraction methods. FACTOR also accepts matrix input in the form of correlation matrices, covariance matrices, or factor-loading matrices and can write the matrix materials to a matrix data file.

Options

Analysis Phase Options. You can choose to analyze a correlation or covariance matrix using the METHOD subcommand. You can select a subset of cases for the analysis phase using the SELECT subcommand. You can tailor the statistical display for an analysis using the PRINT subcommand. You can sort the output in the factor pattern and structure matrices with the FORMAT subcommand. You can also request scree plots and plots of the variables in factor space on the PLOT subcommand.

Extraction Phase Options. With the EXTRACTION subcommand, you can specify one of six extraction methods in addition to the default principal components extraction: principal axis factoring, alpha factoring, image factoring, unweighted least squares, generalized least squares, and maximum likelihood. You can supply initial diagonal values for principal axis factoring on the DIAGONAL subcommand. On the CRITERIA subcommand, you can alter the default statistical criteria used in the extraction.

Rotation Phase Options. You can control the criteria for factor rotation with the CRITERIA subcommand. On the ROTATION subcommand, you can choose among four rotation methods (equamax, quartimax, promax, and oblimin) in addition to the default varimax rotation, or you can specify no rotation.

Factor Scores. You can save factor scores as new variables in the active dataset using any of the three methods available on the SAVE subcommand.

Matrix Input and Output. With the MATRIX subcommand, you can write a correlation matrix, a covariance matrix, or a factor-loading matrix. You can also read matrix materials written either by a previous FACTOR procedure or by a procedure that writes correlation or covariance matrices.

Basic Specification

The basic specification is the VARIABLES subcommand with a variable list. FACTOR performs principal components analysis with a varimax rotation on all variables in the analysis using default criteria.

- When matrix materials are used as input, do not specify VARIABLES. Use the ANALYSIS subcommand to specify a subset of the variables in the matrix.

Subcommand Order

- METHOD and SELECT can be specified anywhere. VARIABLES must be specified before any other subcommands, unless an input matrix is specified. MISSING must be specified before ANALYSIS.
- The ANALYSIS, EXTRACTION, ROTATION, and SAVE subcommands must be specified in the order they are listed here. If you specify these subcommands out of order, you may get unpracticed results. For example, if you specify EXTRACTION before ANALYSIS and SAVE before ROTATION, EXTRACTION and SAVE are ignored. If no EXTRACTION and SAVE subcommands are specified in proper order, the default will be used (that is, PC for EXTRACTION and no SAVE).
- The FORMAT subcommand can be specified anywhere after the VARIABLES subcommand.
- If an ANALYSIS subcommand is present, the statistical display options on PRINT, PLOT, or DIAGONAL must be specified after it. PRINT, PLOT, and DIAGONAL subcommands specified before the ANALYSIS subcommand are ignored. If no such commands are specified after the ANALYSIS subcommand, the default is used.
- The CRITERIA subcommand can be specified anywhere, but applies only to the subcommands that follow. If no CRITERIA subcommand is specified before EXTRACTION or ROTATION, the default criteria for the respective subcommand are used.

Example

```
FACTOR VAR=V1 TO V12
  /ANALYSIS=V1 TO V8
  /CRITERIA=FACTORS(3)
  /EXTRACTION=PAF
  /ROTATION=QUARTIMAX.
```

- The default CORRELATION method is used. FACTOR performs a factor analysis of the correlation matrix based on the first eight variables in the active dataset (*V1* to *V8*).
- The procedure extracts three factors using the principal axis method and quartimax rotation.
- LISTWISE (the default for MISSING) is in effect. Cases with missing values for any one of the variables from *V1* to *V12* are omitted from the analysis. As a result, if you ask for the factor analysis using VAR=V1 TO V8 and ANALYSIS=ALL, the results may be different even though the variables used in the analysis are the same.

Syntax Rules

- Each FACTOR procedure performs only one analysis with one extraction and one rotation. Use multiple FACTOR commands to perform multiple analyses.
- VARIABLES or MATRIX=IN can be specified only once. Any other subcommands can be specified multiple times but only the last in proper order takes effect.

Operations

- VARIABLES calculates a correlation and a covariance matrix. If SELECT is specified, only the selected cases are used.
- The correlation or covariance matrix (either calculated from the data or read in) is the basis for the factor analysis.

- Factor scores are calculated for all cases (selected and unselected).
- This procedure uses the multithreaded options specified by SET THREADS and SET MCACHE.

Example

```
FACTOR VARIABLES=V1 TO V12.
```

- This example uses the default CORRELATION method.
- It produces the default principal components analysis of 12 variables. Those with eigenvalues greater than 1 (the default criterion for extraction) are rotated using varimax rotation (the default).

VARIABLES Subcommand

VARIABLES names all the variables to be used in the FACTOR procedure.

- VARIABLES is required except when matrix input is used. When FACTOR reads a matrix data file, the VARIABLES subcommand cannot be used.
- The specification on VARIABLES is a list of numeric variables.
- Keyword ALL on VARIABLES refers to all variables in the active dataset.
- Only one VARIABLES subcommand can be specified, and it must be specified first.

MISSING Subcommand

MISSING controls the treatment of cases with missing values.

- If MISSING is omitted or included without specifications, listwise deletion is in effect.
- MISSING must precede the ANALYSIS subcommand.
- The LISTWISE, PAIRWISE, and MEANSUB keywords are alternatives, but any one of them can be used with INCLUDE.

LISTWISE *Delete cases with missing values listwise*. Only cases with nonmissing values for all variables named on the VARIABLES subcommand are used. Cases are deleted even if they have missing values only for variables listed on VARIABLES and have valid values for all variables listed on ANALYSIS. Alias DEFAULT.

PAIRWISE *Delete cases with missing values pairwise*. All cases with nonmissing values for each pair of variables correlated are used to compute that correlation, regardless of whether the cases have missing values for any other variable.

MEANSUB *Replace missing values with the variable mean*. All cases are used after the substitution is made. If INCLUDE is also specified, user-missing values are included in the computation of the means, and means are substituted only for the system-missing value. If SELECT is in effect, only the values of selected cases are used in calculating the means used to replace missing values for selected cases in analysis and for all cases in computing factor scores.

INCLUDE *Include user-missing values*. Cases with user-missing values are treated as valid.

METHOD Subcommand

METHOD specifies whether the factor analysis is performed on a correlation matrix or a covariance matrix.

- Only one METHOD subcommand is allowed. If more than one is specified, the last is in effect.

CORRELATION	*Perform a correlation matrix analysis.* This is the default.
COVARIANCE	*Perform a covariance matrix analysis.* Valid only with principal components, principal axis factoring, or image factoring methods of extraction. The program issues an error if this keyword is specified when the input is a factor-loading matrix or a correlation matrix that does not contain standard deviations (STDDEV or SD).

SELECT Subcommand

SELECT limits cases used in the analysis phase to those with a specified value for any one variable.

- Only one SELECT subcommand is allowed. If more than one is specified, the last is in effect.
- The specification is a variable name and a valid value in parentheses. A string value must be specified within quotes. Multiple variables or values are not permitted.
- The selection variable does not have to be specified on the VARIABLES subcommand.
- Only cases with the specified value for the selection variable are used in computing the correlation or covariance matrix. You can compute and save factor scores for the unselected cases as well as the selected cases.
- SELECT is not valid if MATRIX = IN is specified.

Example

```
FACTOR VARIABLES = V1 TO V10
  /SELECT=COMPLETE(1)
  /SAVE (4).
```

- FACTOR analyzes all ten variables named on VARIABLES, using only cases with a value of 1 for the variable *COMPLETE*.
- By default, FACTOR uses the CORRELATION method and performs the principal components analysis of the selected cases. Those with eigenvalues greater than 1 are rotated using varimax rotation.
- Four factor scores, for both selected and unselected cases, are computed using the default regression method and four new variables are saved in the active dataset.

ANALYSIS Subcommand

The ANALYSIS subcommand specifies a subset of the variables named on VARIABLES for use in an analysis.

- The specification on ANALYSIS is a list of variables, all of which must have been named on the VARIABLES subcommand. For matrix input, ANALYSIS can specify a subset of the variables in a correlation or covariance matrix.

- Only one ANALYSIS subcommand is allowed. When multiple ANALYSIS subcommands are specified, the last is in effect.
- If no ANALYSIS is specified, all variables named on the VARIABLES subcommand (or included in the matrix input file) are used.
- Keyword TO in a variable list on ANALYSIS refers to the order in which variables are named on the VARIABLES subcommand, not to their order in the active dataset.
- Keyword ALL refers to all variables named on the VARIABLES subcommand.

Example

```
FACTOR VARIABLES=V1 V2 V3 V4 V5 V6
   /ANALYSIS=V4 TO V6.
```

- This example requests a factor analysis of *V4*, *V5*, and *V6*. Keyword TO on ANALYSIS refers to the order of variables on VARIABLES, not the order in the active dataset.
- Cases with missing values for all variables specified on VARIABLES are omitted from the analysis. (The default setting for MISSING.)
- By default, the CORRELATION method is used and a principal components analysis with a varimax rotation is performed.

FORMAT Subcommand

FORMAT modifies the format of factor pattern and structure matrices.

- FORMAT can be specified anywhere after VARIABLES and MISSING. If more than one FORMAT is specified, the last is in effect.
- If FORMAT is omitted or included without specifications, variables appear in the order in which they are named on ANALYSIS and all matrix entries are displayed.

SORT	*Order the factor loadings in descending order.* Variables are displayed in descending order of the factor 1 loadings until a loading for factor 2 exceeds the loading for factor 1. The remaining variables are then displayed in descending order of the factor 2 loadings until a loading for factor 3 exceeds the loading for factor 2, and so on. The result shows blocks of variables that are similar.
BLANK(n)	*Suppress display of coefficients lower than* n *in absolute value*. The corresponding cells in the table will be blank.
DEFAULT	*Turn off keywords SORT and BLANK.*

Example

```
FACTOR VARIABLES=V1 TO V12
  /MISSING=MEANSUB
  /FORMAT=SORT BLANK(.3)
  /EXTRACTION=ULS
  /ROTATION=NOROTATE.
```

- This example specifies an analysis of all variables between and including *V1* and *V12* in the active dataset.
- The default CORRELATION method is used.

- The MISSING subcommand substitutes variable means for missing values.
- The FORMAT subcommand orders variables in factor pattern matrices by descending value of loadings. Factor loadings with an absolute value less than 0.3 are omitted.
- Factors are extracted using unweighted least squares and are not rotated.

PRINT Subcommand

PRINT controls the statistical display in the output.

- Keywords INITIAL, EXTRACTION, and ROTATION are the defaults if PRINT is omitted or specified without keywords.
- If any keywords are specified, only the output specifically requested is produced.
- The requested statistics are displayed only for variables specified on the last ANALYSIS subcommand.
- If more than one PRINT subcommand is specified, the last is in effect.
- If any ANALYSIS subcommand is explicitly specified, all PRINT subcommands specified before the last ANALYSIS subcommand are ignored. If no PRINT subcommand is specified after the last ANALYSIS subcommand, the default takes effect.

INITIAL	*Initial communalities for each variable, eigenvalues of the unreduced correlation matrix, and percentage of variance for each factor.*
EXTRACTION	*Factor pattern matrix, revised communalities, the eigenvalue of each factor retained, and the percentage of variance each eigenvalue represents.*
ROTATION	*Rotated factor pattern matrix, factor transformation matrix, factor correlation matrix, and the post-rotation sums of squared loadings*.
UNIVARIATE	*Valid number of cases, means, and standard deviations*. (Not available with matrix input.) If MISSING=MEANSUB or PAIRWISE, the output also includes the number of missing cases.
CORRELATION	*Correlation matrix.* Ignored if the input is a factor-loading matrix.
COVARIANCE	*Covariance matrix.* Ignored if the input is a factor-loading matrix or a correlation matrix that does not contain standard deviations (STDDEV or SD).
SIG	*Matrix of significance levels of correlations*.
DET	*Determinant of the correlation or covariance matrix, depending on the specification on* METHOD.
INV	*Inverse of the correlation or covariance matrix, depending on the specification on* METHOD.
AIC	*Anti-image covariance and correlation matrices*(Kaiser, 1970). The measure of sampling adequacy for the individual variable is displayed on the diagonal of the anti-image correlation matrix.
KMO	*Kaiser-Meyer-Olkin measure of sampling adequacy and Bartlett's test of sphericity*. Always based on the correlation matrix. Not computed for an input matrix when it does not contain *N* values.
REPR	*Reproduced correlations and residuals or reproduced covariance and residuals, depending on the specification on* METHOD.
FSCORE	*Factor score coefficient matrix*. Factor score coefficients are calculated using the method requested on the SAVE subcommand. The default is the regression method.

ALL *All available statistics.*

DEFAULT INITIAL, EXTRACTION, *and* ROTATION.

Example

```
FACTOR VARS=V1 TO V12
  /SELECT=COMPLETE ('yes')
  /MISS=MEANSUB
  /PRINT=DEF AIC KMO REPR
  /EXTRACT=ULS
  /ROTATE=VARIMAX.
```

- This example specifies a factor analysis that includes all variables between and including *V1* and *V12* in the active dataset.
- Only cases with the value "yes" on *COMPLETE* are used.
- Variable means are substituted for missing values. Only values for the selected cases are used in computing the mean. This mean is used to substitute missing values in analyzing the selected cases and in computing factor scores for all cases.
- The output includes the anti-image correlation and covariance matrices, the Kaiser-Meyer-Olkin measure of sampling adequacy, the reproduced correlation and residual matrix, as well as the default statistics.
- Factors are extracted using unweighted least squares.
- The factor pattern matrix is rotated using the varimax rotation.

PLOT Subcommand

Use PLOT to request scree plots or plots of variables in rotated factor space.

- If PLOT is omitted, no plots are produced. If PLOT is used without specifications, it is ignored.
- If more than one PLOT subcommand is specified, only the last one is in effect.
- If any ANALYSIS subcommand is explicitly specified, all PLOT subcommands specified before the last ANALYSIS subcommand are ignored. If no PLOT subcommand is specified after the last ANALYSIS subcommand, no plot is produced.

EIGEN *Scree plot*(Cattell, 1966). The eigenvalues from each extraction are plotted in descending order.

ROTATION *Plots of variables in factor space.* When used without any additional specifications, ROTATION can produce only high-resolution graphics. If three or more factors are extracted, a 3-D plot is produced with the factor space defined by the first three factors. You can request two-dimensional plots by specifying pairs of factor numbers in parentheses; for example, PLOT ROTATION(1,2)(1,3)(2,3) requests three plots, each defined by two factors. The ROTATION subcommand must be explicitly specified when you enter the keyword ROTATION on the PLOT subcommand.

DIAGONAL Subcommand

DIAGONAL specifies values for the diagonal in conjunction with principal axis factoring.

- If DIAGONAL is omitted or included without specifications, FACTOR uses the default method for specifying the diagonal.
- DIAGONAL is ignored with extraction methods other than PAF. The values are automatically adjusted by corresponding variances if METHOD=COVARIANCE.
- If more than one DIAGONAL subcommand is specified, only the last one is in effect.
- If any ANALYSIS subcommand is explicitly specified, DIAGONAL subcommands specified before the last ANALYSIS subcommand are ignored. If no DIAGONAL is specified after the last ANALYSIS subcommand, the default is used.
- Default communality estimates for PAF are squared multiple correlations. If these cannot be computed, the maximum absolute correlation between the variable and any other variable in the analysis is used.

valuelist *Diagonal values.* The number of values supplied must equal the number of variables in the analysis block. Use the notation n* before a value to indicate that the value is repeated *n* times.

DEFAULT *Initial communality estimates.*

Example

```
FACTOR VARIABLES=V1 TO V12
  /DIAGONAL=.56 .55 .74 2*.56 .70 3*.65 .76 .64 .63
  /EXTRACTION=PAF
  /ROTATION=VARIMAX.
```

- The factor analysis includes all variables between and including *V1* and *V12* in the active dataset.
- DIAGONAL specifies 12 values to use as initial estimates of communalities in principal axis factoring.
- The factor pattern matrix is rotated using varimax rotation.

CRITERIA Subcommand

CRITERIA controls extraction and rotation criteria.

- CRITERIA can be specified anywhere after VARIABLES and MISSING.
- Only explicitly specified criteria are changed. Unspecified criteria keep their defaults.
- Multiple CRITERIA subcommands are allowed. Changes made by a previous CRITERIA subcommand are overwritten by a later CRITERIA subcommand.
- Any CRITERIA subcommands specified after the last EXTRACTION subcommand have no effect on extraction.
- Any CRITERIA subcommands specified after the last ROTATION subcommand have no effect on rotation.

The following keywords on CRITERIA apply to extractions:

FACTORS(n) *Number of factors extracted*. The default is the number of eigenvalues greater than MINEIGEN. When specified, FACTORS overrides MINEIGEN.

MINEIGEN(n) *Minimum eigenvalue used to control the number of factors extracted.* If METHOD=CORRELATION, the default is 1. If METHOD=COVARIANCE, the default is computed as (Total Variance/Number of Variables)**n*, where Total Variance is the total weighted variance principal components or principal axis factoring extraction and the total image variance for image factoring extraction.

ECONVERGE(n) *Convergence criterion for extraction*. The default is 0.001.

The following keywords on CRITERIA apply to rotations:

RCONVERGE(n) *Convergence criterion for rotation*. The default is 0.0001.

KAISER *Kaiser normalization in the rotation phase.* This is the default. The alternative is NOKAISER.

NOKAISER *No Kaiser normalization*.

The following keywords on CRITERIA apply to both extractions and rotations:

ITERATE(n) *Maximum number of iterations for solutions in the extraction or rotation phases.* The default is 25.

DEFAULT *Reestablish default values for all criteria.*

Example

```
FACTOR VARIABLES=V1 TO V12
  /CRITERIA=FACTORS(6)
  /EXTRACTION=PC
  /ROTATION=NOROTATE
  /PLOT=ROTATION.
```

- This example analyzes all variables between and including *V1* and *V12* in the active dataset.
- Six factors are extracted using the default principal components method, and the factor pattern matrix is not rotated.
- PLOT sends all extracted factors to the graphics editor and shows a 3-D plot of the first three factors.

EXTRACTION Subcommand

EXTRACTION specifies the factor extraction technique.

- Only one EXTRACTION subcommand is allowed. If multiple EXTRACTION subcommands are specified, only the last is performed.
- If any ANALYSIS subcommand is explicitly specified, all EXTRACTION subcommands before the last ANALYSIS subcommand are ignored. If no EXTRACTION subcommand is specified after the last ANALYSIS subcommand, the default extraction is performed.
- If EXTRACTION is not specified or is included without specifications, principal components extraction is used.

- If you specify criteria for EXTRACTION, the CRITERIA subcommand must precede the EXTRACTION subcommand.
- When you specify EXTRACTION, you should always explicitly specify the ROTATION subcommand. If ROTATION is not specified, the factors are not rotated.

PC	*Principal components analysis*(Harman, 1976). This is the default. PC can also be requested with keyword PA1 or DEFAULT.
PAF	*Principal axis factoring.* PAF can also be requested with keyword PA2.
ALPHA	*Alpha factoring*(Kaiser and Caffry, 1965). Invalid if METHOD=COVARIANCE.
IMAGE	*Image factoring*(Kaiser, 1963).
ULS	*Unweighted least squares*(Jöreskog, 1977). Invalid if METHOD=COVARIANCE.
GLS	*Generalized least squares.* Invalid if METHOD=COVARIANCE.
ML	*Maximum likelihood*(Jöreskog and Lawley, 1968). Invalid if METHOD=VARIANCE.

Example

```
FACTOR VARIABLES=V1 TO V12
  /ANALYSIS=V1 TO V6
  /EXTRACTION=ULS
  /ROTATE=NOROTATE.
```

- This example analyzes variables *V1* through *V6* with an unweighted least-squares extraction. No rotation is performed.

ROTATION Subcommand

ROTATION specifies the factor rotation method. It can also be used to suppress the rotation phase entirely.

- Only one ROTATION subcommand is allowed. If multiple ROTATION subcommands are specified, only the last is performed.
- If any ANALYSIS subcommand is explicitly specified, all ROTATION subcommands before the last ANALYSIS subcommand are ignored. If any EXTRACTION subcommand is explicitly specified, all ROTATION subcommands before the last EXTRACTION subcommand are ignored.
- If ROTATION is omitted together with EXTRACTION, varimax rotation is used.
- If ROTATION is omitted but EXTRACTION is not, factors are not rotated.
- Keyword NOROTATE on the ROTATION subcommand produces a plot of variables in unrotated factor space if the PLOT subcommand is also included for the analysis.

VARIMAX	*Varimax rotation*. This is the default if ROTATION is entered without specifications or if EXTRACTION and ROTATION are both omitted. Varimax rotation can also be requested with keyword DEFAULT.
EQUAMAX	*Equamax rotation*.
QUARTIMAX	*Quartimax rotation*.
OBLIMIN(n)	*Direct oblimin rotation*. This is a nonorthogonal rotation; thus, a factor correlation matrix will also be displayed. You can specify a delta ($n \leq 0.8$) in parentheses. The value must be less than or equal to 0.8. The default is 0.

PROMAX(n)	*Promax rotation*. This is a nonorthogonal rotation; thus, a factor correlation matrix will also be displayed. For this method, you can specify a real-number value greater than 1. The default is 4.
NOROTATE	*No rotation*.

Example

```
FACTOR VARIABLES=V1 TO V12
  /EXTRACTION=ULS
  /ROTATION
  /ROTATION=OBLIMIN.
```

- The first ROTATION subcommand specifies the default varimax rotation.
- The second ROTATION subcommand specifies an oblimin rotation based on the same extraction of factors.

SAVE Subcommand

SAVE allows you to save factor scores from any rotated or unrotated extraction as new variables in the active dataset. You can use any of the three methods for computing the factor scores.

- Only one SAVE subcommand is executed. If you specify multiple SAVE subcommands, only the last is executed.
- SAVE must follow the last ROTATION subcommand.
- If no ROTATION subcommand is specified after the last EXTRACTION subcommand, SAVE must follow the last EXTRACTION subcommand and no rotation is used.
- If neither ROTATION nor EXTRACTION is specified, SAVE must follow the last ANALYSIS subcommand and the default extraction and rotation are used to compute the factor scores.
- SAVE subcommands before any explicitly specified ANALYSIS, EXTRACTION, or ROTATION subcommands are ignored.
- You cannot use the SAVE subcommand if you are replacing the active dataset with matrix materials. (For more information, see Matrix Output on p. 662.)
- The new variables are added to the end of the active dataset.

Keywords to specify the method of computing factor scores are:

REG	*Regression method.* This is the default.
BART	*Bartlett method.*
AR	*Anderson-Rubin method.*
DEFAULT	*The same as REG.*

- After one of the above keywords, specify in parentheses the number of scores to save and a rootname to use in naming the variables.
- You can specify either an integer or the keyword ALL. The maximum number of scores you can specify is the number of factors in the solution.

- FACTOR forms variable names by appending sequential numbers to the rootname you specify. The rootname must begin with a letter and conform to the rules for variable names. For information on variable naming rules, see Variable Names on p. 43.
- If you do not specify a rootname, FACTOR forms unique variable names using the formula *FACn_m,* where *m* increments to create a new rootname and *n* increments to create a unique variable name. For example, *FAC1_1, FAC2_1, FAC3_1*, and so on will be generated for the first set of saved scores and *FAC1_2, FAC2_2, FAC3_2*, and so on for the second set.
- FACTOR automatically generates variable labels for the new variables. Each label contains information about the method of computing the factor score, its sequential number, and the sequential number of the analysis.

Example

```
FACTOR VARIABLES=V1 TO V12
  /CRITERIA FACTORS(4)
  /ROTATION
  /SAVE REG (4,PCOMP).
```

- Since there is no EXTRACTION subcommand before the ROTATION subcommand, the default principal components extraction is performed.
- The CRITERIA subcommand specifies that four principal components should be extracted.
- The ROTATION subcommand requests the default varimax rotation for the principal components.
- The SAVE subcommand calculates scores using the regression method. Four scores will be added to the file: *PCOMP1*, *PCOMP2*, *PCOMP3*, and *PCOMP4*.

MATRIX Subcommand

MATRIX reads and writes SPSS-format matrix data files.

- MATRIX must always be specified first.
- Only one IN and one OUT keyword can be specified on the MATRIX subcommand. If either IN or OUT is specified more than once, the FACTOR procedure is not executed.
- The matrix type must be indicated on IN or OUT. The types are COR for a correlation matrix, COV for a covariance matrix, and FAC for a factor-loading matrix. Indicate the matrix type within parentheses immediately before you identify the matrix file.

- If you use both IN and OUT on MATRIX, you can specify them in either order. You cannot write a covariance matrix if the input matrix is a factor-loading matrix or a correlation matrix that does not contain standard deviations (STDDEV or SD).
- If you read in a covariance matrix and write out a factor-loading matrix, the output factor loadings are rescaled.

OUT (matrix type= 'savfile'|'dataset')
Write a matrix data file. Specify the matrix type (COR, COV, FAC, or FSC) and the matrix file in parentheses. For the matrix data file, specify a filename to store the matrix materials on disk, a previously declared dataset available in the current session, or an asterisk to replace the active dataset. If you specify an asterisk or a dataset name, the matrix data file is not stored on disk unless you use SAVE or XSAVE.

IN (matrix type= 'savfile'|'dataset')
Read a matrix data file. Specify the matrix type (COR, COV, or FAC) and the matrix file in parentheses. For the matrix data file, specify an asterisk if the matrix data file is the active dataset. If the matrix file is another file, specify the filename or dataset name in parentheses. A matrix file read from an external file or another dataset in the current session does not replace the active dataset.

Matrix Output

FACTOR can write matrix materials in the form of a correlation matrix, a covariance matrix, a factor-loading matrix, or a factor score coefficients matrix.

- The correlation and covariance matrix materials include counts, means, and standard deviations in addition to correlations or covariances.
- The factor-loading matrix materials contain only factor values and no additional statistics.
- The factor score coefficients materials include means and standard deviations, in addition to factor score coefficients.
- See Format of the Matrix Data File on p. 663 for a description of the file.
- FACTOR generates one matrix per split file.
- Any documents contained in the active dataset are not transferred to the matrix file.

Matrix Input

- FACTOR can read matrix materials written either by a previous FACTOR procedure or by a procedure that writes correlation or covariance matrices. For more information, see Universals on p. 31.
- MATRIX=IN cannot be used unless a active dataset has already been defined. To read an existing matrix data file at the beginning of a session, first use GET to retrieve the matrix file and then specify IN(COR=*), IN(COV=*) or IN(FAC=*) on MATRIX.
- The VARIABLES subcommand cannot be used with matrix input.
- For correlation and covariance matrix input, the ANALYSIS subcommand can specify a subset of the variables in the matrix. You cannot specify a subset of variables for factor-loading matrix input. By default, the ANALYSIS subcommand uses all variables in the matrix.

Format of the Matrix Data File

- For correlation or covariance matrices, the matrix data file has two special variables created by the program: *ROWTYPE_* and *VARNAME_*. Variable *ROWTYPE_* is a short string variable with the value CORR (for Pearson correlation coefficient) or COV (for covariance) for each matrix row. Variable *VARNAME_* is a short string variable whose values are the names of the variables used to form the correlation matrix.
- For factor-loading matrices, the program generates two special variables named *ROWTYPE_* and *FACTOR_*. The value for *ROWTYPE_* is always FACTOR. The values for *FACTOR_* are the ordinal numbers of the factors.
- For factor score coefficient matrices, the matrix data file has two special variables created: *ROWTYPE_* and *VARNAME_*. If split-file processing is in effect, the split variables appear first in the matrix output file, followed by *ROWTYPE_*, *VARNAME_*, and the variables in the analysis. *ROWTYPE_* is a short string with three possible values: MEAN, STDDEV, and FSCOEF. There is always one occurrence of the value MEAN. If `/METHOD = CORRELATION` then there is one occurrence of the value STDDEV. Otherwise, this value does not appear. There are as many occurrences of FSCOEF as the number of extracted factors. *VARNAME_* is a short string who values are FAC*n* where *n* is the sequence of the saved factor when *ROWTYPE_* equals FSCOEF. Otherwise the value is empty.
- The remaining variables are the variables used to form the matrix.

Split Files

- `FACTOR` can read or write split-file matrices.
- When split-file processing is in effect, the first variables in the matrix data file are the split variables, followed by *ROWTYPE_*, *VARNAME_* (or *FACTOR_*), and then the variables used to form the matrix.
- A full set of matrix materials is written for each split-file group defined by the split variables.
- A split variable cannot have the same variable name as any other variable written to the matrix data file.
- If split-file processing is in effect when a matrix is written, the same split file must be in effect when that matrix is read by any other procedure.

Example: Factor Correlation Matrix Output to External File

```
GET FILE='/data/GSS80.sav'
  /KEEP ABDEFECT TO ABSINGLE.
FACTOR VARIABLES=ABDEFECT TO ABSINGLE
  /MATRIX OUT(COR='/data/cormtx.sav').
```

- `FACTOR` retrieves the *GSS80.sav* file and writes a factor correlation matrix to the file *cormtx.sav*.
- The active dataset is still *GSS80.sav*. Subsequent commands will be executed on this file.

Example: Factor Correlation Matrix Output Replacing Active Dataset

```
GET FILE='/data/GSS80.sav'
```

```
  /KEEP ABDEFECT TO ABSINGLE.
FACTOR VARIABLES=ABDEFECT TO ABSINGLE
  /MATRIX OUT(COR=*).
LIST.
```

- FACTOR writes the same matrix as in the previous example.
- The active dataset is replaced with the correlation matrix. The LIST command is executed on the matrix file, not on *GSS80*.

Example: Factor-Loading Matrix Output Replacing Active Dataset

```
GET FILE='/dataGSS80.sav'
  /KEEP ABDEFECT TO ABSINGLE.
FACTOR VARIABLES=ABDEFECT TO ABSINGLE
  /MATRIX OUT(FAC=*).
```

- FACTOR generates a factor-loading matrix that replaces the active dataset.

Example: Matrix Input from active dataset

```
GET FILE='/data/country.sav'
  /KEEP SAVINGS POP15 POP75 INCOME GROWTH.
REGRESSION MATRIX OUT(*)
  /VARS=SAVINGS TO GROWTH
  /MISS=PAIRWISE
  /DEP=SAVINGS /ENTER.
FACTOR MATRIX IN(COR=*) /MISSING=PAIRWISE.
```

- The GET command retrieves the *country.sav* file and selects the variables needed for the analysis.
- The REGRESSION command computes correlations among five variables with pairwise deletion. MATRIX=OUT writes a matrix data file, which replaces the active dataset.
- MATRIX IN(COR=*) on FACTOR reads the matrix materials REGRESSION has written to the active dataset. An asterisk is specified because the matrix materials are in the active dataset. FACTOR uses pairwise deletion, since this is what was in effect when the matrix was built.

Example: Matrix Input from External File

```
GET FILE='/data/country.sav'
  /KEEP SAVINGS POP15 POP75 INCOME GROWTH.
REGRESSION
  /VARS=SAVINGS TO GROWTH
  /MISS=PAIRWISE
  /DEP=SAVINGS /ENTER.
FACTOR MATRIX IN(COR=CORMTX).
```

- This example performs a regression analysis on file *country.sav* and then uses a different file for FACTOR. The file is an existing matrix data file.
- MATRIX=IN specifies the matrix data file *CORMTX*.
- *CORMTX* does not replace *country.sav* as the active dataset.

Example: Matrix Input from active dataset

```
GET FILE='/data/cormtx.sav'.
FACTOR MATRIX IN(COR=*).
```

- This example starts a new session and reads an existing matrix data file. GET retrieves the matrix data file *cormtx.sav*.
- MATRIX=IN specifies an asterisk because the matrix data file is the active dataset. If MATRIX=IN(cormtx.sav) is specified, the program issues an error message.
- If the GET command is omitted, the program issues an error message.

Example: Using Saved Coefficients to Score an External File

```
MATRIX.
GET A /FILE="fsc.sav".
GET B /FILE="ext_data.sav" /VAR=varlist.
COMPUTE SCORES=A*B.
SAVE SCORES /OUTFILE="scored.sav".
END MATRIX.
```

- This example scores an external file using the factor score coefficients from a previous analysis.
- Factor score coefficients are read from *fsc.sav* into *A*.
- The data are read from *ext_data.sav* into *B*. The variable values in the external file should be standardized. If there are missing values, add /MISSING=OMIT or /MISSING=0 to the second GET statement to remove cases with missing values or impute the mean (0, since the variables are standardized).
- The scores are saved to *scored.sav*.

FILE HANDLE

```
FILE HANDLE handle /NAME='path and/or file specifications'
                  [/MODE={CHARACTER }] [/RECFORM={FIXED   } [/LRECL=n]
                         {BINARY    }            {VARIABLE}
                         {MULTIPUNCH}            {SPANNED }
                         {IMAGE     }
                         {360       }
                  [/ENCODING = 'encoding specification']
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Release History

Release 13.0

- The NAME subcommand is modified to accept a path and/or file.

Release 16.0

- ENCODING subcommand added for Unicode support.

Example

```
FILE HANDLE thisMonthFile /NAME='/sales/data/july.sav'.
FILE HANDLE dataDirectory /NAME='/sales/data'.
GET FILE 'thisMonthFile'.
GET FILE 'dataDirectory/july.sav'.
```

Overview

FILE HANDLE assigns a unique *file handle* to a path and/or file and supplies operating system specifications for the file. A defined file handle can be specified on any subsequent FILE, OUTFILE, MATRIX, or WRITE subcommands of various procedures.

Syntax Rules

- FILE HANDLE is required for reading data files with record lengths greater than 8,192. For more information, see LRECL Subcommand on p. 668.
- FILE HANDLE is required for reading IBM VSAM datasets, EBCDIC data files, binary data files, and character data files that are not delimited by ASCII line feeds.
- If you specify 360 on the MODE subcommand, you must specify RECFORM.
- If you specify IMAGE on the MODE subcommand, you must specify LRECL.

Operations

A file handle is used only during the current session. The handle is never saved as part of an SPSS-format data file. The normal quoting conventions for file specifications apply, with or without file handles.

Example

```
FILE HANDLE thisMonthFile /NAME='/sales/data/july.sav'.
FILE HANDLE dataDirectory /NAME='/sales/data'.
GET FILE 'thisMonthFile'.
GET FILE 'dataDirectory/july.sav'.
```

- The first FILE HANDLE command defines a file handle that refers to a specific file.
- The second FILE HANDLE command only specifies a directory path.
- The two subsequent GET FILE commands are functionally equivalent. Note that both file specifications are enclosed in quotes (a good general practice).

NAME Subcommand

NAME specifies the path and/or file you want to refer to by the file handle. The file specifications must conform to the file naming convention for the type of computer and operating system on which the program is run. See the documentation for your system for specific information about the file naming convention.

If NAME specifies a relative path or does not include a path, the path is set to the current working directory at the time the FILE HANDLE command is executed.

MODE Subcommand

MODE specifies the type of file you want to refer to by the file handle.

CHARACTER	*Character file whose logical records are delimited by ASCII line feeds.*
BINARY	*Unformatted binary file generated by Microsoft FORTRAN.*
MULTIPUNCH	*Column binary file.*
IMAGE	*Binary file consisting of fixed-length records.*
360	*EBCDIC data file.*

Example

```
FILE HANDLE ELE48 /NAME='/data/ELE48.DAT' /MODE=MULTIPUNCH.
DATA LIST FILE=ELE48.
```

- FILE HANDLE defines *ELE48* as the handle for the file.
- The MODE subcommand indicates that the file contains multipunch data.
- The file specification on NAME conforms to VMS convention: the file *ELE48.DAT* is located in the directory *data*.
- The FILE subcommand on DATA LIST refers to the handle defined on the FILE HANDLE command.

RECFORM Subcommand

RECFORM specifies the record format and is necessary when you specify 360 on MODE. RECFORM has no effect with other specifications on MODE.

FIXED	*Fixed-length record.* All records have the same length. Alias F. When FIXED is specified, the record length must be specified on the LRECL subcommand.
VARIABLE	*Variable-length record.* No logical record is larger than one physical block. Alias V.
SPANNED	*Spanned record.* Records may be larger than fixed-length physical blocks. Alias VS.

LRECL Subcommand

LRECL specifies the length of each record in the file. When you specify IMAGE under UNIX, OS/2, or Microsoft Windows, or 360 for IBM360 EBCDIC data files, you must specify LRECL. You can specify a record length greater than the default (8,192) for an image file, a character file, or a binary file. The maximum record length is 2,147,483,647. Do not use LRECL with MULTIPUNCH.

Example

```
FILE HANDLE TRGT1 /NAME='/data/RGT.DAT'
                  /MODE=IMAGE LRECL=16.
DATA LIST FILE=TRGT1.
```

- IMAGE is specified on the MODE subcommand. Subcommand LRECL must be specified.
- The file handle is used on the DATA LIST command.

ENCODING Subcommand

ENCODING specifies the encoding format of the file. The keyword is followed by an equals sign and a quoted encoding specification.

- In Unicode mode, the default is UTF8. For more information, see SET command, UNICODE subcommand.
- In code page mode, the default is the current locale setting. For more information, see SET command, LOCALE subcommand.
- The quoted encoding value can be: Locale (the current locale setting), UTF8, UTF16, UTF16BE (big endian), UTF16LE (little endian), a numeric Windows code page value (for example, '1252'), or an IANA code page value (for example, 'iso8859-1' or cp1252).
- In Unicode mode, the defined width of string variables is tripled for code page and UTF-16 text data files. Use ALTER TYPE to automatically adjust the defined width of string variables.

FILE LABEL

```
FILE LABEL label text
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Example

```
FILE LABEL Original survey responses prior to recoding.
```

Overview

FILE LABEL provides a descriptive label for a data file.

Basic Specification

The basic specification is the command name followed by the label text.

Syntax Rules

- The label text cannot exceed 64 bytes.
- Labels do not need to be enclosed in quotes.
- If the label is enclosed in quotes—or starts with a quotation mark (single or double)—standard rules for quoted strings apply. For more information, see String Values in Command Specifications on p. 35.

Operations

- If the file is saved as an SPSS-format data file, the label is saved in the dictionary.
- The file label is displayed in the Notes tables generated by procedures.
- An SPSS data file can only contain one file label. Subsequent FILE LABEL commands replace the label text.

Example

```
FILE LABEL Respondent's original data.
FILE LABEL "Respondent's original data".
FILE LABEL 'Respondent's original data.'
```

- The first two commands are functionally equivalent. The enclosing double-quotes in the second command are not included as part of the label text, and the apostrophe (single quote) is preserved.
- In the last command, everything after the apostrophe in *Respondent's* will be omitted from the label because the apostrophe will be interpreted as the closing single quote to match the opening single quote.

FILE TYPE-END FILE TYPE

For mixed file types:

```
FILE TYPE MIXED [FILE='file'] [ENCODING='encoding specification']
  RECORD=[varname] column location [(format)]

  [WILD={NOWARN}]
        {WARN  }
```

For grouped file types:

```
FILE TYPE GROUPED [FILE='file'] [ENCODING='encoding specification']
  RECORD=[varname] column location [(format)]

 CASE=[varname] column location [(format)]

 [WILD={WARN  }] [DUPLICATE={WARN  }]
       {NOWARN}             {NOWARN}

 [MISSING={WARN  }] [ORDERED={YES}]
          {NOWARN}           {NO }
```

For nested file types:

```
FILE TYPE NESTED [FILE='file'] [ENCODING='encoding specification']
  RECORD=[varname] column location [(format)]

 [CASE=[varname] column location [(format)]]

 [WILD={NOWARN}] [DUPLICATE={NOWARN}]
       {WARN  }             {WARN  }
                            {CASE  }

 [MISSING={NOWARN}]
          {WARN  }

END FILE TYPE
```

Release History

Release 16.0

- ENCODING subcommand added for Unicode support.

Example

```
FILE TYPE  MIXED RECORD=RECID 1-2.
RECORD TYPE 23.
DATA LIST   /SEX 5 AGE 6-7 DOSAGE 8-10 RESULT 12.
END FILE TYPE.

BEGIN DATA
21  145010 1
22  257200 2
25  235  250  2
35  167          300    3
24  125150 1
23  272075 1
21  149050 2
25  134  035  3
30  138          300    3
```

```
32  229          500    3
END DATA.
```

Overview

The FILE TYPE-END FILE TYPE structure defines data for any one of the three types of complex raw data files: **mixed files**, which contain several types of records that define different types of cases; **hierarchical** or **nested files**, which contain several types of records with a defined relationship among the record types; or **grouped files**, which contain several records for each case with some records missing or duplicated. A fourth type of complex file, files with **repeating groups** of information, can be defined with the REPEATING DATA command.

FILE TYPE must be followed by at least one RECORD TYPE command and one DATA LIST command. Each pair of RECORD TYPE and DATA LIST commands defines one type of record in the data. END FILE TYPE signals the end of file definition.

Within the FILE TYPE structure, the lowest-level record in a nested file can be read with a REPEATING DATA command rather than a DATA LIST command. In addition, any record in a mixed file can be read with REPEATING DATA.

Basic Specification

The basic specification on FILE TYPE is one of the three file type keywords (MIXED, GROUPED, or NESTED) and the RECORD subcommand. RECORD names the record identification variable and specifies its column location. If keyword GROUPED is specified, the CASE subcommand is also required. CASE names the case identification variable and specifies its column location.

The FILE TYPE-END FILE TYPE structure must enclose at least one RECORD TYPE and one DATA LIST command. END FILE TYPE is required to signal the end of file definition.

- RECORD TYPE specifies the values of the record type identifier (see RECORD TYPE).
- DATA LIST defines variables for the record type specified on the preceding RECORD TYPE command (see DATA LIST).
- Separate pairs of RECORD TYPE and DATA LIST commands must be used to define each different record type.

The resulting active dataset is always a rectangular file, regardless of the structure of the original data file.

Syntax Rules

- For mixed files, if the record types have different variables or if they have the same variables recorded in different locations, separate RECORD TYPE and DATA LIST commands are required for each record type.
- For mixed files, the same variable name can be used on different DATA LIST commands, since each record type defines a separate case.
- For mixed files, if the same variable is defined for more than one record type, the format type and length of the variable should be the same on all DATA LIST commands. The program refers to the *first* DATA LIST command that defines a variable for the print and write formats to include in the dictionary of the active dataset.

- For grouped and nested files, the variable names on each DATA LIST must be unique, since a case is built by combining all record types together into a single record.
- For nested files, the order of the RECORD TYPE commands defines the hierarchical structure of the file. The first RECORD TYPE defines the highest-level record type, the next RECORD TYPE defines the next highest-level record, and so forth. The last RECORD TYPE command defines a case in the active dataset. By default, variables from higher-level records are spread to the lowest-level record.
- For nested files, the SPREAD subcommand on RECORD TYPE can be used to spread the values in a record type only to the *first* case built from each record of that type. All other cases associated with that record are assigned the system-missing value for the variables defined on that type. See RECORD TYPE for more information.
- String values specified on the RECORD TYPE command must be enclosed in quotes.

Operations

- For mixed file types, the program skips all records that are not specified on one of the RECORD TYPE commands.
- If different variables are defined for different record types in mixed files, the variables are assigned the system-missing value for those record types on which they are not defined.
- For nested files, the first record in the file should be the type specified on the first RECORD TYPE command—the highest level of the hierarchy. If the first record in the file is not the highest-level type, the program skips all records until it encounters a record of the highest-level type. If MISSING or DUPLICATE has been specified, these records may produce warning messages but will not be used to build a case in the active dataset.
- When defining complex files, you are effectively building an input program and can use only commands that are allowed in the input state.

Examples

Reading multiple record types from a mixed file

```
FILE TYPE  MIXED FILE='/data/treatmnt.txt' RECORD=RECID 1-2.
+ RECORD TYPE 21,22,23,24.
+ DATA LIST   /SEX 5 AGE 6-7 DOSAGE 8-10 RESULT 12.
+ RECORD TYPE 25.
+ DATA LIST   /SEX 5 AGE 6-7 DOSAGE 10-12 RESULT 15.
END FILE TYPE.
```

- Variable *DOSAGE* is read from columns 8–10 for record types 21, 22, 23, and 24 and from columns 10–12 for record type 25. *RESULT* is read from column 12 for record types 21, 22, 23, and 24, and from column 15 for record type 25.
- The active dataset contains values for all variables defined on the DATA LIST commands for record types 21 through 25. All other record types are skipped.

Reading only one record type from a mixed file

```
FILE TYPE  MIXED RECORD=RECID 1-2.
RECORD TYPE 23.
DATA LIST   /SEX 5 AGE 6-7 DOSAGE 8-10 RESULT 12.
```

```
END FILE TYPE.

BEGIN DATA
21  145010 1
22  257200 2
25  235  250  2
35  167          300    3
24  125150 1
23  272075 1
21  149050 2
25  134  035  3
30  138          300    3
32  229          500    3
END DATA.
```

- FILE TYPE begins the file definition and END FILE TYPE indicates the end of file definition. FILE TYPE specifies a mixed file type. Since the data are included between BEGIN DATA-END DATA, the FILE subcommand is omitted. The record identification variable *RECID* is located in columns 1 and 2.
- RECORD TYPE indicates that records with value 23 for variable *RECID* will be copied into the active dataset. All other records are skipped. the program does not issue a warning when it skips records in mixed files.
- DATA LIST defines variables on records with the value 23 for variable *RECID*.

A grouped file of student test scores

```
FILE TYPE GROUPED RECORD=#TEST 6 CASE=STUDENT 1-4.
RECORD TYPE 1.
DATA LIST  /ENGLISH 8-9 (A).
RECORD TYPE 2.
DATA LIST /READING 8-10.
RECORD TYPE 3.
DATA LIST /MATH 8-10.
END FILE TYPE.

BEGIN DATA
0001 1 B+
0001 2  74
0001 3  83
0002 1 A
0002 2 100
0002 3  71
0003 1 B-
0003 2  88
0003 3  81
0004 1 C
0004 2  94
0004 3  91
END DATA.
```

- FILE TYPE identifies the file as a grouped file. As required for grouped files, all records for a single case are together in the data. The record identification variable *#TEST* is located in column 6. A scratch variable is specified so it won't be saved in the active dataset. The case identification variable *STUDENT* is located in columns 1–4.
- Because there are three record types, there are three RECORD TYPE commands. For each RECORD TYPE, there is a DATA LIST to define variables on that record type.
- END FILE TYPE signals the end of file definition.

- The program builds four cases—one for each student. Each case includes the case identification variable plus the variables defined for each record type (the test scores). The values for *#TEST* are not saved in the active dataset. Thus, each case in the active dataset has four variables: *STUDENT*, *ENGLISH*, *READING*, and *MATH*.

A nested file of accident records

```
FILE TYPE NESTED RECORD=6 CASE=ACCID 1-4.
RECORD TYPE 1.
DATA LIST /ACC_ID 9-11 WEATHER 12-13 STATE 15-16 (A) DATE 18-24 (A).
RECORD TYPE 2.
DATA LIST /STYLE 11 MAKE 13 OLD 14 LICENSE 15-16(A) INSURNCE 18-21 (A).
RECORD TYPE 3.
DATA LIST /PSNGR_NO 11 AGE 13-14 SEX 16 (A) INJURY 18 SEAT 20-21 (A)
          COST 23-24.
END FILE TYPE.

BEGIN DATA
0001 1  322 1 IL 3/13/88   /* Type 1:  accident record
0001 2    1 44MI 134M      /* Type 2:    vehicle record
0001 3    1 34 M 1 FR  3   /* Type 3:      person record
0001 2    2 16IL 322F      /*            vehicle record
0001 3    1 22 F 1 FR 11   /*              person record
0001 3    2 35 M 1 FR  5   /*              person record
0001 3    3 59 M 1 BK  7   /*              person record
0001 2    3 21IN 146M      /*            vehicle record
0001 3    1 46 M 0 FR  0   /*              person record
END DATA.
```

- `FILE TYPE` specifies a nested file type. The record identifier, located in column 6, is not assigned a variable name, so the default scratch variable name *####RECD* is used. The case identification variable *ACCID* is located in columns 1–4.
- Because there are three record types, there are three `RECORD TYPE` commands. For each `RECORD TYPE`, there is a `DATA LIST` command to define variables on that record type. The order of the `RECORD TYPE` commands defines the hierarchical structure of the file.
- `END FILE TYPE` signals the end of file definition.
- The program builds a case for each lowest-level (type 3) record, representing each person in the file. There can be only one type 1 record for each type 2 record, and one type 2 record for each type 3 record. Each vehicle can be in only one accident, and each person can be in only one vehicle. The variables from the type 1 and type 2 records are spread to their corresponding type 3 records.

Specification Order

- `FILE TYPE` must be the first command in the `FILE TYPE-END FILE TYPE` structure. `FILE TYPE` subcommands can be named in any order.
- Each `RECORD TYPE` command must precede its corresponding `DATA LIST` command.
- `END FILE TYPE` must be the last command in the structure.

Types of Files

The first specification on FILE TYPE is a file type keyword, which defines the structure of the data file. There are three file type keywords: MIXED, GROUPED, and NESTED. Only one of the three types can be specified on FILE TYPE.

MIXED *Mixed file type.* MIXED specifies a file in which each record type named on a RECORD TYPE command defines a case. You do not need to define all types of records in the file. In fact, FILE TYPE MIXED is useful for reading only one type of record because the program can decide whether to execute the DATA LIST for a record by simply reading the variable that identifies the record type.

GROUPED *Grouped file type.* GROUPED defines a file in which cases are defined by grouping together record types with the same identification number. Each case usually has one record of each type. All records for a single case must be together in the file. By default, the program assumes that the records are in the same sequence within each case.

NESTED *Nested file type.* NESTED defines a file in which the record types are related to each other hierarchically. The record types are grouped together by a case identification number that identifies the highest level—the first record type—of the hierarchy. Usually, the last record type specified—the lowest level of the hierarchy—defines a case. For example, in a file containing household records and records for each person living in the household, each person record defines a case. Information from higher record types may be *spread* to each case. For example, the value for a variable on the household record, such as *CITY*, can be spread to the records for each person in the household.

Subcommands and Their Defaults for Each File Type

The specifications on the FILE TYPE differ for each type of file. The following table shows whether each subcommand is required or optional and, where applicable, what the default specification is for each file type. N/A indicates that the subcommand is not applicable to that type of file.

Table 79-1
Summary of FILE TYPE subcommands for different file types

Subcommand	Mixed	Grouped	Nested
FILE	Conditional	Conditional	Conditional
RECORD	Required	Required	Required
CASE	Not Applicable	Required	Optional
WILD	NOWARN	WARN	NOWARN
DUPLICATE	N/A	WARN	NOWARN
MISSING	N/A	WARN	NOWARN
ORDERED	N/A	YES	N/A

- FILE is required unless data are inline (included between BEGIN DATA-END DATA).
- RECORD is always required.
- CASE is required for grouped files.
- The subcommands CASE, DUPLICATE, and MISSING can also be specified on the associated RECORD TYPE commands for grouped files. However, DUPLICATE=CASE is invalid.

- For nested files, CASE and MISSING can be specified on the associated RECORD TYPE commands.
- If the subcommands CASE, DUPLICATE, or MISSING are specified on a RECORD TYPE command, the specification on the FILE TYPE command (or the default) is overridden only for the record types listed on that RECORD TYPE command. The FILE TYPE specification or default applies to all other record types.

FILE Subcommand

FILE specifies a text file containing the data. FILE is not used when the data are inline.

Example

```
FILE TYPE  MIXED FILE='/data/treatmnt.txt' RECORD=RECID 1-2.
```

- Data are in the file *treatmnt.txt*. The file type is mixed. The record identification variable *RECID* is located in columns 1 and 2 of each record.

ENCODING Subcommand

ENCODING specifies the encoding format of the file. The keyword is followed by an equals sign and a quoted encoding specification.

- In Unicode mode, the default is UTF8. For more information, see SET command, UNICODE subcommand.
- In code page mode, the default is the current locale setting. For more information, see SET command, LOCALE subcommand.
- The quoted encoding value can be: Locale (the current locale setting), UTF8, UTF16, UTF16BE (big endian), UTF16LE (little endian), a numeric Windows code page value (for example, '1252'), or an IANA code page value (for example, 'iso8859-1' or cp1252).
- In Unicode mode, the defined width of string variables is tripled for code page and UTF-16 text data files. Use ALTER TYPE to automatically adjust the defined width of string variables.
- If there is no FILE subcommand, the ENCODING subcommand is ignored.

RECORD Subcommand

RECORD specifies the name and column location of the record identification variable.

- The column location of the record identifier is required. The variable name is optional.
- If you do not want to save the record type variable, you can assign a scratch variable name by using the # character as the first character of the name. If a variable name is not specified on RECORD, the record identifier is defined as the scratch variable *####RECD*.

- The value of the identifier for each record type must be unique and must be in the same location on all records. However, records do not have to be sorted according to type.
- A column-style format can be specified for the record identifier. For example, the following two specifications are valid:

```
RECORD=V1 1-2(N)
RECORD=V1 1-2(F,1)
```

FORTRAN-like formats cannot be used because the column location must be specified explicitly.

- Specify A in parentheses after the column location to define the record type variable as a string variable.

Example

```
FILE TYPE  MIXED FILE='/data/treatmnt.txt' RECORD=RECID 1-2.
```

- The record identifier is variable *RECID*, located in columns 1 and 2 of the hospital treatment data file.

CASE Subcommand

CASE specifies a name and column location for the case identification variable. CASE is required for grouped files and optional for nested files. It cannot be used with mixed files.

- For grouped files, each unique value for the case identification variable defines a case in the active dataset.
- For nested files, the case identification variable identifies the highest-level record of the hierarchy. The program issues a warning message for each record with a case identification number not equal to the case identification number on the last highest-level record. However, the record with the invalid case number is used to build the case.
- The column location of the case identifier is required. The variable name is optional.
- If you do not want to save the case identification variable, you can assign a scratch variable name by using the # character as the first character of the name. If a variable name is not specified on CASE, the case identifier is defined as the scratch variable *####CASE*.
- A column-style format can be specified for the case identifier. For example, the following two specifications are valid:

```
CASE=V1 1-2(N)
CASE=V1 1-2(F,1)
```

FORTRAN-like formats cannot be used because the column location must be specified explicitly.

- Specify A in parentheses after the column location to define the case identification variable as a string variable.
- If the case identification number is not in the same columns on all record types, use the CASE subcommand on the RECORD TYPE commands as well as on the FILE TYPE command (see RECORD TYPE).

Example

```
* A grouped file of student test scores.

FILE TYPE GROUPED RECORD=#TEST 6 CASE=STUDENT 1-4.
RECORD TYPE 1.
DATA LIST  /ENGLISH 8-9 (A).
RECORD TYPE 2.
DATA LIST /READING 8-10.
RECORD TYPE 3.
DATA LIST /MATH 8-10.
END FILE TYPE.

BEGIN DATA
0001 1 B+
0001 2  74
0001 3  83
0002 1 A
0002 2 100
0002 3  71
0003 1 B-
0003 2  88
0003 3  81
0004 1 C
0004 2  94
0004 3  91
END DATA.
```

- CASE is required for grouped files. CASE specifies variable *STUDENT*, located in columns 1–4, as the case identification variable.
- The data contain four different values for *STUDENT*. The active dataset therefore has four cases, one for each value of *STUDENT*. In a grouped file, each unique value for the case identification variable defines a case in the active dataset.
- Each case includes the case identification variable plus the variables defined for each record type. The values for *#TEST* are not saved in the active dataset. Thus, each case in the active dataset has four variables: *STUDENT, ENGLISH, READING*, and *MATH*.

Example

```
* A nested file of accident records.

FILE TYPE NESTED RECORD=6 CASE=ACCID 1-4.
RECORD TYPE 1.
DATA LIST   /ACC_ID 9-11 WEATHER 12-13 STATE 15-16 (A) DATE 18-24 (A).
RECORD TYPE 2.
DATA LIST /STYLE 11 MAKE 13 OLD 14 LICENSE 15-16 (A) INSURNCE 18-21 (A).
RECORD TYPE 3.
DATA LIST /PSNGR_NO 11 AGE 13-14 SEX 16 (A) INJURY 18 SEAT 20-21 (A)
           COST 23-24.
END FILE TYPE.

BEGIN DATA
0001 1  322 1 IL 3/13/88   /* Type 1:  accident record
0001 2    1 44MI 134M      /* Type 2:    vehicle record
0001 3    1 34 M 1 FR  3   /* Type 3:       person record
0001 2    2 16IL 322F      /*            vehicle record
0001 3    1 22 F 1 FR 11   /*               person record
0001 3    2 35 M 1 FR  5   /*               person record
0001 3    3 59 M 1 BK  7   /*               person record
0001 2    3 21IN 146M      /*            vehicle record
0001 3    1 46 M 0 FR  0   /*               person record
```

```
END DATA.
```

- CASE specifies variable *ACCID*, located in columns 1–4, as the case identification variable. *ACCID* identifies the highest level of the hierarchy: the level for the accident records.
- As each case is built, the value of the variable *ACCID* is checked against the value of *ACCID* on the last highest-level record (record type 1). If the values do not match, a warning message is issued. However, the record is used to build the case.
- The data in this example contain only one value for *ACCID*, which is spread across all cases. In a nested file, the lowest-level record type determines the number of cases in the active dataset. In this example, the active dataset has five cases because there are five person records.

Example

```
* Specifying case on the RECORD TYPE command.

FILE TYPE GROUPED FILE=HUBDATA RECORD=#RECID 80 CASE=ID 1-5.
RECORD TYPE 1.
DATA LIST   /MOHIRED YRHIRED 12-15 DEPT79 TO DEPT82 SEX 16-20.
RECORD TYPE 2.
DATA LIST   /SALARY79 TO SALARY82 6-25 HOURLY81 HOURLY82 40-53 (2)
            PROMO81 72  AGE 54-55 RAISE82 66-70.
RECORD TYPE 3  CASE=75-79.
DATA LIST   /JOBCAT 6 NAME 25-48 (A).
END FILE TYPE.
```

- The CASE subcommand on FILE TYPE indicates that the case identification number is located in columns 1–5. However, for type 3 records, the case identification number is located in columns 75–79. The CASE subcommand is therefore specified on the third RECORD TYPE command to override the case setting for type 3 records.
- The format of the case identification variable must be the same on all records. If the case identification variable is defined as a string on the FILE TYPE command, it cannot be defined as a numeric variable on the RECORD TYPE command, and vice versa.

WILD Subcommand

WILD determines whether the program issues a warning when it encounters undefined record types in the data file. Regardless of whether the warning is issued, undefined records are not included in the active dataset.

- The only specification on WILD is keyword WARN or NOWARN.
- WARN cannot be specified if keyword OTHER is specified on the last RECORD TYPE command to indicate all other record types (see RECORD TYPE).

WARN *Issue warning messages.* The program displays a warning message and the first 80 characters of the record for each record type that is not mentioned on a RECORD TYPE command. This is the default for grouped file types.

NOWARN *Suppress warning messages.* The program simply skips all record types not mentioned on a RECORD TYPE command and does not display warning messages. This is the default for mixed and nested file types.

Example

```
FILE TYPE  MIXED FILE='/data/treatmnt.txt' RECORD=RECID 1-2 WILD=WARN.
```

- WARN is specified on the WILD subcommand. The program displays a warning message and the first 80 characters of the record for each record type that is not mentioned on a RECORD TYPE command.

DUPLICATE Subcommand

DUPLICATE determines how the program responds when it encounters more than one record of each type for a single case. DUPLICATE is optional for grouped and nested files. DUPLICATE cannot be used with mixed files.

- The only specification on DUPLICATE is keyword WARN, NOWARN, or CASE.

WARN *Issue warning messages.* The program displays a warning message and the first 80 characters of the last record of the duplicate set of record types. Only the *last* record from a set of duplicates is included in the active dataset. This is the default for grouped files.

NOWARN *Suppress warning messages.* The program does not display warning messages when it encounters duplicate record types. Only the *last* record from a set of duplicates is included in the active dataset. This is the default for nested files.

CASE *Build a case in the active dataset for each duplicate record.* The program builds one case in the active dataset for each duplicate record, spreading information from any higher-level records and assigning system-missing values to the variables defined on lower-level records. This option is available only for nested files.

Example

```
* A nested file of accident records.
* Issue a warning for duplicate record types.

FILE TYPE NESTED RECORD=6 CASE=ACCID 1-4 DUPLICATE=WARN.
RECORD TYPE 1.
DATA LIST   /ACC_ID 9-11 WEATHER 12-13 STATE 15-16 (A) DATE 18-24 (A).
RECORD TYPE 2.
DATA LIST /STYLE 11 MAKE 13 OLD 14 LICENSE 15-16 (A) INSURNCE 18-21 (A).
RECORD TYPE 3.
DATA LIST /PSNGR_NO 11 AGE 13-14 SEX 16 (A) INJURY 18 SEAT 20-21 (A)
          COST 23-24.
END FILE TYPE.

BEGIN DATA
0001 1  322 1 IL 3/13/88   /*          accident record
0001 2    1 44MI 134M      /*            vehicle record
0001 3    1 34 M 1 FR  3   /*               person record
0001 2    1 31IL 134M      /*  duplicate vehicle record
0001 2    2 16IL 322F      /*            vehicle record
0001 3    1 22 F 1 FR 11   /*               person record
0001 3    2 35 M 1 FR  5   /*               person record
0001 3    3 59 M 1 BK  7   /*               person record
0001 2    3 21IN 146M      /*            vehicle record
0001 3    1 46 M 0 FR  0   /*               person record
END DATA.
```

- In the data, there are two vehicle (type 2) records above the second set of person (type 3) records. This implies that an empty (for example, parked) vehicle was involved, or that each of the three persons was in two vehicles, which is impossible.
- DUPLICATE specifies keyword WARN. The program displays a warning message and the first 80 characters of the second of the duplicate set of type 2 records. The first duplicate record is skipped, and only the second is included in the active dataset. This assumes that no empty vehicles were involved in the accident.
- If the duplicate record represents an empty vehicle, it can be included in the active dataset by specifying keyword CASE on DUPLICATE. The program builds one case in the active dataset for the first duplicate record, spreading information to that case from the previous type 1 record and assigning system-missing values to the variables defined for type 3 records. The second record from the duplicate set is used to build the three cases for the associated type 3 records.

MISSING Subcommand

MISSING determines whether the program issues a warning when it encounters a missing record type for a case. Regardless of whether the program issues the warning, it builds the case in the active dataset with system-missing values for the variables defined on the missing record. MISSING is optional for grouped and nested files.

- MISSING cannot be used with mixed files and is optional for grouped and nested files.
- For grouped and nested files, the program verifies that each defined case includes one record of each type.
- The only specification is keyword WARN or NOWARN.

WARN *Issue a warning message when a record type is missing for a case.* This is the default for grouped files.

NOWARN *Suppress the warning message when a record type is missing for a case.* This is the default for nested files.

Example

```
* A grouped file with missing records.

FILE TYPE GROUPED RECORD=#TEST 6 CASE=STUDENT 1-4 MISSING=NOWARN.
RECORD TYPE 1.
DATA LIST  /ENGLISH 8-9 (A).
RECORD TYPE 2.
DATA LIST /READING 8-10.
RECORD TYPE 3.
DATA LIST /MATH 8-10.
END FILE TYPE.

BEGIN DATA
0001 1 B+
0001 2  74
0002 1 A
0002 2 100
0002 3  71
0003 3  81
0004 1 C
0004 2  94
0004 3  91
```

```
END DATA.
```

- The data contain records for three tests administered to four students. However, not all students took all tests. The first student took only the English and reading tests. The third student took only the math test.
- One case in the active dataset is built for each of the four students. If a student did not take a test, the system-missing value is assigned in the active dataset to the variable for the missing test. Thus, the first student has the system-missing value for the math test, and the third student has missing values for the English and reading tests.
- Keyword NOWARN is specified on MISSING. Therefore, no warning messages are issued for the missing records.

Example

```
* A nested file with missing records.

FILE TYPE NESTED RECORD=6 CASE=ACCID 1-4 MISSING=WARN.
RECORD TYPE 1.
DATA LIST   /ACC_ID 9-11 WEATHER 12-13 STATE 15-16 (A) DATE 18-24 (A).
RECORD TYPE 2.
DATA LIST /STYLE 11 MAKE 13 OLD 14 LICENSE 15-16 (A) INSURNCE 18-21 (A).
RECORD TYPE 3.
DATA LIST /PSNGR_NO 11 AGE 13-14 SEX 16 (A) INJURY 18 SEAT 20-21 (A)
           COST 23-24.
END FILE TYPE.

BEGIN DATA
0001 1  322 1 IL 3/13/88   /*          accident record
0001 3    1 34 M 1 FR  3   /*               person record
0001 2    2 16IL 322F      /*            vehicle record
0001 3    1 22 F 1 FR 11   /*               person record
0001 3    2 35 M 1 FR  5   /*               person record
0001 3    3 59 M 1 BK  7   /*               person record
0001 2    3 21IN 146M      /*            vehicle record
0001 3    1 46 M 0 FR  0   /*               person record
END DATA.
```

- The data contain records for one accident. The first record is a type 1 (accident) record, and the second record is a type 3 (person) record. However, there is no type 2 record, and therefore no vehicle associated with the first person. The person may have been a pedestrian, but it is also possible that the vehicle record is missing.
- One case is built for each person record. The first case has missing values for the variables specified on the vehicle record.
- Keyword WARN is specified on MISSING. A warning message is issued for the missing record.

ORDERED Subcommand

ORDERED indicates whether the records are in the same order as they are defined on the RECORD TYPE commands. Regardless of the order of the records in the data file and the specification on ORDERED, the program builds cases in the active dataset with records in the order defined on the RECORD TYPE commands.

- ORDERED can be used only for grouped files.

- The only specification is keyword YES or NO.
- If YES is in effect but the records are not in the order defined on the RECORD TYPE commands, the program issues a warning for each record that is out of order. The program still uses these records to build cases.

YES *Records for each case are in the same order as they are defined on the RECORD TYPE commands.* This is the default.

NO *Records are not in the same order within each case.*

Example

```
* A grouped file with records out of order.

FILE TYPE GROUPED RECORD=#TEST 6 CASE=STUDENT 1-4  MISSING=NOWARN
  ORDERED=NO.
RECORD TYPE 1.
DATA LIST  /ENGLISH 8-9 (A).
RECORD TYPE 2.
DATA LIST /READING 8-10.
RECORD TYPE 3.
DATA LIST /MATH 8-10.
END FILE TYPE.

BEGIN DATA
0001 2  74
0001 1 B+
0002 3  71
0002 2 100
0002 1 A
0003 2  81
0004 2  94
0004 1 C
0004 3  91
END DATA.
```

- The first RECORD TYPE command specifies record type 1, the second specifies record type 2, and the third specifies record type 3. However, records for each case are not always ordered type 1, type 2, and type 3.
- NO is specified on ORDERED. The program builds cases without issuing a warning that they are out of order in the data.
- Regardless of whether YES or NO is in effect for ORDERED, the program builds cases in the active dataset in the same order specified on the RECORD TYPE commands.

FILTER

```
FILTER  {BY var}
        {OFF   }
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Example

```
FILTER BY SEX.
FREQUENCIES BONUS.
```

Overview

FILTER is used to exclude cases from program procedures without deleting them from the active dataset. When FILTER is in effect, cases with a zero or missing value for the specified variable are not used in program procedures. Those cases are not actually deleted and are available again if the filter is turned off. To see the current filter status, use the SHOW command.

Basic Specification

The basic specification is keyword BY followed by a variable name. Cases that have a zero or missing value for the filter variable are excluded from subsequent procedures.

Syntax Rules

- Only one numeric variable can be specified. The variable can be one of the original variables in the data file or a variable computed with transformation commands.
- Keyword OFF turns off the filter. All cases in the active dataset become available to subsequent procedures.
- If FILTER is specified without a keyword, FILTER OFF is assumed but the program displays a warning message.
- FILTER can be specified anywhere in the command sequence. Unlike SELECT IF, FILTER has the same effect within an input program as it does outside an input program. Attention must be paid to the placement of any transformation command used to compute values for the filter variable (see INPUT PROGRAM).

Operations

- FILTER performs case selection without changing the active dataset. Cases that have a zero or missing value are excluded from subsequent procedures but are not deleted from the file.
- Both system-missing and user-missing values are treated as missing. The FILTER command does not offer options for changing selection criteria. To set up different criteria for exclusion, create a numeric variable and conditionally compute its values before specifying it on FILTER.

- If FILTER is specified after TEMPORARY, FILTER affects the next procedure only. After that procedure, the filter status reverts to whatever it was before the TEMPORARY command.
- The filter status does not change until another FILTER command is specified, a USE command is specified, or the active dataset is replaced.
- FILTER and USE are mutually exclusive. USE automatically turns off any previous FILTER command, and FILTER automatically turns off any previous USE command.
- If the specified filter variable is renamed, it is still in effect. The SHOW command will display the new name of the filter variable. However, the filter is turned off if the filter variable is recoded into a string variable or is deleted from the file.
- If the active dataset is replaced after a MATCH FILES, ADD FILES, or UPDATE command and the active dataset is one of the input files, the filter remains in effect if the new active dataset has a numeric variable with the name of the filter variable. If the active dataset does not have a numeric variable with that name (for example, if the filter variable was dropped or renamed), the filter is turned off.
- If the active dataset is replaced by an entirely new data file (for example, by a DATA LIST, GET, or IMPORT command), the filter is turned off.
- The FILTER command changes the filter status and takes effect when a procedure is executed or an EXECUTE command is encountered.

Examples

Filter by a variable with values of 0 and 1

```
FILTER BY SEX.
FREQUENCIES BONUS.
```

- This example assumes that *SEX* is a numeric variable, with male and female coded as 0 and 1, respectively. The FILTER command excludes males and cases with missing values for *SEX* from the subsequent procedures. The FREQUENCIES command generates a frequency table of *BONUS* for females only.

Recoding the filter variable to change the filter criterion

```
RECODE SEX (1=0)(0=1).
FILTER BY SEX.
FREQUENCIES BONUS.
```

- This example assumes the same coding scheme for *SEX* as the previous example. Before FILTER is specified, variable *SEX* is recoded. The FILTER command then excludes females and cases with missing values for *SEX*. The FREQUENCIES command generates a frequency table of *BONUS* for males only.

FINISH

```
FINISH
```

Overview

FINISH causes the program to stop reading commands.

Operations

- FINISH immediately causes the program to stop reading commands.
- The appearance of FINISH on the printback of commands in the display file indicates that the session has been completed.

Example

```
DATA LIST FILE=RAWDATA /NAME 1-15(A) V1 TO V15 16-30.
LIST.
FINISH.
REPORT FORMAT=AUTO LIST /VARS=NAME V1 TO V10.
```

- FINISH causes the program to stop reading commands after LIST is executed. The REPORT command is not executed.

Basic Specification

The basic specification is keyword FINISH. There are no additional specifications.

Command Files

- FINISH is optional in a command file and is used to mark the end of a session.
- FINISH causes the program to stop reading commands. Anything following FINISH in the command file is ignored. Any commands following FINISH in an INCLUDE file are ignored.
- FINISH cannot be used within a DO IF structure to end a session conditionally. FINISH within a DO IF structure will end the session unconditionally.

Prompted Sessions

- FINISH is required in a prompted session to terminate the session.
- Because FINISH is a program command, it can be used only after the command line prompt for the program, which expects a procedure name. FINISH cannot be used to end a prompted session from a DATA>, CONTINUE>, HELP>, or DEFINE> prompt.

FIT

```
FIT [[ERRORS=] residual series names]

    [/OBS=observed series names]

    [/{DFE=error degrees of freedom     }]
      {DFH=hypothesis degrees of freedom}
```

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
FIT.
```

Overview

FIT displays a variety of descriptive statistics computed from the residual series as an aid in evaluating the goodness of fit of one or more models.

Options

Statistical Output. You can produce statistics for a particular residual series by specifying the names of the series after FIT. You can also obtain percent error statistics for specified residual series by specifying observed series on the OBS subcommand.

Degrees of Freedom. You can specify the degrees of freedom for the residual series using the DFE or DFH subcommands.

Basic Specification

The basic specification is simply the command keyword FIT. All other specifications are optional.

- By default, FIT calculates the mean error, mean percent error, mean absolute error, mean absolute percent error, sum of squared errors, mean square error, root mean square error, and the Durbin-Watson statistic for the last *ERR_n* (residual) series generated and the corresponding observed series in the active dataset.
- If neither residual nor observed series are specified, percent error statistics for the default residual and observed series are included.

Syntax Rules

- If OBS is specified, the ERRORS subcommand naming the residual series is required.

Operations

- Observed series and degrees of freedom are matched with residual series according to the order in which they are specified.

- If residual series are explicitly specified but observed series are not, percent error statistics are not included in the output. If neither residual nor observed series are specified, percent error statistics for the default residual and observed series are included.
- If subcommand DFH is specified, FIT calculates the DFE (error degrees of freedom) by subtracting the DFH (hypothesis degrees of freedom) from the number of valid cases in the series.
- If a PREDICT period (validation period) starts before the end of the observed series, statistics are reported separately for the USE period (historical period) and the PREDICT period.

Limitations

- There is no limit on the number of residual series specified. However, the number of observed series must equal the number of residual series.

Example

```
FIT ERR_4 ERR_5 ERR_6.
```

- This command requests goodness-of-fit statistics for the residual series *ERR_4*, *ERR_5*, and *ERR_6*, which were generated by previous procedures. Percent error statistics are not included in the output, since only residual series are named.

ERRORS Subcommand

ERRORS specifies the residual (error) series.

- The actual keyword ERRORS can be omitted. VARIABLES is an alias for ERRORS.
- The minimum specification on ERRORS is a residual series name.
- The ERRORS subcommand is required if the OBS subcommand is specified.

OBS Subcommand

OBS specifies the observed series to use for calculating the mean percentage error and mean absolute percentage error.

- OBS can be used only when the residual series are explicitly specified.
- The number and order of observed series must be the same as that of the residual series.
- If more than one residual series was calculated from a single observed series, the observed series is specified once for each residual series that is based on it.

Example

```
FIT ERRORS=ERR#1 ERR#2
  /OBS=VAR1 VAR1.
```

- This command requests FIT statistics for two residual series, *ERR#1* and *ERR#2*, which were computed from the same observed series, *VAR1*.

DFE and DFH Subcommands

DFE and DFH specify the degrees of freedom for each residual series. With DFE, error degrees of freedom are entered directly. DFH specifies hypothesis degrees of freedom so FIT can compute the DFE.

- Only one DFE or DFH subcommand should be specified. If both are specified, only the last one is in effect.
- The specification on DFE or DFH is a list of numeric values. The order of these values should correspond to the order of the residual series list.
- The error degrees of freedom specified on DFE are used to compute the mean square error (MSE) and root mean square (RMS).
- The value specified for DFH should equal the number of parameters in the model (including the constant if it is present). Differencing is not considered in calculating DFH, since any observations lost due to differencing are system-missing.
- If neither DFE or DFH are specified, FIT sets DFE equal to the number of observations.

Example

```
FIT ERR#1 ERR#2
  /OBS=VAR1 VAR2
  /DFE=47 46.
```

- In this example, the error degrees of freedom for the first residual series, *ERR#1*, is 47. The error degrees of freedom for the second residual series, *ERR#2*, is 46.

Output Considerations for SSE

The sum of squared errors (SSE) reported by FIT may not be the same as the SSE reported by the estimation procedure. The SSE from the procedure is an estimate of sigma squared for that model. The SSE from FIT is simply the sum of the squared residuals.

FLIP

```
FLIP [VARIABLES= {ALL     }]
                 {varlist}

     [/NEWNAMES=variable]
```

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
FLIP.
```

Overview

The program requires a file structure in which the variables are the columns and observations (cases) are the rows. If a file is organized such that variables are in rows and observations are in columns, you need to use FLIP to reorganize it. FLIP transposes the rows and columns of the data in the active dataset so that, for example, row 1, column 2 becomes row 2, column 1, and so forth.

Options

Variable Subsets. You can transpose specific variables (columns) from the original file using the VARIABLES subcommand.

Variable Names. You can use the values of one of the variables from the original file as the variable names in the new file, using the NEWNAMES subcommand.

Basic Specification

The basic specification is the command keyword FLIP, which transposes all rows and columns.

- By default, FLIP assigns variable names *VAR001* to *VARn* to the variables in the new file. It also creates the new variable *CASE_LBL*, whose values are the variable names that existed before transposition.

Subcommand Order

VARIABLES must precede NEWNAMES.

Operations

- FLIP replaces the active dataset with the transposed file and displays a list of variable names in the transposed file.
- FLIP discards any previous VARIABLE LABELS, VALUE LABELS, and WEIGHT settings. Values defined as user-missing in the original file are translated to system-missing in the transposed file.

- FLIP obeys any SELECT IF, N, and SAMPLE commands in effect.
- FLIP does not obey the TEMPORARY command. Any transformations become permanent when followed by FLIP.
- String variables in the original file are assigned system-missing values after transposition.
- Numeric variables are assigned a default format of F8.2 after transposition (with the exceptions of *CASE_LBL* and the variable specified on NEWNAMES).
- The variable *CASE_LBL* is created and added to the active dataset each time FLIP is executed.
- If *CASE_LBL* already exists as the result of a previous FLIP, its current values are used as the names of variables in the new file (if NEWNAMES is not specified).

Example

The following is the LIST output for a data file arranged in a typical spreadsheet format, with variables in rows and observations in columns:

```
A              B         C         D

Income     22.00     31.00     43.00
Price      34.00     29.00     50.00
Year     1970.00   1971.00   1972.00
```

The command

```
FLIP.
```

transposes all variables in the file. The LIST output for the transposed file is as follows:

```
CASE_LBL    VAR001    VAR002    VAR003

A             .         .         .
B           22.00     34.00   1970.00
C           31.00     29.00   1971.00
D           43.00     50.00   1972.00
```

- The values for the new variable *CASE_LBL* are the variable names from the original file.
- Case A has system-missing values, since variable *A* had the string values *Income*, *Price*, and *Year*.
- The names of the variables in the new file are *CASE_LBL, VAR001, VAR002,* and *VAR003*.

VARIABLES Subcommand

VARIABLES names one or more variables (columns) to be transposed. The specified variables become observations (rows) in the new active dataset.

- The VARIABLES subcommand is optional. If it is not used, all variables are transposed.
- If the VARIABLES subcommand is specified, variables that are not named are discarded.

Example

Using the untransposed file from the previous example, the command

```
FLIP VARIABLES=A TO C.
```

transposes only variables *A* through *C*. Variable *D* is not transposed and is discarded from the active dataset. The LIST output for the transposed file is as follows:

```
CASE_LBL    VAR001    VAR002    VAR003

A              .         .         .
B           22.00     34.00   1970.00
C           31.00     29.00   1971.00
```

NEWNAMES Subcommand

NEWNAMES specifies a variable whose values are used as the new variable names.

- The NEWNAMES subcommand is optional. If it is not used, the new variable names are either *VAR001* to *VARn*, or the values of *CASE_LBL* if it exists.
- Only one variable can be specified on NEWNAMES.
- The variable specified on NEWNAMES does not become an observation (case) in the new active dataset, regardless of whether it is specified on the VARIABLES subcommand.
- If the variable specified is numeric, its values become a character string beginning with the prefix*K*_.
- Characters not allowed in variables names, such as blank spaces, are replaced with underscore (_) characters.
- If the variable's values are not unique, unique variable names are created by appending a sequential suffix of the general form _A, _B, _C,..._AA, _AB, _AC,..._AAA, _AAB, _AAC,...etc.

Example

Using the untransposed file from the first example, the command

```
FLIP NEWNAMES=A.
```

uses the values for variable *A* as variable names in the new file. The LIST output for the transposed file is as follows:

```
CASE_LBL    INCOME     PRICE      YEAR

B           22.00      34.00   1970.00
C           31.00      29.00   1971.00
D           43.00      50.00   1972.00
```

- Variable *A* does not become an observation in the new file. The string values for *A* are converted to upper case.

The following command transposes this file back to a form resembling its original structure:

```
FLIP.
```

The LIST output for the transposed file is as follows:

```
CASE_LBL       B         C         D
```

```
INCOME      22.00      31.00      43.00
PRICE       34.00      29.00      50.00
YEAR      1970.00    1971.00    1972.00
```

- Since the NEWNAMES subcommand is not used, the values of *CASE_LBL* from the previous FLIP (*B, C,* and *D*) are used as variable names in the new file.
- The values of *CASE_LBL* are now *INCOME*, *PRICE*, and *YEAR*.

FORMATS

```
FORMATS varlist(format) [varlist...]
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Example

```
FORMATS SALARY (DOLLAR8) / HOURLY (DOLLAR7.2) / RAISE BONUS (PCT2).
```

Overview

FORMATS changes variable print and write formats. In this program, print and write formats are *output* formats. **Print formats**, also called display formats, control the form in which values are displayed by a procedure or by the PRINT command; **write formats** control the form in which values are written by the WRITE command.

FORMATS changes both print and write formats. To change only print formats, use PRINT FORMATS. To change only write formats, use WRITE FORMATS. For information on assigning input formats during data definition, see DATA LIST.

For detailed information on available formats and specifications, see Variable Types and Formats.

Basic Specification

The basic specification is a variable list followed by a format specification in parentheses. All variables on the list receive the new format.

Operations

- Unlike most transformations, FORMATS takes effect as soon as it is encountered in the command sequence. Special attention should be paid to its position among commands. For more information, see Command Order on p. 36.
- Variables not specified on FORMATS retain their current print and write formats in the active dataset. To see the current formats, use the DISPLAY command.
- The new formats are changed only in the active dataset and are in effect for the duration of the current session or until changed again with a FORMATS, PRINT FORMATS, or WRITE FORMATS command. Formats in the original data file (if one exists) are not changed unless the file is resaved with the SAVE or XSAVE command.
- New numeric variables created with transformation commands are assigned default print and write formats of F8.2 (or the format specified on the FORMAT subcommand of SET). The FORMATS command can be used to change the new variable's print and write formats.

- For string variables, you can only use FORMATS to switch between A and AHEX formats, and the AHEX length must be exactly twice the A length. FORMATS cannot be used to change the length of string variables. To change the defined length of a string variable, use the ALTER TYPE command.
- If a numeric data value exceeds its width specification, the program attempts to display some value nevertheless. The program first rounds decimal values, then removes punctuation characters, then tries scientific notation, and finally, if there is still not enough space, produces asterisks indicating that a value is present but cannot be displayed in the assigned width.

Syntax Rules

- You can specify more than one variable or variable list, followed by a format in parentheses. Only one format can be specified after each variable list. For clarity, each set of specifications can be separated by a slash.
- You can use keyword TO to refer to consecutive variables in the active dataset.
- The specified width of a format must include enough positions to accommodate any punctuation characters such as decimal points, commas, dollar signs, or date and time delimiters. (This differs from assigning an *input* format on DATA LIST, where the program automatically expands the input format to accommodate punctuation characters in output.)
- Custom currency formats (CCw, CCw.d) must first be defined on the SET command before they can be used on FORMATS.
- For string variables, you can only use FORMATS to switch between A and AHEX formats.FORMATS cannot be used to change the length of string variables. To change the length of a string variable, declare a new variable of the desired length with the STRING command and then use COMPUTE to copy values from the existing string into the new variable.
- To save the new print and write formats, you must save the active dataset as an SPSS-format data file with the SAVE or XSAVE command.

Examples

Changing Formats for Multiple Variables

```
FORMATS SALARY (DOLLAR8) /HOURLY (DOLLAR7.2)
        /RAISE BONUS (PCT2).
```

- The print and write formats for *SALARY* are changed to DOLLAR format with eight positions, including the dollar sign and comma when appropriate. The value 11550 is displayed as $11,550. An eight-digit number would require a DOLLAR11 format: eight characters for the digits, two characters for commas, and one character for the dollar sign.
- The print and write formats for *HOURLY* are changed to DOLLAR format with seven positions, including the dollar sign, decimal point, and two decimal places. The value 115 is displayed as $115.00. If DOLLAR6.2 had been specified, the value 115 would be displayed as $115.0. The program would truncate the last 0 because a width of 6 is not enough to display the full value.

- The print and write formats for both *RAISE* and *BONUS* are changed to PCT with two positions: one position for the percentage and one position for the percent sign. The value 9 is displayed as 9%. Because the width allows for only two positions, the value 10 is displayed as 10, since the percent sign is truncated.

Changing Default Variable Formats

```
COMPUTE V3=V1 + V2.
FORMATS V3 (F3.1).
```

- COMPUTE creates the new numeric variable *V3*. By default, *V3* is assigned an F8.2 format (or the default format specified on SET).
- FORMATS changes both the print and write formats for *V3* to F3.1.

Working With Custom Currency Formats

```
SET CCA='-/-.Dfl ..-'.
FORMATS COST (CCA14.2).
```

- SET defines a European currency format for the custom currency format type CCA.
- FORMATS assigns format CCA to variable *COST*. With the format defined for CCA on SET, the value 37419 is displayed as Dfl 37.419,00. See the SET command for more information on custom currency formats.

FREQUENCIES

```
FREQUENCIES VARIABLES=varlist [varlist...]

 [/FORMAT= [{NOTABLE }] [{AVALUE**}]
           {LIMIT(n)}   {DVALUE  }
                        {AFREQ   }
                        {DFREQ   }

 [/MISSING=INCLUDE]

 [/BARCHART=[MINIMUM(n)] [MAXIMUM(n)] [{FREQ(n)   }]]
                                      {PERCENT(n)}

 [/PIECHART=[MINIMUM(n)] [MAXIMUM(n)] [{FREQ   }] [{MISSING  }]]
                                      {PERCENT}   {NOMISSING}

 [/HISTOGRAM=[MINIMUM(n)] [MAXIMUM(n)] [{FREQ(n)   }] [{NONORMAL}] ]
                                                       {NORMAL  }

 [/GROUPED=varlist [{(width)        }]]
                   {(boundary list)}

 [/NTILES=n]

 [/PERCENTILES=value list]

 [/STATISTICS=[DEFAULT] [MEAN] [STDDEV] [MINIMUM] [MAXIMUM]
              [SEMEAN] [VARIANCE] [SKEWNESS] [SESKEW] [RANGE]
              [MODE] [KURTOSIS] [SEKURT] [MEDIAN] [SUM] [ALL]
                [NONE]]

 [/ORDER=[{ANALYSIS}] [{VARIABLE}]
```

** Default if subcommand is omitted or specified without keyword.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
FREQUENCIES VARIABLES = RACE.
```

Overview

FREQUENCIES produces Frequency tables showing frequency counts and percentages of the values of individual variables. You can also use FREQUENCIES to obtain Statistics tables for categorical variables and to obtain Statistics tables and graphical displays for continuous variables.

Options

Display Format. You can suppress tables and alter the order of values within tables using the FORMAT subcommand.

Statistical Display. Percentiles and ntiles are available for numeric variables with the PERCENTILES and NTILES subcommands. The following statistics are available with the STATISTICS subcommand: mean, median, mode, standard deviation, variance, skewness, kurtosis, and sum.

Plots. Histograms can be specified for numeric variables on the HISTOGRAM subcommand. Bar charts can be specified for numeric or string variables on the BARCHART subcommand.

Input Data. On the GROUPED subcommand, you can indicate whether the input data are grouped (or collapsed) so that a better estimate can be made of percentiles.

Basic Specification

The basic specification is the VARIABLES subcommand and the name of at least one variable. By default, FREQUENCIES produces a Frequency table.

Subcommand Order

Subcommands can be named in any order.

Syntax Rules

- You can specify multiple NTILES subcommands.
- BARCHART and HISTOGRAM are mutually exclusive.
- You can specify numeric variables (with or without decimal values) or string variables. Only the short-string portion of long-string variables are tabulated.
- Keyword ALL can be used on VARIABLES to refer to all user-defined variables in the active dataset.

Operations

- Variables are tabulated in the order they are mentioned on the VARIABLES subcommand.
- If a requested ntile or percentile cannot be calculated, a period (.) is displayed.
- FREQUENCIES dynamically builds the table, setting up one cell for each unique value encountered in the data.

Limitations

- Maximum 1,000 variables total per FREQUENCIES command.

Examples

Including a Statistics Table in the Output

```
FREQUENCIES VARIABLES = RACE /STATISTICS=ALL.
```

- FREQUENCIES requests a Frequency table and a Statistics table showing all statistics for the categorical variable *RACE*.

Suppressing the Frequency Tables in the Output

```
FREQUENCIES STATISTICS=ALL /HISTOGRAM
 /VARIABLES=SEX TVHOURS SCALE1 TO SCALE5
 /FORMAT=NOTABLE.
```

- FREQUENCIES requests statistics and histograms for *SEX, TVHOURS,* and all variables between and including *SCALE1* and *SCALE5* in the active dataset.
- FORMAT suppresses the Frequency tables, which are not useful for continuous variables.

VARIABLES Subcommand

VARIABLES names the variables to be tabulated and is the only required subcommand.

FORMAT Subcommand

FORMAT controls various features of the output, including order of categories and suppression of tables.

- The minimum specification is a single keyword.
- By default, FREQUENCIES displays the Frequency table and sort categories in ascending order of values for numeric variables and in alphabetical order for string variables.

Table Order

AVALUE	*Sort categories in ascending order of values (numeric variables) or in alphabetical order (string variables).* This is the default.
DVALUE	*Sort categories in descending order of values (numeric variables) or in reverse alphabetical order (string variables).* This is ignored when HISTOGRAM, NTILES, or PERCENTILES is requested.
AFREQ	*Sort categories in ascending order of frequency.* This is ignored when HISTOGRAM, NTILES, or PERCENTILES is requested.
DFREQ	*Sort categories in descending order of frequency.* This is ignored when HISTOGRAM, NTILES, or PERCENTILES is requested.

Table Suppression

LIMIT(n)	*Suppress frequency tables with more than* n *categories.* The number of missing and valid cases and requested statistics are displayed for suppressed tables.
NOTABLE	*Suppress all frequency tables.* The number of missing and valid cases are displayed for suppressed tables. NOTABLE overrides LIMIT.

BARCHART Subcommand

BARCHART produces a bar chart for each variable named on the VARIABLES subcommand. By default, the horizontal axis for each bar chart is scaled in frequencies, and the interval width is determined by the largest frequency count for the variable being plotted. Bar charts are labeled with value labels or with the value itself if no label is defined.

- The minimum specification is the BARCHART keyword, which generates default bar charts.
- BARCHART cannot be used with HISTOGRAM.

MIN(n)	*Lower bound below which values are not plotted.*
MAX(n)	*Upper bound above which values are not plotted.*
FREQ(n)	*Vertical axis scaled in frequencies, where optional* n *is the maximum.* If *n* is not specified or if it is too small, FREQUENCIES chooses 5, 10, 20, 50, 100, 200, 500, 1000, 2000, and so forth, depending on the largest category. This is the default.
PERCENT(n)	*Vertical axis scaled in percentages, where optional* n *is the maximum.* If *n* is not specified or if it is too small, FREQUENCIES chooses 5, 10, 25, 50, or 100, depending on the frequency count for the largest category.

Producing a Basic Bar Chart

```
FREQUENCIES VARIABLES = RACE /BARCHART.
```

- FREQUENCIES produces a frequency table and the default bar chart for variable *RACE*.

Producing a Custom Bar Chart

```
FREQUENCIES VARIABLES = V1 V2 /BAR=MAX(10).
```

- FREQUENCIES produces a frequency table and bar chart with values through 10 for each of variables *V1* and *V2*.

PIECHART Subcommand

PIECHART produces a pie chart for each variable named on the VARIABLES subcommand. By default, one slice corresponds to each category defined by the variable with one slice representing all missing values. Pie charts are labeled with value labels or with the value if no label is defined.

- The minimum specification is the PIECHART keyword, which generates default pie charts.
- PIECHART can be requested together with either BARCHART or HISTOGRAM.
- FREQ and PERCENT are mutually exclusive. If both are specified, only the first specification is in effect.
- MISSING and NOMISSING are mutually exclusive. If both are specified, only the first specification is in effect.

MIN(n)	*Lower bound below which values are not plotted.*
MAX(n)	*Upper bound above which values are not plotted.*
FREQ	*The pie charts are based on frequencies.* Frequencies are displayed when you request values in the Chart Editor. This is the default.
PERCENT	*The pie charts are based on percentage.* Percentage is displayed when you request values in the Chart Editor.
MISSING	*User-missing and system-missing values are treated as one category.* This is the default. Specify INCLUDE on the MISSING subcommand to display system-missing and user-missing values as separate slices.
NOMISSING	*Missing values are excluded from the chart.* If you specify INCLUDE on the MISSING subcommand, each user-missing value is represented by one slice.

Producing a Basic Pie Chart

```
FREQUENCIES VARIABLES = RACE /PIECHART.
```

- FREQUENCIES produces a frequency table and the default pie chart for variable *RACE*.

Producing a Custom Pie Chart

```
FREQUENCIES VARIABLES = V1 V2 /PIE=MAX(10).
```

- For each variable *V1* and *V2*, FREQUENCIES produces a frequency table and a pie chart with values through 10.

HISTOGRAM Subcommand

HISTOGRAM displays a plot for each numeric variable named on the VARIABLES subcommand. By default, the horizontal axis of each histogram is scaled in frequencies and the interval width is determined by the largest frequency count of the variable being plotted.

- The minimum specification is the HISTOGRAM keyword, which generates default histograms.
- HISTOGRAM cannot be used with BARCHART.

MIN(n)	*Lower bound below which values are not plotted.*
MAX(n)	*Upper bound above which values are not plotted.*
FREQ(n)	*Vertical axis scaled in frequencies, where optional* n *is the scale.* If *n* is not specified or if it is too small, FREQUENCIES chooses 5, 10, 20, 50, 100, 200, 500, 1000, 2000, and so forth, depending on the largest category. This is the default.
NORMAL	*Superimpose a normal curve.* The curve is based on all valid values for the variable, including values excluded by MIN and MAX.
NONORMAL	*Suppress the normal curve.* This is the default.

Example

```
FREQUENCIES VARIABLES = V1 /HIST=NORMAL.
```

- FREQUENCIES requests a histogram with a superimposed normal curve.

GROUPED Subcommand

When the values of a variable represent grouped or collapsed data, it is possible to estimate percentiles for the original, ungrouped data from the grouped data. The GROUPED subcommand specifies which variables have been grouped. It affects only the output from the PERCENTILES and NTILES subcommands and the MEDIAN statistic from the STATISTICS subcommand.

- Multiple GROUPED subcommands can be used on a single FREQUENCIES command. Multiple variable lists, separated by slashes, can appear on a single GROUPED subcommand.
- The variables named on GROUPED must have been named on the VARIABLES subcommand.

- The value or value list in the parentheses is optional. When it is omitted, the program treats the values of the variables listed on GROUPED as midpoints. If the values are not midpoints, they must first be recoded with the RECODE command.
- A single value in parentheses specifies the width of each grouped interval. The data values must be group midpoints, but there can be empty categories. For example, if you have data values of 10, 20, and 30 and specify an interval width of 5, the categories are 10 ± 2.5, 20 ± 2.5, and 30 ± 2.5. The categories 15 ± 2.5 and 25 ± 2.5 are empty.
- A value list in the parentheses specifies interval boundaries. The data values do not have to represent midpoints, but the lowest boundary must be lower than any value in the data. If any data values exceed the highest boundary specified (the last value within the parentheses), they will be assigned to an open-ended interval. In this case, some percentiles cannot be calculated.

Basic Example

```
RECODE AGE (1=15) (2=25) (3=35) (4=45) (5=55)
           (6=65) (7=75) (8=85) (9=95)
  /INCOME  (1=5)  (2=15) (3=25) (4=35) (5=45)
           (6=55) (7=65) (8=75) (9=100).

FREQUENCIES VARIABLES=AGE, SEX, RACE, INCOME
  /GROUPED=AGE, INCOME
  /PERCENTILES=5,25,50,75,95.
```

- The *AGE* and *INCOME* categories of 1, 2, 3, and so forth are recoded to category midpoints. Note that data can be recoded to category midpoints on any scale; here *AGE* is recoded in years, but *INCOME* is recoded in thousands of dollars.
- The GROUPED subcommand on FREQUENCIES allows more accurate estimates of the requested percentiles.

Specifying the Width of Each Grouped Interval

```
FREQUENCIES VARIABLES=TEMP
  /GROUPED=TEMP (0.5)
  /NTILES=10.
```

- The values of *TEMP* (temperature) in this example were recorded using an inexpensive thermometer whose readings are precise only to the nearest half degree.
- The observed values of 97.5, 98, 98.5, 99, and so on, are treated as group midpoints, smoothing out the discrete distribution. This yields more accurate estimates of the deciles.

Specifying Interval Boundaries

```
FREQUENCIES VARIABLES=AGE
  /GROUPED=AGE (17.5, 22.5, 27.5, 32.5, 37.5, 42.5, 47.5
                52.5, 57.5, 62.5, 67.5, 72.5, 77.5, 82.5)
  /PERCENTILES=5, 10, 25, 50, 75, 90, 95.
```

- The values of *AGE* in this example have been estimated to the nearest five years. The first category is 17.5 to 22.5, the second is 22.5 to 27.5, and so forth. The artificial clustering of age estimates at multiples of five years is smoothed out by treating *AGE* as grouped data.
- It is not necessary to recode the ages to category midpoints, since the interval boundaries are explicitly given.

PERCENTILES Subcommand

PERCENTILES displays the value below which the specified percentage of cases falls. The desired percentiles must be explicitly requested. There are no defaults.

Example

```
FREQUENCIES VARIABLES = V1 /PERCENTILES=10 25 33.3 66.7 75.
```

- FREQUENCIES requests the values for percentiles 10, 25, 33.3, 66.7, and 75 for *V1*.

NTILES Subcommand

NTILES calculates the percentages that divide the distribution into the specified number of categories and displays the values below which the requested percentages of cases fall. There are no default ntiles.

- Multiple NTILES subcommands are allowed. Each NTILES subcommand generates separate percentiles. Any duplicate percentiles generated by different NTILES subcommands are consolidated in the output.

Basic Example

```
FREQUENCIES VARIABLES=V1 /NTILES=4.
```

- FREQUENCIES requests quartiles (percentiles 25, 50, and 75) for *V1*.

Working With Multiple NTILES Subcommands

```
FREQUENCIES VARIABLES=V1 /NTILES=4 /NTILES=10.
```

- The first NTILES subcommand requests percentiles 25, 50, and 75.
- The second NTILES subcommand requests percentiles 10 through 90 in increments of 10.
- The 50th percentile is produced by both specifications but is displayed only once in the output.

STATISTICS Subcommand

STATISTICS controls the display of statistics. By default, cases with missing values are excluded from the calculation of statistics.

- The minimum specification is the keyword STATISTICS, which generates the mean, standard deviation, minimum, and maximum (these statistics are also produced by keyword DEFAULT).

MEAN	*Mean.*
SEMEAN	*Standard error of the mean*.
MEDIAN	*Median.* Ignored when AFREQ or DFREQ are specified on the FORMAT subcommand.
MODE	*Mode.* If there is more than one mode, only the first mode is displayed.
STDDEV	*Standard deviation*.

VARIANCE	*Variance.*
SKEWNESS	*Skewness.*
SESKEW	*Standard error of the skewness statistic.*
KURTOSIS	*Kurtosis.*
SEKURT	*Standard error of the kurtosis statistic.*
RANGE	*Range.*
MINIMUM	*Minimum.*
MAXIMUM	*Maximum.*
SUM	*Sum.*
DEFAULT	*Mean, standard deviation, minimum, and maximum.*
ALL	*All available statistics.*
NONE	*No statistics.*

Specifying a Particular Statistic

```
FREQUENCIES VARIABLES = AGE /STATS=MODE.
```

- `STATISTICS` requests the mode of *AGE*.

Including the Default Statistics

```
FREQUENCIES VARIABLES = AGE /STATS=DEF MODE.
```

- `STATISTICS` requests the default statistics (mean, standard deviation, minimum, and maximum) plus the mode of *AGE*.

MISSING Subcommand

By default, both user-missing and system-missing values are labeled as missing in the table but are not included in the valid and cumulative percentages, in the calculation of descriptive statistics, or in charts and histograms.

INCLUDE	*Include cases with user-missing values.* Cases with user-missing values are included in statistics and plots.

ORDER Subcommand

You can organize your output by variable or by analysis. Frequencies output that is organized by analysis has a single statistics table for all variables. Output organized by variable has a statistics table and a frequency table for each variable.

ANALYSIS	*Organize output by analysis.* Displays a single statistics table for all variables. This is the default.
VARIABLE	*Organize output by variable.* Displays a statistics table and a frequency table for each variable.

GENLIN

GENLIN is available in the Advanced Models option.

Note: Equals signs (=) used in the syntax chart are required elements. All subcommands are optional.

** Default if the subcommand or keyword is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Release History

Release 15.0

- Command introduced.

Release 16.0

- Added multinomial and tweedie distributions; added MLE estimation option for ancillary parameter of negative binomial distribution (MODEL subcommand, DISTRIBUTION keyword). Notes related to the addition of the new distributions added throughout.
- Added cumulative Cauchit, cumulative complementary log-log, cumulative logit, cumulative negative log-log, and cumulative probit link functions (MODEL subcommand, LINK keyword).
- Added likelihood-ratio chi-square statistics as an alternative to Wald statistics (CRITERIA subcommand, ANALYSISTYPE keyword).
- Added profile likelihood confidence intervals as an alternative to Wald confidence intervals (CRITERIA subcommand, CITYPE keyword).
- Added option to specify initial value for ancillary parameter of negative binomial distribution (CRITERIA subcommand, INITIAL keyword).
- Changed default display of the likelihood function for GEEs to show the full value instead of the kernel (CRITERIA subcommand, LIKELIHOOD keyword).

Example

```
GENLIN mydepvar BY a b c WITH x y z
  /MODEL a b c x y z.
```

Overview

The GENLIN procedure fits the generalized linear model and generalized estimating equations.

The generalized linear model includes one dependent variable and usually one or more independent effects. Subjects are assumed to be independent. The generalized linear model covers not only widely used statistical models such as linear regression for normally distributed responses, logistic models for binary data, and loglinear models for count data, but also many other statistical models via its very general model formulation. However, the independence assumption prohibits the model from being applied to correlated data.

Generalized estimating equations extend the generalized linear model to correlated longitudinal data and clustered data. More particularly, generalized estimating equations model correlations within subjects. Data across subjects are still assumed independent.

Options

Independence Assumption. The GENLIN procedure fits either the generalized linear model assuming independence across subjects, or generalized estimating equations assuming correlated measurements within subjects but independence across subjects.

Events/Trials Specification for Binomial Distribution. The typical dependent variable specification will be a single variable, but for the binomial distribution the dependent variable may be specified using a number-of-events variable and a number-of-trials variable. Alternatively, if the number of trials is the same across all subjects, then trials may be specified using a fixed number instead of a variable.

Probability Distribution of Dependent Variable. The probability distribution of the dependent variable may be specified as normal, binomial, gamma, inverse Gaussian, multinomial, negative binomial, Poisson, or Tweedie.

Link Function. GENLIN offers the following link functions: Identity, complementary log-log, log, log-complement, logit, negative binomial, negative log-log, odds power, power, and probit. For the multinomial distribution, the following link functions are available: cumulative Cauchit, cumulative complementary log-log, cumulative logit, cumulative negative log-log, and cumulative probit.

Correlation Structure for Generalized Estimating Equations. When measurements within subjects are assumed correlated, the correlation structure may be specified as independent, AR(1), exchangeable, fixed, *m*-dependent, or unstructured.

Estimated Marginal Means. Estimated marginal means may be computed for one or more crossed factors and may be based on either the response or the linear predictor.

Basic Specification

- The basic specification is a MODEL subcommand with one or more model effects and a variable list identifying the dependent variable, the factors (if any), and the covariates (if any).
- If the MODEL subcommand is not specified, or is specified with no model effects, then the default model is the intercept-only model using the normal distribution and identity link.
- If the REPEATED subcommand is not specified, then subjects are assumed to be independent.
- If the REPEATED subcommand is specified, then generalized estimating equations, which model correlations within subjects, are fit. By default, generalized estimating equations use the independent correlation structure.
- The basic specification displays default output, including a case processing summary table, variable information, model information, goodness of fit statistics, model summary statistics, and parameter estimates and related statistics.

Syntax Rules

- The dependent variable, or an events/trials specification is required. All other variables and subcommands are optional.
- It is invalid to specify a dependent variable and an events/trials specification in the same GENLIN command.
- Multiple EMMEANS subcommands may be specified; each is treated independently. All other subcommands may be specified only once.
- The EMMEANS subcommand may be specified without options. All other subcommands must be specified with options.
- Each keyword may be specified only once within a subcommand.
- The command name, all subcommand names, and all keywords must be spelled in full.
- Subcommands may be specified in any order.
- Within subcommands, keyword settings may be specified in any order.
- The following variables, if specified, must be numeric: events and trials variables, covariates, OFFSET variable, and SCALEWEIGHT variable. The following, if specified, may be numeric or string variables: the dependent variable, factors, SUBJECT variables, and WITHINSUBJECT variables.
- All variables must be unique within and across the following variables or variable lists: the dependent variable, events variable, trials variable, factor list, covariate list, OFFSET variable, and SCALEWEIGHT variable.
- The dependent variable, events variable, trials variable, and covariates may not be specified as SUBJECT or WITHINSUBJECT variables.
- SUBJECT variables may not be specified as WITHINSUBJECT variables.
- The minimum syntax is a dependent variable. This specification fits an intercept-only model.

Case Frequency

- If an WEIGHT variable is specified, then its values are used as frequency weights by the GENLIN procedure.

- Weight values are rounded to the nearest whole numbers before use. For example, 0.5 is rounded to 1, and 2.4 is rounded to 2.
- The WEIGHT variable may not be specified on any subcommand in the GENLIN procedure.
- Cases with missing weights or weights less than 0.5 are not used in the analyses.

Examples

Poisson Regression

```
* Generalized Linear Models.
GENLIN damage_incidents BY type construction operation (ORDER=DESCENDING)
  /MODEL type construction operation  INTERCEPT=YES  OFFSET=log_months_service
    DISTRIBUTION=POISSON LINK=LOG
  /CRITERIA METHOD=FISHER(1) SCALE=PEARSON COVB=MODEL MAXITERATIONS=100
    MAXSTEPHALVING=5 PCONVERGE=1E-006(ABSOLUTE) SINGULAR=1E-012
    ANALYSISTYPE=3(WALD) CILEVEL=95 CITYPE=WALD LIKELIHOOD=FULL
  /EMMEANS TABLES=type SCALE=TRANSFORMED COMPARE=type CONTRAST=PAIRWISE
    PADJUST=SEQSIDAK
  /EMMEANS TABLES=construction SCALE=TRANSFORMED COMPARE=construction
    CONTRAST=PAIRWISE PADJUST=SEQSIDAK
  /MISSING CLASSMISSING=EXCLUDE
  /PRINT CPS DESCRIPTIVES MODELINFO FIT SUMMARY SOLUTION
  /SAVE XBPRED STDDEVIANCERESID.
```

- The procedure fits a model for the dependent variable *damage_incidents*, using *type*, *construction*, and *operation* as factors.
- The model specification assumes that *damage_incidents* has a Poisson distribution. A log link function relates the distribution of *damage_incidents* to a linear combination of the predictors, including an intercept term, and an offset equal to the values *log_months_service*.
- The Pearson chi-square method is used to estimate the scale parameter. All other model fitting criteria are set to their default values.
- Estimated marginal means are computed on the scale of the linear predictor for *type* and *construction* using pairwise contrasts. The sequential Sidak method for multiple comparisons is used to adjust *p*-values.
- Print outputs are set to their default values.
- The model-estimated values of the linear predictor and the standardized deviance residual are saved to the active dataset.

Gamma Regression

```
* Generalized Linear Models.
GENLIN claimamt BY holderage vehiclegroup vehicleage (ORDER=DESCENDING)
  /MODEL holderage vehiclegroup vehicleage  INTERCEPT=YES
    SCALEWEIGHT=nclaims DISTRIBUTION=GAMMA LINK=POWER(-1)
  /CRITERIA METHOD=FISHER(1) SCALE=PEARSON COVB=MODEL MAXITERATIONS=100
    MAXSTEPHALVING=5 PCONVERGE=1E-006(ABSOLUTE) SINGULAR=1E-012
    ANALYSISTYPE=3(WALD) CILEVEL=95 CITYPE=WALD LIKELIHOOD=FULL
  /EMMEANS TABLES=holderage SCALE=ORIGINAL COMPARE=holderage
    CONTRAST=REPEATED PADJUST=SEQSIDAK
  /EMMEANS TABLES=vehiclegroup SCALE=ORIGINAL COMPARE=vehiclegroup
    CONTRAST=PAIRWISE PADJUST=SEQSIDAK
  /EMMEANS TABLES=vehicleage SCALE=ORIGINAL COMPARE=vehicleage
```

```
    CONTRAST=REPEATED PADJUST=SEQSIDAK
  /MISSING CLASSMISSING=EXCLUDE
  /PRINT CPS DESCRIPTIVES MODELINFO FIT SUMMARY SOLUTION
  /SAVE XBPRED STDDEVIANCERESID.
```

- The procedure fits a model for the dependent variable *claimamt*, using *holderage*, *vehiclegroup*, and *vehicleage* as factors. The category order for all factors is descending values of factor levels.
- The model specification assumes that *claimamt* has a gamma distribution. A power link function with -1 as the exponent relates the distribution of *claimamt* to a linear combination of the predictors (including an intercept term).
- The Pearson chi-square method is used to estimate the scale parameter, with *nclaims* providing scale weights. All other model fitting criteria are set to their default values.
- Estimated marginal means are computed for *holderage*, using repeated contrasts; *vehiclegroup*, using pairwise contrasts; and *vehicleage*, using repeated contrasts. All tests are adjusted using the sequential Sidak method.
- Print outputs are set to their default values.
- The model-estimated values of the linear predictor and the standardized deviance residual are saved to the active dataset.

Complementary Log-log Regression for Interval-Censored Survival Data

```
* Generalized Linear Models.
GENLIN result2 (REFERENCE=FIRST) BY id duration treatment period
    (ORDER=DESCENDING) WITH age
  /MODEL period duration treatment age  INTERCEPT=NO
    DISTRIBUTION=BINOMIAL LINK=CLOGLOG
  /CRITERIA METHOD=FISHER(1) SCALE=1 COVB=MODEL MAXITERATIONS=100
    MAXSTEPHALVING=5 PCONVERGE=1E-006(ABSOLUTE) SINGULAR=1E-012
    ANALYSISTYPE=3(WALD) CILEVEL=95 CITYPE=WALD LIKELIHOOD=FULL
  /MISSING CLASSMISSING=EXCLUDE
  /PRINT CPS DESCRIPTIVES MODELINFO FIT SUMMARY SOLUTION.
```

- The procedure fits a model for the dependent variable *result2*, using *id* as a factor to determine subpopulations and *duration*, *treatment*, and *period* as factors to predict values, with *age* as a covariate. The first category of *result2* is used as the reference category, and the category order for all factors is descending values of factor levels.
- The model specification assumes that *result2* has a binomial distribution. A complementary log-log link function relates the probability of *result2* to a linear combination of the predictors, excluding an intercept term.
- Model fitting criteria and print output are set to their default values.

Repeated Measures Logistic Regression (Generalized Estimating Equation)

```
* Generalized Estimating Equations.
GENLIN
    wheeze (REFERENCE=LAST) BY age smoker (ORDER=ASCENDING)
  /MODEL age smoker   INTERCEPT=YES
    DISTRIBUTION=BINOMIAL LINK=LOGIT
  /CRITERIA METHOD=FISHER(1) SCALE=1 MAXITERATIONS=100 MAXSTEPHALVING=5
    PCONVERGE=1E-006(ABSOLUTE) SINGULAR=1E-012 ANALYSISTYPE=3(WALD)
```

```
  CILEVEL=95
/REPEATED SUBJECT=id WITHINSUBJECT=age SORT=YES CORRTYPE=UNSTRUCTURED
  ADJUSTCORR=YES COVB=ROBUST MAXITERATIONS=100 PCONVERGE=1e-006(ABSOLUTE)
  UPDATECORR=1
/MISSING CLASSMISSING=EXCLUDE
/PRINT CPS DESCRIPTIVES MODELINFO FIT SUMMARY SOLUTION WORKINGCORR.
```

- The procedure fits a model for the dependent variable *wheeze*, using *smoker* and *age* as factors. The first category of *wheeze* is used as the reference category.
- The model specification assumes that *wheeze* has a binomial distribution. A logit link function relates the probability of *wheeze* to a linear combination of the predictors, including an intercept term.
- Clusters of correlated observations are defined by values of the subject variable *id*. Repeated measurements are ordered within subjects by values of *age*. An unstructured working correlation matrix is estimated.
- Model fitting criteria are set to their default values.
- The working correlation matrix is requested as output in addition to the default output.

Variable List

The GENLIN command variable list specifies the dependent variable using either a single variable or events and trials variables. Alternatively, the number of trials may be specified as a fixed number. The variable list also specifies any factors and covariates.

If an events/trials specification is used for the dependent variable, then the GENLIN procedure automatically computes the ratio of the events variable over the trials variable or number. Technically, the procedure treats the events variable as the dependent variable in the sense that predicted values and residuals are based on the events variable rather than the events/trials ratio.

- The first specification on GENLIN must be a single dependent variable name or an events/trials specification.
- If the dependent variable is specified as a single variable, then it may be scale, an integer-valued count variable, binary, or ordinal.
- If the dependent variable is binary, then it may be numeric or string and there may be only two distinct valid data values.
- If the dependent variable is categorical, then it may be numeric or string and must have at least two distinct valid data values.
- If the dependent variable is not binary or categorical, then it must be numeric.
- The REFERENCE keyword specifies the dependent variable value to use as the reference category for parameter estimation. No model parameters are assigned to the reference category.

REFERENCE = LAST

The last dependent variable value is the reference category. The last dependent variable value is defined based on the ascending order of the data values. This is the default.

If REFERENCE = LAST, then the procedure models the first value as the response, treating the last value as the reference category.

REFERENCE = FIRST

The first dependent variable value is the reference category. The first dependent variable value is defined based on the ascending order of the data values.

If REFERENCE = FIRST, then the procedure models the last value as the response, treating the first value as the reference category.

REFERENCE = value

The specified dependent variable value is the reference category. Put the value inside a pair of quotes if it is formatted (such as date or time) or if the dependent variable is of string type; note, however, that this does not work for custom currency formats.

If REFERENCE = value, then the procedure models the unspecified value as the response, treating the specified value as the reference category.

- The REFERENCE specification is honored only if the dependent variable is binary and the binomial distribution is used (that is, DISTRIBUTION = BINOMIAL is specified on the MODEL subcommand). Otherwise, this specification is silently ignored.
- If the dependent variable is a string variable, then the value at the highest or lowest level is locale-dependent.
- If a value is specified as the reference category of the dependent variable, then the value must exist in the data.
- The ORDER keyword following the dependent variable is honored only if the dependent variable is categorical and the multinomial distribution is used (/MODEL DISTRIBUTION = MULTINOMIAL). Otherwise, this specification is silently ignored.
- ORDER determines the sort order of the dependent variable's values. Cumulative link functions are applied based on this order.

ORDER = ASCENDING

Dependent variable values are sorted in ascending order, from the lowest value to the highest value. This is the default.

ORDER = DATA

Dependent variable values are not sorted. The first value encountered in the data defines the first category, the last value encountered defines the last category. This option may not be specified if splits are defined on the SPLIT FILE command.

ORDER = DESCENDING

Dependent variable values are sorted in descending order, from the highest value to the lowest value.

- If the dependent variable is a string variable, then ascending and descending order are locale-dependent.
- If an events/trials specification is used, then the events variable must be specified first, followed by the OF keyword, and then the trials variable or number.
- If an events/trials specification is used, then DISTRIBUTION = BINOMIAL must be specified on the MODEL subcommand. In this case, the procedure automatically computes the ratio of the events variable over the trials variable or number.
- The events and trials variables must be numeric.

- The events variable is usually the number of successes for each case. Data values must be nonnegative integers. Cases with invalid values are not used in the analysis.
- If a trials variable is specified, data values must be positive integers, and each value must be greater than or equal to the corresponding events value for a case. Cases with invalid values are not used in the analysis. If a number is specified, then it must be a positive integer, and it must be greater than or equal to the events value for each case. Cases with invalid values are not used in the analysis.
- The events and trials options are invalid if a dependent variable name is specified.
- The names of the factors and covariates, if any, follow the dependent variable or events/trials specification. Names of factors are specified following the keyword `BY`. Names of covariates are specified following the keyword `WITH`.
- The `ORDER` specification following a list of factor variable names determines the sort order of factor values. This order is relevant for determining a factor's last level, which may be associated with a redundant parameter in the estimation algorithm.

ORDER = ASCENDING

Factor variable values are sorted in ascending order, from the lowest value to the highest value. This is the default order.

ORDER = DATA

Factor variable values are not sorted. The first value encountered in the data defines the first category; the last value encountered defines the last category.

This option may not be specified if splits are defined on the `SPLIT FILE` command.

ORDER = DESCENDING

Factor variable values are sorted in descending order, from the highest value to the lowest value.

- Covariates must be numeric, but factors can be numeric or string variables.
- Each variable may be specified only once on the variable list.
- The `OFFSET` and `SCALEWEIGHT` variables may not be specified on the `GENLIN` command variable list.
- The `SUBJECT` and `WITHINSUBJECT` variables may not be specified as dependent, events, or trials variables on the `GENLIN` command variable list.
- Cases with missing values on the dependent variable, the events or trials variable, or any covariate are not used in the analysis.

MODEL Subcommand

The `MODEL` subcommand is used to specify model effects, an offset or scale weight variable if either exists, the probability distribution, and the link function.

- The effect list includes all effects to be included in the model except for the intercept, which is specified using the `INTERCEPT` keyword. Effects must be separated by spaces or commas.
- If the multinomial distribution is used (`DISTRIBUTION = MULTINOMIAL`), then the intercept is inapplicable. The multinomial model always includes threshold parameters. The number of threshold parameters is one less than the number of dependent variable categories.

- To include a term for the main effect of a factor, enter the variable name of the factor.
- To include a term for an interaction between factors, use the keyword BY or an asterisk (*) to join the factors involved in the interaction. For example, A*B means a two-way interaction effect of A and B, where A and B are factors. A*A is not allowed because factors in an interaction effect must be distinct.
- To include a term for nesting one effect within another, use a pair of parentheses. For example, A(B) means that A is nested within B.
- Multiple nesting is allowed. For example, A(B(C)) means that B is nested within C, and A is nested within B(C). When more than one pair of parentheses is present, each pair of parentheses must be enclosed or nested within another pair of parentheses. Thus, A(B)(C) is not valid.
- Interactions between nested effects are not valid. For example, neither A(C)*B(C) nor A(C)*B(D) is valid.
- To include a covariate term in the design, enter the variable name of the covariate.
- Covariates can be connected, but not nested, through the * operator to form another covariate effect. Interactions among covariates such as X1*X1 and X1*X2 are valid, but X1(X2) is not.
- Factor and covariate effects can be connected only by the * operator. Suppose A and B are factors, and X1 and X2 are covariates. Examples of valid factor-by-covariate interaction effects are A*X1, A*B*X1, X1*A(B), A*X1*X1, and B*X1*X2.
- If the MODEL subcommand is not specified, or if it is specified with no model effects, then the GENLIN procedure fits the intercept-only model (unless the intercept is excluded on the INTERCEPT keyword). If the multinomial distribution is being used, then the GENLIN procedure fits the thresholds-only model.

INTERCEPT Keyword

The INTERCEPT keyword controls whether an intercept term is included in the model.

- If the multinomial distribution is in effect (DISTRIBUTION = MULTINOMIAL), then the INTERCEPT keyword is silently ignored.

YES	*The intercept is included in the model.* This is the default.
NO	*The intercept is not included in the model.* If no model effects are defined and INTERCEPT = NO is specified, then a null model is fit.

OFFSET Keyword

The OFFSET keyword specifies an offset variable or fixes the offset at a number.

- The offset variable, if specified, must be numeric.
- The offset variable may not be a dependent variable, events or trials variable, factor, covariate, SCALEWEIGHT, SUBJECT, or WITHINSUBJECT variable.
- Cases with missing values on the OFFSET variable are not used in the analysis.

- Specifying a number when INTERCEPT = YES is equivalent to adding a constant to the intercept.
- Specifying a number when INTERCEPT = NO is equivalent to fixing the intercept at the specified number.

SCALEWEIGHT Keyword

The SCALEWEIGHT keyword specifies a variable that contains omega weight values for the scale parameter.

- The scale weight variable must be numeric.
- The scale weight variable may not be a dependent variable, events or trials variable, factor, covariate, OFFSET, SUBJECT, or WITHINSUBJECT variable.
- Cases with scale weight values that are less than or equal to 0, or missing, are not used in the analysis.

DISTRIBUTION Keyword

The DISTRIBUTION keyword specifies the probability distribution of the dependent variable.

- The default probability distribution depends on the specification format of the dependent variable. If an events/trials specification is used, then the default distribution is BINOMIAL. If a single variable specification is used, then the default distribution is NORMAL.
- Caution must be exercised when the dependent variable has events/trials format, and the LINK but not the DISTRIBUTION keyword is used. In this condition, depending on the LINK specification, the default DISTRIBUTION = BINOMIAL may yield an improper combination of DISTRIBUTION and LINK settings.
- Also, caution must be exercised when the dependent variable has single variable format, and the LINK but not the DISTRIBUTION keyword is used. In this condition, if the dependent variable is a string then an error will result because a string variable cannot have a normal probability distribution. Moreover, depending on the LINK specification, the default DISTRIBUTION = NORMAL may yield an improper combination of DISTRIBUTION and LINK settings.
- The discussion of the LINK keyword below gives details about proper and improper combinations of DISTRIBUTION and LINK settings.

BINOMIAL *Binomial probability distribution.* If the dependent variable is specified as a single variable, then it may be numeric or string and there may be only two distinct valid data values.

If the events and trials options are specified on the GENLIN command, then the procedure automatically computes the ratio of the events variable over the trials variable or number. The events variable—and the trials variable if specified—must be numeric. Data values for the events variable must be integers greater than or equal to zero. Data values for the trials variable must be integers greater than zero. For each case, the trials value must be greater than or equal to the events value. If an events value is noninteger, less than zero, or missing, then the corresponding case is not used in the analysis. If a trials value is noninteger, less than or equal to zero, less than the events value, or missing, then the corresponding case is not used in the analysis.

If the trials option specifies a number, then it must be a positive integer, and it must be greater than or equal to the events value for each case. Cases with invalid values are not used in the analysis.

This is the default probability distribution if the dependent variable is specified using events/trials format.

GAMMA *Gamma probability distribution.* The dependent variable must be numeric, with data values greater than zero. If a data value is less than or equal to zero, or missing, then the corresponding case is not used in the analysis.

IGAUSS *Inverse Gaussian probability distribution.* The dependent variable must be numeric, with data values greater than zero. If a data value is less than or equal to zero, or missing, then the corresponding case is not used in the analysis.

MULTINOMIAL *Multinomial probability distribution.* The dependent variable must be specified as a single variable, it may be numeric or string, and it must have at least two distinct valid data values. The dependent variable is assumed to be ordinal with values having an intrinsic ordering.

NEGBIN(number | MLE)

Negative binomial probability distribution. The dependent variable must be numeric, with data values that are integers greater than or equal to zero. If a data value is noninteger, less than zero, or missing, then the corresponding case is not used in the analysis.

The option specifies the negative binomial distribution's ancillary parameter. Specify a number greater than or equal to zero to fix the parameter at the number. Specify `MLE` to use the maximum likelihood estimate of the parameter. The default value is 1.

If the `REPEATED` subcommand is specified, then the ancillary parameter is treated as follows. (1) If the ancillary parameter is specified as a number, then it is fixed at that number for the initial generalized linear model and the generalized estimating equations. (2) If the ancillary parameter is estimated using maximum likelihood in the initial generalized linear model, then the estimate is passed to the generalized estimating equations, where it is treated as a fixed number. (3) If `NEGBIN(MLE)` is specified but the initial generalized linear model is bypassed and initial values are directly input to the generalized estimating equations (see the discussion of Initial Values and Generalized Estimating Equations in REPEATED Subcommand), then the initial value of the ancillary parameter is passed to the generalized estimating equations, where it is treated as a fixed number.

NORMAL *Normal probability distribution.* The dependent variable must be numeric. This is the default probability distribution if the dependent variable is specified using single-variable format.

POISSON *Poisson probability distribution.* The dependent variable must be numeric, with data values that are integers greater than or equal to zero. If a data value is noninteger, less than zero, or missing, then the corresponding case is not used in the analysis.

TWEEDIE(number)

Tweedie probability distribution. The dependent variable must be numeric, with data values greater than or equal to zero. If a data value is less than zero or missing, then the corresponding case is not used in the analysis. The required number specification is the fixed value of the Tweedie distribution's parameter. Specify a number greater than one and less than two. There is no default value.

LINK Keyword

The `LINK` keyword specifies the link function. The following link functions are available.

- If the multinomial distribution is in effect (`DISTRIBUTION = MULTINOMIAL`), then only the the cumulative link functions are available. Keywords corresponding to these functions have prefix `CUM`. If a non-cumulative link function is specified for the multinomial distribution, then an error is issued.

IDENTITY *Identity link function.* $f(x)=x$

CLOGLOG *Complementary log-log link function.* $f(x)=\ln(-\ln(1-x))$

LOG *Log link function.* $f(x)=\ln(x)$

LOGC *Log complement link function.* $f(x)=\ln(1-x)$

LOGIT *Logit link function.* $f(x)=\ln(x / (1-x))$

NEGBIN *Negative binomial link function.* $f(x)=\ln(x / (x+k^{-1}))$

NLOGLOG *Negative log-log link function.* $f(x)=-\ln(-\ln(x))$

ODDSPOWER(number)

Odds power link function. $f(x)=[(x/(1-x))^{\alpha}-1]/\alpha$, if $\alpha\neq 0$. $f(x)=\ln(x)$, if $\alpha=0$. α is the required number specification and must be a real number. There is no default value.

POWER(number)

Power link function. $f(x)=x^{\alpha}$, if $\alpha\neq 0$. $f(x)=\ln(x)$, if $\alpha=0$. α is the required number specification and must be a real number. If $|\alpha| < 2.2e\text{-}16$, α is treated as 0. There is no default value.

PROBIT *Probit link function.* $f(x)=\Phi^{-1}(x)$, where Φ^{-1} is the inverse standard normal cumulative distribution function.

CUMCAUCHIT *Cumulative Cauchit link function.* $f(x) = \tan(\pi\ (x - 0.5))$. May be specified only if `DISTRIBUTION = MULTINOMIAL`.

CUMCLOGLOG *Cumulative complementary log-log link function.* $f(x)=\ln(-\ln(1-x))$. May be specified only if `DISTRIBUTION = MULTINOMIAL`.

CUMLOGIT *Cumulative logit link function.* $f(x)=\ln(x / (1-x))$. May be specified only if `DISTRIBUTION = MULTINOMIAL`.

CUMNLOGLOG *Cumulative negative log-log link function.* $f(x)=-\ln(-\ln(x))$. May be specified only if `DISTRIBUTION = MULTINOMIAL`.

CUMPROBIT *Cumulative probit link function.* $f(x)=\Phi^{-1}(x)$, where Φ^{-1} is the inverse standard normal cumulative distribution function. May be specified only if `DISTRIBUTION = MULTINOMIAL`.

- If neither the `DISTRIBUTION` nor the `LINK` keyword is specified, then the default link function is `IDENTITY`.
- If `DISTRIBUTION` is specified but `LINK` is not, then the default setting for `LINK` depends on the `DISTRIBUTION` setting as shown in the following table.

DISTRIBUTION Setting	Default LINK Setting
NORMAL	IDENTITY
BINOMIAL	LOGIT
GAMMA	POWER(−1)
IGAUSS	POWER(−2)
MULTINOMIAL	CUMLOGIT
NEGBIN	LOG

DISTRIBUTION Setting	Default LINK Setting
POISSON	LOG
TWEEDIE	POWER(1−p), where p is the Tweedie distrubution's parameter

- The GENLIN procedure will fit a model if a permissible combination of LINK and DISTRIBUTION specifications is given. The table below indicates the permissible LINK and DISTRIBUTION combinations. Specifying an improper combination will yield an error message.
- Note that the default setting for DISTRIBUTION is NORMAL irrespective of the LINK specification, and that not all LINK specifications are valid for DISTRIBUTION = NORMAL. Thus, if LINK is specified but DISTRIBUTION is not, then the default DISTRIBUTION = NORMAL may yield an improper combination of DISTRIBUTION and LINK settings.

Table 86-1
Valid combinations of distribution and link function

Link	Distribution						
	NORMAL	BINOMIAL	GAMMA	IGAUSS	NEGBIN	POISSON	TWEEDIE
IDENTITY	X	X	X	X	X	X	X
CLOGLOG		X					
LOG	X	X	X	X	X	X	X
LOGC		X					
LOGIT		X					
NEGBIN					X		
NLOGLOG		X					
ODDSPOWER		X					
PROBIT		X					
POWER	X	X	X	X	X	X	X

Note: The NEGBIN link function is not available if DISTRIBUTION = NEGBIN(0) is specified.

CRITERIA Subcommand

The CRITERIA subcommand controls statistical criteria for the generalized linear model and specifies numerical tolerance for checking singularity.

Note that if the REPEATED subcommand is used, then the GENLIN procedure fits generalized estimating equations, which comprise a generalized linear model and a working correlation matrix that models within-subject correlations. In this case, the GENLIN procedure first fits a generalized linear model assuming independence and uses the final parameter estimates as the initial values for the linear model part of the generalized estimating equations. (For more information, see REPEATED Subcommand on p. 725.) The description of each CRITERIA subcommand keyword

below is followed by a statement indicating how the keyword is affected by specification of the REPEATED subcommand.

ANALYSISTYPE = 3 | 1 | ALL (WALD | LR)

Type of analysis for each model effect. Specify 1 for a type I analysis, 3 for type III analysis, or ALL for both. Each of these specifications computes chi-square statistics for each model effect.

Optionally, 1, 3, or ALL may be followed by WALD or LR in parentheses to specify the type of chi-square statistics to compute. WALD computes Wald statistics, LR computes likelihood-ratio statistics.

If likelihood-ratio statistics are computed, then the log-likelihood convergence criterion is used in all reduced models if type I analysis is in effect , or in all constrained models if type III analysis is in effect, irrespective of the convergence criteria used for parameter estimation in the full model. That is, for reduced or constrained models, any HCONVERGE and PCONVERGE specifications are not used, but all LCONVERGE specifications are used. (See the discussions of the HCONVERGE, PCONVERGE, and LCONVERGE keywords below.) If the log-likelihood convergence criterion is not in effect for the full model, then the reduced or constrained models use the log-likelihood convergence criterion with tolerance level 1E-4 and absolute change. The maximum number of iterations (MAXITERATIONS), maximum number of step-halvings (MAXSTEPHALVING), and starting iteration for checking complete and quasi-complete separation (CHECKSEP) are the same for reduced or constrained models as for the full model.

The default value is 3(WALD).

If the REPEATED subcommand is specified, then the option on the ANALYSISTYPE keyword is used for the generalized estimating equations. In this case, the WALD option computes Wald statistics, but the LR option computes generalized score statistics instead of likelihood-ratio statistics. For generalized score statistics, the convergence criteria for reduced or constrained models are the same as for the full model; that is, HCONVERGE or PCONVERGE as specified on the REPEATED subcommand.

CHECKSEP = integer

Starting iteration for checking complete and quasi-complete separation. Specify an integer greater than or equal to zero. This criterion is not used if the value is 0. The default value is 20. This criterion is used only for the binomial or multinomial probability distributions (that is, if DISTRIBUTION = BINOMIAL or MULTINOMIAL is specified on the MODEL subcommand). For all other probability distributions, it is silently ignored.

If the CHECKSEP value is greater than 0 and the binomial or multinomial probability distribution is being used, then separation is always checked following the final iteration.

If the REPEATED subcommand is specified, then the CHECKSEP keyword is applicable only to the initial generalized linear model.

CILEVEL = number

Confidence interval level for coefficient estimates and estimated marginal means. Specify a number greater than or equal to 0, and less than 100. The default value is 95.

If the REPEATED subcommand is specified, then the CILEVEL keyword is applicable to any parameter that is fit in the process of computing the generalized estimating equations.

CITYPE = WALD | PROFILE(number)

Confidence interval type. Specify WALD for Wald confidence intervals, or PROFILE for profile likelilhood confidence intervals. The default value is WALD.

PROFILE may be followed optionally by parentheses containing the tolerance level used by the two convergence criteria. The default value is 1E-4.

If the REPEATED subcommand is specified, then the CITYPE keyword is applicable only to the initial generalized linear model. For the linear model part of the generalized estimating equations, Wald confidence intervals are always used.

COVB = MODEL | ROBUST

Parameter estimate covariance matrix. Specify MODEL to use the model-based estimator of the parameter estimate covariance matrix, or ROBUST to use the robust estimator. The default value is MODEL.

If the REPEATED subcommand is specified, then the CRITERIA subcommand COVB keyword is silently ignored. The REPEATED subcommand COVB keyword is applicable to the linear model part of the generalized estimating equations.

HCONVERGE = number (ABSOLUTE | RELATIVE)

Hessian convergence criterion. Specify a number greater than or equal to 0, and the ABSOLUTE or RELATIVE keyword in parentheses to define the type of convergence. The number and keyword may be separated by a space character or a comma. The Hessian convergence criterion is not used if the number is 0. The default value is 0 (ABSOLUTE).

At least one of the CRITERIA subcommand keywords HCONVERGE, LCONVERGE, PCONVERGE must specify a nonzero number.

For a model with a normal distribution and identity link function, an iterative process is not used for parameter estimation. Thus, if DISTRIBUTION = NORMAL and LINK = IDENTITY on the MODEL subcommand, then the HCONVERGE keyword is silently ignored.

If the REPEATED subcommand is specified, then the CRITERIA subcommand HCONVERGE keyword is applicable only to the initial generalized linear model. The REPEATED subcommand HCONVERGE keyword is applicable to the linear model part of the generalized estimating equations.

INITIAL = number-list | 'savfile' | 'dataset'

Initial values for parameter estimates. Specify a list of numbers or an SPSS dataset. If a list of numbers is specified, then each number must be separated by a space character or a comma. If the filename of an SPSS dataset is specified, then the full path and filename must be given in quotes.

If the INITIAL keyword is specified, then initial values must be supplied for all parameters (including redundant parameters) in the generalized linear model. The ordering of the initial values should correspond to the ordering of the model parameters used by the GENLIN procedure. One way to determine how parameters are ordered for a given model is to run the GENLIN procedure for the model – without the INITIAL keyword – and examine the PRINT subcommand SOLUTION output.

If INITIAL is not specified, then the GENLIN procedure automatically determines the initial values.

If DISTRIBUTION = NORMAL and LINK = IDENTITY on the MODEL subcommand, then the INITIAL keyword is ignored with a warning.

If the REPEATED subcommand is specified, then the CRITERIA subcommand INITIAL keyword is applicable only to the initial generalized linear model. See the REPEATED subcommand below for a detailed discussion of initial values and generalized estimating equations.

Initial Values Specified using a List of Numbers

For all distributions except multinomial, if MODEL INTERCEPT = YES, then the initial values must begin with the initial value for the intercept parameter. If MODEL INTERCEPT = NO, then the initial values must begin with the initial value for the first regression parameter.

If SCALE = MLE, then the initial values must continue with the initial value for the scale parameter. If SCALE = DEVIANCE, PEARSON, or a fixed number, then a value may be given for the scale parameter but it is optional and always silently ignored.

Finally, if DISTRIBUTION = NEGBIN(MLE), then the initial values may end with an initial value for the negative binomial distribution's ancillary parameter. The initial value for this parameter must be specified as NEGBIN(number), where number is a number greater than or equal to zero. The default value is 1. If DISTRIBUTION = NEGBIN(MLE) is not in effect, then NEGBIN(number) is silently ignored.

For the multinomial distribution, the ordering of initial values is: threshold parameters, regression parameters.

Any additional unused numbers at the end of the list; that is, any numbers beyond those that are mapped to parameters, are silently ignored.

If the SPLIT FILE command is in effect, then the exact same list is applied to all splits. That is, each split must have the same set of parameters, and the same list is applied to each split. If the list contains too few or too many numbers for any split, then an error message is displayed.

Initial Values Specified using an SPSS Dataset

If an SPSS dataset is specified, then the file structure must be the same as that used in the OUTFILE subcommand CORB and COVB files. This structure allows the final values from one run of the GENLIN procedure to be saved in a CORB or COVB file and input as initial values in a subsequent run of the procedure.

In the dataset, the ordering of variables from left to right must be: *RowType_*, *VarName_*, *P1*, *P2*, …. The variables *RowType_* and *VarName_* are string variables. *P1*, *P2*, … are numeric variables corresponding to an ordered list of the parameters. (Variable names *P1*, *P2*, … are not required; the procedure will accept any valid variable names for the parameters. The mapping of variables to parameters is based on variable position, not variable name.) Any variables beyond the last parameter are ignored.

Initial values are supplied on a record with value 'EST' for variable *RowType_*; the actual initial values are given under variables *P1*, *P2*, …. The GENLIN procedure ignores all records for which *RowType_* has a value other than 'EST', as well as any records beyond the first occurrence of *RowType_* equal to 'EST'.

The required order of the intercept (if any) or threshold parameters, and regression parameters, is the same as for the list of numbers specification. However, when initial values are entered via an SPSS dataset, these parameters must always be followed by the scale parameter and then, if DISTRIBUTION = NEGBIN, by the negative binomial parameter.

If SPLIT FILE is in effect, then the variables must begin with the split-file variable or variables in the order specified on the SPLIT FILE command, followed by *RowType_*, *VarName_*, *P1*, *P2*, … as above. Splits must occur in the specified dataset in the same order as in the original dataset.

Examples.
The following example specifies initial values using a list of numbers. Suppose factor A has three levels. The INITIAL keyword supplies initial value 1 for the intercept, 1.5 for the first level of factor A, 2.5 for the second level, 0 for the last level, and 3 for the covariate X.

```
GENLIN depvar BY a WITH x
       /MODEL a x
       /CRITERIA INITIAL = 1 1.5 2.5 0 3.
```

The next example outputs the final estimates from one run of the GENLIN procedure and inputs these estimates as the initial values in the second run.

```
GENLIN depvar BY a WITH x
       /MODEL a x
       /OUTFILE COVB = '/work/estimates.sav'.
GENLIN depvar BY a WITH x
       /MODEL a x
       /CRITERIA INITIAL = '/work/estimates.sav'.
```

LCONVERGE = number (ABSOLUTE | RELATIVE)

Log-likelihood convergence criterion. Specify a number greater than or equal to 0, and the ABSOLUTE or RELATIVE keyword in parentheses to define the type of convergence. The number and keyword may be separated by a space character or a comma. The log-likelihood convergence criterion is not used if the number is 0. The default value is 0 (ABSOLUTE).

At least one of the CRITERIA subcommand keywords HCONVERGE, LCONVERGE, PCONVERGE must specify a nonzero number.

If DISTRIBUTION = NORMAL and LINK = IDENTITY on the MODEL subcommand, then the LCONVERGE keyword is silently ignored.

If the REPEATED subcommand is specified, then the LCONVERGE keyword is applicable only to the initial generalized linear model.

LIKELIHOOD = FULL | KERNEL

Form of the log-likelihood or log-quasi-likelihood function. Specify FULL for the full function, or KERNEL for the kernel of the function. The default value is FULL.

For generalized linear models, the LIKELIHOOD keyword specifies the form of the log likelihood function. If the REPEATED subcommand is specified, then it specifies the form of the log quasi-likelihood function.

MAXITERATIONS = integer

Maximum number of iterations. Specify an integer greater than or equal to 0. The default value is 100. If DISTRIBUTION = NORMAL and LINK = IDENTITY on the MODEL subcommand, then the MAXITERATIONS keyword is silently ignored.

If the REPEATED subcommand is specified, then the CRITERIA subcommand MAXITERATIONS keyword is applicable only to the initial generalized linear model. The REPEATED subcommand MAXITERATIONS keyword is applicable to the linear model part of the generalized estimating equations.

MAXSTEPHALVING = integer

Maximum number of steps in step-halving method. Specify an integer greater than 0. The default value is 5. If DISTRIBUTION = NORMAL and LINK = IDENTITY on the MODEL subcommand, then the MAXSTEPHALVING keyword is silently ignored.

If the REPEATED subcommand is specified, then the MAXSTEPHALVING keyword is applicable only to the initial generalized linear model.

METHOD = FISHER | NEWTON | FISHER(integer)

Model parameters estimation method. Specify FISHER to use the Fisher scoring method, NEWTON to use the Newton-Raphson method, or FISHER(integer) to use a hybrid method.

In the hybrid method option, *integer* is an integer greater than 0 and specifies the maximum number of Fisher scoring iterations before switching to the Newton-Raphson method. If convergence is achieved during the Fisher scoring phase of the hybrid method, then additional Newton-Raphson steps are performed until convergence is achieved for Newton-Raphson too.

The default algorithm for the generalized linear model uses Fisher scoring in the first iteration and Newton-Raphson thereafter; the default value for the METHOD keyword is FISHER(1).

If DISTRIBUTION = NORMAL and LINK = IDENTITY on the MODEL subcommand, then the METHOD keyword is silently ignored.

If the REPEATED subcommand is specified, then the METHOD keyword is applicable only to the initial generalized linear model.

PCONVERGE = number (ABSOLUTE | RELATIVE)

Parameter convergence criterion. Specify a number greater than or equal to 0, and the ABSOLUTE or RELATIVE keyword in parentheses to define the type of convergence. The number and keyword may be separated by a space character or a comma. The parameter convergence criterion is not used if the number is 0. The default value is 1E-6 (ABSOLUTE).

At least one of the CRITERIA subcommand keywords HCONVERGE, LCONVERGE, PCONVERGE must specify a nonzero number.

If DISTRIBUTION = NORMAL and LINK = IDENTITY on the MODEL subcommand, then the PCONVERGE keyword is silently ignored.

If the REPEATED subcommand is specified, then the CRITERIA subcommand PCONVERGE keyword is applicable only to the initial generalized linear model. The REPEATED subcommand PCONVERGE keyword is applicable to the linear model part of the generalized estimating equations.

SCALE = MLE | DEVIANCE | PEARSON | number

Method of fitting the scale parameter. Specify MLE to compute a maximum likelihood estimate, DEVIANCE to compute the scale parameter using the deviance, PEARSON to compute it using the Pearson chi-square, or a number greater than 0 to fix the scale parameter.

If the MODEL subcommand specifies DISTRIBUTION = NORMAL, IGAUSS, GAMMA, or TWEEDIE then any of the SCALE options may be used. For these distributions, the default value is MLE.

If the MODEL subcommand specifies DISTRIBUTION = NEGBIN, POISSON, BINOMIAL, or MULTINOMIAL, then DEVIANCE, PEARSON, or a fixed number may be used. For these distributions, the default value is the fixed number 1.

If the REPEATED subcommand is specified, then the SCALE keyword is directly applicable only to the initial generalized linear model. For the linear model part of the generalized estimating equations, the scale parameter is treated as follows:

- If SCALE = MLE, then the scale parameter estimate from the initial generalized linear model is passed to the generalized estimating equations, where it is updated by the Pearson chi-square divided by its degrees of freedom.
- If SCALE = DEVIANCE or PEARSON, then the scale parameter estimate from the initial generalized linear model is passed to the generalized estimating equations, where it is treated as a fixed number.
- If SCALE is specified with a fixed number, then the scale parameter is also held fixed at the same number in the generalized estimating equations.

SINGULAR = number

Tolerance value used to test for singularity. Specify a number greater than 0. The default value is 1E-12.

If the REPEATED subcommand is specified, then the SINGULAR keyword is applicable to any linear model that is fit in the process of computing the generalized estimating equations.

REPEATED Subcommand

The REPEATED subcommand specifies the correlation structure used by generalized estimating equations to model correlations within subjects and controls statistical criteria in the nonlikelihood-based iterative fitting algorithm. If the REPEATED subcommand is not specified, then the GENLIN procedure fits a generalized linear model assuming independence.

Initial Values and Generalized Estimating Equations

Generalized estimating equations require initial values for the parameter estimates in the linear model. Initial values are not needed for the working correlation matrix because matrix elements are based on the parameter estimates.

The GENLIN procedure automatically supplies initial values to the generalized estimating equations algorithm. The default initial values are the final parameter estimates from the ordinary generalized linear model, assuming independence, that is fit based on the MODEL and CRITERIA subcommand specifications.

Recall that if the REPEATED subcommand is specified, then the CRITERIA subcommand SCALE keyword is directly applicable only to the initial generalized linear model. For the linear model part of the generalized estimating equations, the scale parameter is treated as follows.

- If SCALE = MLE, then the scale parameter estimate from the initial generalized linear model is passed to the generalized estimating equations, where it is updated by the Pearson chi-square divided by its degrees of freedom. Pearson chi-square is used because generalized estimating equations do not have the concept of likelihood, and hence the scale estimate cannot be updated by methods related to maximum likelihood estimation.
- If SCALE = DEVIANCE or PEARSON, then the scale parameter estimate from the initial generalized linear model is passed to the generalized estimating equations, where it is treated as a fixed number.
- If SCALE is specified with a fixed number, then the scale parameter is also held fixed in the generalized estimating equations.

It is possible to bypass fitting the generalized linear model and directly input initial values to the generalized estimating equations algorithm. To do this, specify the linear model as usual on the MODEL subcommand. Then, on the CRITERIA subcommand, specify initial values for the linear model on the INITIAL keyword and set MAXITERATIONS = 0.

For example, suppose factor A has three levels. The INITIAL keyword supplies initial value 1 for the intercept, 1.5 for the first level of factor A, 2.5 for the second level, 0 for the last level, and 3 for the covariate X. Because MAXITERATIONS = 0, no iterations are performed for the generalized linear model and the specified initial values are passed directly to the generalized estimating equations algorithm.

```
GENLIN depvar BY a WITH x
  /MODEL a x
    DISTRIBUTION = BINOMIAL
    LINK = LOGIT
    INITIAL = 1 1.5 2.5 0 3
    MAXITERATIONS = 0
```

```
  /REPEATED
    SUBJECT=idvar.
```

It is also possible to use a maximum likelihood estimate of the scale parameter as the initial value and to fix the scale parameter at this initial value for the generalized estimating equations. That is, we can override the default updating by the Pearson chi-square divided by its degrees of freedom. To do this, first fit a generalized linear model, estimating the scale parameter via maximum likelihood, and save the final parameter estimates in an external file (using the OUTFILE subcommand CORB or COVB option). Next, open this external file and copy the scale parameter estimate in full precision. Finally, fit the generalized estimating equations, using the final parameter estimates from the generalized linear model as the initial values, with MAXITERATIONS = 0 on the CRITERIA subcommand and SCALE fixed at the scale parameter estimate on the CRITERIA subcommand. The following example syntax assumes that the maximum likelihood estimate of the scale parameter is 0.1234567890123456.

```
GENLIN depvar BY a WITH x
  /MODEL a x
     DISTRIBUTION = NORMAL
     LINK = LOG
  /CRITERIA
     SCALE = MLE
  /OUTFILE
     COVB = '/work/estimates.sav'.

GENLIN depvar BY a WITH x
  /MODEL a x
     DISTRIBUTION = NORMAL
     LINK = LOG
  /CRITERIA
     INITIAL = '/work/estimates.sav'
     MAXITERATIONS = 0
     SCALE = 0.1234567890123456
  /REPEATED
     SUBJECT=idvar.
```

When the negative binomial distribution is used (/MODEL DISTRIBUTION = NEGBIN), the distribution's ancillary parameter is treated as follows:

1. If the ancillary parameter is specified as a number, then it is fixed at that number for the initial generalized linear model and the generalized estimating equations.
2. If the ancillary parameter is estimated using maximum likelihood in the initial generalized linear model, then the estimate is passed to the generalized estimating equations, where it is treated as a fixed number.
3. If NEGBIN(MLE) is specified but the initial generalized linear model is bypassed and initial values are directly input to the generalized estimating equations, then the initial value of the ancillary parameter is passed to the generalized estimating equations, where it is treated as a fixed number.

SUBJECT Keyword

The SUBJECT keyword identifies subjects in the active dataset. Complete independence is assumed *across* subjects, but responses *within* subjects are assumed to be correlated.

- Specify a single variable or a list of variables connected by asterisks (*) or the keyword BY.

- Variables may be numeric or string variables.
- The number of subjects equals the number of distinct combinations of values of the variables.
- If the active dataset is sorted by the subject variables, then all records with equal values on the subject variables are contiguous and define the measurements for one subject.
- In contrast, if the active dataset is not sorted, then the GENLIN procedure reads the data record by record. Each block of equal values on the subject variables defines a new subject. Please be aware that this approach may produce invalid results if all records for a subject are not contiguous in the active dataset.
- By default, the GENLIN procedure automatically sorts the active dataset by subject and any within-subject variables before performing analyses. See the SORT keyword below for more information.
- All specified variables must be unique.
- The dependent, events, trials, and WITHINSUBJECT variables may not be specified as SUBJECT variables.
- The SUBJECT keyword is required if the REPEATED subcommand is used.
- Cases with missing values for any of the subject variables are not used in the analysis.

WITHINSUBJECT Keyword

The WITHINSUBJECT keyword gives the within-subject or time effect. This effect defines the ordering of measurements within subjects. If some measurements do not appear in the data for some subjects, then the existing measurements are ordered and the omitted measurements are treated as missing values. If WITHINSUBJECT is not used, then measurements may be improperly ordered and missing values assumed for the last measurements within subjects.

- Specify a single variable or a list of variables connected by asterisks (*) or the keyword BY.
- Variables may be numeric or string variables.
- The WITHINSUBJECT keyword is honored only if the default SORT = YES is in effect. The number of measurements within a subject equals the number of distinct combinations of values of the WITHINSUBJECT variables.
- The WITHINSUBJECT keyword is ignored and a warning is issued if SORT = NO is in effect. In this case, the GENLIN procedure reads the records for a subject in the order given in the active dataset.
- By default, the GENLIN procedure automatically sorts the active dataset by subject and any within-subject variables before performing analyses. See the SORT keyword below for more information.
- All specified variables must be unique.
- The dependent, events, trials, and SUBJECT variables may not be specified as WITHINSUBJECT variables.
- The WITHINSUBJECT keyword is not required if the data are properly ordered within each subject.
- Cases with missing values for any of the within-subject variables are not used in the analysis.

SORT Keyword

The SORT keyword indicates whether to sort cases in the working dataset by the subject effect and the within-subject effect.

YES *Sort cases by subject and any within-subject variables.* The GENLIN procedure sorts the active dataset before performing analyses. The subject and any within-subject variables are sorted based on the ascending sort order of their data values. If any of the variables are strings, then their sort order is locale-dependent. This is the default. This sort is temporary—it is in effect only for the duration of the GENLIN procedure.

NO *Do not sort cases by subject and any within-subject variables.* If SORT = NO is specified, then the GENLIN procedure does not sort the active dataset before performing analyses.

CORRTYPE Keyword

The CORRTYPE keyword specifies the working correlation matrix structure.

INDEPENDENT *Independent working correlation matrix.* This is the default working correlation matrix structure.

AR(1) *AR(1) working correlation matrix.*

EXCHANGEABLE *Exchangeable working correlation matrix.*

FIXED(list) *Fixed working correlation matrix.* Specify a list of numbers, with each number separated by a space character or a comma.

The list of numbers must define a valid working correlation matrix. The number of rows and the number of columns must equal the dimension of the working correlation matrix. This dimension depends on the subject effect, the within-subject effect, whether the active dataset is sorted, and the data. The simplest way to determine the working correlation matrix dimension is to run the GENLIN procedure first for the model using the default working correlation matrix structure (instead of the FIXED structure) and examine the PRINT MODELINFO output for the working correlation matrix dimension. Then, rerun the procedure with the FIXED specification.

Specify only the lower triangular portion of the matrix. Matrix elements must be specified row-by-row. All elements must be between 0 and 1 inclusive.

For example, if there are three measurements per subject, then the following specification defines a 3 * 3 working correlation matrix.

```
CORRTYPE = FIXED(0.84 0.65 0.75)

1.00 0.84 0.65
0.84 1.00 0.75
0.65 0.75 1.00
```

There is no default value for the fixed working correlation matrix.

MDEPENDENT(integer)

m-dependent working correlation matrix. Specify the value of *m* in parentheses as an integer greater than or equal to 0. The specified m should be less than the number of row or column levels in the working correlation matrix. If the specified *m* is greater than the dimension of the working correlation matrix, then *m* is set equal to the number of row or column levels minus 1. For example, if the dimension of the working correlation matrix is 4, then *m* should be 3 or less. In this case, if you specify *m* > 3, then *m* will be set equal to 3. There is no default value.

UNSTRUCTURED *Unstructured working correlation matrix.*

ADJUSTCORR Keyword

The ADJUSTCORR keyword indicates whether to adjust the working correlation matrix estimator by the number of nonredundant parameters.

YES *Adjust the working correlation matrix estimator.* This is the default.

NO *Compute the working correlation matrix estimator without the adjustment.*

COVB Keyword

The COVB keyword specifies whether to use the robust or the model-based estimator of the parameter estimate covariance matrix for generalized estimating equations.

ROBUST *Robust estimator of the parameter estimate covariance matrix.* This is the default.

MODEL *Model-based estimator of the parameter estimate covariance matrix.*

HCONVERGE Keyword

The HCONVERGE keyword specifies the Hessian convergence criterion for the generalized estimating equations algorithm. For generalized estimating equations, the Hessian convergence criterion is always absolute.

- Specify a number greater than or equal to 0. The Hessian convergence criterion is not used if the number is 0. The default value is 0.
- At least one of the REPEATED subcommand keywords HCONVERGE, PCONVERGE must specify a nonzero number.

MAXITERATIONS Keyword

The MAXITERATIONS keyword specifies the maximum number of iterations for the generalized estimating equations algorithm.

- Specify an integer greater than or equal to 0. The default value is 100.

PCONVERGE Keyword

The PCONVERGE keyword specifies the parameter convergence criterion for the generalized estimating equations algorithm.

- Specify a number greater than or equal to 0, and the ABSOLUTE or RELATIVE keyword in parentheses to define the type of convergence. The number and keyword may be separated by a space character or a comma. The parameter convergence criterion is not used if the number is 0. The default value is 1E-6 (ABSOLUTE).
- At least one of the REPEATED subcommand keywords HCONVERGE, PCONVERGE must specify a nonzero number.

UPDATECORR Keyword

The UPDATECORR keyword specifies the number of iterations between updates of the working correlation matrix. Elements in the working correlation matrix are based on the parameter estimates, which are updated in each iteration of the algorithm. The UPDATECORR keyword specifies the iteration interval at which to update working correlation matrix elements. Specifying a value greater than 1 may reduce processing time.

- Specify an integer greater than 0.
- The working correlation matrix is not updated at all if the value is 0. In this case, the initial working correlation matrix is used throughout the estimation process.
- The default value is 1. By default, the working correlation matrix is updated after every iteration, beginning with the first.
- The UPDATECORR value must be less than or equal to the REPEATED MAXITERATIONS value.

EMMEANS Subcommand

The EMMEANS subcommand displays estimated marginal means of the dependent variable for all level combinations of a set of factors. Note that these are predicted, not observed, means. Estimated marginal means can be computed based on the original scale of the dependent variable or the based on the link function transformation.

- Multiple EMMEANS subcommands are allowed. Each is treated independently.
- The EMMEANS subcommand may be specified with no additional keywords. The output for an empty EMMEANS subcommand is the overall estimated marginal mean of the response, collapsing over any factors and holding any covariates at their overall means.
- Estimated marginal means are not available if the multinomial distribution is used. If DISTRIBUTION = MULTINOMIAL on the MODEL subcommand and the EMMEANS subcommand is specified, then EMMEANS is ignored and a warning is issued.

TABLES Keyword

The TABLES keyword specifies the cells for which estimated marginal means are displayed.

- Valid options are factors appearing on the GENLIN command factor list, and crossed factors constructed of factors on the factor list. Crossed factors can be specified using an asterisk (*) or the keyword BY. All factors in a crossed factor specification must be unique.
- If the TABLES keyword is specified, then the GENLIN procedure collapses over any factors on the GENLIN command factor list but not on the TABLES keyword before computing the estimated marginal means for the dependent variable.
- If the TABLES keyword is not specified, then the overall estimated marginal mean of the dependent variable, collapsing over any factors, is computed.

CONTROL Keyword

The CONTROL keyword specifies the covariate values to use when computing the estimated marginal means.

- Specify one or more covariates appearing on the GENLIN command covariate list, each of which must be followed by a numeric value or the keyword MEAN in parentheses.
- If a numeric value is given for a covariate, then the estimated marginal means will be computed by holding the covariate at the supplied value. If the keyword MEAN is used, then the estimated marginal means will be computed by holding the covariate at its overall mean. If a covariate is not specified on the CONTROL option, then its overall mean will be used in estimated marginal means calculations.
- Any covariate may occur only once on the CONTROL keyword.

SCALE Keyword

The SCALE keyword specifies whether to compute estimated marginal means based on the original scale of the dependent variable or based on the link function transformation.

ORIGINAL *Estimated marginal means are based on the original scale of the dependent variable.* Estimated marginal means are computed for the response. This is the default. Note that when the dependent variable is specified using the events/trials option, ORIGINAL gives the estimated marginal means for the events/trials proportion rather than for the number of events.

TRANSFORMED *Estimated marginal means are based on the link function transformation.* Estimated marginal means are computed for the linear predictor.

Example

The following syntax specifies a logistic regression model with binary dependent variable Y and categorical predictor A. Estimated marginal means are requested for each level of A. Because SCALE = ORIGINAL is used, the estimated marginal means are based on the original response. Thus, the estimated marginal means are real numbers between 0 and 1. If SCALE = TRANSFORMED had been used instead, then the estimated marginal means would be based on the logit-transformed response and would be real numbers between negative and positive infinity.

```
GENLIN y BY a
  /MODEL a
    DISTRIBUTION=BINOMIAL
```

```
  LINK=LOGIT
/EMMEANS TABLES=a SCALE=ORIGINAL.
```

COMPARE Keyword

The COMPARE keyword specifies a factor or a set of crossed factors, the levels or level combinations of which are compared using the contrast type specified on the CONTRAST keyword.

- Valid options are factors appearing on the TABLES keyword. Crossed factors can be specified using an asterisk (*) or the keyword BY. All factors in a crossed factor specification must be unique.
- The COMPARE keyword is valid only if the TABLES keyword is also specified.
- If a single factor is specified, then levels of the factor are compared for each level combination of any other factors on the TABLES keyword.
- If a set of crossed factors is specified, then level combinations of the crossed factors are compared for each level combination of any other factors on the TABLES keyword. Crossed factors may be specified only if PAIRWISE is specified on the CONTRAST keyword.
- By default, the GENLIN procedure sorts levels of the factors in ascending order and defines the highest level as the last level. (If the factor is a string variable, then the value of the highest level is locale-dependent.) However, the sort order can be modified using the ORDER keyword following the factor list on the GENLIN command.
- Only one COMPARE keyword is allowed on a given EMMEANS subcommand.

CONTRAST Keyword

The CONTRAST keyword specifies the type of contrast to use for the levels of the factor, or level combinations of the crossed factors, on the COMPARE keyword. The CONTRAST keyword creates an **L** matrix (that is, a coefficient matrix) such that the columns corresponding to the factor(s) match the contrast given. The other columns are adjusted so that the **L** matrix is estimable.

- The CONTRAST keyword is valid only if the COMPARE keyword is also specified.
- If a single factor is specified on the COMPARE keyword, then any contrast type may be specified on the CONTRAST keyword.
- If a set of crossed factors is specified on the COMPARE keyword, then only the PAIRWISE keyword may be specified on the CONTRAST keyword.
- Only one CONTRAST keyword is allowed on a given EMMEANS subcommand.
- If the COMPARE keyword is specified without CONTRAST, then pairwise comparisons are performed for the factor(s) on COMPARE.
- DIFFERENCE, HELMERT, REPEATED, and SIMPLE contrasts are defined with respect to a first or last level. The first or last level is determined by the ORDER specification following the factors on the GENLIN command line. By default, ORDER = ASCENDING and the last level corresponds to the last level.

The following contrast types are available.

PAIRWISE *Pairwise comparisons are computed for all level combinations of the specified or implied factors.* This is the default contrast type.

For example,

```
GENLIN y BY a b c
  …
  /EMMEANS TABLES=a*b*c COMPARE a*b CONTRAST=PAIRWISE.
```

The specified contrast performs pairwise comparisons of all level combinations of factors A and B, for each level of factor C.

Pairwise contrasts are not orthogonal.

DEVIATION (value)

Each level of the factor is compared to the grand mean. Deviation contrasts are not orthogonal.

DIFFERENCE *Each level of the factor except the first is compared to the mean of previous levels.* In a balanced design, difference contrasts are orthogonal.

HELMERT *Each level of the factor except the last is compared to the mean of subsequent levels.* In a balanced design, Helmert contrasts are orthogonal.

POLYNOMIAL (number list)

Polynomial contrasts. The first degree of freedom contains the linear effect across the levels of the factor, the second contains the quadratic effect, and so on. By default, the levels are assumed to be equally spaced; the default metric is (1 2 . . . *k*), where *k* levels are involved. The `POLYNOMIAL` keyword may be followed optionally by parentheses containing a number list. Numbers in the list must be separated by spaces or commas. Unequal spacing may be specified by entering a metric consisting of one number for each level of the factor. Only the relative differences between the terms of the metric matter. Thus, for example, (1 2 4) is the same metric as (2 3 5) or (20 30 50) because, in each instance, the difference between the second and third numbers is twice the difference between the first and second. All numbers in the metric must be unique; thus, (1 1 2) is not valid.

A user-specified metric must supply at least as many numbers as there are levels of the compared factor. If too few numbers are specified, then a warning is issued and hypothesis tests are not performed. If too many numbers are specified, then a warning is issued but hypothesis tests are still performed. In the latter case, the contrast is created based on the specified numbers beginning with the first and using as many numbers as there are levels of the compared factor. In any event, we recommend printing the L matrix (`/PRINT LMATRIX`) to confirm that the proper contrast is being constructed.

For example,

```
GENLIN y BY a
  …
  /EMMEANS TABLES=a CONTRAST=POLYNOMIAL(1 2 4).
```

Suppose that factor A has three levels. The specified contrast indicates that the three levels of A are actually in the proportion 1:2:4.

Alternatively, suppose that factor A has two levels. In this case, the specified contrast indicates that the two levels of A are in the proportion 1:2.

In a balanced design, polynomial contrasts are orthogonal.

REPEATED *Each level of the factor except the last is compared to the next level.* Repeated contrasts are not orthogonal.

SIMPLE (value)

Each level of the factor except the last is compared to the last level. The `SIMPLE` keyword may be followed optionally by parentheses containing a value. Put the value inside a pair of quotes if it is formatted (such as date or currency) or if the factor is of string type. If a value is specified, then the factor level with that value is used as the omitted reference category. If the specified value does not exist in the data, then a warning is issued and the last level is used.

For example,

```
GENLIN y BY a
  …
  /EMMEANS TABLES=a CONTRAST=SIMPLE(1).
```

The specified contrast compares all levels of factor A (except level 1) to level 1.

Simple contrasts are not orthogonal.

PADJUST Keyword

The `PADJUST` keyword indicates the method of adjusting the significance level.

LSD *Least significant difference.* This method does not control the overall probability of rejecting the hypotheses that some linear contrasts are different from the null hypothesis value(s). This is the default.

BONFERRONI

Bonferroni. This method adjusts the observed significance level for the fact that multiple contrasts are being tested.

SEQBONFERRONI

Sequential Bonferroni. This is a sequentially step-down rejective Bonferroni procedure that is much less conservative in terms of rejecting individual hypotheses but maintains the same overall significance level.

SIDAK *Sidak.* This method provides tighter bounds than the Bonferroni approach.

SEQSIDAK *Sequential Sidak.* This is a sequentially step-down rejective Sidak procedure that is much less conservative in terms of rejecting individual hypotheses but maintains the same overall significance level.

MISSING Subcommand

The `MISSING` subcommand specifies how missing values are handled.

- Cases with system missing values on any variable used by the `GENLIN` procedure are excluded from the analysis.

- Cases must have valid data for the dependent variable or the events and trials variables, any covariates, the OFFSET variable if it exists, the SCALEWEIGHT variable if it exists, and any SUBJECT and WITHINSUBJECT variables. Cases with missing values for any of these variables are not used in the analysis.
- The CLASSMISSING keyword specifies whether user-missing values of any factors are treated as valid.

EXCLUDE *Exclude user-missing values among any factor or subpopulation variables.* Treat user-missing values for these variables as invalid data. This is the default.

INCLUDE *Include user-missing values among any factor or subpopulation variables.* Treat user-missing values for these variables as valid data.

PRINT Subcommand

The PRINT subcommand is used to display optional output.

- If the PRINT subcommand is not specified, then the default output indicated below is displayed.
- If the PRINT subcommand is specified, then the GENLIN procedure displays output only for those keywords that are specified.

CORB *Correlation matrix for parameter estimates.*

COVB *Covariance matrix for parameter estimates.*

CPS *Case processing summary.* For generalized estimating equations, this keyword also displays the Correlated Data Summary table. This is the default output if the PRINT subcommand is not specified.

DESCRIPTIVES

Descriptive statistics. Displays descriptive statistics and summary information about the dependent variable, covariates, factors. This is the default output if the PRINT subcommand is not specified.

FIT *Goodness of fit.* For generalized linear models, displays deviance and scaled deviance, Pearson chi-square and scaled Pearson chi-square, log likelihood, Akaike's information criterion (AIC), finite sample corrected AIC (AICC), Bayesian information criterion (BIC), and consistent AIC (CAIC).

Note that when the scale parameter is fit using the deviance (/CRITERIA SCALE = DEVIANCE) or Pearson chi-square (/CRITERIA SCALE = PEARSON), the algorithm begins by assuming the scale parameter equals 1. Following estimation of the regression coefficients, the estimated scale parameter is calculated. Finally, estimated standard errors, Wald confidence intervals, and significance tests are adjusted based on the estimated scale parameter. However, in order to ensure fair comparison in the information criteria and the model fit omnibus test (see the SUMMARY keyword below), the log likelihood is not revised by the estimated scale parameter. Instead, when the scale parameter is fit using the deviance or Pearson chi-square, the log likelihood is computed with the scale parameter set equal to 1.

For generalized estimating equations, displays two extensions of AIC for model selection: Quasi-likelihood under the independence model criterion (QIC) for choosing the best correlation structure, and corrected quasi-likelihood under the independence model criterion (QICC) for choosing the best subset of predictors.

The quasi-likelihood functions are computed with the scale parameter set equal to a fixed value if a fixed value is specified on the `/CRITERIA SCALE` keyword. Otherwise, if `/CRITERIA SCALE = MLE`, `DEVIANCE`, or `PEARSON`, then the quasi-likelihood functions are computed with the scale parameter set equal to 1.

Goodness of fit statistics are not available for generalized estimating equations when the multinomial distribution is used. Thus, if the `REPEATED` subcommand and `/MODEL DISTRIBUTION = MULTINOMIAL` are specified, then the `FIT` keyword is silently ignored.

This is the default output if the `PRINT` subcommand is not specified.

GEF *General estimable function.*

HISTORY (integer)

Iteration history. For generalized linear models, displays the iteration history for the parameter estimates and log-likelihood, and prints the last evaluation of the gradient vector and the Hessian matrix. Also displays the iteration history for the profile likelihood confidence intervals (if requested via `CRITERIA CITYPE = PROFILE`) and for type I or III analyses (if requested via `PRINT SUMMARY`).

For generalized estimating equations, displays the iteration history for the parameter estimates, and prints the last evaluation of the generalized gradient and the Hessian matrix. Also displays the iteration history for type III analyses (if requested via `PRINT SUMMARY`).

The `HISTORY` keyword may be followed optionally by an integer *n* in parentheses, where the integer is greater than zero. The iteration history table displays parameter estimates for every *n* iterations beginning with the 0th iteration (the initial estimates). The default is to print every iteration (*n* = 1). If `HISTORY` is specified, then the last iteration is always displayed regardless of the value of *n*.

LAGRANGE *Lagrange multiplier test.* For the normal, gamma, inverse Gaussian, and Tweedie distributions, displays Lagrange multiplier test statistics for assessing the validity of a scale parameter that is computed using the deviance or Pearson chi-square, or set at a fixed number. For the negative binomial distribution, tests the fixed ancillary parameter.

The `LAGRANGE` keyword is honored if `MODEL DISTRIBUTION = NORMAL`, `GAMMA`, `IGAUSS`, or `TWEEDIE` and `CRITERIA SCALE = DEVIANCE`, `PEARSON`, or `number`; or if `MODEL DISTRIBUTION = NEGBIN(number)` is specified. Otherwise the keyword is ignored and a warning is issued.

If the `REPEATED` subcommand is specified, then the `LAGRANGE` keyword is silently ignored.

LMATRIX *Set of contrast coefficient (L) matrices.* Displays contrast coefficients for the default effects and for the estimated marginal means if requested.

MODELINFO *Model information.* Displays the dataset name, dependent variable or events and trials variables, offset variable, scale weight variable, probability distribution, and link function.

For generalized estimating equations, also displays the subject variables, within-subject variables, and working correlation matrix structure.

This is the default output if the PRINT subcommand is not specified.

SOLUTION *Parameter estimates and corresponding statistics.* This is the default output if the PRINT subcommand is not specified.

The SOLUTION keyword may be followed optionally by the keyword EXPONENTIATED in parentheses to display exponentiated parameter estimates in addition to the raw parameter estimates.

SUMMARY *Model summary statistics.* Displays model fit tests, including likelihood ratio statistics for the model fit omnibus test, and statistics for the type I or III contrasts for each effect (depending on the CRITERIA ANALYSISTYPE specification). This is default output if the PRINT subcommand is not specified.

If the REPEATED subcommand is specified, then only the statistics for each effect are displayed.

WORKINGCORR

Working correlation matrix. This keyword is honored only if the REPEATED is in effect. Otherwise it is silently ignored.

NONE *No PRINT subcommand output.* None of the PRINT subcommand output is displayed. If NONE is specified, then no other keywords are allowed on the PRINT subcommand.

SAVE Subcommand

The SAVE subcommand adds predicted, residual, leverage, or Cook's distance values to the working dataset.

- Specify one or more temporary variables, each followed by an optional new name in parentheses.
- The optional names must be unique, valid variable names.
- If new names are not specified, then GENLIN uses the default names. If the default names conflict with existing variable names, then a suffix is added to the default names to make them unique.

The following rules describe the functionality of the SAVE subcommand when the response variable—either the dependent variable or the events or trials variable—has an invalid value for a case.

- If all factors and covariates in the model have valid values for the case, then the procedure computes predicted values but not the residuals. (The MISSING subcommand setting is taken into account when defining valid/invalid values for a factor.)
- An additional restriction for factors is that only those values of the factor actually used in building the model are considered valid. For example, suppose factor A takes values 1, 2, and 3 when the procedure builds the model. Also suppose there is a case with an invalid dependent variable value, a value of 4 on factor A, and valid values on all other factors and covariates. For this case, no predicted value is saved because there is no model coefficient corresponding to factor A = 4.

XBPRED (varname | rootname:n)

Predicted value(s) of the linear predictor. For all distributions except the multinomial, XBPRED creates one variable and the default variable name is *XBPredicted*. Specify a variable name in parentheses to override the default.

For the multinomial distribution, one variable is created for each dependent variable category except the last (see the dependent variable ORDER keyword in the section Variable List). XBPRED saves the predicted values of the linear predictor for the first 25 categories, up to but not including the last, by default. The default root name is *XBPredicted*, and the default variable names are *XBPredicted_1*, *XBPredicted_2*, and so on, corresponding to the order of the dependent variable categories. Specify a root name in parentheses to override the default. Specify a colon and a positive integer giving the number of categories to override the default 25. To specify a number without a root name, simply enter a colon before the number.

XBSTDERROR (varname | rootname:n)

Estimated standard error(s) of the predicted value of the linear predictor. For all distributions except the multinomial, XBSTDERROR creates one variable and the default variable name is *XBStandardError*. Specify a variable name in parentheses to override the default.

For the multinomial distribution, one variable is created for each dependent variable category except the last (see the dependent variable ORDER keyword in the section Variable List). XBSTDERROR saves the estimated standard errors for the first 25 categories, up to but not including the last, by default. The default root name is *XBStandardError*, and the default variable names are *XBStandardError_1*, *XBStandardError_2*, and so on, corresponding to the order of the dependent variable categories. Specify a root name in parentheses to override the default. Specify a colon and a positive integer giving the number of categories to override the default 25. To specify a number without a root name, simply enter a colon before the number.

MEANPRED (varname | rootname:n)

Predicted value(s) of the mean of the response. For all distributions except the multinomial, MEANPRED creates one variable and the default variable name is *MeanPredicted*. Specify a variable name in parentheses to override the default.

If the binomial distribution is used and the dependent variable is in single variable format, then MEANPRED computes a predicted probability. Suppose the dependent variable has data values 0 and 1. If the default reference category is in effect, that is, REFERENCE = LAST on the GENLIN command line, then 1 is the reference category and MEANPRED computes the predicted probability that the dependent variable equals 0. To compute the predicted probability that the dependent variable equals 1 instead, specify REFERENCE = FIRST on the GENLIN command line.

If the binomial distribution is used and the dependent variable is in events/trials format, then MEANPRED computes the predicted number of events.

For the multinomial distribution, one variable is created for each dependent variable category except the last (see the dependent variable ORDER keyword in the section Variable List). MEANPRED saves the cumulative predicted probability for the first 25 categories, up to but not including the last, by default. The default root name is *CumMeanPredicted*, and the default variable names are *CumMeanPredicted_1*, *CumMeanPredicted_2*, and so on, corresponding to the order of the dependent variable categories. Specify a root name in parentheses to override the default. Specify a colon and a positive integer giving the number of categories to override the default 25. To specify a number without a root name, simply enter a colon before the number.

CIMEANPREDL (varname | rootname:n)

Lower bound(s) of the confidence interval for the mean of the response. For all distributions except the multinomial, CIMEANPREDL creates one variable and the default variable name is *CIMeanPredictedLower*. Specify a variable name in parentheses to override the default.

For the multinomial distribution, one variable is created for each dependent variable category except the last (see the dependent variable ORDER keyword in the section Variable List). CIMEANPREDL saves the lower bound of the cumulative predicted probability for the first 25 categories, up to but not including the last, by default. The default root name is *CICumMeanPredictedLower*, and the default variable names are *CICumMeanPredictedLower_1*, *CICumMeanPredictedLower_2*, and so on, corresponding to the order of the dependent variable categories. Specify a root name in parentheses to override the default. Specify a colon and a positive integer giving the number of categories to override the default 25. To specify a number without a root name, simply enter a colon before the number.

CIMEANPREDU (varname | rootname:n)

Upper bound(s) of the confidence interval for the mean of the response. For all distributions except the multinomial, CIMEANPREDU creates one variable and the default variable name is *CIMeanPredictedUpper*. Specify a variable name in parentheses to override the default.

For the multinomial distribution, one variable is created for each dependent variable category except the last (see the dependent variable ORDER keyword in the section Variable List). CIMEANPREDU saves the upper bound of the cumulative predicted probability for the first 25 categories, up to but not including the last, by default. The default root name is *CICumMeanPredictedUpper*, and the default variable names are *CICumMeanPredictedUpper_1*, *CICumMeanPredictedUpper_2*, and so on, corresponding to the order of the dependent variable categories. Specify a root name in parentheses to override the default. Specify a colon and a positive integer giving the number of categories to override the default 25. To specify a number without a root name, simply enter a colon before the number.

PREDVAL (varname)

Predicted category value for binomial or multinomial distribution. The class or value predicted by the model if the binomial or multinomial distribution is in effect. This keyword is honored only if the binomial distribution is used, that is, if DISTRIBUTION = BINOMIAL is specified or implied on the MODEL subcommand and the dependent variable is in single variable format, or the multinomial distribution is used (DISTRIBUTION = MULTINOMIAL). Otherwise, the PREDVAL keyword is ignored with a warning. The default variable name is *PredictedValue*.

LEVERAGE (varname)

Leverage value. The default variable name is *Leverage*. Leverage values are not available for the multinomial distribution or generalized estimating equations.

RESID (varname)

Raw residual. The default variable name is *Residual*. Raw residuals are not available for the multinomial distribution.

PEARSONRESID (varname)

Pearson residual. The default variable name is *PearsonResidual*. Pearson residuals are not available for the multinomial distribution.

DEVIANCERESID (varname)

Deviance residual. The default variable name is *DevianceResidual*. Deviance residuals are not available for the multinomial distribution or generalized estimating equations.

STDPEARSONRESID (varname)

Standardized Pearson residual. The default variable name is *StdPearsonResidual*. Standardized Pearson residuals are not available for the multinomial distribution or generalized estimating equations.

STDDEVIANCERESID (varname)

Standardized deviance residual. The default variable name is *StdDevianceResidual*. Standardized deviance residuals are not available for the multinomial distribution or generalized estimating equations.

LIKELIHOODRESID (varname)

Likelihood residual. The default variable name is *LikelihoodResidual*. Likelihood residuals are not available for the multinomial distribution or generalized estimating equations.

COOK (varname)

Cook's distance. The default variable name is *CooksDistance*. Cook's distances are not available for the multinomial distribution or generalized estimating equations.

OUTFILE Subcommand

The `OUTFILE` subcommand saves an SPSS-format dataset containing the parameter correlation or covariance matrix with parameter estimates, standard errors, significance values, and degrees of freedom. It also saves the parameter estimates and the parameter covariance matrix in XML format.

- At least one keyword and a filename are required.
- The `COVB` and `CORB` keywords are mutually exclusive, as are the `MODEL` and `PARAMETER` keywords.
- The filename must be specified in full. `GENLIN` does not supply an extension.

COVB = 'savfile' | 'dataset'

Writes the parameter covariance matrix and other statistics to an SPSS dataset.

CORB = 'savfile' | 'dataset'

Writes the parameter correlation matrix and other statistics to an SPSS dataset.

MODEL = 'file'

Writes the parameter estimates and the parameter covariance matrix to an XML file.

PARAMETER = 'file'

Writes the parameter estimates to an XML file.

GENLOG

GENLOG is available in the Advanced Models option.

```
GENLOG varlist[BY] varlist [WITH covariate varlist]

 [/CSTRUCTURE=varname]

 [/GRESID=varlist]

 [/GLOR=varlist]

 [/MODEL={POISSON**  }]
         {MULTINOMIAL}

 [/CRITERIA=[CONVERGE({0.001**})][ITERATE({20**})][DELTA({0.5**})]
                       {n      }           {n   }          {n    }

            [CIN({95**})] [EPS({1E-8**})]
                 {n   }       {n     }

            [DEFAULT]

 [/PRINT=[FREQ**][RESID**][ADJRESID**][DEV**]
         [ZRESID][ITERATE][COV][DESIGN][ESTIM][COR]
         [ALL] [NONE]
         [DEFAULT]]

 [/MISSING=[{EXCLUDE**}]]
           {INCLUDE  }

 [/DESIGN=effect[(n)] effect[(n)]... effect {BY} effect...]
                                            {* }
```

**Default if the subcommand or keyword is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
GENLOG DPREF RACE CAMP.
```

Overview

GENLOG is a general procedure for model fitting, hypothesis testing, and parameter estimation for any model that has categorical variables as its major components. As such, GENLOG subsumes a variety of related techniques, including general models of multiway contingency tables, logit models, logistic regression on categorical variables, and quasi-independence models.

GENLOG, following the regression approach, uses dummy coding to construct a design matrix for estimation and produces maximum likelihood estimates of parameters by means of the Newton-Raphson algorithm. Since the regression approach uses the original parameter spaces, the parameter estimates correspond to the original levels of the categories and are therefore easier to interpret.

HILOGLINEAR, which uses an iterative proportional-fitting algorithm, is more efficient for hierarchical models and useful in model building, but it cannot produce parameter estimates for unsaturated models, does not permit specification of contrasts for parameters, and does not display a correlation matrix of the parameter estimates.

The General Loglinear Analysis and Logit Loglinear Analysis dialog boxes are both associated with the GENLOG command. In previous releases, these dialog boxes were associated with the LOGLINEAR command. The LOGLINEAR command is now available only as a syntax command. The differences are described in the discussion of the LOGLINEAR command.

Options

Cell Weights. You can specify cell weights (such as structural zero indicators) for the model with the CSTRUCTURE subcommand.

Linear Combinations. You can compute linear combinations of observed cell frequencies, expected cell frequencies, and adjusted residuals using the GRESID subcommand.

Generalized Log-Odds Ratios. You can specify contrast variables on the GLOR subcommand and test whether the generalized log-odds ratio equals 0.

Model Assumption. You can specify POISSON or MULTINOMIAL on the MODEL subcommand to request the Poisson loglinear model or the product multinomial loglinear model.

Tuning the Algorithm. You can control the values of algorithm-tuning parameters with the CRITERIA subcommand.

Output Display. You can control the output display with the PRINT subcommand.

Optional Plots. You can request plots of adjusted or deviance residuals against observed and expected counts, or normal plots and detrended normal plots of adjusted or deviance residuals using the PLOT subcommand.

Basic Specification

The basic specification is one or more factor variables that define the tabulation. By default, GENLOG assumes a Poisson distribution and estimates the saturated model. Default output includes the factors or effects, their levels, and any labels; observed and expected frequencies and percentages for each factor and code; and residuals, adjusted residuals, and deviance residuals.

Limitations

- Maximum 10 factor variables (dependent *and* independent).
- Maximum 200 covariates.

Subcommand Order

- The variable specification must come first.
- Subcommands can be specified in any order.
- When multiple subcommands are specified, only the last specification takes effect.

Examples

```
GENLOG DPREF RACE CAMP.
```

- *DPREF*, *RACE*, and *CAMP* are categorical variables.
- This is a general loglinear model because no BY keyword appears.
- The design defaults to a saturated model that includes all main effects and two-way and three-way interaction effects.

Example: Specifying a Custom Model

```
GENLOG GSLEVEL EDUC SEX
  /DESIGN=GSLEVEL EDUC SEX.
```

- *GSLEVEL*, *EDUC*, and *SEX* are categorical variables.
- DESIGN specifies a model with main effects only.

Variable List

The variable list specifies the variables to be included in the model. GENLOG analyzes two classes of variables—categorical and continuous. Categorical variables are used to define the cells of the table. Continuous variables are used as cell covariates.

- The list of categorical variables must be specified first. Categorical variables must be numeric.
- Continuous variables can be specified only after the WITH keyword following the list of categorical variables.
- To specify a logit model, use the keyword BY(see Logit Model on p. 743). A variable list without the keyword BY generates a general loglinear model.
- A variable can be specified only once in the variable list—as a dependent variable immediately following GENLOG, as an independent variable following the keyword BY, or as a covariate following the keyword WITH.
- No range needs to be specified for categorical variables.

Logit Model

The logit model examines the relationships between dependent and independent factor variables.

- To separate the independent variables from the dependent variables in a logit model, use the keyword BY. The categorical variables preceding BY are the dependent variables; the categorical variables following BY are the independent variables.
- Up to 10 variables can be specified, including both dependent and independent variables.

- For the logit model, you must specify MULTINOMIAL on the MODEL subcommand.
- GENLOG displays an analysis of dispersion and two measures of association—entropy and concentration. These measures are discussed elsewhere (Haberman, 1982) and can be used to quantify the magnitude of association among the variables. Both are proportional-reduction-in-error measures. The entropy statistic is analogous to Theil's entropy measure, while the concentration statistic is analogous to Goodman and Kruskal's tau-*b*. Both statistics measure the strength of association between the dependent variable and the independent variable set.

Example

```
GENLOG  GSLEVEL BY EDUC SEX
  /MODEL=MULTINOMIAL
  /DESIGN=GSLEVEL, GSLEVEL BY EDUC, GSLEVEL BY SEX.
```

- The keyword BY on the variable list specifies a logit model in which *GSLEVEL* is the dependent variable and *EDUC* and *SEX* are the independent variables.
- A logit model is multinomial.
- DESIGN specifies a model that can test for the absence of the joint effect of *SEX* and *EDUC* on *GSLEVEL*.

Cell Covariates

- Continuous variables can be used as covariates. When used, the covariates must be specified after the WITH keyword following the list of categorical variables.
- A variable cannot be named as both a categorical variable and a cell covariate.
- To enter cell covariates into a model, the covariates must be specified on the DESIGN subcommand.
- Cell covariates are not applied on a case-by-case basis. The weighted covariate mean for a cell is applied to that cell.

Example

```
GENLOG DPREF RACE CAMP WITH X
  /DESIGN=DPREF RACE CAMP X.
```

- The variable *X* is a continuous variable specified as a cell covariate. Cell covariates must be specified after the keyword WITH following the variable list. No range is defined for cell covariates.
- To include the cell covariate in the model, the variable *X* is specified on DESIGN.

CSTRUCTURE Subcommand

CSTRUCTURE specifies the variable that contains values for computing cell weights, such as structural zero indicators. By default, cell weights are equal to 1.

- The specification must be a numeric variable.

- Variables specified as dependent or independent variables in the variable list cannot be specified on CSTRUCTURE.
- Cell weights are not applied on a case-by-case basis. The weighted mean for a cell is applied to that cell.
- CSTRUCTURE can be used to impose structural, or *a priori*, zeros on the model. This feature is useful in specifying a quasi-symmetry model and in excluding cells from entering into estimation.
- If multiple CSTRUCTURE subcommands are specified, the last specification takes effect.

Example

```
COMPUTE  CWT=(HUSED NE WIFED).
GENLOG HUSED WIFED WITH DISTANCE
  /CSTRUCTURE=CWT
  /DESIGN=HUSED WIFED DISTANCE.
```

- The Boolean expression assigns *CWT* the value of 1 when *HUSED* is not equal to *WIFED*, and the value of 0 otherwise.
- CSTRUCTURE imposes structural zeros on the diagonal of the symmetric crosstabulation.

GRESID Subcommand

GRESID (Generalized Residual) calculates linear combinations of observed and expected cell frequencies as well as simple, standardized, and adjusted residuals.

- The variables specified must be numeric, and they must contain coefficients of the desired linear combinations.
- Variables specified as dependent or independent variables in the variable list cannot be specified on GRESID.
- The generalized residual coefficient is not applied on a case-by-case basis. The weighted coefficient mean of the value for all cases in a cell is applied to that cell.
- Each variable specified on the GRESID subcommand contains a single linear combination.
- If multiple GRESID subcommands are specified, the last specification takes effect.

Example

```
COMPUTE GR_1=(MONTH LE 6).
COMPUTE GR_2=(MONTH GE 7).
GENLOG  MONTH WITH Z
 /GRESID=GR_1 GR_2
 /DESIGN=Z.
```

- The first variable, *GR_1*, combines the first six months into a single effect; the second variable, *GR_2*, combines the rest of the months.
- For each effect, GENLOG displays the observed and expected counts as well as the simple, standardized, and adjusted residuals.

GLOR Subcommand

GLOR (Generalized Log-Odds Ratio) specifies the population contrast variable(s). For each variable specified, GENLOG tests the null hypothesis that the generalized log-odds ratio equals 0 and displays the Wald statistic and the confidence interval. You can specify the level of the confidence interval using the CIN significance-level keyword on CRITERIA. By default, the confidence level is 95%.

- The variable sum is 0 for the loglinear model and for each combined level of independent variables for the logit model.
- Variables specified as dependent or independent variables in the variable list cannot be specified on GLOR.
- The coefficient is not applied on a case-by-case basis. The weighted mean for a cell is applied to that cell.
- If multiple GLOR subcommands are specified, the last specification takes effect.

Example

```
GENLOG A B
 /GLOR=COEFF
 /DESIGN=A B.
```

- The variable *COEFF* contains the coefficients of two dichotomous factors *A* and *B*.
- If the weighted cell mean for *COEFF* is 1 when *A* equals *B* and –1 otherwise, this example tests whether the log-odds ratio equals 0, or in this case, whether variables *A* and *B* are independent.

MODEL Subcommand

MODEL specifies the assumed distribution of your data.

- You can specify only one keyword on MODEL. The default is POISSON.
- If more than one MODEL subcommand is specified, the last specification takes effect.

POISSON	*The Poisson distribution.* This is the default.
MULTINOMIAL	*The multinomial distribution.* For the logit model, you must specify MULTINOMIAL.

CRITERIA Subcommand

CRITERIA specifies the values used in tuning the parameters for the Newton-Raphson algorithm.

- If multiple CRITERIA subcommands are specified, the last specification takes effect.

CONVERGE(n)	*Convergence criterion.* Specify a positive value for the convergence criterion. The default is 0.001.
ITERATE(n)	*Maximum number of iterations.* Specify an integer. The default number is 20.

DELTA(n)	*Cell delta value.* Specify a non-negative value to add to each cell frequency for the first iteration. (For the saturated model, the delta value is added for all iterations.) The default is 0.5. The delta value is used to solve mathematical problems created by 0 observations; if all of your observations are greater than 0, we recommend that you set DELTA to 0.
CIN(n)	*Level of confidence interval.* Specify the percentage interval used in the test of generalized log-odds ratios and parameter estimates. The value must be between 50 and 99.99, inclusive. The default is 95.
EPS(n)	*Epsilon value used for redundancy checking in design matrix.* Specify a positive value. The default is 0.00000001.
DEFAULT	*Default values are used.* DEFAULT can be used to reset all criteria to default values.

Example

```
GENLOG  DPREF BY RACE ORIGIN CAMP
 /MODEL=MULTINOMIAL
 /CRITERIA=ITERATION(50) CONVERGE(.0001).
```

- ITERATION increases the maximum number of iterations to 50.
- CONVERGE lowers the convergence criterion to 0.0001.

PRINT Subcommand

PRINT controls the display of statistics.

- By default, GENLOG displays the frequency table and simple, adjusted, and deviance residuals.
- When PRINT is specified with one or more keywords, only the statistics requested by these keywords are displayed.
- When multiple PRINT subcommands are specified, the last specification takes effect.

The following keywords can be used on PRINT:

FREQ	*Observed and expected cell frequencies and percentages.* This is displayed by default.
RESID	*Simple residuals.* This is displayed by default.
ZRESID	*Standardized residuals.*
ADJRESID	*Adjusted residuals.* This is displayed by default.
DEV	*Deviance residuals.* This is displayed by default.
DESIGN	*The design matrix of the model.* The design matrix corresponding to the specified model is displayed.
ESTIM	*The parameter estimates of the model.* The parameter estimates refer to the original categories.
COR	*The correlation matrix of the parameter estimates.*
COV	*The covariance matrix of the parameter estimates.*
ALL	*All available output.*

DEFAULT	*FREQ, RESID, ADJRESID, and DEV.* This keyword can be used to reset PRINT to its default setting.
NONE	*The design and model information with goodness-of-fit statistics only.* This option overrides all other specifications on the PRINT subcommand.

Example

```
GENLOG A B
 /PRINT=ALL
 /DESIGN=A B.
```

- The DESIGN subcommand specifies a main-effects model, which tests the hypothesis of no interaction. The PRINT subcommand displays all available output for this model.

PLOT Subcommand

PLOT specifies which plots you want to display. Plots of adjusted residuals against observed and expected counts, and normal and detrended normal plots of the adjusted residuals are displayed if PLOT is not specified or is specified without a keyword. When multiple PLOT subcommands are specified, only the last specification is executed.

DEFAULT	*RESID (ADJRESID) and NORMPROB (ADJRESID).* This is the default if PLOT is not specified or is specified with no keyword.
RESID (type)	*Plots of residuals against observed and expected counts.* You can specify the type of residuals to plot. ADJRESID plots adjusted residuals; DEV plots deviance residuals. ADJRESID is the default if you do not specify a type.
NORMPROB (type)	*Normal and detrended normal plots of the residuals.* You can specify the type of residuals to plot. ADJRESID plots adjusted residuals; DEV plots deviance residuals. ADJRESID is the default if you do not specify a type.
NONE	*No plots.*

Example

```
GENLOG  RESPONSE BY SEASON
  /MODEL=MULTINOMIAL
  /PLOT=RESID(ADJRESID,DEV)
  /DESIGN=RESPONSE SEASON(1) BY RESPONSE.
```

- This example requests plots of adjusted and deviance residuals against observed and expected counts.
- Note that if you specify /PLOT=RESID(ADJRESID) RESID(DEV), only the deviance residuals are plotted. The first keyword specification, RESID(ADJRESID), is ignored.

MISSING Subcommand

MISSING controls missing values. By default, GENLOG excludes all cases with system- or user-missing values for any variable. You can specify INCLUDE to include user-missing values.

EXCLUDE *Delete cases with user-missing values.* This is the default if the subcommand is omitted. You can also specify the keyword DEFAULT.

INCLUDE *Include cases with user-missing values.* Only cases with system-missing values are deleted.

Example

```
MISSING VALUES A(0).
GENLOG A B
 /MISSING=INCLUDE
 /DESIGN=B.
```

- Even though 0 was specified as missing, it is treated as a nonmissing category of *A* in this analysis.

SAVE Subcommand

SAVE saves specified temporary variables into the active dataset. You can assign a new name to each temporary variable saved.

- The temporary variables you can save include *RESID* (raw residual), *ZRESID* (standardized residual), *ADJRESID* (adjusted residual), *DEV* (deviance residual), and *PRED* (predicted cell frequency). An explanatory label is assigned to each saved variable.
- A temporary variable can be saved only once on a SAVE subcommand.
- To assign a name to a saved temporary variable, specify the new name in parentheses following that temporary variable. The new name must conform to SPSS naming conventions and must be unique in the active dataset. The names cannot begin with # or $.
- If you do not specify a variable name in parentheses, GENLOG assigns default names to the saved temporary variables. A default name starts with the first three characters of the name of the saved temporary variable, followed by an underscore and a unique number. For example, *RESID* will be saved as *RES_n*, where *n* is a number incremented each time a default name is assigned to a saved *RESID*.
- The saved variables are pertinent to cells in the contingency table, not to individual observations. In the Data Editor, all cases that define one cell receive the same value. To make sense of these values, you need to aggregate the data to obtain cell counts.

Example

```
GENLOG A B
 /SAVE PRED (PREDA_B)
 /DESIGN = A, B.
```

- SAVE saves the predicted values for two independent variables *A* and *B*.
- The saved variable is renamed *PREDA_B* and added to the active dataset.

DESIGN Subcommand

DESIGN specifies the model to be fit. If DESIGN is omitted or used with no specifications, the saturated model is produced. The saturated model fits all main effects and all interaction effects.

- Only one design can be specified on the subcommand.
- To obtain main-effects models, name all of the variables listed on the variables specification.
- To obtain interactions, use the keyword BY or an asterisk (*) to specify each interaction, for example, A BY B or C*D. To obtain the single-degree-of-freedom partition of a specified factor, specify the partition in parentheses following the factor (see the example below).
- To include cell covariates in the model, first identify them on the variable list by naming them after the keyword WITH, and then specify the variable names on DESIGN.
- Effects that involve only independent variables result in redundancy. GENLOG removes these effects from the model.
- If your variable list includes a cell covariate (identified by the keyword WITH), you cannot imply the saturated model by omitting DESIGN or specifying it alone. You need to request the model explicitly by specifying all main effects and interactions on DESIGN.

Example

```
COMPUTE X=MONTH.
GENLOG MONTH WITH X
  /DESIGN X.
```

- This example tests the linear effect of the dependent variable.
- The variable specification identifies *MONTH* as a categorical variable. The keyword WITH identifies *X* as a covariate.
- DESIGN tests the linear effect of *MONTH*.

Example

```
GENLOG A B
  /DESIGN=A.

GENLOG A B
  /DESIGN=A,B.
```

- Both designs specify main-effects models.
- The first design tests the homogeneity of category probabilities for *B*; it fits the marginal frequencies on *A* but assumes that membership in any of the categories of *B* is equiprobable.
- The second design tests the independence of *A* and *B*. It fits the marginals on both *A* and *B*.

Example

```
GENLOG A  B  C
  /DESIGN=A,B,C, A BY B.
```

- This design consists of the *A* main effect, the *B* main effect, the *C* main effect, and the interaction of *A* and *B*.

Example

```
GENLOG A BY B
 /MODEL=MULTINOMIAL
 /DESIGN=A,A BY B(1).
```

- This example specifies single-degree-of-freedom partitions.
- The value 1 following *B* to the first category of *B*.

Example

```
GENLOG HUSED WIFED WITH DISTANCE
  /DESIGN=HUSED WIFED DISTANCE.
```

- The continuous variable *DISTANCE* is identified as a cell covariate by the keyword `WITH`. The cell covariate is then included in the model by naming it on `DESIGN`.

Example

```
COMPUTE  X=1.
GENLOG  MONTH WITH X
  /DESIGN=X.
```

- This example specifies an equiprobability model.
- The design tests whether the frequencies in the table are equal by using a constant of 1 as a cell covariate.

GET

```
GET FILE='file'
 [/KEEP={ALL**  }] [/DROP=varlist]
        {varlist}
 [/RENAME=(old varnames=new varnames)...]
 [/MAP]
```

**Default if the subcommand is omitted.

Example

```
GET FILE='/data/empl.sav'.
```

Overview

GET reads an SPSS-format data file that was created by the SAVE or XSAVE command. It also reads SPSS PC+ data files, but you should not read SPSS PC+ data files in Unicode mode (see Operations below).

GET is used only for reading SPSS-format data files. See DATA LIST for information on reading and defining data in a text data file. See MATRIX DATA for information on defining matrix materials in a text data file. For information on defining complex data files that cannot be defined with DATA LIST alone, see FILE TYPE and REPEATING DATA.

The program can also read data files created for other software applications. See IMPORT for information on reading *portable files* created with EXPORT. See the relevant commands, such as GET TRANSLATE and GET SAS, for information on reading files created by other software programs.

Options

Variable Subsets and Order. You can read a subset of variables and reorder the variables that are copied into the active dataset using the DROP and KEEP subcommands.

Variable Names. You can rename variables as they are copied into the active dataset with the RENAME subcommand.

Variable Map. To confirm the names and order of variables in the active dataset, use the MAP subcommand. MAP displays the variables in the active dataset next to their corresponding names in the SPSS-format data file.

Basic Specification

- The basic specification is the FILE subcommand, which specifies the SPSS-format data file to be read.

- By default, GET copies all variables from the SPSS-format data file into the active dataset. Variables in the active dataset are in the same order and have the same names as variables in the SPSS-format data file. Documentary text from the SPSS-format data file is copied into the dictionary of the active dataset.

Subcommand Order

- FILE must be specified first.
- The remaining subcommands can be specified in any order.

Syntax Rules

- FILE is required and can be specified only once.
- KEEP, DROP, RENAME, and MAP can be used as many times as needed.
- Documentary text copied from the SPSS-format data file can be dropped from the active dataset with the DROP DOCUMENTS command.
- GET cannot be used inside a DO IF–END IF or LOOP–END LOOP structure.

Operations

- If KEEP is not specified, variables in the active dataset are in the same order as the original data file.
- A file saved with weighting in effect maintains weighting the next time the file is accessed. For a discussion of turning off weights, see WEIGHT.
- In Unicode mode, for code page data files and data files created in releases prior to 16.0, the defined width of string variables in tripled. You can use ALTER TYPE to automatically adjust the width of all string variables.See SET command, UNICODE subcommand for more information.
- In Unicode mode, SPSS PC+ and data files may not be read correctly.

FILE Subcommand

FILE specifies the SPSS-format data file to be read. FILE is required and can be specified only once. It must be the first specification on GET.

DROP and KEEP Subcommands

DROP and KEEP are used to copy a subset of variables into the active dataset. DROP specifies variables that should not be copied into the active dataset. KEEP specifies variables that should be copied. Variables not specified on KEEP are dropped.

- Variables can be specified in any order. The order of variables on KEEP determines the order of variables in the active dataset. The order of variables on DROP does not affect the order of variables in the active dataset.
- The keyword ALL on KEEP refers to all remaining variables not previously specified on KEEP. ALL must be the last specification on KEEP.

- If a variable is specified twice on the same subcommand, only the first mention is recognized.
- Multiple DROP and KEEP subcommands are allowed. However, specifying a variable named on a previous DROP or not named on a previous KEEP results in an error, and the GET command is not executed.
- The keyword TO can be used to specify a group of consecutive variables in the SPSS-format data file.

Example

```
GET FILE='/data/hubtemp.sav'   /DROP=DEPT79 TO DEPT84 SALARY79.
```

- The active dataset is copied from the SPSS-format data file *hubtemp.sav*. All variables between and including *DEPT79* and *DEPT84*, as well as *SALARY79*, are excluded from the active dataset. All other variables are copied into the active dataset.
- Variables in the active dataset are in the same order as the variables in the *hubtemp.sav* file.

Example

```
GET FILE='/data/prsnl.sav' /DROP=GRADE STORE
               /KEEP=LNAME NAME TENURE JTENURE ALL.
```

- The variables *GRADE* and *STORE* are dropped when the file *prsnl.sav* is copied into the active dataset.
- KEEP specifies that *LNAME*, *NAME*, *TENURE*, and *JTENURE* are the first four variables in the active dataset, followed by all remaining variables (except those dropped by the previous DROP subcommand). These remaining variables are copied into the active dataset in the same sequence in which they appear in the *prsnl.sav* file.

RENAME Subcommand

RENAME changes the names of variables as they are copied into the active dataset.

- The specification on RENAME is a list of old variable names followed by an equals sign and a list of new variable names. The same number of variables must be specified on both lists. The keyword TO can be used on the first list to refer to consecutive variables in the SPSS-format data file and on the second list to generate new variable names. The entire specification must be enclosed in parentheses.
- Alternatively, you can specify each old variable name individually, followed by an equals sign and the new variable name. Multiple sets of variable specifications are allowed. The parentheses around each set of specifications are optional.
- Old variable names do not need to be specified according to their order in the SPSS-format data file.
- Name changes take place in one operation. Therefore, variable names can be exchanged between two variables.
- Variables cannot be renamed to scratch variables.
- Multiple RENAME subcommands are allowed.
- On a subsequent DROP or KEEP subcommand, variables are referred to by their new names.

Example

```
GET FILE='/data/empl88.sav'
  /RENAME  AGE=AGE88 JOBCAT=JOBCAT88.
```

- RENAME specifies two name changes for the active dataset. *AGE* is renamed to *AGE88* and *JOBCAT* is renamed to *JOBCAT88*.

Example

```
GET FILE='/data/empl88.sav'
  /RENAME (AGE JOBCAT=AGE88 JOBCAT88).
```

- The name changes are identical to those in the previous example. *AGE* is renamed to *AGE88* and *JOBCAT* is renamed to *JOBCAT88*. The parentheses are required with this method.

MAP Subcommand

MAP displays a list of the variables in the active dataset and their corresponding names in the SPSS-format data file.

- The only specification is the keyword MAP. There are no additional specifications.
- Multiple MAP subcommands are allowed. Each MAP subcommand maps the results of subcommands that precede it; results of subcommands that follow it are not mapped.

Example

```
GET FILE='/data/empl88.sav'
 /RENAME=(AGE=AGE88) (JOBCAT=JOBCAT88)
 /KEEP=LNAME NAME JOBCAT88 ALL /MAP.
```

- MAP is specified to confirm the new names for the variables *AGE* and *JOBCAT* and the order of variables in the active dataset (*LNAME*, *NAME*, and *JOBCAT88*, followed by all remaining variables in the SPSS-format data file).

GET CAPTURE

GET CAPTURE is supported for compatibility purposes. GET DATA is the preferred command for reading databases. For more information, see GET DATA on p. 759.

```
GET CAPTURE {ODBC    }*

 [/CONNECT='connection string']
 [/LOGIN=login] [/PASSWORD=password]
 [/SERVER=host] [/DATABASE=database name]†

 /SQL 'select statement'
      ['continuation of select statement']
```

* You can import data from any database for which you have an ODBC driver installed.

† Optional subcommands are database-specific. For more information, see Overview below.

Example

```
GET CAPTURE ODBC
  /CONNECT='DSN=sales.mdb;DBQ=/data/saledata.mdb;DriverId=281;FIL=MS'+
  ' Access;MaxBufferSize=2048;PageTimeout=5;'
  /SQL = 'SELECT  T0.ID AS ID`,  T0.JOBCAT AS JOBCAT,  '
  '`T0`.`REGION` AS `REGION`,  `T0`.`DIVISION` AS `DIVISION`,`T0`.`TRAVEL`'
  ' AS `TRAVEL`,  `T0`.`SALES` AS `SALES`,  `T0`.`VOLUME96` AS `VOLUME96`,  '
  '`T1`.`REGION` AS `REGION1`,  `T1`.`AVGINC` AS `AVGINC`,`T1`.`AVGAGE` AS'
  ' `AVGAGE`,  `T1`.`POPULAT` AS `POPULAT` FROM { oj `Regions` `T1` LEFT '
  'OUTER JOIN `EmployeeSales` `T0` ON `T1`.`REGION` = `T0`.`REGION` } '.
```

Overview

GET CAPTURE retrieves data from a database and converts them to a format that can be used by program procedures. GET CAPTURE retrieves data and data information and builds an active dataset for the current session.

Note: Although GET CAPTURE is still supported, equivalent functionality and additional features are provided in the newer GET DATA command.

Basic Specification

The basic specification is one of the subcommands specifying the database type followed by the SQL subcommand and any select statement in quotation marks or apostrophes. Each line of the select statement should be enclosed in quotation marks or apostrophes, and no quoted string should exceed 255 characters.

Subcommand Order

The subcommand specifying the type of database must be the first specification. The SQL subcommand must be the last.

Syntax Rules

- Only one subcommand specifying the database type can be used.
- The CONNECT subcommand must be specified if you use the Microsoft ODBC (Open Database Connectivity) driver.

Operations

- GET CAPTURE retrieves the data specified on SQL.
- The variables are in the same order in which they are specified on the SQL subcommand.
- The data definition information captured from the database is stored in the active dataset dictionary.

Limitations

- A maximum of 3,800 characters (approximately) can be specified on the SQL subcommand. This translates to 76 lines of 50 characters. Characters beyond the limit are ignored.

CONNECT Subcommand

CONNECT is required to access any database that has an installed Microsoft ODBC driver.

- You cannot specify the connection string directly in the syntax window, but you can paste it with the rest of the command from the Results dialog box, which is the last of the series of dialog boxes opened with the Database Wizard.

SQL Subcommand

SQL specifies any SQL select statement accepted by the database that you access. With ODBC, you can now select columns from more than one related table in an ODBC data source using either the inner join or the outer join.

Data Conversion

GET CAPTURE converts variable names, labels, missing values, and data types, wherever necessary, to a format that conforms to SPSS-format conventions.

Variable Names and Labels

Database columns are read as variables.

- A column name is converted to a variable name if it conforms to SPSS-format naming conventions and is different from all other names created for the active dataset. If not, GET CAPTURE gives the column a name formed from the first few letters of the column and its column number. If this is not possible, the letters *COL* followed by the column number are used. For example, the seventh column specified in the select statement could be *COL7*.

- GET CAPTURE labels each variable with its full column name specified in the original database.
- You can display a table of variable names with their original database column names using the DISPLAY LABELS command.

Missing Values

Null values in the database are transformed into the system-missing value in numeric variables or into blanks in string variables.

GET DATA

```
GET DATA
  /TYPE = {ODBC }
          {OLEDB}
          {XLS  }
          {XLSX }
          {XLSM }
          {TXT  }

  /FILE = 'filename'

Subcommands for TYPE = ODBC and OLEDB
  /CONNECT='connection string'
  /UNENCRYPTED
  /SQL 'select statement'
      ['select statement continued']

Subcommands for TYPE=ODBC, TYPE=OLEDB, XLS, XLSX, and XLSM
 [/ASSUMEDSTRWIDTH={255**}]
                   {n    }

Subcommands for TYPE = XLS, XLSX, and XLSM*
  [/SHEET = {INDEX**} {sheet number}]
            {NAME   } {'sheet name'}
  [/CELLRANGE = {RANGE }  {'start point:end point' }]
                {FULL**}
  [/READNAMES = {on** }]
                 {off  }

Subcommands for TYPE = TXT
  [/ARRANGEMENT = {FIXED      }]
                  {DELIMITED**}
  [/FIRSTCASE = {n}]
  [/DELCASE = {LINE**     }]1
              {VARIABLES n}

  [/FIXCASE = n]
  [/IMPORTCASE = {ALL**    }]
                 {FIRST n  }
                 {PERCENT n}
  [/DELIMITERS = {"delimiters"}]
  [/QUALIFIER = "qualifier"]

VARIABLES subcommand for ARRANGEMENT = DELIMITED
  /VARIABLES = varname  {format}

VARIABLES subcommand for ARRANGEMENT = FIXED
  /VARIABLES varname {startcol - endcol} {format}
     {/rec#} varname {startcol - endcol} {format}
```

*For Excel 4.0 or earlier files, use `GET TRANSLATE`.

**Default if the subcommand is omitted.

Release History

Release 13.0

- ASSUMEDSTRWIDTH subcommand introduced for TYPE=ODBC.

Release 14.0

- ASSUMEDSTRWIDTH subcommand extended to TYPE=XLS.
- TYPE=OLEDB introduced.

Release 15.0

- ASSUMEDSTRWIDTH subcommand extended to TYPE=OLEDB.

Release 16.0

- TYPE=XLSX and TYPE=XLSM introduced.

Example

```
GET DATA
   /TYPE=XLS
   /FILE='/PlanningDocs/files10.xls'
   /SHEET=name 'First Quarter'
   /CELLRANGE=full
   /READNAMES=on.
```

Overview

GET DATA reads data from ODBC OLE DB data sources (databases), Excel files (release 5 or later), and text data files. It contains functionality and syntax similar to GET CAPTURE, GET TRANSLATE, and DATA LIST.

- GET DATA /TYPE=ODBC is almost identical to GET CAPTURE ODBC in both syntax and functionality.
- GET DATA /TYPE=XLS reads Excel 95 through Excel 2003 files; GET DATA /TYPE=XLSX and GET DATA /TYPE=XLSM read Excel 2007 or later files. GET TRANSLATE reads Excel 4 or earlier, Lotus, and dBASE files.
- GET DATA /TYPE=TXT is similar to DATA LIST but does not create a temporary copy of the data file, significantly reducing temporary file space requirements for large data files.

TYPE Subcommand

The TYPE subcommand is required and must be the first subcommand specified.

ODBC *Data sources accessed with ODBC drivers.*

OLEDB *Data sources accessed with Microsoft OLEDB technology.* Available only on Windows platforms and requires .NET framework and Dimensions Data Model and OLE DB Access. Versions of these components compatible with this release can be installed from the installation CD and are available on the AutoPlay menu. This is available only on Windows operating systems.

XLS	*Excel 95 through Excel 2003 files.* For earlier versions of Excel files, Lotus 1-2-3 files, and dBASE files, see the GET TRANSLATE command.
XLSX and **XLSM**	*Excel 2007 files.* Macros in XLSM files are ignored. XLSB (binary) format files are not supported.
TXT	*Simple (ASCII) text data files.*

FILE Subcommand

The FILE subcommand is required for TYPE=XLS, TYPE=XLSX, TYPE=XLSM, and TYPE=TXT and must immediately follow the TYPE subcommand. It specifies the file to read. File specifications should be enclosed in quotes.

Subcommands for TYPE=ODBC and TYPE=OLEDB

The CONNECT and SQL subcommands are both required, and SQL must be the last subcommand.

Example

```
GET DATA /TYPE=ODBC
  /CONNECT=
 'DSN=MS Access Database;DBQ=/examples/data/dm_demo.mdb;'+
 'DriverId=25;FIL=MS Access;MaxBufferSize=2048;PageTimeout=5;'
 /SQL = 'SELECT * FROM CombinedTable'.
```

CONNECT Subcommand

The CONNECT subcommand identifies the database source. The recommended method for generating a valid CONNECT specification is to initially use the Database Wizard and paste the resulting syntax to a syntax window in the last step of the wizard.

- The entire connect string must be enclosed in quotation marks.
- For long connect strings, you can use multiple quoted strings on separate lines, using a plus sign (+) to combine the quoted strings.

UNENCRYPTED Subcommand

Allows unencrypted passwords to be used in the CONNECT subcommand. This subcommand has no keywords or arguments. By default, passwords are assumed to be encrypted.

SQL Subcommand

SQL specifies any SQL select statement accepted by the database that you access.

- You can select columns from more than one related table in a data source using either the inner join or the outer join.
- Each line of SQL must be enclosed in quotation marks and cannot exceed 255 characters.

- When the command is processed, all of the lines of the SQL statement are merged together in a very literal fashion; so each line should either begin or end with a blank space where spaces should occur between specifications.
- For TYPE=OLEDB (available only on Windows operating systems), table joins are not supported; you can specify fields only from a single table.

Example

```
GET DATA /TYPE=ODBC /CONNECT=
  'DSN=Microsoft Access;DBQ=/data/demo.mdb;DriverId=25;'+
  'FIL=MS Access;MaxBufferSize=2048;PageTimeout=5;'
 /SQL =
  'SELECT  SurveyResponses.ID,  SurveyResponses.Internet,'
  ' [Value Labels].[Internet Label]'
  ' FROM SurveyResponses LEFT OUTER JOIN [Value Labels]'
  ' ON SurveyResponses.Internet'
  ' = [Value Labels].[Internet Value]'.
```

If the SQL contains WHERE clauses with expressions for case selection, dates and times in expressions need to be specified in a special manner (including the curly braces shown in the examples):

- Date literals should be specified using the general form `{d 'yyyy-mm-dd'}`.
- Time literals should be specified using the general form `{t 'hh:mm:ss'}`.
- Date/time literals (timestamps) should be specified using the general form `{ts 'yyyy-mm-dd hh:mm:ss'}`.
- The entire date and/or time value must be enclosed in single quotes. Years must be expressed in four-digit form, and dates and times must contain two digits for each portion of the value. For example January 1, 2005, 1:05 AM would be expressed as:

  ```
  {ts '2005-01-01 01:05:00'}
  ```

For functions used in expressions, a list of standard functions is available at *http://msdn.microsoft.com/library/en-us/odbc/htm/odbcscalar_functions.asp*.

ASSUMEDSTRWIDTH Subcommand

For TYPE=ODBC, TYPE=OLEDB, and TYPE=XLS, this controls the width of variable-width string values. By default, the width is 255 bytes, and only the first 255 bytes will be read. The width can be up to 32,767 bytes. Although you probably don't want to truncate string values, you also don't want to specify an unnecessarily large value, since this will be used as the display width for those string values.

Subcommands for TYPE=XLS, XLSX, and XLSM

For Excel 95 or later files, you can specify a spreadsheet within the workbook, a range of cells to read, and the contents of the first row of the spreadsheet (variable names or data). For files from earlier versions of Excel, use GET TRANSLATE .

Example

```
GET DATA /TYPE=XLS
   /FILE='/data/sales.xls'
   /SHEET=name 'June Sales'
   /CELLRANGE=range 'A1:C3'
   /READNAMES=on.
```

SHEET Subcommand

The SHEET subcommand indicates the worksheet in the Excel file that will be read. Only one sheet can be specified. If no sheet is specified, the first sheet will be read.

INDEX n *Read the specified sheet number.* The number represents the sequential order of the sheet within the workbook.

NAME 'name' *Read the specified sheet name.* If the name contains spaces, it must be enclosed in quotes.

CELLRANGE Subcommand

The CELLRANGE subcommand specifies a range of cells to read within the specified worksheet. By default, the entire worksheet is read.

FULL *Read the entire worksheet.* This is the default.

RANGE 'start:end' *Read the specified range of cells.* Specify the beginning column letter and row number, a colon, and the ending column letter and row number, as in A1:K14. The cell range must be enclosed in quotes.

READNAMES Subcommand

ON *Read the first row of the sheet or specified range as variable names.* This is the default. Values that contain invalid characters or do not meet other criteria for variable names are converted to valid variable names. For more information, see Variable Names on p. 43.

OFF *Read the first row of the sheet or specified range as data.* Default variable names are assigned, and all rows are read as data.

Subcommands for TYPE=TXT

The VARIABLES subcommand is required and must be the last GET DATA subcommand.

Example

```
GET DATA  /TYPE = TXT
  /FILE = '/data/textdata.dat'
  /DELCASE = LINE
  /DELIMITERS = "\t ,"
  /ARRANGEMENT = DELIMITED
  /FIRSTCASE = 2
  /IMPORTCASE = FIRST 200
  /VARIABLES = id F3.0 gender A1 bdate DATE10 educ F2.0
```

```
jobcat F1.0 salary DOLLAR8 salbegin DOLLAR8
jobtime F4.2 prevexp F4.2 minority F3.0.
```

ARRANGEMENT Subcommand

The ARRANGEMENT subcommand specifies the data format.

DELIMITED *Spaces, commas, tabs, or other characters are used to separate variables.* The variables are recorded in the same order for each case but not necessarily in the same column locations. This is the default.

FIXED *Each variable is recorded in the same column location for every case.*

FIRSTCASE Subcommand

FIRSTCASE specifies the first line (row) to read for the first case of data. This allows you to bypass information in the first *n* lines of the file that either don't contain data or contain data that you don't want to read. This subcommand applies to both fixed and delimited file formats.

The only specification for this subcommand is an integer greater than zero that indicates the number of lines to skip. The default is 1.

DELCASE Subcommand

The DELCASE subcommand applies to delimited data (ARRANGEMENT=DELIMITED) only.

LINE *Each case is contained on a single line (row).* This is the default.

VARIABLES n *Each case contains n variables.* Multiple cases can be contained on the same line, and data for one case can span more than one line. A case is defined by the number of variables.

FIXCASE Subcommand

The FIXCASE subcommand applies to fixed data (ARRANGEMENT=FIXED) only. It specifies the number of lines (records) to read for each case.

The only specification for this subcommand is an integer greater than zero that indicates the number of lines (records) per case. The default is 1.

IMPORTCASES Subcommand

The IMPORTCASES subcommand allows you to specify the number of cases to read.

ALL *Read all cases in the file.* This is the default.

FIRST n *Read the first n cases.* The value of *n* must be a positive integer.

PERCENT n *Read approximately the first n percent of cases.* The value of *n* must be a positive integer less than 100. The percentage of cases actually selected only approximates the specified percentage. The more cases there are in the data file, the closer the percentage of cases selected is to the specified percentage.

DELIMITERS Subcommand

The DELIMITERS subcommand applies to delimited data (ARRANGEMENT=DELIMITED) only. It specifies the characters to read as delimiters between data values.

- Each delimiter can be only a single character, except for the specification of a tab or a backslash as a delimiter (see below).
- The list of delimiters must be enclosed in quotes.
- There should be no spaces or other delimiters between delimiter specifications, except for a space that indicates a space as a delimiter.
- To specify a tab as a delimiter use "\t". This must be the first delimiter specified.
- To specify a backslash as a delimiter, use two backslashes ("\\"). This must be the first delimiter specified unless you also specify a tab as a delimiter, in which case the backslash specification should come second—immediately after the tab specification.

Missing data with delimited data. Multiple consecutive spaces in a data file are treated as a single space and cannot be used to indicate missing data. For any other delimiter, multiple delimiters without any intervening data indicate missing data.

Example

```
DELIMITERS "\t\\ ,;"
```

In this example, tabs, backslashes, spaces, commas, and semicolons will be read as delimiters between data values.

QUALIFIER Subcommand

The QUALIFIERS subcommand applies to delimited data (ARRANGEMENT=DELIMITED) only. It specifies the character used to enclose values that contain delimiter characters. For example, if a comma is the delimiter, values that contain commas will be read incorrectly unless there is a text qualifier enclosing the value, preventing the commas in the value from being interpreted as delimiters between values. CSV-format data files exported from Excel use a double quote (") as a text qualifier.

- The text qualifier appears at both the beginning and end of the value, enclosing the entire value.
- The qualifier value must be enclosed in single or double quotes. If the qualifier is a single quote, the value should be enclosed in double quotes. If the qualifier value is a double quote, the value should be enclosed in single quotes.

Example

```
/QUALIFIER = '"'
```

VARIABLES Subcommand for ARRANGEMENT = DELIMITED

For delimited files, the VARIABLES subcommand specifies the variable names and variable formats.

- Variable names must conform to variable naming rules. For more information, see Variable Names on p. 43.
- Each variable name must be followed by a format specification. For more information, see Variable Format Specifications for TYPE = TXT on p. 766.

VARIABLES Subcommand for ARRANGEMENT = FIXED

For fixed-format files, the VARIABLES subcommand specifies variable names, start and end column locations, and variable formats.

- Variable names must conform to variable naming rules. For more information, see Variable Names on p. 43.
- Each variable name must be followed by column specifications. Start and end columns must be separated by a dash, as in 0-10.
- Column specifications must include both the start and end column positions, even if the width is only one column, as in 32-32.
- Each column specification must be followed by a format specification.
- Column numbering starts with 0, not 1 (in contrast to DATA LIST).

Multiple records. If each case spans more than one record (as specified with the FIXCASE subcommand), delimit variable specifications for each record with a slash (/) followed by the record number, as in:

```
VARIABLES = /1 var1 0-10 F var2 11-20 DATE
/2 var3 0-5 A var4 6-10 F
/3 var5 0-20 A var6 21-30 DOLLAR
```

Variable Format Specifications for TYPE = TXT

For both fixed and delimited files, available formats include (but are not limited to):

Fn.d	*Numeric.* Specification of the total number of characters (*n*) and decimals (*d*) is optional.
An	*String (alphanumeric).* Specification of the maximum string length (*n*) is optional.
DATEn	*nDates of the general format dd-mmm-yyyy.* Specification of the maximum length (*n*) is optional but must be eight or greater if specified.
ADATEn	*Dates of the general format mm/dd/yyyy.* Specification of the maximum length (*n*) is optional but must be eight or greater if specified.
DOLLARn.d	*Currency with or without a leading dollar sign ($).* Input values can include a leading dollar sign, but it is not required. Specification of the total number of characters (*n*) and decimals (*d*) is optional.

For a complete list of variable formats, see Variable Types and Formats on p. 49.

Note: For default numeric (F) format and scientific notation (E) format, the decimal indicator of the input data must match the SPSS locale decimal indicator (period or comma). Use SHOW DECIMAL to display the current decimal indicator and SET DECIMAL to set the decimal indicator.

(Comma and Dollar formats recognize only the period as the decimal indicator, and Dot format recognizes only the comma as the decimal indicator.)

GET SAS

```
GET SAS DATA='file' [DSET(dataset)]
 [/FORMATS=file]
```

Example

```
GET SAS DATA='/data/elect.sd7'.
```

Overview

GET SAS builds an SPSS-format active dataset from a SAS dataset or a SAS transport file. A SAS transport file is a sequential file written in SAS transport format and can be created by the SAS export engine available in SAS Release 6.06 or higher or by the EXPORT option on the COPY or XCOPY procedure in earlier versions. GET SAS reads SAS files up to version 6.12.

Options

Retrieving User-Defined Value Labels. For native SAS datasets, you can specify a file on the FORMATS subcommand to retrieve user-defined value labels associated with the data being read. This file must be created by the SAS PROC FORMAT statement and can be used only for native SAS datasets. For SAS transport files, the FORMATS subcommand is ignored.

Specifying the Dataset. You can name a dataset contained in a specified SAS file, using DSET on the DATA subcommand. GET SAS reads the specified dataset from the SAS file.

Basic Specification

The basic specification is the DATA subcommand followed by the name of the SAS file to read. By default, the first SAS dataset is copied into the active dataset and any necessary data conversions are made.

Syntax Rules

- The subcommand DATA and the SAS filename are required and must be specified first.
- The subcommand FORMATS is optional. This subcommand is ignored for SAS transport files.
- GET SAS does not allow KEEP, DROP, RENAME, and MAP subcommands. To use a subset of the variables, rename them, or display the file content, you can specify the appropriate commands after the active dataset is created.

Operations

- GET SAS reads data from the specified or default dataset contained in the SAS file named on the DATA subcommand.

- Value labels retrieved from a SAS user-defined format are used for variables associated with that format, becoming part of the SPSS dictionary.
- All variables from the SAS dataset are included in the active dataset, and they are in the same order as in the SAS dataset.

DATA Subcommand

DATA specifies the file that contains the SAS dataset to be read.

- DATA is required and must be the first specification on GET SAS.
- The file specification varies from operating system to operating system. File specifications should be enclosed in quotes.
- The optional DSET keyword on DATA determines which dataset within the specified SAS file is to be read. The default is the first dataset.

DSET (dataset) *Dataset to be read.* Specify the name of the dataset in parentheses. If the specified dataset does not exist in the SAS file, GET SAS displays a message informing you that the dataset was not found.

Example

```
GET SAS DATA='/data/elect.sd7' DSET(Y1948).
```

- The SAS file *elect.sd7* is opened and the dataset named *Y1948* is used to build the active dataset for the session.

FORMATS Subcommand

FORMATS specifies the file containing user-defined value labels to be applied to the retrieved data.

- File specifications should be enclosed in quotation marks.
- If FORMATS is omitted, no value labels are available.
- Value labels are applied only to numeric integer values. They are not applied to non-integer numeric values or string variables.
- The file specified on the FORMATS subcommand must be created with the SAS PROC FORMAT statement.
- For SAS transport files, the FORMATS subcommand is ignored.

Example

```
GET SAS /DATA='/data/elect.sd7' DSET(Y1948)
 /FORMATS='ELECTFM'.
```

- Value labels read from the SAS file *ELECTFM* are converted to conform to SPSS conventions.

Creating a Formats File with PROC FORMAT

To create a file containing SAS value labels, run the following program in SAS:

```
libname mylib 'path';
proc format library = mylib
cntlout = mylib.sas_fmts;
run;
```

where `'path'` is the directory that contains your input data file.

This procedure creates a SAS file in the directory `'path'` that has the format information for each SAS data file. In this case, the file will have the name *SAS_FMTS.SD2* and be found in the same directory as the input SAS data file.

SAS Data Conversion

Although SAS and SPSS data files have similar attributes, they are not identical. The following conversions are made to force SAS datasets to comply with SPSS conventions.

Variable Names

SAS variable names that do not conform to SPSS variable name rules are converted to valid variable names.

Variable Labels

SAS variable labels specified on the `LABEL` statement in the `DATA` step are used as variable labels.

Value Labels

SAS value formats that assign value labels are read from the dataset specified on the `FORMATS` subcommand. The SAS value labels are then converted to SPSS value labels in the following manner:

- Labels assigned to single values are retained.
- Labels assigned to a range of values are ignored.
- Labels assigned to the SAS keywords `LOW`, `HIGH`, and `OTHER` are ignored.
- Labels assigned to string variables and non-integer numeric values are ignored.

Missing Values

Since SAS has no user-defined missing values, all SAS missing codes are converted to SPSS system-missing values.

Variable Types

- Both SAS and SPSS allow two basic types of variables: numeric and character string. During conversion, SAS numeric variables become SPSS numeric variables, and SAS string variables become SPSS string variables of the same length.
- Date, time, and date/time SAS variables are converted to equivalent SPSS date, time, and date/time variables. All other numeric formats are converted to the default numeric format.

GET STATA

```
GET STATA FILE='file'
```

Release History

Release 14.0

- Command introduced.

Example

```
GET STATA FILE='/data/empl.dta'.
```

Overview

GET STATA reads Stata-format data files created by Stata versions 4–8.

Basic Specification

- The only specification is the FILE keyword, which specifies the Stata data file to be read.

Operations

- **Variable names.** Stata variable names are converted to SPSS variable names in case-sensitive form. Stata variable names that are identical except for case are converted to valid variable names by appending an underscore and a sequential letter (*_A*, *_B*, *_C*, ..., *_Z*, *_AA*, *_AB*, ..., etc.).
- **Variable labels.** Stata variable labels are converted to SPSS variable labels.
- **Value labels.** Stata value labels are converted to SPSS value labels, except for Stata value labels assigned to "extended" missing values.
- **Missing values.** Stata "extended" missing values are converted to system-missing values.
- **Date conversion.** Stata date format values are converted to SPSS DATE format (d-m-y) values. Stata "time-series" date format values (weeks, months, quarters, etc.) are converted to simple numeric (F) format, preserving the original, internal integer value, which is the number of weeks, months, quarters, etc., since the start of 1960.

FILE Keyword

FILE specifies the Stata data file to be read. FILE is the only specification; it is required and can be specified only once. The keyword name is followed by an equals sign and a quoted file specification (or quoted file handle) that specifies the Stata data file to read.

GET TRANSLATE

```
GET TRANSLATE FILE=file

 [/TYPE={WK }]
        {WK1}
        {WKS}
        {SYM}
        {SLK}
        {XLS}
        {DBF}
        {TAB}
        {SYS}

  [/FIELDNAMES]*

  [/RANGE={range name }]*
          {start..stop}
          {start:stop }

  [/KEEP={ALL**  }] [/DROP=varlist]
         {varlist}

[/MAP]
```

*Available only for spreadsheet and tab-delimited ASCII files.

**Default if the subcommand is omitted.

Keyword	Type of file
WK	Any Lotus 1-2-3 or Symphony file
WK1	1-2-3 Release 2.0
WKS	1-2-3 Release 1A
WR1	Symphony Release 2.0
WRK	Symphony Release 1.0
SLK	Microsoft Excel and Multiplan in SYLK (symbolic link) format
XLS	Microsoft Excel (for Excel 5 or later, use GET DATA)
DBF	All dBASE files
TAB	Tab-delimited ASCII file
SYS	Systat data file

Example

```
GET TRANSLATE FILE='PROJECT.WKS'
 /FIELDNAMES
 /RANGE=D3..J279.
```

Overview

GET TRANSLATE creates an active dataset from files produced by other software applications. Supported formats are 1-2-3, Symphony, Multiplan, Excel, dBASE II, dBASE III, dBASE IV, and tab-delimited ASCII files.

Options

Variable Subsets. You can use the DROP and KEEP subcommands to specify variables to omit or retain in the resulting active dataset.

Variable Names. You can rename variables as they are translated using the RENAME subcommand.

Variable Map. To confirm the names and order of the variables in the active dataset, use the MAP subcommand. MAP displays the variables in the active dataset and their corresponding names in the other application.

Spreadsheet Files. You can use the RANGE subcommand to translate a subset of cells from a spreadsheet file. You can use the FIELDNAMES subcommand to translate field names in the spreadsheet file to variable names.

Basic Specification

- The basic specification is FILE with a file specification enclosed in apostrophes.
- If the file's extension is not the default for the type of file you are reading, TYPE must also be specified.

Subcommand Order

Subcommands can be named in any order.

Limitations

The maximum number of variables that can be translated into the active dataset depends on the maximum number of variables that the other software application can handle:

Application	Maximum variables
1-2-3	256
Symphony	256
Multiplan	255
Excel	256
dBASE IV	255
dBASE III	128
dBASE II	32

Operations

GET TRANSLATE replaces an existing active dataset.

Spreadsheets

A spreadsheet file suitable for this program should be arranged so that each row represents a case and each column, a variable.

- By default, the new active dataset contains all rows and up to 256 columns from Lotus 1-2-3, Symphony, or Excel, or up to 255 columns from Multiplan.
- By default, `GET TRANSLATE` uses the column letters as variable names in the active dataset.
- The first row of a spreadsheet or specified range may contain field labels immediately followed by rows of data. These names can be transferred as SPSS variable names. For more information, see FIELDNAMES Subcommand on p. 778.
- The current value of a formula is translated to the active dataset.
- Blank, ERR, and NA values in 1-2-3 and Symphony and error values such as #N/A in Excel are translated as system-missing values in the active dataset.
- Hidden columns and cells in 1-2-3 Release 2 and Symphony files are translated and copied into the active dataset.
- Column width and format type are transferred to the dictionary of the active dataset.
- The format type is assigned from values in the first data row. By default, the first data row is row 1. If `RANGE` is specified, the first data row is the first row in the range. If `FIELDNAMES` is specified, the first data row follows immediately after the single row containing field names.
- If a cell in the first data row is empty, the variable is assigned the global default format from the spreadsheet.

The formats from 1-2-3, Symphony, Excel, and Multiplan are translated as follows:

1-2-3/Symphony	Excel	SYLK	SPSS
Fixed	0.00; #,##0.00	Fixed	F
	0; #,##0	Integer	F
Scientific	0.00E+00	Exponent	E
Currency	$#,##0_);...	$ (dollar)	DOLLAR
, (comma)			COMMA
General	General	General	F
+/–		* (bargraph)	F
Percent	0%; 0.00%	Percent	PCT
Date	m/d/yy;d-mmm-yy...		DATE
Time	h:mm; h:mm:ss...		TIME
Text/Literal			F
Label		Alpha	String

- If a string is encountered in a column with numeric format, it is converted to the system-missing value in the active dataset.
- If a numeric value is encountered in a column with string format, it is converted to a blank in the active dataset.
- Blank lines are translated as cases containing the system-missing value for numeric variables and blanks for string variables.
- 1-2-3 and Symphony date and time indicators (shown at the bottom of the screen) are not transferred from *WKS*, *WK1*, or *SYM* files.

Databases

Database files are logically very similar to SPSS-format data files.

- By default, all fields and records from dBASE II, dBASE III, or dBASE IV files are included in the active dataset.
- Field names are automatically translated into variable names. If the `FIELDNAMES` subcommand is used with database files, it is ignored.
- Field names are converted to valid SPSS variable names.
- Colons used in dBASE II field names are translated to underscores.
- Records in dBASE II, dBASE III, or dBASE IV that have been marked for deletion but that have not actually been purged are included in the active dataset. To differentiate these cases, `GET TRANSLATE` creates a new string variable, *D_R*, which contains an asterisk for cases marked for deletion. Other cases contain a blank for *D_R*.
- Character, floating, and numeric fields are transferred directly to variables. Logical fields are converted into string variables. Memo fields are ignored.

dBASE formats are translated as follows:

dBASE	SPSS
Character	String
Logical	String
Date	Date
Numeric	Number
Floating	Number
Memo	Ignored

Tab-Delimited ASCII Files

Tab-delimited ASCII files are simple spreadsheets produced by a text editor, with the columns delimited by tabs and rows, by carriage returns. The first row is usually occupied by column headings.

- By default all columns of all rows are treated as data. Default variable names *VAR1*, *VAR2*, and so on are assigned to each column. The data type (numeric or string) for each variable is determined by the first data value in the column.
- If `FIELDNAMES` is specified, the program reads in the first row as variable names and determines the data type by the values read in from the second row.
- Any value that contains non-numeric characters is considered a string value. Dollar and date formats are not recognized and are treated as strings. When string values are encountered for a numeric variable, they are converted to the system-missing value.
- For numeric variables, the assigned format is `F8.2` or the format of the first data value in the column, whichever is wider. Values that exceed the defined width are rounded for display, but the entire value is stored internally.

- For string variables, the assigned format is A8 or the format of the first data value in the column, whichever is wider. Values that exceed the defined width are truncated.
- ASCII data files delimited by space (instead of tabs) or in fixed format should be read by DATA LIST.

FILE Subcommand

FILE names the file to read. The only specification is the name of the file.

- File specifications should be enclosed in quotation marks or apostrophes.

Example

```
GET TRANSLATE FILE='PROJECT.WKS'.
```

- GET TRANSLATE creates an active dataset from the 1-2-3 Release 1.0 spreadsheet with the name *PROJECT.WKS*.
- The active dataset contains all rows and columns and uses the column letters as variable names.
- The format for each variable is determined by the format of the value in the first row of each column.

TYPE Subcommand

TYPE indicates the format of the file.

- TYPE can be omitted if the file extension named on FILE is the default for the type of file that you are reading.
- The TYPE subcommand takes precedence over the file extension.
- You can create a Lotus format file in Multiplan and translate it to an active dataset by specifying WKS on TYPE.

WK	*Any Lotus 1-2-3 or Symphony file.*
WK1	*1-2-3 Release 2.0.*
WKS	*1-2-3 Release 1A.*
SYM	*Symphony Release 2.0 or Symphony Release 1.0.*
SLK	*Microsoft Excel and Multiplan saved in SYLK (symbolic link) format.*
XLS	*Microsoft Excel.* For Excel 5 or later, use GET DATA.
DBF	*All dBASE files.*
TAB	*Tab-delimited ASCII data file.*

Example

```
GET TRANSLATE FILE='PROJECT.OCT' /TYPE=SLK.
```

- GET TRANSLATE creates an active dataset from the Multiplan file *PROJECT.OCT*.

FIELDNAMES Subcommand

FIELDNAMES translates spreadsheet field names into variable names.

- FIELDNAMES can be used with spreadsheet and tab-delimited ASCII files only. FIELDNAMES is ignored when used with database files.
- Each cell in the first row of the spreadsheet file (or the specified range) must contain a field name. If a column does not contain a name, the column is dropped.
- Field names are converted to valid SPSS variable names.
- If two or more columns in the spreadsheet have the same field name, digits are appended to all field names after the first, making them unique.
- Illegal characters in field names are changed to underscores in this program.
- If the spreadsheet file uses reserved words (ALL, AND, BY, EQ, GE, GT, LE, LT, NE, NOT, OR, TO, or WITH) as field names, GET TRANSLATE appends a dollar sign ($) to the variable name. For example, columns named *GE*, *GT*, *EQ*, and *BY* will be renamed *GE$*, *GT$*, *EQ$*, and *BY$* in the active dataset.

Example

```
GET TRANSLATE FILE='MONTHLY.SYM' /FIELDNAMES.
```

- GET TRANSLATE creates a active dataset from a Symphony 1.0 spreadsheet. The first row in the spreadsheet contains field names that are used as variable names in the active dataset.

RANGE Subcommand

RANGE translates a specified set of cells from a spreadsheet file.

- RANGE cannot be used for translating database files.
- For 1-2-3 or Symphony, specify the beginning of the range with a column letter and row number followed by two periods and the end of the range with a column letter and row number, as in A1..K14.
- For Multiplan spreadsheets, specify the beginning and ending cells of the range separated by a colon, as in R1C1:R14C11.
- For Excel files, specify the beginning column letter and row number, a colon, and the ending column letter and row number, as in A1:K14.
- You can also specify the range using range names supplied in Symphony, 1-2-3, or Multiplan.
- If you specify FIELDNAMES with RANGE, the first row of the range must contain field names.

Example

```
GET TRANSLATE FILE='PROJECT.WKS' /FIELDNAMES /RANGE=D3..J279.
```

- GET TRANSLATE creates an active dataset from the 1-2-3 Release 1A file *PROJECT.WKS*.
- The field names in the first row of the range (row 3) are used as variable names.
- Data from cells D4 through J279 are transferred to the active dataset.

DROP and KEEP Subcommands

DROP and KEEP are used to copy a subset of variables into the active dataset. DROP specifies the variables not to copy into the active dataset. KEEP specifies the variables to copy. Variables not specified on KEEP are dropped.

- DROP and KEEP cannot precede the FILE or TYPE subcommands.
- DROP and KEEP specifications use variable names. By default, this program uses the column letters from spreadsheets and the field names from databases as variable names.
- If FIELDNAMES is specified when translating from a spreadsheet, the DROP and KEEP subcommands must refer to the field names, not the default column letters.
- Variables can be specified in any order. Neither DROP nor KEEP affects the order of variables in the resulting file. Variables are kept in their original order.
- If a variable is referred to twice on the same subcommand, only the first mention of the variable is recognized.
- Multiple DROP and KEEP subcommands are allowed; the effect is cumulative. Specifying a variable named on a previous DROP or not named on a previous KEEP results in an error and the command is not executed.
- If you specify both RANGE and KEEP, the resulting file contains only variables that are both within the range and specified on KEEP.
- If you specify both RANGE and DROP, the resulting file contains only variables within the range and excludes those mentioned on DROP, even if they are within the range.

Example

```
GET TRANSLATE FILE='ADDRESS.DBF' /DROP=PHONENO, ENTRY.
```

- GET TRANSLATE creates an active dataset from the dBASE file *ADDRESS.DBF*, omitting the fields named *PHONENO* and *ENTRY*.

Example

```
GET TRANSLATE FILE='PROJECT.OCT' /TYPE=WK1 /FIELDNAMES
 /KEEP=NETINC, REP, QUANTITY, REGION, MONTH, DAY, YEAR.
```

- GET TRANSLATE creates a active dataset from the 1-2-3 Release 2.0 file called *PROJECT.OCT*.
- The subcommand FIELDNAMES indicates that the first row of the spreadsheet contains field names, which will be translated into variable names in the active dataset.
- The subcommand KEEP translates columns with the field names *NETINC*, *REP*, *QUANTITY*, *REGION*, *MONTH*, *DAY*, and *YEAR* to the active dataset.

MAP Subcommand

MAP displays a list of the variables in the active dataset and their corresponding names in the other application.

- The only specification is the keyword MAP. There are no additional specifications.

- Multiple MAP subcommands are allowed. Each MAP subcommand maps the results of subcommands that precede it; results of subcommands that follow it are not mapped.

Example

```
GET TRANSLATE FILE='ADDRESS.DBF' /DROP=PHONENO, ENTRY /MAP.
```

- MAP is specified to confirm that the variables *PHONENO* and *ENTRY* have been dropped.

GGRAPH

Note: Square brackets used in the GGRAPH syntax chart are required parts of the syntax and are not used to indicate optional elements. Any equals signs (=) displayed in the syntax chart are required. The GRAPHSPEC subcommand is required.

```
GGRAPH

  /GRAPHDATASET NAME="name"

                DATASET=datasetname

                VARIABLES=variablespec

                TRANSFORM={NO**                                          }
                          {VARSTOCASES(SUMMARY="varname" INDEX="varname")}

                MISSING={LISTWISE**    } REPORTMISSING={NO**}
                        {VARIABLEWISE  }               {YES }

                CASELIMIT={1000000**}
                          {value    }

  /GRAPHSPEC    SOURCE={INLINE               }
                       {GPLFILE("filespec")  }
                       {VIZMLFILE("filespec")}

                EDITABLE={YES**}
                         {NO   }

                LABEL="string"

                DEFAULTTEMPLATE={YES**} TEMPLATE=["filespec" ...]
                                {NO   }
```

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Release History

Release 14.0

- Command introduced.

Release 15.0

- RENAME syntax qualifier deprecated.
- COUNTCI, MEDIANCI, MEANCI, MEANSD, and MEANSE functions introduced.

Examples

```
GGRAPH
  /GRAPHDATASET NAME="graphdataset" VARIABLES=jobcat COUNT()
  /GRAPHSPEC SOURCE=GPLFILE("simplebarchart.gpl").
```

```
GGRAPH
  /GRAPHDATASET NAME="graphdataset" VARIABLES=jobcat COUNT()
  /GRAPHSPEC SOURCE=INLINE.
BEGIN GPL
  SOURCE: s=userSource(id("graphdataset"))
  DATA: jobcat=col(source(s), name("jobcat"), unit.category())
  DATA: count=col(source(s), name("COUNT"))
  GUIDE: axis(dim(1), label("Employment Category"))
  GUIDE: axis(dim(2), label("Count"))
  ELEMENT: interval(position(jobcat*count))
END GPL.
```

Overview

GGRAPH generates a graph by computing statistics from variables in a data source and constructing the graph according to the graph specification, which may be written in the Graphics Productions Language (GPL) or ViZml.

Basic Specification

The basic specification is the GRAPHSPEC subcommand.

Syntax Rules

- Subcommands and keywords can appear in any order.
- Subcommand names and keywords must be spelled out in full.
- The GRAPHDATASET and GRAPHSPEC subcommands are repeatable.
- Parentheses, equals signs, and slashes shown in the syntax chart are required.
- Strings in the GPL are enclosed in quotation marks. You cannot use single quotes (apostrophes).
- With the SPSS Batch Facility (available only with SPSS Server), use the -i switch when submitting command files that contain BEGIN GPL–END GPL blocks.

GRAPHDATASET Subcommand

GRAPHDATASET creates graph datasets based on open SPSS-format data files. The subcommand is repeatable, allowing you to create multiple graph datasets that can be referenced in a graph specification. Furthermore, multiple graph specifications (the ViZml or GPL code that defines a graph) can reference the same graph dataset.

Graph datasets contain the data that accompany a graph. The actual variables and statistics in the graph dataset are specified by the VARIABLES keyword.

Example

```
GGRAPH
  /GRAPHDATASET NAME="graphdataset" VARIABLES=jobcat COUNT()
  /GRAPHSPEC SOURCE=GPLFILE("simplebarchart.gpl").
```

NAME Keyword

The NAME keyword specifies the name that identifies the graph dataset when it is referenced in a graph specification. There is no default name, so you must specify one. You can choose any name that honors variable naming rules. (For more information about naming rules, see Variable Names on p. 43.) When the same graph dataset name is used in multiple GRAPHDATASET subcommands, the name in the last GRAPHDATASET subcommand is honored.

DATASET Keyword

The DATASET keyword specifies the dataset name of an open SPSS-format data file to use for the graph dataset. If the keyword is omitted, GGRAPH uses the active dataset. You can also use an asterisk (*) to refer to the active dataset.

The following are honored only for the active dataset (which cannot be named except with an asterisk):

- FILTER
- USE
- SPLIT FILE
- Weight filtering (exclusion of cases with non-positive weights)
- Temporary transformations
- Pending transformations

Example

```
GGRAPH
  /GRAPHDATASET NAME="graphdataset" DATASET=DataSet2 VARIABLES=jobcat COUNT()
  /GRAPHSPEC SOURCE=GPLFILE("simplebarchart.gpl").
```

VARIABLES Keyword

The VARIABLES keyword identifies the variables, statistics, and utility function results that are included in the graph dataset. These are collectively identified as a **variable specification**. The minimum variable specification is a variable. An aggregation or summary function is required when the variable specification includes a multiple-response set. The order of the variables and functions in the variable specification does not matter. Multiple aggregation or summary functions are allowed so that you can graph more than one statistic. You can also use the ALL and TO keywords to include multiple variables without explicitly listing them. For information about the ALL keyword, see Keyword ALL on p. 46. For information about the TO keyword, see Keyword TO on p. 45.

When the variable specification includes an aggregation function and does *not* include the CASEVALUE function, the graph dataset is aggregated. Any stand-alone variables in the variable specification act as categorical break variables for the aggregation (including scale variables that are not parameters of a summary function). The function is evaluated for each unique value in each break variable. When the variable specification includes only variables or includes the CASEVALUE function, the graph dataset is unaggregated. The built-in variable $CASENUM is

included in the unaggregated dataset. $CASENUM cannot be specified or renamed in the variable specification, but you can refer to it in the graph specification.

An unaggregated graph dataset includes a case for every case in the SPSS dataset. An aggregated dataset includes a case for every combination of unique break variable values. For example, assume that there are two categorical variables that act as break variables. If there are three categories in one variable and two in the other, there are six cases in the aggregated graph dataset, as long as there are values for each category.

Note: If the dataset is aggregated, be sure to include all of the break variables in the graph specification (the ViZml or GPL). For example, if the variable specification includes two categorical variables and a summary function of a scale variable, the graph specification should use one of the categorical variables as the *x*-axis variable and one as a grouping or panel variable. Otherwise, the resulting graph will not be correct because it does not contain all of the information used for the aggregation.

Example

```
GGRAPH
  /GRAPHDATASET NAME="graphdataset" VARIABLES=jobcat[NAME="empcat" LEVEL=NOMINAL] COUNT()
  /GRAPHSPEC SOURCE=GPLFILE("simplebarchart.gpl").
```

- The NAME qualifier renames a variable. For more information, see Variable and Function Names on p. 784.
- The LEVEL qualifier specifies a temporary measurement level for a variable. For more information, see Measurement Level on p. 785.

Variable and Function Names

The variable name that you use in the variable specification is the same as the name defined in the data dictionary. This also the default name for referencing the variable in the graph specification. To use a different name in the graph specification, rename the variable by appending the qualifier [NAME="name"] to the name in the variable specification. You might do this to avoid name conflicts across datasets, to shorten the name, or to reuse the same graph specification even if the datasets have different variable names. For example:

```
GGRAPH
  /GRAPHDATASET NAME="graphdataset" VARIABLES=jobcat[NAME="catvar"] COUNT()
  /GRAPHSPEC SOURCE=INLINE.
BEGIN GPL
  SOURCE: s=userSource(id("graphdataset"))
  DATA: catvar=col(source(s), name("catvar"), unit.category())
  DATA: count=col(source(s), name("COUNT"))
  GUIDE: axis(dim(1), label("Employment Category"))
  GUIDE: axis(dim(2), label("Count"))
  ELEMENT: interval(position(catvar*count))
END GPL.
```

The default name for a summary function is the function name in uppercase letters followed by the parameters separated by underscores. For example, if the function is MEAN(salary), the default name for referencing this function in the graph specification is MEAN_salary. For GPTILE(salary,90), the default name is GPTILE_salary_90. You can also change the

default function name using the qualifier [NAME="name"], just as you do with variables. For example:

```
GGRAPH
  /GRAPHDATASET NAME="graphdataset"
                VARIABLES=jobcat MEDIAN(salary) MEAN(salary)[NAME="meansal"]
  /GRAPHSPEC SOURCE=INLINE.
BEGIN GPL
  SOURCE: s=userSource(id("graphdataset"))
  DATA: jobcat=col(source(s), name("jobcat"), unit.category())
  DATA: medsal=col(source(s), name("MEDIAN_salary"))
  DATA: meansal=col(source(s), name("meansal"))
  GUIDE: axis(dim(1), label("Employment Category"))
  GUIDE: axis(dim(2), label("Salary"))
  ELEMENT: line(position(jobcat*medsal), color("Median"))
  ELEMENT: line(position(jobcat*meansal), color("Mean"))
END GPL.
```

Error interval functions produce three values (a summary value, an upper bound, and a lower bound), so there are three default names for these functions. The default name for the summary value follows the same rule as the default name for a summary function: the function name in uppercase letters followed by the parameters separated by underscores. The other two values are this name with _HIGH appended to the name for the upper bound and _LOW appended to the name for the lower bound. For example, if the function is MEANCI(salary, 95), the default names for referencing the results of this function in the graph specification are MEANCI_salary_95, MEANCI_salary_95_HIGH, and MEANCI_salary_95_LOW. You can change the names of the values using the qualifiers [NAME="name" HIGH="name" LOW="name"]. For example:

```
GGRAPH
  /GRAPHDATASET NAME="graphdataset"
                VARIABLES=jobcat COUNTCI(95)[NAME="stat" HIGH="high" LOW="low"]
  /GRAPHSPEC SOURCE=INLINE.
BEGIN GPL
  SOURCE: s=userSource(id("graphdataset"))
  DATA: jobcat=col(source(s), name("jobcat"), unit.category())
  DATA: stat=col(source(s), name("stat"))
  DATA: high=col(source(s), name("high"))
  DATA: low=col(source(s), name("low"))
  GUIDE: axis(dim(1), label("Employment Category"))
  GUIDE: axis(dim(2), label("Count with 95% CI"))
  ELEMENT: point(position(jobcat*stat))
  ELEMENT: interval(position(region.spread.range(jobcat*(low+high))), shape(shape.ibeam))
END GPL.
```

Measurement Level

You can change a variable's measurement level temporarily by appending the qualifier [LEVEL=measurement level] to the name in the variable specification. (The variable's measurement level in the dictionary is unaffected.) Valid values for the measurement level are SCALE, NOMINAL, and ORDINAL. Currently, the measurement level qualifier is used to influence the behavior of the REPORTMISSING keyword. If the measurement level is set to SCALE, missing values are not reported for that variable, even if the value of the REPORTMISSING keyword is

YES. If you are using the NAME qualifier for the same variable, both qualifiers are enclosed in the same pair of square brackets. For example:

```
GGRAPH
  /GRAPHDATASET NAME="graphdataset" VARIABLES=jobcat[NAME="empcat" LEVEL=NOMINAL] COUNT()
  /GRAPHSPEC SOURCE=GPLFILE("simplebarchart.gpl").
```

Functions

Utility functions:

CASEVALUE(var) *Yields the value of the specified variable for each case.* CASEVALUE always produces one value for each case and always results in GGRAPH creating an unaggregated graph dataset. Use this function when you are creating graphs of individual cases and want to use the values of the specified variable as the axis tick labels for each case. This function cannot be used with multiple response sets or aggregation functions.

Aggregation functions:

Three groups of aggregation functions are available: count functions, summary functions, and error interval functions.

Count functions:

Note: Percent and cumulative statistic functions are not available in the variable specification. Use the summary percent and cumulative statistic functions that are available in the Graphics Production Language (GPL) itself.

COUNT() *Frequency of cases in each category.*

RESPONSES() *Number of responses for a multiple dichotomy set.*

RESPONSES(DUP / NODUP)

Number of responses for a multiple category set. The argument (DUP or NODUP) specifies whether the function counts duplicates. The argument is optional, and the default is not to count duplicates. This function cannot be used with a multiple dichotomy set.

- Count functions yield the count of valid cases within categories determined by the other variables in the variable specification (including other scale variables that are not parameters of a summary function).
- Count functions do not use variables as parameters.

Summary functions:

MINIMUM(var) *Minimum value of the variable.*

MAXIMUM(var) *Maximum value of the variable.*

VALIDN(var) *Number of cases for which the variable has a nonmissing value.*

SUM(var) *Sum of the values of the variable.*

MEAN(var) *Mean of the variable.*

STDDEV(var) *Standard deviation of the variable.*

VARIANCE(var) *Variance of the variable.*

MEDIAN(var) *Median of the variable.*

GMEDIAN(var) *Group median of the variable.*

MODE(var) *Mode of the variable.*

PTILE(var,x) X*th percentile value of the variable. X* must be greater than 0 and less than 100.

GPTILE(var,x) X*th percentile value of the variable, where the percentile is calculated as if the values were uniformly distributed over the whole interval. X* must be greater than 0 and less than 100.

PLT(var,x) *Percentage of cases for which the value of the variable is less than* x.

PGT(var,x) *Percentage of cases for which the value of the variable is greater than* x.

NLT(var,x) *Number of cases for which the value of the variable is less than* x.

NGT(var,x) *Number of cases for which the value of the variable is greater than* x.

PIN(var,x1,x2) *Percentage of cases for which the value of the variable is greater than or equal to* x1 *and less than or equal to* x2. *x1* cannot exceed *x2*.

NIN(var,x1,x2) *Number of cases for which the value of the variable is greater than or equal to* x1 *and less than or equal to* x2. *x1* cannot exceed *x2*.

NLE(var,x) *Number of cases for which the value of the variable is less than or equal to* x.

PLE(var,x) *Percentage of cases for which the value of the variable is less than or equal to* x.

NEQ(var,x) *Number of cases for which the value of the variable is equal to* x.

PEQ(var,x) *Percentage of cases for which the value of the variable is equal to* x.

NGE(var,x) *Number of cases for which the value of the variable is greater than or equal to* x.

PGE(var,x) *Percentage of cases for which the value of the variable is greater than or equal to* x.

- Summary functions yield a single value.
- Summary functions operate on summary variables (variables that record continuous values, such as age or expenses). To use a summary function, specify the name of one or more variables as the first parameter of the function and then specify other required parameters as shown. The variable used as a parameter cannot contain string data.

Error interval functions:

COUNTCI(alpha) *Confidence intervals for the count with a confidence level of* alpha. *alpha* must be greater than or equal to 50 and less than 100.

MEDIANCI(var,alpha) *Confidence intervals for median of the variable with a confidence level of* alpha. *alpha* must be greater than or equal to 50 and less than 100.

MEANCI(var,alpha) *Confidence intervals for mean of the variable with a confidence level of* alpha. *alpha* must be greater than or equal to 50 and less than 100.

MEANSD(var,multiplier)

Standard deviations for mean of the variable with a multiplier. *multiplier* must be an integer greater than 0.

MEANSE(var,multiplier)

Standard deviations for median of the variable with a multiplier. *multiplier* must be an integer greater than 0.

- Error functions yield three values: a summary value, a lower bound value, and an upper bound value.
- Error functions may or may not operate on summary variables (variables that record continuous values, such as age or expenses). To use a summary function that operates on a variable, specify the name of the variable as the first parameter of the function and then specify other required parameters as shown. The variable used as a parameter cannot contain string data.

TRANSFORM Keyword

The TRANSFORM keyword applies a transformation to the graph dataset.

NO *Do not transform the graph dataset.*

VARSTOCASES(SUMMARY="varname" INDEX="varname")

Transform the summary function results to cases in the graph dataset. Use this when you are creating graphs of separate variables. The results of each summary function becomes a case in the graph dataset, and the data elements drawn for each case act like categories in a categorical graph. Each case is identified by an index variable whose value is a unique sequential number. The result of the summary function is stored in the summary variable. The upper and lower bound of error interval functions are also stored in two other variables. By default, the names of the variables are #INDEX for the index variable, #SUMMARY for the summary variable, #HIGH for the upper bound variable, and #LOW for the lower bound variable. You can change these names by using the SUMMARY, INDEX, HIGH, and LOW qualifiers. Furthermore, break variables in the variable specification are treated as fixed variables and are not transposed. Note that this transformation is similar to the VARSTOCASES command (see VARSTOCASES on p. 1964).

Examples

```
GGRAPH
  /GRAPHDATASET NAME="graphdataset" VARIABLES=MEAN(salbegin) MEAN(salary)
   TRANSFORM=VARSTOCASES(SUMMARY="meansal" INDEX="variables")

END GPL.
```

MISSING Keyword

The MISSING keyword specifies how missing values are handled when the variable specification includes an aggregation function. When the variable specification includes only variables or includes the CASEVALUE function, this keyword does not affect the treatment of missing values. The graph dataset is unaggregated, so cases with system- and user-missing values are always included in the graph dataset.

LISTWISE *Exclude the whole case if any one of the variables in the variable specification has a missing value.* This is the default.

VARIABLEWISE *Exclude a case from the aggregation function if the value is missing for a particular variable being analyzed.* This means that a case is excluded if that case has a missing value for a variable that is a summary function parameter.

REPORTMISSING Keyword

The REPORTMISSING keyword specifies whether to create a category for each unique user-missing value.

NO *Do not create a category for each unique user-missing value.* User-missing values are treated like system-missing values. This is the default.

YES *Create a category for each unique user-missing value.* User-missing values are treated as valid categories, are included as break variables for aggregation functions, and are drawn in the graph. Note that this does not affect variables identified as SCALE by the LEVEL qualifier in the VARIABLES keyword.

CASELIMIT Keyword

The CASELIMIT keyword specifies a limit to the number of cases that are included in the graph dataset. The limit does not apply to the number of cases use for analysis in any functions specified by the VARIABLES keyword. It only limits the number of cases in the graph dataset, which may or may not affect the number cases drawn in the resulting chart. You may want to limit the

number of cases for very large datasets that are not summarized by a function. A scatterplot is an example. Limiting cases may improve performance.

value *Limit the number of cases in the graph dataset to the specified value.* The default value is 1000000.

GRAPHSPEC Subcommand

GRAPHSPEC defines a graph specification. A graph specification identifies the source used to create the graph, in addition to other features like templates. GRAPHSPEC is repeatable, allowing you to define multiple graph specifications to create multiple graphs with one GGRAPH command.

Example

```
GGRAPH
  /GRAPHDATASET NAME="graphdataset" VARIABLES=jobcat COUNT()
  /GRAPHSPEC SOURCE=GPLFILE("simplebarchart.gpl").
```

SOURCE Keyword

The SOURCE keyword specifies the source of the graph specification.

INLINE *An inline graph specification follows the GGRAPH command.* Currently, the BEGIN GPL/END GPL block is used for the inline graph specification. This block must follow the GGRAPH command, and there must be as many blocks as there are GRAPHSPEC subcommands with SOURCE=INLINE. For more information, see BEGIN GPL-END GPL on p. 210. See Overview on p. 210 for limitations.

GPLFILE("filespec")

*Use the specified GPL file as the graph specification.*See the *GPL Reference Guide* on the manuals CD for more details about GPL. The examples in the GPL documentation may look different compared to the syntax pasted from the Chart Builder. The main difference is in when aggregation occurs. See Working with the GPL below for information about the differences. See Examples on p. 794 for examples with GPL that is similar to the pasted syntax.

VIZMLFILE("filespec")

Use the specified ViZml file as the graph specification. You can save ViZml from the Chart Editor.

Examples

```
GGRAPH
  /GRAPHDATASET NAME="graphdataset" VARIABLES=jobcat COUNT()
  /GRAPHSPEC SOURCE=INLINE.
BEGIN GPL
  SOURCE: s=userSource(id("graphdataset"))
  DATA: jobcat=col(source(s), name("jobcat"), unit.category())
  DATA: count=col(source(s), name("COUNT"))
  GUIDE: axis(dim(1), label("Employment Category"))
  GUIDE: axis(dim(2), label("Count"))
  ELEMENT: interval(position(jobcat*count))
END GPL.

GGRAPH
  /GRAPHDATASET NAME="graphdataset" VARIABLES=jobcat COUNT()
```

```
  /GRAPHSPEC SOURCE=GPLFILE("simplebarchart.gpl").

GGRAPH
  /GRAPHDATASET NAME="graphdataset" VARIABLES=jobcat COUNT()
  /GRAPHSPEC SOURCE=VIZMLFILE("simplebarchart.xml").
```

Working with the GPL

The Chart Builder allows you to paste GGRAPH syntax. This syntax contains inline GPL

You may want to edit the GPL to create a chart or add a feature that isn't available from the Chart Builder. You can use the GPL documentation to help you. However, the GPL documentation always uses unaggregated data and includes GPL statistics in the examples to aggregate the data. The pasted syntax, on the other hand, may use data aggregated by a GGRAPH summary function. Also, the pasted syntax includes defaults that you may have to change when you edit the syntax. Therefore, it may be confusing how you can use the pasted syntax to create the examples. Following are some tips.

- Variables must be specified in two places: in the VARIABLES keyword in the GGRAPH command and in the DATA statements in the GPL. So, if you add a variable, make sure a reference to it appears in both places.
- Pasted syntax often uses the VARIABLES keyword to specify summary statistics. Like other variables, the summary function name is specified in the GPL DATA statement. You do not need to use GGRAPH summary functions. Instead, you can use the equivalent GPL statistic for aggregation. However, for very large data sets, you may find that pre-aggregating the data with GGRAPH is faster than using the aggregation in the GPL itself. Try both approaches and stick with the one that feels comfortable to you. In the examples that follow, you can compare the different approaches.
- Make sure that you understand how the functions are being used in the GPL. You may need to modify one or more of them when you add a variable to pasted syntax. For example, if you change the dimension on which a categorical variable appears, you may need to change references to the dimension in the GUIDE and SCALE statements. If you are unsure about whether you need a particular function, try removing it and see if you get the results you expect.

Here's an example from the GPL documentation:

Figure 94-1
Example from GPL documentation

```
SOURCE: s=usersource(id("Employeedata"))
DATA: jobcat = col(source(s), name("jobcat"), unit.category())
DATA: gender = col(source(s), name("gender"), unit.category())
DATA: salary = col(source(s), name("salary"))
SCALE: linear(dim(2), include(0))
GUIDE: axis(dim(3), label("Gender"))
GUIDE: axis(dim(2), label("Mean Salary"))
GUIDE: axis(dim(1), label("Job Category"))
ELEMENT: interval(position(summary.mean(jobcat*salary*gender)))
```

The simplest way to use the example is to use unaggregated data and VARIABLES=ALL like this:

Figure 94-2
Modified example with unaggregated data

```
GGRAPH
  /GRAPHDATASET NAME="Employeedata" VARIABLES=ALL
  /GRAPHSPEC SOURCE=INLINE.
BEGIN GPL
SOURCE: s=usersource(id("Employeedata"))
DATA: jobcat = col(source(s), name("jobcat"), unit.category())
DATA: gender = col(source(s), name("gender"), unit.category())
DATA: salary = col(source(s), name("salary"))
SCALE: linear(dim(2), include(0))
GUIDE: axis(dim(3), label("Gender"))
GUIDE: axis(dim(2), label("Mean Salary"))
GUIDE: axis(dim(1), label("Job Category"))
ELEMENT: interval(position(summary.mean(jobcat*salary*gender)))
END GPL
```

Note that specifying VARIABLES=ALL includes all the data in the graph. You can improve performance by using only those variables that you need. In this example, VARIABLES=jobcat gender salary would have been sufficient.

You can also use aggregated data like the following, which is more similar to the pasted syntax:

Figure 94-3
Modified example with aggregated data

```
GGRAPH
  /GRAPHDATASET NAME="Employeedata" VARIABLES=jobcat gender MEAN(salary)
  /GRAPHSPEC SOURCE=INLINE.
BEGIN GPL
  SOURCE: s=userSource(id("Employeedata"))
  DATA: jobcat=col(source(s), name("jobcat"), unit.category())
  DATA: gender=col(source(s), name("gender"), unit.category())
  DATA: MEAN_salary=col(source(s), name("MEAN_salary"))
  SCALE: linear(dim(2), include(0))
  GUIDE: axis(dim(3), label("Gender"))
  GUIDE: axis(dim(2), label("Mean Salary"))
  GUIDE: axis(dim(1), label("Job Category"))
  ELEMENT: interval(position(jobcat*MEAN_salary*gender))
END GPL.
```

EDITABLE Keyword

The EDITABLE keyword specifies that the resulting graph can be edited in the Chart Editor. If you are creating a complicated graph with the graph specification, it may be useful to prevent editing because not all of the graph's features may be supported in the Chart Editor.

YES *The graph can be edited in the Chart Editor.* This is the default.

NO *The graph cannot be edited in the Chart Editor.*

LABEL Keyword

The LABEL keyword specifies the output label. This label appears in the Output Viewer. It is also used in Output XML (OXML) as a chartTitle element, which is not the same as the title in the graph itself.

string *Use the specified string as the label.*

DEFAULTTEMPLATE Keyword

The DEFAULTTEMPLATE keyword specifies whether GGRAPH applies the default styles to the graph. Most default styles are defined in the Options dialog box, which you can access by choosing Options from the Edit menu. Then click the Charts tab. Some SET commands also define default aesthetics. Finally, other default styles are set to improve the presentation of graphs. These are controlled by the *chart_style.sgt* template file located in the installation directory.

YES *Apply default styles to the graph.* This is the default.

NO *Do not apply default styles to the graph.* This option is useful when you are using a custom ViZml or GPL file that defines styles that you do not want to be overridden by the default styles.

TEMPLATE Keyword

The TEMPLATE keyword identifies an existing template file or files and applies them to the graph requested by the current GGRAPH command. The template overrides the default settings that are used to create any graph, and the specifications on the current GGRAPH command override the template. Templates are created in the Chart Editor by saving an existing chart as a template.

The keyword is followed by an equals sign (=) and square brackets ([ ]) that contain one or more file specifications. Each file specification is enclosed in quotation marks. The square brackets are optional if there is only one file, but the file must be enclosed in quotation marks. Note that the order in which the template files are specified is the order in which GGRAPH applies the templates. Therefore, template files that appear after other template files can override the templates that were applied earlier.

filespec *Apply the specified template file or files to the graph being created.*

Example

```
GGRAPH
  /GRAPHDATASET NAME="graphdataset" VARIABLES=jobcat COUNT()
  /GRAPHSPEC SOURCE=GPLFILE("simplebarchart.gpl")
             TEMPLATE=["mytemplate.sgt"
                       "/myothertemplate.sgt"].
```

Examples

Following are some graph examples. Pictures are not included to encourage you to run the examples. Except when noted, all examples use *Employee data.sav*, which is located in the product installation directory.

Simple Bar Chart

```
GGRAPH
  /GRAPHDATASET NAME="graphdataset" VARIABLES=jobcat MEAN(salary)
  /GRAPHSPEC SOURCE=INLINE.
BEGIN GPL
  SOURCE: s=userSource(id("graphdataset"))
  DATA: jobcat=col(source(s), name("jobcat"), unit.category())
  DATA: meansal=col(source(s), name("MEAN_salary"))
  GUIDE: axis(dim(1), label("Employment Category"))
  GUIDE: axis(dim(2), label("Mean Current Salary"))
  ELEMENT: interval(position(jobcat*meansal))
END GPL.
```

Simple Bar Chart Using a Multiple-Response Set

Note: This example uses *1991 U.S. General Social Survey.sav*, which is located in the product installation directory.

```
GGRAPH
  /GRAPHDATASET NAME="graphdataset" VARIABLES=$prob RESPONSES()[NAME="RESPONSES"]
  /GRAPHSPEC SOURCE=INLINE.
BEGIN GPL
  SOURCE: s=userSource(id("graphdataset"))
  DATA: prob=col(source(s), name("$prob"), unit.category())
  DATA: responses=col(source(s), name("RESPONSES"))
  GUIDE: axis(dim(1), label("Most Important Problems in Last 12 Months"))
  GUIDE: axis(dim(2), label("Responses"))
  ELEMENT: interval(position(prob*responses))
END GPL.
```

Stacked Bar Chart

```
GGRAPH
  /GRAPHDATASET NAME="graphdataset" VARIABLES=jobcat gender COUNT()
  /GRAPHSPEC SOURCE=INLINE.
BEGIN GPL
  SOURCE: s=userSource(id("graphdataset"))
  DATA: jobcat=col(source(s), name("jobcat"), unit.category())
  DATA: gender=col(source(s), name("gender"), unit.category())
  DATA: count=col(source(s), name("COUNT"))
  GUIDE: axis(dim(1), label("Employment Category"))
  GUIDE: axis(dim(2), label("Count"))
  ELEMENT: interval.stack(position(jobcat*count), color(gender))
END GPL.
```

Clustered Bar Chart

```
GGRAPH
  /GRAPHDATASET NAME="graphdataset" VARIABLES=jobcat gender MEAN(salary)
  /GRAPHSPEC SOURCE=INLINE.
BEGIN GPL
  SOURCE: s=userSource(id("graphdataset"))
  DATA: jobcat=col(source(s), name("jobcat"), unit.category())
  DATA: gender=col(source(s), name("gender"), unit.category())
  DATA: meansal=col(source(s), name("MEAN_salary"))
  COORD: rect(dim(1,2), cluster(3,0))
  GUIDE: axis(dim(1), label("Employment Category"))
  GUIDE: axis(dim(2), label("Mean Current Salary"))
  ELEMENT: interval(position(gender*meansal*jobcat), color(gender))
END GPL.
```

Paneled Bar Chart

```
GGRAPH
  /GRAPHDATASET NAME="graphdataset" VARIABLES=jobcat gender MEAN(salary)
  /GRAPHSPEC SOURCE=INLINE.
BEGIN GPL
  SOURCE: s=userSource(id("graphdataset"))
  DATA: jobcat=col(source(s), name("jobcat"), unit.category())
  DATA: gender=col(source(s), name("gender"), unit.category())
  DATA: meansal=col(source(s), name("MEAN_salary"))
  GUIDE: axis(dim(1), label("Gender"))
  GUIDE: axis(dim(2), label("Mean Current Salary"))
  GUIDE: axis(dim(3), label("Employment Category"))
  ELEMENT: interval(position(gender*meansal*jobcat))
END GPL.
```

3-D Bar Chart

```
GGRAPH
  /GRAPHDATASET NAME="graphdataset" VARIABLES=jobcat gender MEAN(salary)
  /GRAPHSPEC SOURCE=INLINE.
BEGIN GPL
  SOURCE: s=userSource(id("graphdataset"))
  DATA: jobcat=col(source(s), name("jobcat"), unit.category())
  DATA: gender=col(source(s), name("gender"), unit.category())
  DATA: meansal=col(source(s), name("MEAN_salary"))
  GUIDE: axis(dim(1), label("Gender"))
  GUIDE: axis(dim(2), label("Employment Category"))
  GUIDE: axis(dim(3), label("Mean Current Salary"))
  COORD: rect(dim(1,2,3))
  ELEMENT: interval(position(gender*jobcat*meansal))
END GPL.
```

Simple Scatterplot

```
GGRAPH
  /GRAPHDATASET NAME="graphdataset" VARIABLES=salbegin salary
  /GRAPHSPEC SOURCE=INLINE.
BEGIN GPL
  SOURCE: s=userSource(id("graphdataset"))
  DATA: salbegin=col(source(s), name("salbegin"))
  DATA: salary=col(source(s), name("salary"))
  GUIDE: axis(dim(1), label("Beginning Salary"))
  GUIDE: axis(dim(2), label("Current Salary"))
  ELEMENT: point(position(salbegin*salary))
END GPL.
```

Simple Scatterplot with Fit Line

```
GGRAPH
  /GRAPHDATASET NAME="graphdataset" VARIABLES=salbegin salary
  /GRAPHSPEC SOURCE=INLINE.
BEGIN GPL
  SOURCE: s=userSource(id("graphdataset"))
  DATA: salbegin=col(source(s), name("salbegin"))
  DATA: salary=col(source(s), name("salary"))
  GUIDE: axis(dim(1), label("Beginning Salary"))
  GUIDE: axis(dim(2), label("Current Salary"))
  ELEMENT: point(position(salbegin*salary))
  ELEMENT: line(position(smooth.linear(salbegin*salary)))
END GPL.
```

Pie Chart

```
GGRAPH
  /GRAPHDATASET NAME="graphdataset" VARIABLES=jobcat COUNT()
  /GRAPHSPEC SOURCE=INLINE.
BEGIN GPL
  SOURCE:s=userSource(id("graphdataset"))
  DATA: jobcat=col(source(s), name("jobcat"), unit.category())
  DATA: count=col(source(s), name("COUNT"))
  GUIDE: axis(dim(1), null())
  COORD: polar.theta()
  SCALE: linear(dim(1), dataMinimum(), dataMaximum())
  ELEMENT: interval.stack(position(summary.percent(count)),color(jobcat))
END GPL.
```

Area Chart

```
GGRAPH
  /GRAPHDATASET NAME="graphdataset" VARIABLES=jobcat MEAN(salary)
  /GRAPHSPEC SOURCE=INLINE.
BEGIN GPL
  SOURCE: s=userSource(id("graphdataset"))
  DATA: jobcat=col(source(s), name("jobcat"), unit.category())
  DATA: meansal=col(source(s), name("MEAN_salary"))
  GUIDE: axis(dim(1), label("Employment Category"))
  GUIDE: axis(dim(2), label("Mean Current Salary"))
  ELEMENT: area(position(jobcat*meansal))
END GPL.
```

Grouped Line Chart

```
GGRAPH
  /GRAPHDATASET NAME="graphdataset" VARIABLES=jobcat gender MEAN(salary)
  /GRAPHSPEC SOURCE=INLINE.
BEGIN GPL
  SOURCE: s=userSource(id("graphdataset"))

† WSDESIGN uses the same specification as DESIGN, with only within-subjects factors.

‡ DEVIATION is the default for between-subjects factors, while POLYNOMIAL is the default for within-subjects factors.

** Default if the subcommand or keyword is omitted.

Temporary variables (tempvar) are:

```
PRED, WPRED, RESID, WRESID, DRESID, ZRESID, SRESID, SEPRED, COOK, LEVER
```

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Overview

GLM (general linear model) is a general procedure for analysis of variance and covariance, as well as regression. GLM is the most versatile of the analysis-of-variance procedures and can be used for both univariate and multivariate designs. GLM allows you to:

- Include interaction and nested effects in your design model. Multiple nesting is allowed; for example, *A* within *B* within *C* is specified as *A*(*B*(*C*)).
- Include covariates in your design model. GLM also allows covariate-by-covariate and covariate-by-factor interactions, such as *X* by *X* (or *X***X*), *X* by *A* (or *X***A*), and *X* by *A* within *B* (or *X***A*(*B*)). Thus, polynomial regression or a test of the homogeneity of regressions can be performed.
- Select appropriate sums-of-squares hypothesis tests for effects in balanced design models, unbalanced all-cells-filled design models, and some-cells-empty design models. The estimable functions that correspond to the hypothesis test for each effect in the model can also be displayed.
- Display the general form of estimable functions.

- Display expected mean squares, automatically detecting and using the appropriate error term for testing each effect in mixed-effects and random-effects models.
- Select commonly used contrasts or specify custom contrasts to perform hypothesis tests.
- Customize hypothesis testing, based on the null hypothesis **LBM** = **K**, where **B** is the parameter vector or matrix.
- Display a variety of post hoc tests for multiple comparisons.
- Display estimates of population marginal cell means for both between-subjects factors and within-subjects factors, adjusted for covariates.
- Perform multivariate analysis of variance and covariance.
- Estimate parameters by using the method of weighted least squares and a generalized inverse technique.
- Graphically compare the levels in a model by displaying plots of estimated marginal cell means for each level of a factor, with separate lines for each level of another factor in the model.
- Display a variety of estimates and measures that are useful for diagnostic checking. All of these estimates and measures can be saved in a data file for use by another procedure.
- Perform repeated measures analysis of variance.
- Display homogeneity tests for testing underlying assumptions in multivariate and univariate analyses.

General Linear Model (GLM) and MANOVA

MANOVA, the other generalized procedure for analysis of variance and covariance, is available only in syntax. The major distinction between GLM and MANOVA in terms of statistical design and functionality is that GLM uses a non-full-rank, or overparameterized, indicator variable approach to parameterization of linear models instead of the full-rank reparameterization approach that is used in MANOVA. GLM employs a generalized inverse approach and employs aliasing of redundant parameters to 0. These processes employed by GLM allow greater flexibility in handling a variety of data situations, particularly situations involving empty cells. GLM offers the following features that are unavailable in MANOVA:

- Identification of the general forms of estimable functions.
- Identification of forms of estimable functions that are specific to four types of sums of squares (Types I–IV).
- Tests that use the four types of sums of squares, including Type IV, specifically designed for situations involving empty cells.
- Flexible specification of general comparisons among parameters, using the syntax subcommands LMATRIX, MMATRIX, and KMATRIX; sets of contrasts can be specified that involve any number of orthogonal or nonorthogonal linear combinations.
- Nonorthogonal contrasts for within-subjects factors (using the syntax subcommand WSFACTORS).
- Tests against nonzero null hypotheses, using the syntax subcommand KMATRIX.

- Feature where estimated marginal means (EMMEANS) and standard errors (adjusted for other factors and covariates) are available for all between-subjects and within-subjects factor combinations in the original variable metrics.
- Uncorrected pairwise comparisons among estimated marginal means for any main effect in the model, for both between- and within-subjects factors.
- Feature where post hoc or multiple comparison tests for unadjusted one-way factor means are available for between-subjects factors in ANOVA designs; twenty different types of comparisons are offered.
- Weighted least squares (WLS) estimation, including saving of weighted predicted values and residuals.
- Automatic handling of random effects in random-effects models and mixed models, including generation of expected mean squares and automatic assignment of proper error terms.
- Specification of several types of nested models via dialog boxes with proper use of the interaction operator (*), due to the nonreparameterized approach.
- Univariate homogeneity-of-variance assumption, tested by using the Levene test.
- Between-subjects factors that do not require specification of levels.
- Profile (interaction) plots of estimated marginal means for visual exploration of interactions involving combinations of between-subjects and/or within-subjects factors.
- Saving of casewise temporary variables for model diagnosis:
  - Predicted values—unstandardized (raw), weighted unstandardized.
  - Residuals—unstandardized, weighted unstandardized, standardized, Studentized, deleted.
  - Standard error of prediction.
  - Cook's distance.
  - Leverage.
- Saving of an SPSS file with parameter estimates and their degrees of freedom and significance level.

To simplify the presentation, GLM reference material is divided into three sections: *univariate* designs with one dependent variable, *multivariate* designs with several interrelated dependent variables, and *repeated measures* designs, in which the dependent variables represent the same types of measurements, taken at more than one time.

The full syntax diagram for GLM is presented here. The following GLM sections include partial syntax diagrams, showing the subcommands and specifications that are discussed in that section. Individually, those diagrams are incomplete. Subcommands that are listed for univariate designs are available for any analysis, and subcommands that are listed for multivariate designs can be used in any multivariate analysis, including repeated measures.

Models

The following examples are models that can be specified by using GLM:

Model 1: Univariate or Multivariate Simple and Multiple Regression

```
GLM Y WITH X1 X2.

GLM Y1 Y2 WITH X1 X2 X3.
```

Model 2: Fixed-effects ANOVA and MANOVA

```
GLM Y1 Y2 BY B.
```

Model 3: ANCOVA and Multivariate ANCOVA (MANCOVA)

```
GLM Y1 Y2 BY B WITH X1 X2 X3.
```

Model 4: Random-effects ANOVA and ANCOVA

```
GLM Y1 BY C WITH X1 X2
 /RANDOM = C.
```

Model 5: Mixed-model ANOVA and ANCOVA

```
GLM Y1 BY B, C WITH X1 X2
 /RANDOM = C.
```

Model 6: Repeated Measures Analysis Using a Split-plot Design

(Univariate mixed models approach with subject as a random effect)

If *drug* is a between-subjects factor and *time* is a within-subjects factor,

```
GLM Y BY DRUG SUBJECT TIME
 /RANDOM = SUBJECT
 /DESIGN = DRUG SUBJECT*DRUG TIME DRUG*TIME.
```

Model 7: Repeated Measures Using the WSFACTOR Subcommand

Use this model only when there is no random between-subjects effect in the model. For example, if *Y1*, *Y2*, *Y3*, and *Y4* are the dependent variables, measured at times 1 to 4,

```
GLM Y1 Y2 Y3 Y4 BY DRUG
 /WSFACTOR = TIME 4
 /DESIGN.
```

Model 8: Repeated Measures Doubly Multivariate Model

Repeated measures fixed-effects MANOVA is also called a doubly multivariate model. Varying or time-dependent covariates are not available. This model can be used only when there is no random between-subjects effect in the model.

```
GLM X11 X12 X13 X21 X22 X23
          Y11 Y12 Y13 Y21 Y22 Y23 BY C D
/MEASURE = X Y
/WSFACTOR = A 2 B 3
/WSDESIGN = A B A*B
/DESIGN = C D.
```

Model 9: Means Model for ANOVA and MANOVA

This model takes only fixed-effect factors (no random effects and covariates) and always assumes the highest order of the interactions among the factors. For example, *B*, *D*, and *E* are fixed factors, and *Y1* and *Y2* are two dependent variables. You can specify a means model by suppressing the intercept effect and specifying the highest order of interaction on the DESIGN subcommand.

```
GLM Y1 Y2 BY B, D, E
/INTERCEPT = EXCLUDE
/DESIGN = B*D*E.
```

Custom Hypothesis Specifications

GLM provides a flexible way to customize hypothesis testing based on the general linear hypothesis **LBM** = **K**, where **B** is the parameter vector or matrix. You can specify a customized linear hypothesis by using one or more of the subcommands LMATRIX, MMATRIX, KMATRIX, and CONTRAST.

LMATRIX, MMATRIX, and KMATRIX Subcommands

- The **L** matrix is called the **contrast coefficients matrix**. This matrix specifies coefficients of contrasts, which can be used for studying the between-subjects effects in the model. One way to define the **L** matrix is by specifying the CONTRAST subcommand, on which you select a type of contrast. Another way is to specify your own **L** matrix directly by using the LMATRIX subcommand. For more information, see LMATRIX Subcommand on p. 815.
- The **M** matrix is called the **transformation coefficients matrix**. This matrix provides a transformation for the dependent variables. This transformation can be used to construct contrasts among the dependent variables in the model. The **M** matrix can be specified on the MMATRIX subcommand. For more information, see MMATRIX Subcommand on p. 830.
- The **K** matrix is called the **contrast results matrix**. This matrix specifies the results matrix in the general linear hypothesis. To define your own **K** matrix, use the KMATRIX subcommand. For more information, see KMATRIX Subcommand on p. 817.

For univariate and multivariate models, you can specify one, two, or all three of the **L**, **M**, and **K** matrices. If only one or two types are specified, the unspecified matrices use the defaults that are shown in the following table (read across the rows).

Table 95-1
Default matrices for univariate and multivariate models if one matrix is specified

L matrix	**M** matrix	**K** matrix
If LMATRIX is used to specify the **L** matrix	Default = identity matrix*	Default = zero matrix

Default = intercept matrix†	If MMATRIX is used to specify the **M** matrix	Default = zero matrix
Default = intercept matrix†	Default = identity matrix*	If KMATRIX is used to specify the **K** matrix

* The dimension of the identity matrix is the same as the number of dependent variables that are being studied.

† The intercept matrix is the matrix that corresponds to the estimable function for the intercept term in the model, provided that the intercept term is included in the model. If the intercept term is not included in the model, the **L** matrix is not defined, and this custom hypothesis test cannot be performed.

Example

```
GLM Y1 Y2 BY A B
    /LMATRIX = A 1 -1
    /DESIGN A B.
```

Assume that factor *A* has two levels.

- Because there are two dependent variables, this model is a multivariate model with two main factor effects, *A* and *B*.
- A custom hypothesis test is requested by the LMATRIX subcommand.
- Because no MMATRIX or KMATRIX is specified, the **M** matrix is the default two-dimensional identity matrix, and the **K** matrix is a zero-row vector (0, 0).

For a repeated measures model, you can specify one, two, or all three of the **L**, **M**, and **K** matrices. If only one or two types are specified, the unspecified matrices use the defaults that are shown in the following table (read across the rows).

Table 95-2
Default matrices for repeated measures models if only one matrix is specified

L matrix	**M** matrix	**K** matrix
If LMATRIX is used to specify the **L** matrix	Default = average matrix*	Default = zero matrix
Default = intercept matrix†	If MMATRIX is used to specify the **M** matrix	Default = zero matrix
Default = intercept matrix†	Default = average matrix*	If KMATRIX is used to specify the **K** matrix

* The average matrix is the transformation matrix that corresponds to the transformation for the between-subjects test. The dimension is the number of measures.

† The intercept matrix is the matrix that corresponds to the estimable function for the intercept term in the model, provided that the intercept term is included in the model. If the intercept term is not included in the model, the **L** matrix is not defined, and this custom hypothesis test cannot be performed.

Example

```
GLM Y1 Y2 BY A B
```

```
/WSFACTOR TIME (2)
/MMATRIX Y1 1 Y2 1; Y1 1 Y2 -1
/DESIGN A B.
```

- Because WSFACTOR is specified, this model is a repeated measures model with two between-subjects factors *A* and *B*, and a within-subjects factor, *TIME*.
- A custom hypothesis is requested by the MMATRIX subcommand. The **M** matrix is a 2×2 matrix:

$$\begin{matrix} 1 & 1 \\ 1 & -1 \end{matrix}$$

- Because the **L** matrix and **K** matrix are not specified, their defaults are used. The default for the **L** matrix is the matrix that corresponds to the estimable function for the intercept term in the between-subjects model, and the default for the **K** matrix is a zero-row vector (0, 0).

CONTRAST Subcommand

When the CONTRAST subcommand is used, an **L** matrix, which is used in custom hypothesis testing, is generated according to the chosen contrast. The **K** matrix is always taken to be the zero matrix. If the model is univariate or multivariate, the **M** matrix is always the identity matrix, and its dimension is equal to the number of dependent variables. For a repeated measures model, the **M** matrix is always the average matrix that corresponds to the average transformation for the dependent variable.

GLM: Univariate

GLM is available in the Advanced Models option.

```
GLM dependent var [BY factor list [WITH covariate list]]

[/RANDOM=factor factor...]

[/REGWGT=varname]

[/METHOD=SSTYPE({1  })]

```

```
{[effect effect...]}
```

** Default if the subcommand or keyword is omitted.

Temporary variables (tempvar) are:

```
PRED, WPRED, RESID, WRESID, DRESID, ZRESID, SRESID, SEPRED, COOK, LEVER
```

Example

```
GLM YIELD BY SEED FERT
  /DESIGN.
```

Overview

This section describes the use of GLM for univariate analyses. However, most of the subcommands that are described here can be used in any type of analysis with GLM. For additional subcommands that are used in multivariate analysis, see *GLM: Multivariate*. For additional subcommands that are used in repeated measures analysis, see *GLM: Repeated Measures*. For basic specification, syntax rules, and limitations of the GLM procedures, see *GLM*.

Options

Design Specification. You can use the DESIGN subcommand to specify which terms to include in the design. This allows you to estimate a model other than the default full factorial model, incorporate factor-by-covariate interactions or covariate-by-covariate interactions, and indicate nesting of effects.

Contrast Types. You can specify contrasts other than the default deviation contrasts on the CONTRAST subcommand.

Optional Output. You can choose from a variety of optional output on the PRINT subcommand. Output that is appropriate to univariate designs includes descriptive statistics for each cell, parameter estimates, Levene's test for equality of variance across cells, partial eta-squared for each effect and each parameter estimate, the general estimable function matrix, and a contrast coefficients table (**L'** matrix). The OUTFILE subcommand allows you to write out the covariance or correlation matrix, the design matrix, or the statistics from the between-subjects ANOVA table into a separate SPSS data file.

Using the EMMEANS subcommand, you can request tables of estimated marginal means of the dependent variable and their standard deviations. The SAVE subcommand allows you to save predicted values and residuals in weighted or unweighted and standardized or unstandardized forms. You can use the POSTHOC subcommand to specify different means comparison tests for comparing all possible pairs of cell means. In addition, you can specify your own hypothesis tests by specifying an **L** matrix and a **K** matrix to test the univariate hypothesis **LB** = **K**.

Basic Specification

- The basic specification is a variable list identifying the dependent variable, the factors (if any), and the covariates (if any).
- By default, GLM uses a model that includes the intercept term, the covariate (if any), and the full factorial model, which includes all main effects and all possible interactions among factors. The intercept term is excluded if it is excluded in the model by specifying the keyword EXCLUDE on the INTERCEPT subcommand. Sums of squares are calculated and hypothesis tests are performed by using type-specific estimable functions. Parameters are estimated by using the normal equation and a generalized inverse of the SSCP matrix.

Subcommand Order

- The variable list must be specified first.
- Subcommands can be used in any order.

Syntax Rules

- For many analyses, the GLM variable list and the DESIGN subcommand are the only specifications that are needed.
- If you do not enter a DESIGN subcommand, GLM uses a full factorial model, with main effects of covariates, if any.
- At least one dependent variable must be specified, and at least one of the following specifications must occur: INTERCEPT, a between-subjects factor, or a covariate. The design contains the intercept by default.
- If more than one DESIGN subcommand is specified, only the last subcommand is in effect.
- Dependent variables and covariates must be numeric, but factors can be numeric or string variables.
- If a string variable is specified as a factor, only the first eight bytes of each value are used in distinguishing among values.
- If more than one MISSING subcommand is specified, only the last subcommand is in effect.
- The following words are reserved as keywords or internal commands in the GLM procedure:
  INTERCEPT, BY, WITH, ALL, OVERALL, WITHIN
  Variable names that duplicate these words should be changed before you run GLM.

Limitations

- Any number of factors can be specified, but if the number of between-subjects factors plus the number of split variables exceeds 18, the Descriptive Statistics table is not printed even when you request it.
- Memory requirements depend primarily on the number of cells in the design. For the default full factorial model, this equals the product of the number of levels or categories in each factor.

Example

```
GLM YIELD BY SEED FERT WITH RAINFALL
  /PRINT=DESCRIPTIVE PARAMETER
```

```
  /DESIGN.
```

- *YIELD* is the dependent variable; *SEED* and *FERT* are factors; *RAINFALL* is a covariate.
- The PRINT subcommand requests the descriptive statistics for the dependent variable for each cell and the parameter estimates, in addition to the default tables Between-Subjects Factors and Univariate Tests.
- The DESIGN subcommand requests the default design (a full factorial model with a covariate). This subcommand could have been omitted or could have been specified in full as

```
/DESIGN = INTERCEPT RAINFALL, SEED, FERT, SEED BY FERT.
```

GLM Variable List

The variable list specifies the dependent variable, the factors, and the covariates in the model.

- The dependent variable must be the first specification on GLM.
- The names of the factors follow the dependent variable. Use the keyword BY to separate the factors from the dependent variable.
- Enter the covariates, if any, following the factors. Use the keyword WITH to separate covariates from factors (if any) and the dependent variable.

Example

```
GLM DEPENDNT BY FACTOR1 FACTOR2, FACTOR3.
```

- In this example, three factors are specified.
- A default full factorial model is used for the analysis.

Example

```
GLM Y BY A WITH X
  /DESIGN.
```

- In this example, the DESIGN subcommand requests the default design, which includes the intercept term, the covariate *X*, and the factor *A*.

RANDOM Subcommand

RANDOM allows you to specify which effects in your design are random. When the RANDOM subcommand is used, a table of expected mean squares for all effects in the design is displayed, and an appropriate error term for testing each effect is calculated and used automatically.

- Random always implies a univariate mixed-model analysis.
- If you specify an effect on RANDOM, higher-order effects containing the specified effect (excluding any effects containing covariates) are automatically treated as random effects.
- The keyword INTERCEPT and effects containing covariates are not allowed on this subcommand.

- The RANDOM subcommand cannot be used if there is any within-subjects factor in the model (that is, RANDOM cannot be specified if WSFACTOR is specified).
- When the RANDOM subcommand is used, the appropriate error terms for the hypothesis testing of all effects in the model are automatically computed and used.
- More than one RANDOM subcommand is allowed. The specifications are accumulated.

Example

```
GLM DEP BY A B
  /RANDOM = B
  /DESIGN = A,B, A*B.
```

- In the example, effects *B* and *A*B* are considered as random effects. If only effect *B* is specified in the RANDOM subcommand, *A*B* is automatically considered as a random effect.
- The hypothesis testing for each effect in the design (*A*, *B*, and *A*B*) will be carried out by using the appropriate error term, which is calculated automatically.

REGWGT Subcommand

The only specification on REGWGT is the name of the variable containing the weights to be used in estimating a weighted least-squares model.

- Specify a numeric weight variable name following the REGWGT subcommand. Only observations with positive values in the weight variable will be used in the analysis.
- If more than one REGWGT subcommand is specified, only the last subcommand is in effect.

Example

```
GLM OUTCOME BY TREATMNT
  /REGWGT WT.
```

- The procedure performs a weighted least-squares analysis. The variable *WT* is used as the weight variable.

METHOD Subcommand

METHOD controls the computational aspects of the GLM analysis. You can specify one of four different methods for partitioning the sums of squares. If more than one METHOD subcommand is specified, only the last subcommand is in effect.

SSTYPE(1) *Type I sum-of-squares method.* The Type I sum-of-squares method is also known as the hierarchical decomposition of the sum-of-squares method. Each term is adjusted only for the terms that precede it on the DESIGN subcommand. Under a balanced design, it is an orthogonal decomposition, and the sums of squares in the model add up to the total sum of squares.

SSTYPE(2) *Type II sum-of-squares method.* This method calculates the sum of squares of an effect in the model, adjusted for all other "appropriate" effects. An appropriate effect is an effect that corresponds to all effects that do not contain the effect that is being examined.

For any two effects *F1* and *F2* in the model, *F1* is **contained** in *F2* under the following three conditions: Both effects *F1* and *F2* have the same covariate (if any), *F2* consists of more factors than *F1*, or all factors in *F1* also appear in *F2*. The intercept effect is treated as contained in all the pure factor effects. However, the intercept effect is not contained in any effect involving a covariate. No effect is contained in the intercept effect. Thus, for any one effect *F* of interest, all other effects in the model can be classified as being in one of the following two groups: the effects that do not contain *F* or the effects that contain *F*.

If the model is a main-effects design (that is, only main effects are in the model), the Type II sum-of-squares method is equivalent to the regression approach sums of squares, meaning that each main effect is adjusted for every other term in the model.

SSTYPE(3) *Type III sum-of-squares method.* This setting is the default. This method calculates the sum of squares of an effect *F* in the design as the sum of squares adjusted for any other effects that do not contain it, and *orthogonal* to any effects (if any) that contain it. The Type III sums of squares have one major advantage—they are invariant with respect to the cell frequencies as long as the general form of estimability remains constant. Hence, this type of sums of squares is often used for an unbalanced model with no missing cells. In a factorial design with no missing cells, this method is equivalent to the Yates' weighted squares of means technique, and it also coincides with the overparameterized $\sum$-restricted model.

SSTYPE(4) *Type IV sum-of-squares method.* This method is designed for a situation in which there are missing cells. For any effect *F* in the design, if *F* is not contained in any other effect, then Type IV = Type III = Type II. When *F* is contained in other effects, Type IV equitably distributes the contrasts being made among the parameters in *F* to all higher-level effects.

Example

```
GLM DEP BY A B C
  /METHOD=SSTYPE(3)
  /DESIGN=A, B, C.
```

- The design is a main-effects model.
- The METHOD subcommand requests that the model be fitted with Type III sums of squares.

INTERCEPT Subcommand

INTERCEPT controls whether an intercept term is included in the model. If more than one INTERCEPT subcommand is specified, only the last subcommand is in effect.

INCLUDE *Include the intercept term.* The intercept (constant) term is included in the model. This setting is the default.

EXCLUDE *Exclude the intercept term.* The intercept term is excluded from the model. Specification of the keyword INTERCEPT on the DESIGN subcommand overrides INTERCEPT = EXCLUDE.

MISSING Subcommand

By default, cases with missing values for any of the variables on the GLM variable list are excluded from the analysis. The MISSING subcommand allows you to include cases with user-missing values.

- If MISSING is not specified, the default is EXCLUDE.

- Pairwise deletion of missing data is not available in GLM.
- Keywords INCLUDE and EXCLUDE are mutually exclusive.
- If more than one MISSING subcommand is specified, only the last subcommand is in effect.

EXCLUDE *Exclude both user-missing and system-missing values.* This setting is the default when MISSING is not specified.

INCLUDE *Treat user-missing values as valid.* System-missing values cannot be included in the analysis.

CRITERIA Subcommand

CRITERIA controls the statistical criteria used to build the models.

- More than one CRITERIA subcommand is allowed. The specifications are accumulated. Conflicts across CRITERIA subcommands are resolved by using the conflicting specification that was given on the last CRITERIA subcommand.
- The keyword must be followed by a positive number in parentheses.

EPS(n) *The tolerance level in redundancy detection.* This value is used for redundancy checking in the design matrix. The default value is 1E-8.

ALPHA(n) *The alpha level.* This keyword has two functions. First, the keyword gives the alpha level at which the power is calculated for the *F* test. After the noncentrality parameter for the alternative hypothesis is estimated from the data, the power is the probability that the test statistic is greater than the critical value under the alternative hypothesis. (The observed power is displayed by default for GLM.) The second function of alpha is to specify the level of the confidence interval. If the specified alpha level is *n*, the value $(1-n)\times 100$ indicates the level of confidence for all individual and simultaneous confidence intervals that are generated for the specified model. The value of *n* must be between 0 and 1, exclusive. The default value of alpha is 0.05, which means that the default power calculation is at the 0.05 level, and the default level of the confidence intervals is 95%, because $(1-0.05)\times 100=95$.

PRINT Subcommand

PRINT controls the display of optional output.

- Some PRINT output applies to the entire GLM procedure and is displayed only once.
- Additional output can be obtained on the EMMEANS, PLOT, and SAVE subcommands.
- Some optional output may greatly increase the processing time. Request only the output that you want to see.
- If no PRINT command is specified, default output for a univariate analysis includes a factor information table and a Univariate Tests table (ANOVA) for all effects in the model.
- If more than one PRINT subcommand is specified, only the last subcommand is in effect.

The following keywords are available for GLM univariate analyses. For information about PRINT specifications that are appropriate for other GLM models, see *GLM: Multivariate* and *GLM: Repeated Measures*.

DESCRIPTIVES *Basic information about each cell in the design.* This process determines observed means, standard deviations, and counts for the dependent variable in all cells. The cells are constructed from the highest-order crossing of the between-subjects factors. For a multivariate model, statistics are given for each dependent variable. If the number of between-subjects factors plus the number of split variables exceeds 18, the Descriptive Statistics table is not printed.

HOMOGENEITY *Tests of homogeneity of variance.* Levene's test for equality of variances for the dependent variable across all level combinations of the between-subjects factors. If there are no between-subjects factors, this keyword is not valid. For a multivariate model, tests are displayed for each dependent variable.

PARAMETER *Parameter estimates.* Parameter estimates, standard errors, *t* tests, and confidence intervals.

ETASQ *Partial eta-squared* (η^2). This value is an overestimate of the actual effect size in an *F* test. It is defined as

$$\eta^2 = \frac{dfh \times F}{dfh \times F + dfe}$$

where *F* is the test statistic and *dfh* and *dfe* are its degrees of freedom and degrees of freedom for error. The keyword EFSIZE can be used in place of ETASQ.

GEF *General estimable function table.* This table shows the general form of the estimable functions.

LOF *Instruction to perform a lack-of-fit test (which requires at least one cell to have multiple observations).* If the test is rejected, it implies that the current model cannot adequately account for the relationship between the response variable and the predictors. Either a variable is omitted or extra terms are needed in the model.

OPOWER *Observed power for each test.* The observed power gives the probability that the *F* test would detect a population difference between groups that is equal to the difference that is implied by the sample difference.

TEST(LMATRIX) *Set of contrast coefficients (L) matrices.* The transpose of the **L** matrix (**L'**) is displayed. This set always includes one matrix displaying the estimable function for each between-subjects effect that appears or is implied in the DESIGN subcommand. Also, any **L** matrices generated by the LMATRIX or CONTRAST subcommands are displayed. TEST(ESTIMABLE) can be used in place of TEST(LMATRIX).

Example

```
GLM DEP BY A B WITH COV
  /PRINT=DESCRIPTIVE, TEST(LMATRIX), PARAMETER
  /DESIGN.
```

- Because the design in the DESIGN subcommand is not specified, the default design is used. In this case, the design includes the intercept term, the covariate *COV*, and the full factorial terms of *A* and *B*, which are *A*, *B*, and *A*B*.
- For each combination of levels of *A* and *B*, the descriptive statistics of *DEP* are displayed.

- The set of L matrices that generates the sums of squares for testing each effect in the design is displayed.
- The parameter estimates, their standard errors, *t* tests, confidence intervals, and the observed power for each test are displayed.

PLOT Subcommand

PLOT provides a variety of plots that are useful in checking the assumptions that are needed in the analysis. The PLOT subcommand can be specified more than once. All of the plots that are requested on each PLOT subcommand are produced.

Use the following keywords on the PLOT subcommand to request plots:

SPREADLEVEL *Spread-versus-level plots.* Plots are produced that are plots of observed cell means versus standard deviations and versus variances.

RESIDUALS *Observed by predicted by standardized residuals plot.* A plot is produced for each dependent variable. In a univariate analysis, a plot is produced for the single dependent variable.

PROFILE *Line plots of dependent variable means for one-way, two-way, or three-way crossed factors.* The PROFILE keyword must be followed by parentheses containing a list of one or more factor combinations. All specified factors (either individual or crossed) must be composed of only valid factors on the factor list. Factor combinations on the PROFILE keyword may use an asterisk (*) or the keyword BY to specify crossed factors. A factor cannot occur in a single factor combination more than once.

The order of factors in a factor combination is important, and there is no restriction on the order of factors. If a single factor is specified after the PROFILE keyword, a line plot of estimated means at each level of the factor is produced. If a two-way crossed factor combination is specified, the output includes a multiple-line plot of estimated means at each level of the first specified factor, with a separate line drawn for each level of the second specified factor. If a three-way crossed factor combination is specified, the output includes multiple-line plots of estimated means at each level of the first specified factor, with separate lines for each level of the second factor and separate plots for each level of the third factor.

Example

```
GLM DEP BY A B
  /PLOT = SPREADLEVEL PROFILE(A A*B A*B*C)
  /DESIGN.
```

Assume that each of the factors *A*, *B*, and *C* has three levels.

- Spread-versus-level plots are produced, showing observed cell means versus standard deviations and observed cell means versus variances.
- Five profile plots are produced. For factor *A*, a line plot of estimated means at each level of *A* is produced (one plot). For the two-way crossed factor combination *A*B*, a multiple-line plot of estimated means at each level of *A*is produced (one plot), with a separate line for each level of *B*. For the three-way crossed factor combination *A*B*C*, a multiple-line plot of estimated means at each level of *A* is produced for each of the three levels of *C* (three plots), with a separate line for each level of *B*.

TEST Subcommand

The TEST subcommand allows you to test a hypothesis term against a specified error term.

- TEST is valid only for univariate analyses. Multiple TEST subcommands are allowed, with each subcommand being executed independently.
- You must specify both the hypothesis term and the error term. There is no default.
- The hypothesis term is specified before the keyword VS and must be a valid effect that is specified or implied on the DESIGN subcommand.
- The error term is specified after the keyword VS. You can specify either a linear combination or a value. The linear combination of effects takes the general form: coefficient*effect +/– coefficient*effect ...
- All effects in the linear combination must be specified or implied on the DESIGN subcommand. Effects that are specified or implied on DESIGN but not listed after VS are assumed to have a coefficient of 0.
- Duplicate effects are allowed. GLM adds coefficients associated with the same effect before performing the test. For example, the linear combination 5*A–0.9*B–A is combined to 4*A–0.9B.
- A coefficient can be specified as a fraction with a positive denominator (for example, 1/3 or –1/3 are valid, but 1/–3 is invalid).
- If you specify a value for the error term, you must specify the degrees of freedom after the keyword DF. The degrees of freedom must be a positive real number. DF and the degrees of freedom are optional for a linear combination.

Example

```
GLM DEP BY A B
  /TEST = A VS B + A*B
  /DESIGN = A, B, A*B.
```

- *A* is tested against the pooled effect of *B* + *A*B*.

LMATRIX Subcommand

The LMATRIX subcommand allows you to customize your hypotheses tests by specifying the **L** matrix (contrast coefficients matrix) in the general form of the linear hypothesis **LB** = **K**, where **K** = **0** if it is not specified on the KMATRIX subcommand. The vector **B** is the parameter vector in the linear model.

- The basic format for the LMATRIX subcommand is an optional label in quotation marks, one or more effect names or the keyword ALL, and one or more lists of real numbers.
- The optional label is a string with a maximum length of 255 bytes. Only one label can be specified.
- Only valid effects that appear or are implied on the DESIGN subcommand can be specified on the LMATRIX subcommand.

- The length of the list of real numbers must be equal to the number of parameters (including the redundant parameters) corresponding to that effect. For example, if the effect *A*B* uses six columns in the design matrix, the list after *A*B* must contain exactly six numbers.
- A number can be specified as a fraction with a positive denominator (for example, 1/3 or –1/3 are valid, but 1/–3 is invalid).
- A semicolon (;) indicates the end of a row in the **L** matrix.
- When ALL is specified, the length of the list that follows ALL is equal to the total number of parameters (including the redundant parameters) in the model.
- Effects that appear or are implied on the DESIGN subcommand must be explicitly specified here.
- Multiple LMATRIX subcommands are allowed. Each subcommand is treated independently.

Example

```
GLM DEP BY A B
  /LMATRIX = "B1 vs B2 at A1"
             B 1 -1 0 A*B 1 -1 0 0 0 0 0 0 0
  /LMATRIX = "Effect A"
             A 1 0 -1
             A*B 1/3  1/3  1/3
                  0    0    0
                -1/3 -1/3 -1/3;
             A 0 1 -1
             A*B  0    0    0
                 1/3  1/3  1/3
                -1/3 -1/3 -1/3
  /LMATRIX = "B1 vs B2 at A2"
            ALL  0
                 0  0  0
                 1 -1  0
                 0  0  0  1 -1  0 0  0  0
  /DESIGN = A, B, A*B.
```

Assume that factors *A* and *B* each have three levels. There are three LMATRIX subcommands; each subcommand is treated independently.

- **B1 Versus B2 at A1.** In the first LMATRIX subcommand, the difference is tested between levels 1 and 2 of effect *B* when effect *A* is fixed at level 1. Because there are three levels each in effects *A* and *B*, the interaction effect *A*B* should use nine columns in the design matrix.
- **Effect A.** In the second LMATRIX subcommand, effect *A* is tested. Because there are three levels in effect *A*, no more than two independent contrasts can be formed; thus, there are two rows in the **L** matrix, which are separated by a semicolon (;). The first row tests the difference between levels 1 and 3 of effect *A*, while the second row tests the difference between levels 2 and 3 of effect *A*.
- **B1 Versus B2 at A2.** In the last LMATRIX subcommand, the keyword ALL is used. The first 0 corresponds to the intercept effect; the next three instances of 0 correspond to effect *A*.

KMATRIX Subcommand

The KMATRIX subcommand allows you to customize your hypothesis tests by specifying the **K** matrix (contrast results matrix) in the general form of the linear hypothesis **LB** = **K**. The vector **B** is the parameter vector in the linear model.

- The default **K** matrix is a zero matrix; that is, **LB** = **0** is assumed.
- For the KMATRIX subcommand to be valid, at least one of the following subcommands must be specified: the LMATRIX subcommand or the INTERCEPT = INCLUDE subcommand.
- If KMATRIX is specified but LMATRIX is not specified, the LMATRIX is assumed to take the row vector corresponding to the intercept in the estimable function, provided that the subcommand INTERCEPT = INCLUDE is specified. In this case, the **K** matrix can be only a scalar matrix.
- If KMATRIX and LMATRIX are specified, the number of rows in the requested **K** and **L** matrices must be equal. If there are multiple LMATRIX subcommands, all requested **L** matrices must have the same number of rows, and **K** must have the same number of rows as these **L** matrices.
- A semicolon (;) can be used to indicate the end of a row in the **K** matrix.
- If more than one KMATRIX subcommand is specified, only the last subcommand is in effect.

Example

```
GLM DEP BY A B
  /LMATRIX = "Effect A"
              A 1  0 -1; A 1 -1  0
  /LMATRIX = "Effect B"
              B 1  0 -1; B 1 -1  0
  /KMATRIX = 0; 0
  /DESIGN = A B.
```

In this example, assume that factors *A* and *B* each have three levels.

- There are two LMATRIX subcommands; both subcommands have two rows.
- The first LMATRIX subcommand tests whether the effect of *A* is 0, while the second LMATRIX subcommand tests whether the effect of *B* is 0.
- The KMATRIX subcommand specifies that the **K** matrix also has two rows, each row with value 0.

CONTRAST Subcommand

CONTRAST specifies the type of contrast that is desired among the levels of a factor. For a factor with *k* levels or values, the contrast type determines the meaning of its *k*−1 degrees of freedom.

- Specify the factor name in parentheses following the subcommand CONTRAST.
- You can specify only one factor per CONTRAST subcommand, but you can enter multiple CONTRAST subcommands.
- After closing the parentheses, enter an equals sign followed by one of the contrast keywords.
- This subcommand creates an **L** matrix where the columns corresponding to the factor match the contrast that is given. The other columns are adjusted so that the **L** matrix is estimable.

The following contrast types are available:

DEVIATION *Deviations from the grand mean.* This setting is the default for between-subjects factors. Each level of the factor except one is compared to the grand mean. One category (by default, the last category) must be omitted so that the effects will be independent of one another. To omit a category other than the last category, specify the number of the omitted category (which is not necessarily the same as its value) in parentheses after the keyword `DEVIATION`. An example is as follows:

```
GLM Y BY B /CONTRAST(B)=DEVIATION(1).
```

Suppose factor *B* has three levels, with values 2, 4, and 6. The specified contrast omits the first category, in which *B* has the value 2. Deviation contrasts are not orthogonal.

POLYNOMIAL *Polynomial contrasts.* This setting is the default for within-subjects factors. The first degree of freedom contains the linear effect across the levels of the factor, the second degree of freedom contains the quadratic effect, and so on. In a balanced design, polynomial contrasts are orthogonal. By default, the levels are assumed to be equally spaced; you can specify unequal spacing by entering a metric consisting of one integer for each level of the factor in parentheses after the keyword `POLYNOMIAL`. (All metrics that are specified cannot be equal; thus, (1, 1, . . . 1) is not valid.) An example is as follows:

```
GLM RESPONSE BY STIMULUS /CONTRAST(STIMULUS) =
POLYNOMIAL(1,2,4).
```

Suppose that factor *STIMULUS* has three levels. The specified contrast indicates that the three levels of *STIMULUS* are actually in the proportion 1:2:4. The default metric is always (1, 2, . . . *k*), where *k* levels are involved. Only the relative differences between the terms of the metric matter. (1, 2, 4) is the same metric as (2, 3, 5) or (20, 30, 50) because, in each instance, the difference between the second and third numbers is twice the difference between the first and second.

DIFFERENCE *Difference or reverse Helmert contrasts.* Each level of the factor (except the first level) is compared to the mean of the previous levels. In a balanced design, difference contrasts are orthogonal.

HELMERT *Helmert contrasts.* Each level of the factor (except the last level) is compared to the mean of subsequent levels. In a balanced design, Helmert contrasts are orthogonal.

SIMPLE *Contrast where each level of the factor (except the last level) is compared to the last level.* To use a category other than the last category as the omitted reference category, specify the category's number (which is not necessarily the same as its value) in parentheses following the keyword `SIMPLE`. An example is as follows:

```
GLM Y BY B /CONTRAST(B)=SIMPLE(1).
```

Suppose that factor *B* has three levels with values 2, 4, and 6. The specified contrast compares the other levels to the first level of *B*, in which *B* has the value 2. Simple contrasts are not orthogonal.

REPEATED *Comparison of adjacent levels.* Each level of the factor (except the last level) is compared to the next level. Repeated contrasts are not orthogonal.

SPECIAL *A user-defined contrast.* Values that are specified after this keyword are stored in a matrix in column major order. For example, if factor *A* has three levels, then `CONTRAST(A)=SPECIAL(1 1 1 1 -1 0 0 1 -1)` produces the following contrast matrix:

```
1   1   0
1  -1   1
1   0  -1
```

Orthogonal contrasts are particularly useful. In a balanced design, contrasts are orthogonal if the sum of the coefficients in each contrast row is 0 and if, for any pair of contrast rows, the products of corresponding coefficients sum to 0. DIFFERENCE, HELMERT, and POLYNOMIAL contrasts always meet these criteria in balanced designs.

Example

```
GLM DEP BY FAC
  /CONTRAST(FAC)=DIFFERENCE
  /DESIGN.
```

- Suppose that the factor *FAC* has five categories and, therefore, has four degrees of freedom.
- CONTRAST requests DIFFERENCE contrasts, which compare each level (except the first level) with the mean of the previous levels.

POSTHOC Subcommand

POSTHOC allows you to produce multiple comparisons between means of a factor. These comparisons are usually not planned at the beginning of the study but are suggested by the data during the course of study.

- Post hoc tests are computed for the dependent variable. The alpha value that is used in the tests can be specified by using the keyword ALPHA on the CRITERIA subcommand. The default alpha value is 0.05. The confidence level for any confidence interval that is constructed is $(1-\alpha)\times 100$. The default confidence level is 95. For a multivariate model, tests are computed for all specified dependent variables.
- Only between-subjects factors that appear in the factor list are valid in this subcommand. Individual factors can be specified.
- You can specify one or more effects to be tested. Only fixed main effects that appear or are implied on the DESIGN subcommand are valid test effects.
- Optionally, you can specify an effect defining the error term following the keyword VS after the test specification. The error effect can be any single effect in the design that is not the intercept or a main effect that is named on a POSTHOC subcommand.
- A variety of multiple comparison tests are available. Some tests are designed for detecting homogeneity subsets among the groups of means, some tests are designed for pairwise comparisons among all means, and some tests can be used for both purposes.
- For tests that are used for detecting homogeneity subsets of means, non-empty group means are sorted in ascending order. Means that are not significantly different are included together to form a homogeneity subset. The significance for each homogeneity subset of means is displayed. In a case where the numbers of valid cases are not equal in all groups, for most post hoc tests, the harmonic mean of the group sizes is used as the sample size in the calculation. For QREGW or FREGW, individual sample sizes are used.

- For tests that are used for pairwise comparisons, the display includes the difference between each pair of compared means, the confidence interval for the difference, and the significance. The sample sizes of the two groups that are being compared are used in the calculation.
- Output for tests that are specified on the POSTHOC subcommand is available according to their statistical purposes. The following table illustrates the statistical purpose of the post hoc tests:

Post Hoc Tests	**Statistical Purpose**	
Keyword	**Homogeneity Subsets Detection**	**Pairwise Comparison and Confidence Interval**
LSD		Yes
SIDAK		Yes
BONFERRONI		Yes
GH		Yes
T2		Yes
T3		Yes
C		Yes
DUNNETT		Yes*
DUNNETTL		Yes*
DUNNETTR		Yes*
SNK	Yes	
BTUKEY	Yes	
DUNCAN	Yes	
QREGW	Yes	
FREGW	Yes	
WALLER	Yes†	
TUKEY	Yes	Yes
SCHEFFE	Yes	Yes
GT2	Yes	Yes
GABRIEL	Yes	Yes

* Only CIs for differences between test group means and control group means are given.

† No significance for Waller test is given.

- Tests that are designed for homogeneity subset detection display the detected homogeneity subsets and their corresponding significances.
- Tests that are designed for both homogeneity subset detection and pairwise comparisons display both kinds of output.
- For the DUNNETT, DUNNETTL, and DUNNETTR keywords, only individual factors can be specified.
- The default reference category for DUNNETT, DUNNETTL, and DUNNETTR is the last category. An integer that is greater than 0, specified within parentheses, can be used to specify a different reference category. For example, POSTHOC = A (DUNNETT(2)) requests a DUNNETT test for factor *A*, using the second level of *A* as the reference category.

- The keywords DUNCAN, DUNNETT, DUNNETTL, and DUNNETTR must be spelled out in full; using the first three characters alone is not sufficient.
- If the REGWGT subcommand is specified, weighted means are used in performing post hoc tests.
- Multiple POSTHOC subcommands are allowed. Each specification is executed independently so that you can test different effects against different error terms.

SNK *Student-Newman-Keuls procedure based on the Studentized range test.*

TUKEY *Tukey's honestly significant difference.* This test uses the Studentized range statistic to make all pairwise comparisons between groups.

BTUKEY *Tukey's* b. This procedure is a multiple comparison procedure based on the average of Studentized range tests.

DUNCAN *Duncan's multiple comparison procedure based on the Studentized range test*.

SCHEFFE *Scheffé's multiple comparison* t *test.*

DUNNETT(refcat) *Dunnett's two-tailed* t *test*. Each level of the factor is compared to a reference category. A reference category can be specified in parentheses. The default reference category is the last category. This keyword must be spelled out in full.

DUNNETTL(refcat) *Dunnett's one-tailed* t *test*. This test indicates whether the mean at any level (except the reference category) of the factor is *smaller* than the mean of the reference category. A reference category can be specified in parentheses. The default reference category is the last category. This keyword must be spelled out in full.

DUNNETTR(refcat) *Dunnett's one-tailed* t *test*. This test indicates whether the mean at any level (except the reference category) of the factor is *larger* than the mean of the reference category. A reference category can be specified in parentheses. The default reference category is the last category. This keyword must be spelled out in full.

BONFERRONI *Bonferroni* t *test*. This test is based on Student's *t* statistic and adjusts the observed significance level based on the fact that multiple comparisons are made.

LSD *Least significant difference* t *test*. This test is equivalent to multiple *t* tests between all pairs of groups. This test does not control the overall probability of rejecting the hypotheses that some pairs of means are different, while in fact they are equal.

SIDAK *Sidak* t *test*. This test provides tighter bounds than the Bonferroni test.

GT2 *Hochberg's* GT2. This test is a pairwise comparisons test based on the Studentized maximum modulus test. Unless the cell sizes are extremely unbalanced, this test is fairly robust even for unequal variances.

GABRIEL *Gabriel's pairwise comparisons test based on the Studentized maximum modulus test.*

FREGW *Ryan-Einot-Gabriel-Welsch's multiple stepdown procedure based on an* F *test.*

QREGW *Ryan-Einot-Gabriel-Welsch's multiple stepdown procedure based on the Studentized range test.*

T2 *Tamhane's* T2. This test is Tamhane's pairwise comparisons test based on a *t* test. This test can be applied in situations where the variances are unequal.

T3 *Dunnett's* T3. This test is a pairwise comparisons test based on the Studentized maximum modulus. This test is appropriate when the variances are unequal.

GH *Games and Howell's pairwise comparisons test based on the Studentized range test.* This test can be applied in situations where the variances are unequal.

C *Dunnett's* C. This test conducts pairwise comparisons based on the weighted average of Studentized ranges. This test can be applied in situations where the variances are unequal.

WALLER(kratio) *Waller-Duncan* t *test.* This test uses a Bayesian approach. The test is restricted to cases with equal sample sizes. For cases with unequal sample sizes, the harmonic mean of the sample size is used. The kratio is the Type 1/Type 2 error seriousness ratio. The default value is 100. You can specify an integer that is greater than 1, enclosed within parentheses.

EMMEANS Subcommand

EMMEANS displays estimated marginal means of the dependent variable in the cells (with covariates held at their overall mean value) and their standard errors of the means for the specified factors. These means are predicted, not observed, means. The estimated marginal means are calculated by using a modified definition by Searle, Speed, and Milliken (1980).

- TABLES, followed by an option in parentheses, is required. COMPARE is optional; if specified, COMPARE must follow TABLES.
- Multiple EMMEANS subcommands are allowed. Each subcommand is treated independently.
- If identical EMMEANS subcommands are specified, only the last identical subcommand is in effect. EMMEANS subcommands that are redundant but not identical (for example, crossed factor combinations such as *A*B* and *B*A*) are all processed.

TABLES(option) *Table specification.* Valid options are the keyword OVERALL, factors appearing on the factor list, and crossed factors that are constructed of factors on the factor list. Crossed factors can be specified by using an asterisk (*) or the keyword BY. All factors in a crossed factor specification must be unique.

If OVERALL is specified, the estimated marginal means of the dependent variable are displayed, collapsing over between-subjects factors.

If a between-subjects factor, or a crossing of between-subjects factors, is specified on the TABLES keyword, GLM collapses over any other between-subjects factors before computing the estimated marginal means for the dependent variable. For a multivariate model, GLM collapses over any other between-subjects or within-subjects factors.

COMPARE(factor)
ADJ(method) *Main-effects or simple-main-effects omnibus tests and pairwise comparisons of the dependent variable.* This option gives the mean difference, standard error, significance, and confidence interval for each pair of levels for the effect that is specified in the TABLES command, as well as an omnibus test for that effect. If only one factor is specified on TABLES, COMPARE can be specified by itself; otherwise, the factor specification is required. In this case, levels of the specified factor are compared with each other for each level of the other factors in the interaction.

The optional ADJ keyword allows you to apply an adjustment to the confidence intervals and significance values to account for multiple comparisons. Available methods are LSD (no adjustment), BONFERRONI, or SIDAK.

If OVERALL is specified on TABLES, COMPARE is invalid.

Example

```
GLM DEP BY A B
  /EMMEANS = TABLES(A*B)COMPARE(A)
  /DESIGN.
```

- The output of this analysis includes a pairwise comparisons table for the dependent variable *DEP*.
- Assume that *A* has three levels and *B* has two levels. The first level of *A* is compared with the second and third levels, the second level is compared with the first and third levels, and the third level is compared with the first and second levels. The pairwise comparison is repeated for the two levels of *B*.

SAVE Subcommand

Use SAVE to add one or more residual or fit values to the active dataset.

- Specify one or more temporary variables, each variable followed by an optional new name in parentheses. For a multivariate model, you can optionally specify a new name for the temporary variable related to each dependent variable.
- WPRED and WRESID can be saved only if REGWGT has been specified.
- Specifying a temporary variable on this subcommand results in a variable being added to the active data file for each dependent variable.
- You can specify variable names for the temporary variables. These names must be unique, valid variable names. For a multivariate model, there should be as many variable names specified as there are dependent variables, and names should be listed in the order of the dependent variables as specified on the GLM command. If you do not specify enough variable names, default variable names are used for any remaining variables.
- If new names are not specified, GLM generates a rootname by using a shortened form of the temporary variable name with a suffix. For a multivariate model, the suffix *_n* is added to the temporary variable name, where *n* is the ordinal number of the dependent variable as specified on the GLM command.
- If more than one SAVE subcommand is specified, only the last subcommand is in effect.

PRED	*Unstandardized predicted values.*
WPRED	*Weighted unstandardized predicted values.* This setting is available only if REGWGT has been specified.
RESID	*Unstandardized residuals.*
WRESID	*Weighted unstandardized residuals.* This setting is available only if REGWGT has been specified.
DRESID	*Deleted residuals.*
ZRESID	*Standardized residuals.*
SRESID	*Studentized residuals.*
SEPRED	*Standard errors of predicted value.*
COOK	*Cook's distances.*
LEVER	*Uncentered leverage values.*

OUTFILE Subcommand

The OUTFILE subcommand writes an SPSS data file that can be used in other procedures.

- You must specify a keyword on OUTFILE. There is no default.
- You must specify a quoted file specification or previously declared dataset name (DATASET DECLARE command) in parentheses after a keyword. The asterisk (*) is not allowed.
- If you specify more than one keyword, a different filename is required for each keyword.
- If more than one OUTFILE subcommand is specified, only the last subcommand is in effect.
- For COVB or CORB, the output will contain, in addition to the covariance or correlation matrix, three rows for each dependent variable: a row of parameter estimates, a row of residual degrees of freedom, and a row of significance values for the *t* statistics corresponding to the parameter estimates. All statistics are displayed separately by split.

COVB ('savfile'|'dataset')	*Writes the parameter covariance matrix.*
CORB ('savfile'|'dataset')	*Writes the parameter correlation matrix.*
EFFECT ('savfile'|'dataset')	*Writes the statistics from the between-subjects ANOVA table.* This specification is invalid for repeated measures analyses.
DESIGN ('savfile'|'dataset')	*Writes the design matrix.* The number of rows equals the number of cases, and the number of columns equals the number of parameters. The variable names are *DES_1*, *DES_2*, ..., *DES_p*, where *p* is the number of the parameters.

DESIGN Subcommand

DESIGN specifies the effects included in a specific model. The cells in a design are defined by all of the possible combinations of levels of the factors in that design. The number of cells equals the product of the number of levels of all the factors. A design is *balanced* if each cell contains the same number of cases. GLM can analyze both balanced and unbalanced designs.

- Specify a list of terms to be included in the model, and separate the terms by spaces or commas.
- The default design, if the DESIGN subcommand is omitted or is specified by itself, is a design consisting of the following terms in order: the intercept term (if INTERCEPT=INCLUDE is specified), the covariates that are given in the covariate list, and the full factorial model defined by all factors on the factor list and excluding the intercept.
- To include a term for the main effect of a factor, enter the name of the factor on the DESIGN subcommand.
- To include the intercept term in the design, use the keyword INTERCEPT on the DESIGN subcommand. If INTERCEPT is specified on the DESIGN subcommand, the subcommand INTERCEPT=EXCLUDE is overridden.
- To include a term for an interaction between factors, use the keyword BY or the asterisk (*) to join the factors that are involved in the interaction. For example, *A*B* means a two-way interaction effect of *A* and *B*, where *A* and *B* are factors. *A*A* is not allowed because factors inside an interaction effect must be distinct.

- To include a term for nesting one effect within another effect, use the keyword WITHIN or use a pair of parentheses on the DESIGN subcommand. For example, *A(B)* means that *A* is nested within *B*. The expression *A(B)* is equivalent to the expression *A WITHIN B*. When more than one pair of parentheses is present, each pair of parentheses must be enclosed or nested within another pair of parentheses. Thus, *A(B)(C)* is not valid.
- Multiple nesting is allowed. For example, *A(B(C))* means that *B* is nested within *C* and *A* is nested within *B(C)*.
- Interactions between nested effects are not valid. For example, neither *A(C)*B(C)* nor *A(C)*B(D)* is valid.
- To include a covariate term in the design, enter the name of the covariate on the DESIGN subcommand.
- Covariates can be connected—but not nested—through the * operator to form another covariate effect. Therefore, interactions among covariates such as *X1*X1* and *X1*X2* are valid but not *X1(X2)*. Using covariate effects such as *X1*X1*, *X1*X1*X1*, *X1*X2*, and *X1*X1*X2*X2* makes fitting a polynomial regression model easy in GLM.
- Factor and covariate effects can be connected only by the * operator. Suppose *A* and *B* are factors and *X1* and *X2* are covariates. Examples of valid factor-by-covariate interaction effects are *A*X1*, *A*B*X1*, *X1*A(B)*, *A*X1*X1*, and *B*X1*X2*.
- If more than one DESIGN subcommand is specified, only the last subcommand is in effect.

Example

```
GLM Y BY A B C WITH X
  /DESIGN A B(A) X*A.
```

- In this example, the design consists of a main effect *A*, a nested effect *B* within *A*, and an interaction effect of a covariate *X* with a factor *A*.

GLM: Multivariate

GLM is available in the Advanced Models option.

```

Example

```
GLM SCORE1 TO SCORE4 BY METHOD(1,3).
```

Overview

This section discusses the subcommands that are used in multivariate general linear models and covariance designs with several interrelated dependent variables. The discussion focuses on subcommands and keywords that do not apply—or apply in different manners—to univariate analyses. The discussion does not contain information about all subcommands that you will need to specify the design. For subcommands that are not covered here, see *GLM: Univariate*.

Options

Optional Output. In addition to the output that is described in *GLM: Univariate*, you can have both multivariate and univariate *F* tests. Using the PRINT subcommand, you can request the hypothesis and error sums-of-squares and cross-product matrices for each effect in the design, the transformation coefficient table (M matrix), Box's *M* test for equality of covariance matrices, and Bartlett's test of sphericity.

Basic Specification

- The basic specification is a variable list identifying the dependent variables, with the factors (if any) named after BY and the covariates (if any) named after WITH.
- By default, GLM uses a model that includes the intercept term, the covariates (if any), and the full factorial model, which includes all main effects and all possible interactions among factors. The intercept term is excluded if it is excluded in the model by specifying EXCLUDE on the INTERCEPT subcommand. GLM produces multivariate and univariate *F* tests for each effect in the model. GLM also calculates the power for each test, based on the default alpha value.

Subcommand Order

- The variable list must be specified first.
- Subcommands can be used in any order.

Syntax Rules

- The syntax rules that apply to univariate analysis also apply to multivariate analysis.
- If you enter one of the multivariate specifications in a univariate analysis, GLM ignores it.

Limitations

- Any number of factors can be specified, but if the number of between-subjects factors plus the number of split variables exceeds 18, the Descriptive Statistics table is not printed even when you request it.
- Memory requirements depend primarily on the number of cells in the design. For the default full factorial model, this equals the product of the number of levels or categories in each factor.

Example

Multivariate Analysis of Variance (MANOVA)

```
GLM
  los cost  BY clotsolv proc
  /CONTRAST (clotsolv)=Simple(1)
  /METHOD = SSTYPE(3)
  /INTERCEPT = INCLUDE
  /PRINT = ETASQ TEST(SSCP) HOMOGENEITY
  /PLOT = SPREADLEVEL
  /CRITERIA = ALPHA(.05)
  /DESIGN = clotsolv proc clotsolv*proc .
```

- The procedure fits a model for the dependent variables *los* and *cost* using *clotsolv* and *proc* as factors.
- The `CONTRAST` subcommand specifies simple contrasts for *clotsolv*, using the first category as the reference category, to test differences between the categories. No contrasts are specified for *proc*.
- The `PRINT` subcommand requests tabular output for estimates of effect size, SSCP matrices, and homogeneity tests.
- The `PLOT` subcommand requests spread vs. level plots.
- All other options are set to their default values.

GLM Variable List

- Multivariate `GLM` calculates statistical tests that are valid for analyses of dependent variables that are correlated with one another. The dependent variables must be specified first.
- The factor and covariate lists follow the same rules as in univariate analyses.
- If the dependent variables are uncorrelated, the univariate significance tests have greater statistical power.

PRINT Subcommand

By default, if no PRINT subcommand is specified, multivariate GLM produces multivariate tests (MANOVA) and univariate tests (ANOVA) for all effects in the model. All PRINT specifications that are described in *GLM: Univariate* are available in multivariate analyses. The following additional output can be requested:

TEST(SSCP) *Sums-of-squares and cross-product matrices.* Hypothesis (HSSCP) and error (ESSCP) sums-of-squares and cross-product matrices for each effect in the design are displayed. Each between-subjects effect has a different HSSCP matrix, but there is a single ESSCP matrix for all between-subjects effects. For a repeated measures design, each within-subjects effect has an HSSCP matrix and an ESSCP matrix. If there are no within-subjects effects, the ESSCP matrix for the between-subjects effects is the same as the RSSCP matrix.

TEST(MMATRIX) *Set of transformation coefficients (M) matrices.* Any M matrices that are generated by the MMATRIX subcommand are displayed. If no M matrix is specified on the MMATRIX subcommand, this specification is skipped, unless you are using a repeated measures design. In a repeated measures design, this set always includes the M matrix that is determined by the WSFACTOR subcommand. The specification TEST(TRANSFORM) is equivalent to TEST(MMATRIX).

HOMOGENEITY *Tests of homogeneity of variance.* In addition to Levene's test for equality of variances for each dependent variable, the display includes Box's *M* test of homogeneity of the covariance matrices of the dependent variables across all level combinations of the between-subjects factors.

RSSCP *Sums-of-squares and cross-products of residuals.* Three matrices are displayed:

Residual SSCP matrix. This matrix is a square matrix of sums of squares and cross- products of residuals. The dimension of this matrix is the same as the number of dependent variables in the model.

Residual covariance matrix. This matrix is the residual SSCP matrix divided by the degrees of freedom of the residual.

Residual correlation matrix. This matrix is the standardized form of the residual covariance matrix.

Example

```
GLM Y1 Y2 Y3 BY A B
 /PRINT = HOMOGENEITY RSSCP
 /DESIGN.
```

- Since there are three dependent variables, this model is a multivariate model.
- The keyword RSSCP produces three matrices of sums of squares and cross-products of residuals. The output also contains the result of Bartlett's test of the sphericity of the residual covariance matrix.
- In addition to the Levene test for each dependent variable, the keyword HOMOGENEITY produces the result of Box's *M* test of homogeneity in the multivariate model.

MMATRIX Subcommand

The MMATRIX subcommand allows you to customize your hypothesis tests by specifying the M matrix (transformation coefficients matrix) in the general form of the linear hypothesis LBM = K, where K = 0 if it is not specified on the KMATRIX subcommand. The vector B is the parameter vector in the linear model.

- Specify an optional label in quotation marks. Then either list dependent variable names, each name followed by a real number, or specify the keyword ALL followed by a list of real numbers. Only variable names that appear on the dependent variable list can be specified on the MMATRIX subcommand.
- You can specify one label for each column in the M matrix.
- If you specify ALL, the length of the list that follows ALL should be equal to the number of dependent variables.
- There is no limit on the length of the label.
- For the MMATRIX subcommand to be valid, at least one of the following specifications must be made: the LMATRIX subcommand or INTERCEPT=INCLUDE. (Either of these specifications defines an L matrix.)
- If both LMATRIX and MMATRIX are specified, the L matrix is defined by the LMATRIX subcommand.
- If MMATRIX or KMATRIX is specified but LMATRIX is not specified, the **L** matrix is defined by the estimable function for the intercept effect, provided that the intercept effect is included in the model.
- If LMATRIX is specified but MMATRIX is not specified, the **M** matrix is assumed to be an $r \times r$ identity matrix, where *r* is the number of dependent variables.
- A semicolon (;) indicates the end of a column in the **M** matrix.
- Dependent variables that do not appear on a list of dependent variable names and real numbers are assigned a value of 0.
- Dependent variables that do not appear in the MMATRIX subcommand will have a row of zeros in the **M** matrix.
- A number can be specified as a fraction with a positive denominator (for example, 1/3 or –1/3 is valid, but 1/–3 is invalid).
- The number of columns must be greater than 0. You can specify as many columns as you need.
- If more than one MMATRIX subcommand is specified, only the last subcommand is in effect.

Example

```
GLM Y1 Y2 Y3 BY A B
 /MMATRIX = "Y1-Y2" Y1 1 Y2 -1; "Y1-Y3" Y1 1 Y3 -1
            "Y2-Y3" Y2 1 Y3 -1
 /DESIGN.
```

- In the above example, *Y1*, *Y2*, and *Y3* are the dependent variables.

- The MMATRIX subcommand requests all pairwise comparisons among the dependent variables.
- Because LMATRIX was not specified, the L matrix is defined by the estimable function for the intercept effect.

GLM: Repeated Measures

GLM is available in the Advanced Models option.

```
GLM dependent varlist [BY factor list [WITH covariate list]]

/WSFACTOR=name levels [{DEVIATION [(refcat)]       }] name...
                       {SIMPLE [(refcat)]          }
                       {DIFFERENCE                 }
                       {HELMERT                    }
                       {REPEATED                   }
                       {POLYNOMIAL [({1,2,3...})]**}
                       {             {metric  }    }
                       {SPECIAL (matrix)           }

[/MEASURE=newname newname...]

[/WSDESIGN=effect effect...]

[/REGWGT=varname]

[/METHOD=SSTYPE({1  })]
                {2  }
                {3**}
                {4  }

[/INTERCEPT=[INCLUDE**] [EXCLUDE]]

[/MISSING=[INCLUDE] [EXCLUDE**]]

[/PRINT  = [DESCRIPTIVE] [HOMOGENEITY] [PARAMETER][ETASQ] [RSSCP]
           [GEF] [LOF] [OPOWER] [TEST [([SSCP] [LMATRIX] [MMATRIX])]]

[/SAVE=[tempvar [(list of names)]] [tempvar [(list of names)]]...]
       [DESIGN]

[/EMMEANS=TABLES({OVERALL             })] [COMPARE ADJ(LSD)(BONFERRONI)(SIDAK)]
                 {factor                }
                 {factor*factor...      }
                 {wsfactor              }
                 {wsfactor*wsfactor...  }
                 {factor*...wsfactor*...]
                 {factor*factor...      }

[/DESIGN={[INTERCEPT...]    }]*
         {[effect effect...]}
```

* The DESIGN subcommand has the same syntax as is described in *GLM: Univariate*.

** Default if the subcommand or keyword is omitted.

Example

```
GLM Y1 TO Y4 BY GROUP
  /WSFACTOR=YEAR 4.
```

Overview

This section discusses the subcommands that are used in repeated measures designs, in which the dependent variables represent measurements of the same variable (or variables) taken repeatedly. This section does not contain information on all of the subcommands that you will need to specify

the design. For some subcommands or keywords not covered here, such as DESIGN, see *GLM: Univariate*. For information on optional output and the multivariate significance tests available, see *GLM: Multivariate*.

- In a simple repeated measures analysis, all dependent variables represent different measurements of the same variable for different values (or levels) of a within-subjects factor. Between-subjects factors and covariates can also be included in the model, just as in analyses not involving repeated measures.
- A **within-subjects factor** is simply a factor that distinguishes measurements made on the same subject or case, rather than distinguishing different subjects or cases.
- GLM permits more complex analyses, in which the dependent variables represent levels of two or more within-subjects factors.
- GLM also permits analyses in which the dependent variables represent measurements of several variables for the different levels of the within-subjects factors. These are known as **doubly multivariate designs**.
- A repeated measures analysis includes a within-subjects design describing the model to be tested with the within-subjects factors, as well as the usual between-subjects design describing the effects to be tested with between-subjects factors. The default for the within-subjects factors design is a full factorial model which includes the main within-subjects factor effects and all their interaction effects.
- If a custom hypothesis test is required (defined by the CONTRAST, LMATRIX, or KMATRIX subcommands), the default transformation matrix (**M** matrix) is taken to be the average transformation matrix, which can be displayed by using the keyword TEST(MMATRIX) on the PRINT subcommand. The default contrast result matrix (**K** matrix) is the zero matrix.
- If the contrast coefficient matrix (**L** matrix) is not specified, but a custom hypothesis test is required by the MMATRIX or the KMATRIX subcommand, the contrast coefficient matrix (**L** matrix) is taken to be the **L** matrix which corresponds to the estimable function for the intercept in the between-subjects model. This matrix can be displayed by using the keyword TEST(LMATRIX) on the PRINT subcommand.

Basic Specification

- The basic specification is a variable list followed by the WSFACTOR subcommand.
- Whenever WSFACTOR is specified, GLM performs special repeated measures processing. The multivariate and univariate tests are provided. In addition, for any within-subjects effect involving more than one transformed variable, the Mauchly test of sphericity is displayed to test the assumption that the covariance matrix of the transformed variables is constant on the diagonal and zero off the diagonal. The Greenhouse-Geisser epsilon and the Huynh-Feldt epsilon are also displayed for use in correcting the significance tests in the event that the assumption of sphericity is violated.

Subcommand Order

- The list of dependent variables, factors, and covariates must be first.

Syntax Rules

- The WSFACTOR (within-subjects factors), WSDESIGN (within-subjects design), and MEASURE subcommands are used only in repeated measures analysis.
- WSFACTOR is required for any repeated measures analysis.
- If WSDESIGN is not specified, a full factorial within-subjects design consisting of all main effects and all interactions among within-subjects factors is used by default.
- The MEASURE subcommand is used for doubly multivariate designs, in which the dependent variables represent repeated measurements of more than one variable.

Limitations

- Any number of factors can be specified, but if the number of between-subjects factors plus the number of split variables exceeds 18, the Descriptive Statistics table is not printed even when you request it.
- Maximum of 18 within-subjects factors.
- Memory requirements depend primarily on the number of cells in the design. For the default full factorial model, this equals the product of the number of levels or categories in each factor.

Examples

Repeated Measures ANOVA

```
GLM Y1 TO Y4 BY GROUP
  /WSFACTOR=YEAR 4 POLYNOMIAL
  /WSDESIGN=YEAR
  /PRINT=PARAMETER
  /DESIGN=GROUP.
```

- WSFACTOR specifies a repeated measures analysis in which the four dependent variables represent a single variable measured at four levels of the within-subjects factor. The within-subjects factor is called *YEAR* for the duration of the GLM procedure.
- POLYNOMIAL requests polynomial contrasts for the levels of *YEAR*. Because the four variables, *Y1*, *Y2*, *Y3*, and *Y4*, in the active dataset represent the four levels of *YEAR*, the effect is to perform an orthonormal polynomial transformation of these variables.
- PRINT requests that the parameter estimates be displayed.
- WSDESIGN specifies a within-subjects design that includes only the effect of the *YEAR* within-subjects factor. Because *YEAR* is the only within-subjects factor specified, this is the default design, and WSDESIGN could have been omitted.
- DESIGN specifies a between-subjects design that includes only the effect of the *GROUP* between-subjects factor. This subcommand could have been omitted.

Repeated Measures ANOVA, Unbalanced Design with Missing Cells

```
GLM
  sales.1 sales.2 sales.3 sales.4 BY promo marketid
  /WSFACTOR = week 4
  /MEASURE = sales
  /METHOD = SSTYPE(4)
```

```
/PRINT = ETASQ TEST(SSCP) PARAMETER RSSCP HOMOGENEITY
/PLOT = PROFILE ( week*promo )
/PLOT = PROFILE ( week*marketid )
/CRITERIA = ALPHA(.05)
/WSDESIGN = week
/DESIGN = promo marketid promo*marketid.
```

- The procedure fits a model to the dependent variables *sales.1* through *sales.4* using *promo* and *marketid* as factors.
- WSFACTOR specifies a repeated measures analysis in which the four dependent variables represent a single variable measured at four levels of the within-subjects factor. The within-subjects factor is called *week* for the duration of the GLM procedure.
- METHOD specifies the Type IV method for partitioning sums of squares. This is recommended because the cell frequencies for the layout of *Market ID* and *Promotion * Market ID* are unbalanced and *Promotion * Market ID* has empty cells.
- PRINT requests that the estimates of effect size, SSCP matrices, and homogeneity tests be displayed.
- The first PLOT subcommand requests profile plots for *week*promo*, which will result in a single plot for each dependent variable. Each plot will feature the levels of *week* on the *x*-axis and the estimated marginal means for the levels of *week* on the *y*-axis. A separate line is produced for each level of *promo*.
- The first PLOT subcommand requests profile plots for *week*marketid*, which will result in a single plot for each dependent variable. Each plot will feature the levels of *week* on the *x*-axis and the estimated marginal means for the levels of *week* on the *y*-axis. A separate line is produced for each level of *marketid*.
- All other options are set to their default values.

Doubly Multivariate ANOVA

```
GLM
  tg0 tg1 tg2 tg3 tg4 wgt0 wgt1 wgt2 wgt3 wgt4 BY gender
  /WSFACTOR = time 5 Repeated
  /MEASURE = tg wgt
  /METHOD = SSTYPE(3)
  /PLOT = PROFILE( time*gender )
  /EMMEANS = TABLES(gender*time)
  /PRINT = ETASQ TEST(SSCP)
  /CRITERIA = ALPHA(.05)
  /WSDESIGN = time
  /DESIGN = gender .
```

- The procedure fits a model to the dependent variables *tg0* through *wgt4* using *gender* as a factor.
- WSFACTOR and MEASURE specify a repeated measures analysis in which the ten dependent variables represent two variables measured at five levels of the within-subjects factor. The within-subjects factor is called *time* and the measures are called *tg* and *wgt* for the duration of the GLM procedure. Repeated contrasts are specified for the within-subjects factor.

- PLOT requests profile plots for *time*gender*, which will result in a single plot for each measure. Each plot will feature the levels of *week* on the *x*-axis and the estimated marginal means for the measure at the levels of *week* on the *y*-axis. A separate line is produced for each level of *gender*.
- EMMEANS requests estimated marginal means for *gender*time*, which will results in a tabular representation of the profile plots.
- PRINT requests that the estimates of effect size and SSCP matrices be displayed.
- All other options are set to their default values.

GLM Variable List

The list of dependent variables, factors, and covariates must be specified first.

- WSFACTOR determines how the dependent variables on the GLM variable list will be interpreted.
- The number of dependent variables on the GLM variable list must be a multiple of the number of cells in the within-subjects design. If there are six cells in the within-subjects design, each group of six dependent variables represents a single within-subjects variable that has been measured in each of the six cells.
- Normally, the number of dependent variables should equal the number of cells in the within-subjects design multiplied by the number of variables named on the MEASURE subcommand (if one is used). If you have more groups of dependent variables than are accounted for by the MEASURE subcommand, GLM will choose variable names to label the output, which may be difficult to interpret.
- Covariates are specified after keyword WITH. You can specify constant covariates. Constant covariates represent variables whose values remain the same at each within-subjects level.

Example

```
GLM MATH1 TO MATH4 BY METHOD WITH SES
  /WSFACTOR=SEMESTER 4.
```

- The four dependent variables represent a score measured four times (corresponding to the four levels of *SEMESTER*).
- *SES* is a constant covariate. Its value does not change over the time covered by the four levels of *SEMESTER*.
- Default contrast (POLYNOMIAL) is used.

WSFACTOR Subcommand

WSFACTOR names the within-subjects factors, specifies the number of levels for each, and specifies the contrast for each.

- Presence of the WSFACTOR subcommand implies that the repeated measures model is being used.
- Mauchly's test of sphericity is automatically performed when WSFACTOR is specified.

- Names and number levels for the within-subjects factors are specified on the WSFACTOR subcommand. Factor names must not duplicate any of the dependent variables, factors, or covariates named on the GLM variable list. A type of contrast can also be specified for each within-subjects factor in order to perform comparisons among its levels. This contrast amounts to a transformation on the dependent variables.
- If there are more than one within-subjects factors, they must be named in the order corresponding to the order of the dependent variables on the GLM variable list. GLM varies the levels of the last-named within-subjects factor most rapidly when assigning dependent variables to within-subjects cells (see the example below).
- The number of cells in the within-subjects design is the product of the number of levels for all within-subjects factors.
- Levels of the factors must be represented in the data by the dependent variables named on the GLM variable list.
- The number of levels of each factor must be at least two. Enter an integer equal to or greater than 2 after each factor to indicate how many levels the factor has. Optionally, you can enclose the number of levels in parentheses.
- Enter only the *number of levels* for within-subjects factors, not a range of values.
- If more than one WSFACTOR subcommand is specified, only the last one is in effect.

Contrasts for WSFACTOR

The levels of a within-subjects factor are represented by different dependent variables. Therefore, contrasts between levels of such a factor compare these dependent variables. Specifying the type of contrast amounts to specifying a transformation to be performed on the dependent variables.

- In testing the within-subjects effects, an orthonormal transformation is automatically performed on the dependent variables in a repeated measures analysis.
- The contrast for each within-subjects factor is entered after the number of levels. If no contrast keyword is specified, POLYNOMIAL(1,2,3...) is the default. This contrast is used in comparing the levels of the within-subjects factors. Intrinsically orthogonal contrast types are recommended for within-subjects factors if you wish to examine each degree-of-freedom test, provided compound symmetry is assumed within each within-subjects factor. Other orthogonal contrast types are DIFFERENCE and HELMERT.
- If there are more than one within-subjects factors, the transformation matrix (**M** matrix) is computed as the Kronecker product of the matrices generated by the contrasts specified.
- The transformation matrix (**M** matrix) generated by the specified contrasts can be displayed by using the keyword TEST(MMATRIX) on the subcommand PRINT.
- The contrast types available for within-subjects factors are the same as those on the CONTRAST subcommand for between-subjects factors, described in CONTRAST Subcommand on p. 817 in *GLM: Univariate*.

The following contrast types are available:

DEVIATION *Deviations from the grand mean.* This is the default for between-subjects factors. Each level of the factor except one is compared to the grand mean. One category (by default the last) must be omitted so that the effects will be independent of one another. To omit a category other than the last, specify the number of the omitted category in parentheses after the keyword `DEVIATION`. For example,

```
GLM Y1 Y2 Y3 BY GROUP /WSFACTOR = Y 3 DEVIATION (1)
```

Deviation contrasts are not orthogonal.

POLYNOMIAL *Polynomial contrasts.* This is the default for within-subjects factors. The first degree of freedom contains the linear effect across the levels of the factor, the second contains the quadratic effect, and so on. In a balanced design, polynomial contrasts are orthogonal. By default, the levels are assumed to be equally spaced; you can specify unequal spacing by entering a metric consisting of one integer for each level of the factor in parentheses after the keyword `POLYNOMIAL`. (All metrics specified cannot be equal; thus (1,1,...,1) is not valid.) For example,

```
/WSFACTOR=D 3 POLYNOMIAL(1,2,4).
```

Suppose that factor D has three levels. The specified contrast indicates that the three levels of D are actually in the proportion 1:2:4. The default metric is always (1,2,...,*k*), where *k* levels are involved. Only the relative differences between the terms of the metric matter (1,2,4) is the same metric as (2,3,5) or (20,30,50) because, in each instance, the difference between the second and third numbers is twice the difference between the first and second.

DIFFERENCE *Difference or reverse Helmert contrasts.* Each level of the factor except the first is compared to the mean of the previous levels. In a balanced design, difference contrasts are orthogonal.

HELMERT *Helmert contrasts.* Each level of the factor except the last is compared to the mean of subsequent levels. In a balanced design, Helmert contrasts are orthogonal.

SIMPLE *Each level of the factor except the last is compared to the last level.* To use a category other than the last as the omitted reference category, specify its number in parentheses following keyword `SIMPLE`. For example,

```
/WSFACTOR=B 3 SIMPLE (1).
```

Simple contrasts are not orthogonal.

REPEATED *Comparison of adjacent levels.* Each level of the factor except the last is compared to the next level. Repeated contrasts are not orthogonal.

SPECIAL *A user-defined contrast.* Values specified after this keyword are stored in a matrix in column major order. For example, if factor A has three levels, then `WSFACTOR(A)=SPECIAL(1 1 1 1 -1 0 0 1 -1)` produces the following contrast matrix:

```
1   1   0
1  -1   1
1   0  -1
```

Example

```
GLM X1Y1 X1Y2 X2Y1 X2Y2 X3Y1 X3Y2 BY TREATMNT GROUP
  /WSFACTOR=X 3 Y 2
  /DESIGN.
```

- The `GLM` variable list names six dependent variables and two between-subjects factors, *TREATMNT* and *GROUP*.

- WSFACTOR identifies two within-subjects factors whose levels distinguish the six dependent variables. *X* has three levels, and *Y* has two. Thus, there are 3 × 2 = 6 cells in the within-subjects design, corresponding to the six dependent variables.
- Variable *X1Y1* corresponds to levels 1,1 of the two within-subjects factors; variable *X1Y2* corresponds to levels 1,2; *X2Y1* to levels 2,1; and so on up to *X3Y2*, which corresponds to levels 3,2. The first within-subjects factor named, *X*, varies most slowly, and the last within-subjects factor named, *Y*, varies most rapidly on the list of dependent variables.
- Because there is no WSDESIGN subcommand, the within-subjects design will include all main effects and interactions: *X*, *Y*, and *X* by *Y*.
- Likewise, the between-subjects design includes all main effects and interactions (*TREATMNT*, *GROUP*, and *TREATMNT* by *GROUP*) plus the intercept.
- In addition, a repeated measures analysis always includes interactions between the within-subjects factors and the between-subjects factors. There are three such interactions for each of the three within-subjects effects.

Example

```
GLM SCORE1 SCORE2 SCORE3 BY GROUP
  /WSFACTOR=ROUND 3 DIFFERENCE
  /CONTRAST(GROUP)=DEVIATION
  /PRINT=PARAMETER TEST(LMATRIX).
```

- This analysis has one between-subjects factor, *GROUP*, and one within-subjects factor, *ROUND*, with three levels that are represented by the three dependent variables.
- The WSFACTOR subcommand also specifies difference contrasts for *ROUND*, the within-subjects factor.
- There is no WSDESIGN subcommand, so a default full factorial within-subjects design is assumed. This could also have been specified as WSDESIGN=ROUND, or simply WSDESIGN.
- The CONTRAST subcommand specifies deviation contrasts for *GROUP*, the between-subjects factor. This subcommand could have been omitted because deviation contrasts are the default.
- PRINT requests the display of the parameter estimates for the model and the **L** matrix.
- There is no DESIGN subcommand, so a default full factorial between-subjects design is assumed. This could also have been specified as DESIGN=GROUP, or simply DESIGN.

WSDESIGN Subcommand

WSDESIGN specifies the design for within-subjects factors. Its specifications are like those of the DESIGN subcommand, but it uses the within-subjects factors rather than the between-subjects factors.

- The default WSDESIGN is a full factorial design, which includes all main effects and all interactions for within-subjects factors. The default is in effect whenever a design is processed without a preceding WSDESIGN or when the preceding WSDESIGN subcommand has no specifications.

- A WSDESIGN specification cannot include between-subjects factors or terms based on them, nor does it accept interval-level variables.
- The keyword INTERCEPT is not allowed on WSDESIGN.
- Nested effects are not allowed. Therefore, the symbols ( ) are not allowed here.
- If more than one WSDESIGN subcommand is specified, only the last one is in effect.

Example

```
GLM JANLO,JANHI,FEBLO,FEBHI,MARLO,MARHI BY SEX
  /WSFACTOR MONTH 3 STIMULUS 2
  /WSDESIGN MONTH, STIMULUS
  /DESIGN SEX.
```

- There are six dependent variables, corresponding to three months and two different levels of stimulus.
- The dependent variables are named on the GLM variable list in an order such that the level of stimulus varies more rapidly than the month. Thus, *STIMULUS* is named last on the WSFACTOR subcommand.
- The WSDESIGN subcommand specifies only the main effects for within-subjects factors. There is no *MONTH*-by-*STIMULUS* interaction term.

MEASURE Subcommand

In a doubly multivariate analysis, the dependent variables represent multiple variables measured under the different levels of the within-subjects factors. Use MEASURE to assign names to the variables that you have measured for the different levels of within-subjects factors.

- Specify a list of one or more variable names to be used in labeling the averaged results. If no within-subjects factor has more than two levels, MEASURE has no effect. You can use up to 255 bytes for each name.
- The number of dependent variables in the dependent variables list should equal the product of the number of cells in the within-subjects design and the number of names on MEASURE.
- If you do not enter a MEASURE subcommand and there are more dependent variables than cells in the within-subjects design, GLM assigns names (normally *MEASURE_1*, *MEASURE_2*, and so on) to the different measures.
- All of the dependent variables corresponding to each measure should be listed together and ordered so that the within-subjects factor named last on the WSFACTORS subcommand varies most rapidly.

Example

```
GLM TEMP11 TEMP12 TEMP21 TEMP22 TEMP31 TEMP32,
        WEIGHT11 WEIGHT12 WEIGHT21 WEIGHT22 WEIGHT31 WEIGHT32 BY GROUP
  /WSFACTOR=DAY 3 AMPM 2
  /MEASURE=TEMP WEIGHT
  /WSDESIGN=DAY, AMPM, DAY BY AMPM
  /DESIGN.
```

- There are 12 dependent variables: six temperatures and six weights, corresponding to morning and afternoon measurements on three days.
- WSFACTOR identifies the two factors (*DAY* and *AMPM*) that distinguish the temperature and weight measurements for each subject. These factors define six within-subjects cells.
- MEASURE indicates that the first group of six dependent variables correspond to *TEMP* and the second group of six dependent variables correspond to *WEIGHT*.
- These labels, *TEMP* and *WEIGHT*, are used on the output as the measure labels.
- WSDESIGN requests a full factorial within-subjects model. Because this is the default, WSDESIGN could have been omitted.

EMMEANS Subcommand

EMMEANS displays estimated marginal means of the dependent variables in the cells, adjusted for the effects of covariates at their overall means, for the specified factors. Note that these are predicted, not observed, means. The standard errors are also displayed. For more information, see EMMEANS Subcommand on p. 822.

- For the TABLES and COMPARE keywords, valid options include the within-subjects factors specified in the WSFACTOR subcommand, crossings among them, and crossings among factors specified in the factor list and factors specified on the WSFACTOR subcommand.
- All factors in a crossed-factors specification must be unique.
- If a between- or within-subjects factor, or a crossing of between- or within-subjects factors, is specified on the TABLES keyword, then GLM will collapse over any other between- or within-subjects factors before computing the estimated marginal means for the dependent variables.

** Default if the subcommand is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Release History

Release 13.0

- PANEL subcommand introduced.
- INTERVAL subcommand introduced.

The following table shows all possible function/variable specifications for BAR, LINE, PIE, BLOCK, and PARETO subcommands. For special restrictions, see the individual subcommands. In the table, valuef refers to the value function, countf refers to the count functions, and sumf refers to the summary functions.

	Simple bar, simple or area line, pie, simple high-low, and simple Pareto charts	**Grouped or stacked bar, multiple, drop or difference area, and stacked Pareto charts**
Categorical charts	[countf BY] var	[countf BY] var BY var
	sumf(var) BY var	sumf(var) BY var BY var
	sumf(varlist)	sumf(varlist) BY var
	sumf(var) sumf(var)...	sumf(var) sumf(var)... BY var
Noncategorical charts	valuef(var) [BY var]	valuef(varlist) [BY var]

The following table shows all possible function/variable specifications for the HILO subcommand. Categorical variables for simple high-low-close charts must be dichotomous or trichotomous.

Simple range bar and simple high-low-close charts	**Clustered range bar and clustered high-low-close charts**
[countf BY] var	(sumf(var) sumf(var) [sumf(var)]) (...) ...BY var
sumf(var) sumf(var) sumf(var) BY var	sumf(var) sumf(var) [sumf(var)] BY var BY var
sumf(var) BY var BY var	
valuef(varlist) [BY var]	valuef(varlist) (...) ... [BY var]

Variable specification is required on all types of scatterplots. The following table shows all possible specifications:

BIVARIATE	var WITH var [BY var] [BY var ({NAME })] {IDENTIFY}
OVERLAY	varlist WITH varlist [(PAIR)] [BY var ({NAME })] {IDENTIFY}
MATRIX	varlist [BY var] [BY var ({NAME })] {IDENTIFY}
XYZ	var WITH var WITH var [BY var] [BY var ({NAME })] {IDENTIFY}

Value function:

The VALUE function yields the value of the specified variable for each case. It always produces one bar, point, or slice for each case. The VALUE(X) specification implies the value of *X* by *n*, where *n* is the number of each case. You can specify multiple variables, as in:

```
GRAPH /BAR = VALUE(SALARY BONUS BENEFIT).
```

This command draws a bar chart with the values of *SALARY*, *BONUS*, and *BENEFIT* for each employee (case). A BY variable can be used to supply case labels, but it does not affect the layout of the chart, even if values of the BY variable are the same for multiple cases.

Aggregation functions:

Two groups of aggregation functions are available: count functions and summary functions.

Count functions:

COUNT	*Frequency of cases in each category.*
PCT	*Frequency of cases in each category expressed as a percentage of the whole.*
CUPCT	*Cumulative percentage sorted by category value.*
CUFREQ	*Cumulative frequency sorted by category value.*

- Count functions yield the count or percentage of valid cases within categories determined by one or more BY variables, as in:

```
GRAPH /BAR (SIMPLE) = PCT BY REGION.
```

- Count functions do not have any arguments.
- You can omit the keyword COUNT and the subsequent keyword BY and specify just a variable, as in

```
GRAPH /BAR = DEPT.
```

This command is interpreted as

```
GRAPH /BAR = COUNT BY DEPT.
```

Summary functions:

MINIMUM	*Minimum value of the variable.*
MAXIMUM	*Maximum value of the variable.*
N	*Number of cases for which the variable has a nonmissing value.*
SUM	*Sum of the values of the variable.*
CUSUM	*Sum of the summary variable accumulated across values of the category variable.*
MEAN	*Mean.*
STDDEV	*Standard deviation.*
VARIANCE	*Variance.*
MEDIAN	*Median.*
GMEDIAN	*Group median.*
MODE	*Mode.*
PTILE(x)	X*th percentile value of the variable. X* must be greater than 0 and less than 100.
PLT(x)	*Percentage of cases for which the value of the variable is less than* x.
PGT(x)	*Percentage of cases for which the value of the variable is greater than* x.
NLT(x)	*Number of cases for which the value of the variable is less than* x.
NGT(x)	*Number of cases for which the value of the variable is greater than* x.
PIN(x1,x2)	*Percentage of cases for which the value of the variable is greater than or equal to* x1 *and less than or equal to* x2. *x1* cannot exceed *x2*.
NIN(x1,x2)	*Number of cases for which the value of the variable is greater than or equal to* x1 *and less than or equal to* x2. *x1* cannot exceed *x2*.

- Summary functions are usually used with summary variables (variables that record continuous values, such as age or expenses). To use a summary function, specify the name of one or more variables in parentheses after the name of the function, as in:

```
GRAPH /BAR = SUM(SALARY) BY DEPT.
```

- You can specify multiple summary functions for more chart types. For example, the same function can be applied to a list of variables, as in:

```
GRAPH /BAR = SUM(SALARY BONUS BENEFIT) BY DEPT.
```

This syntax is equivalent to:

```
GRAPH /BAR = SUM(SALARY) SUM(BONUS) SUM(BENEFIT) BY DEPT.
```

Different functions can be applied to the same variable, as in:

```
GRAPH /BAR = MEAN(SALARY) MEDIAN(SALARY) BY DEPT.
```

Different functions and variables can be combined, as in:

```
GRAPH /BAR = MIN(SALARY81) MAX(SALARY81)
                 MIN(SALARY82) MAX(SALARY82) BY JOBCAT.
```

The effect of multiple summary functions on the structure of the charts is illustrated under the discussion of specific chart types.

Overview

GRAPH generates a high-resolution chart by computing statistics from variables in the active dataset and constructing the chart according to your specification. The chart can be a bar chart, pie chart, line chart, error bar chart, high-low-close histogram, scatterplot, or Pareto chart. The chart is displayed where high-resolution display is available and can be edited with a chart editor and saved as a chart file.

Options

Titles and Footnotes. You can specify a title, subtitle, and footnote for the chart using the TITLE, SUBTITLE, and FOOTNOTE subcommands.

Chart Type. You can request a specific type of chart using the BAR, LINE, PIE, ERRORBAR, HILO, HISTOGRAM, SCATTERPLOT, or PARETO subcommand.

Chart Content. You can specify an aggregated categorical chart using various aggregation functions or a nonaggregated categorical chart using the VALUE function.

Templates. You can specify a template, using the TEMPLATE subcommand, to override the default chart attribute settings on your system.

Basic Specification

The basic specification is a chart type subcommand. By default, the generated chart will have no title, subtitle, or footnote.

Subcommand Order

Subcommands can be specified in any order.

Syntax Rules

- Only one chart type subcommand can be specified.
- The function/variable specification is required for all subtypes of bar, line, error bar, hilo, and Pareto charts; the variable specification is required for histograms and all subtypes of scatterplots.
- The function/variable or variable specifications should match the subtype keywords. If there is a discrepancy, GRAPH produces the default chart for the function/variable or variable specification regardless of the specified keyword.

Operations

- GRAPH computes aggregated functions to obtain the values needed for the requested chart and calculates an optimal scale for charting.
- The chart title, subtitle, and footnote are assigned as they are specified on the TITLE, SUBTITLE, and FOOTNOTE subcommands. If you do not use these subcommands, the chart title, subtitle, and footnote are null. The split-file information is displayed as a subtitle if split-file is in effect.
- GRAPH creates labels that provide information about the source of the values being plotted. Labeling conventions vary for different subtypes. Where variable or value labels are defined in the active dataset, GRAPH uses the labels; otherwise, variable names or values are used.

Limitations

Categorical charts cannot display fewer than 2 or more than 3,000 categories.

Examples

```
GRAPH /BAR=SUM (MURDER) BY CITY.
```

- This command generates a simple (default) bar chart showing the number of murders in each city.
- The category axis (*x* axis) labels are defined by the value labels (or values if no value labels exist) of the variable *CITY*.
- The default span (2) and sigma value (3) are used.
- Since no BY variable is specified, the *x* axis is labeled by sequence numbers.

TITLE, SUBTITLE, and FOOTNOTE Subcommands

TITLE, SUBTITLE, and FOOTNOTE specify lines of text placed at the top or bottom of the chart.

- One or two lines of text can be specified for TITLE or FOOTNOTE, and one line of text can be specified for SUBTITLE.

- Each line of text must be enclosed in quotes. The maximum length of any line is 72 characters.
- The default font sizes and types are used for the title, subtitle, and footnote.
- By default, the title, subtitle, and footnote are left-aligned with the *y* axis.
- If you do not specify TITLE, the default title, subtitle, and footnote are null, which leaves more space for the chart. If split-file processing is in effect, the split-file information is provided as a default subtitle.

Example

```
GRAPH TITLE = 'Murder in Major U.S. Cities'
 /SUBTITLE='per 100,000 people'
 /FOOTNOTE='The above data was reported on August 26, 1987'
 /BAR=SUM(MURDER) BY CITY.
```

BAR Subcommand

BAR creates one of five types of bar charts using the keywords SIMPLE, COMPOSITIONAL, GROUPED, STACKED, or RANGE.

- Only one keyword can be specified, and it must be specified in parentheses.
- When no keyword is specified, the default is either SIMPLE or GROUPED, depending on the type of function/variable specification.

SIMPLE *Simple bar chart.* This is the default if no keyword is specified on the BAR subcommand and the variables define a simple bar chart. A simple bar chart can be defined by a single summary or count function and a single BY variable or by multiple summary functions and no BY variable.

GROUPED *Clustered bar chart.* A clustered bar chart is defined by a single function and two BY variables or by multiple functions and a single BY variable. This is the default if no keyword is specified on the BAR subcommand and the variables define a clustered bar chart.

STACKED *Stacked bar chart.* A stacked bar chart displays a series of bars, each divided into segments stacked one on top of the other. The height of each segment represents the value of the category. Like a clustered bar chart, it is defined by a single function and two BY variables or by multiple functions and a single BY variable.

RANGE *Range bar chart.* A range bar chart displays a series of floating bars. The height of each bar represents the range of the category and its position in the chart indicates the minimum and maximum values. A range bar chart can be defined by a single function and two BY variables or by multiple functions and a single BY variable. If a variable list is used as the argument for a function, the list must be of an even number. If a second BY variable is used to define the range, the variable must be dichotomous.

LINE Subcommand

LINE creates one of five types of line charts using the keywords SIMPLE, MULTIPLE, DROP, AREA, or DIFFERENCE.

- Only one keyword can be specified, and it must be specified in parentheses.
- When no keyword is specified, the default is either SIMPLE or MULTIPLE, depending on the type of function/variable specification.

SIMPLE *Simple line chart.* A simple line chart is defined by a single function and a single BY variable or by multiple functions and no BY keyword. This is the default if no keyword is specified on LINE and the data define a simple line.

MULTIPLE *Multiple line chart.* A multiple line chart is defined by a single function and two BY variables or by multiple functions and a single BY variable. This is the default if no keyword is specified on LINE and the data define a multiple line.

DROP *Drop-line chart.* A drop-line chart shows the difference between two or more fluctuating variables. It is defined by a single function and two BY variables or by multiple functions and a single BY variable.

AREA *Area line chart.* An area line chart fills the area beneath each line with a color or pattern. When multiple lines are specified, the second line is the sum of the first and second variables, the third line is the sum of the first, second, and third variables, and so on. The specification is the same as that for a simple or multiple line chart.

DIFFERENCE *Difference area chart.* A difference area chart fills the area between a pair of lines. It highlights the difference between two variables or two groups. A difference area chart is defined by a single function and two BY variables or by two summary functions and a single BY variable. If a second BY variable is used to define the two groups, the variable must be dichotomous.

PIE Subcommand

PIE creates pie charts. A pie chart can be defined by a single function and a single BY variable or by multiple summary functions and no BY variable. A pie chart divides a circle into slices. The size of each slice indicates the value of the category relative to the whole. Cumulative functions (CUPCT, CUFREQ, and CUSUM) are inappropriate for pie charts but are not prohibited. When specified, all cases except those in the last category are counted more than once in the resulting pie.

HILO Subcommand

HILO creates one of two types of high-low-close charts using the keywords SIMPLE or GROUPED. High-low-close charts show the range and the closing (or average) value of a series.

- Only one keyword can be specified.

- When a keyword is specified, it must be specified in parentheses.
- When no keyword is specified, the default is either SIMPLE or GROUPED, depending on the type of function/variable specification.

SIMPLE *Simple high-low-close chart.* A simple high-low-close chart can be defined by a single summary or count function and two BY variables, by three summary functions and one BY variable, or by three values with one or no BY variable. When a second BY variable is used to define a high-low-close chart, the variable must be dichotomous or trichotomous. If dichotomous, the first value defines low and the second value defines high; if trichotomous, the first value defines high, the second defines low, and the third defines close.

GROUPED *Grouped high-low-close chart.* A grouped high-low-close chart is defined by a single function and two BY variables or by multiple functions and a single BY variable. When a variable list is used for a single function, the list must contain two or three variables. If it contains two variables, the first defines the high value and the second defines the low value. If it contains three variables, the first defines the high value, the second defines the low value, and the third defines the close value. Likewise, if multiple functions are specified, they must be in groups of either two or three. The first function defines the high value, the second defines the low value, and the third, if specified, defines the close value.

ERRORBAR Subcommand

ERRORBAR creates either a simple or a clustered error bar chart, depending on the variable specification on the subcommand. A simple error bar chart is defined by one numeric variable with or without a BY variable or a variable list. A clustered error bar chart is defined by one numeric variable with two BY variables or a variable list with a BY variable.

Error bar charts can display confidence intervals, standard deviations, or standard errors of the mean. To specify the statistics to be displayed, one of the following keywords is required:

CI value *Display confidence intervals for mean.* You can specify a confidence level between 50 and 99.9. The default is 95.

STERROR n *Display standard errors of mean.* You can specify any positive number for *n*. The default is 2.

STDDEV n *Display standard deviations.* You can specify any positive number for *n*. The default is 2.

SCATTERPLOT Subcommand

SCATTERPLOT produces two- or three-dimensional scatterplots. Multiple two-dimensional plots can be plotted within the same frame or as a scatterplot matrix. Only variables can be specified; aggregated functions cannot be plotted. When SCATTERPLOT is specified without keywords, the default is BIVARIATE.

BIVARIATE *One two-dimensional scatterplot.* A basic scatterplot is defined by two variables separated by the keyword WITH. This is the default when SCATTERPLOT is specified without keywords.

OVERLAY *Multiple plots drawn within the same frame.* Specify a variable list on both sides of WITH. By default, one scatterplot is drawn for each combination of variables on the left of WITH with variables on the right. You can specify PAIR in parentheses to indicate that the first variable on the left is paired with the first variable on the right, the second variable on the left with the second variable on the right, and so on. All plots are drawn within the same frame and are differentiated by color or pattern. The axes are scaled to accommodate the minimum and maximum values across all variables.

MATRIX *Scatterplot matrix.* Specify at least two variables. One scatterplot is drawn for each combination of the specified variables above the diagonal and a second below the diagonal in a square matrix.

XYZ *One three-dimensional plot.* Specify three variables, each separated from the next with the keyword WITH.

- If you specify a control variable using BY, GRAPH produces a control scatterplot where values of the BY variable are indicated by different colors or patterns. A control variable cannot be specified for overlay plots.
- You can display the value label of an identification variable at the plotting position for each case by adding BY *var* (NAME) or BY *var* (IDENTIFY) to the end of any valid scatterplot specification. When the chart is created, NAME turns the labels on, while IDENTIFY turns the labels off. You can use the Point Selection tool to turn individual labels off or on in the scatterplot.

HISTOGRAM Subcommand

HISTOGRAM creates a histogram.

- Only one variable can be specified on this subcommand.
- GRAPH divides the values of the variable into several evenly spaced intervals and produces a bar chart showing the number of times the values for the variable fall within each interval.
- You can request a normal distribution line by specifying the keyword NORMAL in parentheses.

PARETO Subcommand

PARETO creates one of two types of Pareto charts. A Pareto chart is used in quality control to identify the few problems that create the majority of nonconformities. Only SUM, VALUE, and COUNT can be used with the PARETO subcommand.

Before plotting, PARETO sorts the plotted values in descending order by category. The right axis is always labeled by the cumulative percentage from 0 to 100. By default, a cumulative line is displayed. You can eliminate the cumulative line or explicitly request it by specifying one of the following keywords:

CUM *Display the cumulative line.* This is the default.

NOCUM *Do not display the cumulative line.*

You can request a simple or a stacked Pareto chart by specifying one of the following keywords and define it with appropriate function/variable specifications:

SIMPLE *Simple Pareto chart.* Each bar represents one type of nonconformity. A simple Pareto chart can be defined by a single variable, a single VALUE function, a single SUM function with a BY variable, or a SUM function with a variable list as an argument with no BY variable.

STACKED *Stacked Pareto chart.* Each bar represents one or more types of nonconformity within the category. A stacked Pareto chart can be defined by a single SUM function with two BY variables, a single variable with a BY variable, a VALUE function with a variable list as an argument, or a SUM function with a variable list as an argument and a BY variable.

PANEL Subcommand

The PANEL subcommand specifies the variables and method used for paneling. Each keyword in the subcommand is followed by an equals sign (=) and the value for that keyword.

COLVAR and ROWVAR Keywords

The COLVAR and ROWVAR keywords identify the column and row variables, respectively. Each category in a column variable appears as a vertical column in the resulting chart. Each category in a row variable appears as a horizontal row in the resulting chart.

- If multiple variables are specified for a keyword, the COLOP and ROWOP keywords can be used to change the way in which variable categories are rendered in the chart.
- The ROWVAR keyword is not available for population pyramids.

varlist *The list of variables used for paneling.*

Examples

```
GRAPH
  /BAR(SIMPLE)=COUNT BY educ
  /PANEL COLVAR=gender COLOP=CROSS
```

- There are two columns in the resulting paneled chart, one for each gender.
- Because there is only one paneling variable, there are only as many panels as there are variable values. Therefore, there are two panels.

```
GRAPH
  /BAR(SIMPLE)=COUNT BY educ
```

```
/PANEL COLVAR=minority ROWVAR=jobcat.
```

- There are two columns in the resulting paneled chart (for the *gender* variable values) and three rows (for the *jobcat* variable values).

COLOP and ROWOP Keywords

The COLOP and ROWOP keywords specify the paneling method for the column and row variables, respectively. These keywords have no effect on the chart if there is only one variable in the rows and/or columns. They also have no effect if the data are not nested.

CROSS *Cross variables in the rows or columns.* When the variables are crossed, a panel is created for every combination of categories in the variables. For example, if the categories in one variable are A and B and the categories in another variable are 1 and 2, the resulting chart will display a panel for the combinations of A and 1, A and 2, B and 1, and B and 2. A panel can be empty if the categories in that panel do not cross (for example, if there are no cases in the B category *and* the 1 category). This is the default.

NEST *Nest variables in the rows or columns.* When the variables are nested, a panel is created for each category that is nested in the parent category. For example, if the data contain variables for states and cities, a panel is created for each city and the relevant state. However, panels are not created for cities that are not in certain states, as would happen with CROSS. When nesting, make sure that the variables specified for ROWVAR or COLVAR are in the correct order. Parent variables precede child variables.

Example

Assume you have the following data:

Table 99-1
Nested data

State	City	Temperature
NJ	Springfield	70
MA	Springfield	60
IL	Springfield	50
NJ	Trenton	70
MA	Boston	60

You can create a paneled chart from these data with the following syntax:

```
GRAPH
  /HISTOGRAM=temperature
  /PANEL COLVAR=state city COLOP=CROSS.
```

The command crosses every variable value to create the panels. Because not every state contains every city, the resulting paneled chart will contain blank panels. For example, there will be a blank panel for Springfield and New Jersey. In this dataset, the *city* variable is really nested in the *state* variable. To nest the variables in the panels and eliminate any blank panels, use the following syntax:

```
GRAPH
  /HISTOGRAM=temperature
```

```
  /PANEL COLVAR=state city COLOP=NEST.
```

INTERVAL Subcommand

The INTERVAL subcommand adds errors bars to the chart. This is different from the ERRORBAR subcommand. The ERRORBAR subcommand adds error bar data elements. INTERVAL adds errors bars to other data elements (for example, areas, bars, and lines).

Error bars indicate the variability of the summary statistic being displayed. The length of the error bar on either side of the summary statistic represents a confidence interval or a specified number of standard errors or standard deviations. GRAPH supports error bars for simple or clustered categorical charts displaying means, medians, counts, and percentages.

The keywords are not followed by an equals sign (=). They are followed by a value in parentheses.

Example

```
GRAPH
  /BAR(SIMPLE)=COUNT BY jobcat
  /INTERVAL CI(95).
```

CI Keyword

(value) *The percentage of the confidence interval to use as the length of the error bars.*

STDDEV Keyword

(value) *A multiplier indicating the number of standard deviations to use as the length of the error bars.*

SE Keyword

(value) *A multiplier indicating the number of standard errors to use as the length of the error bars.*

TEMPLATE Subcommand

TEMPLATE uses an existing chart as a template and applies it to the chart requested by the current GRAPH command.

- The specification on TEMPLATE is a chart file saved during a previous session.
- The general rule of application is that the template overrides the default setting, but the specifications on the current GRAPH command override the template. Nonapplicable elements and attributes are ignored.
- Three types of elements and attributes can be applied from a chart template: those dependent on data, those dependent on the chart type, and those dependent on neither.

Elements and Attributes Independent of Chart Types or Data

Elements and attributes common to all chart types are always applied unless overridden by the specifications on the current GRAPH command.

- The title, subtitle, and footnote, including text, color, font type and size, and line alignment are always applied. To give your chart a new title, subtitle, or footnote, specify the text on the TITLE, SUBTITLE, or FOOTNOTE subcommand. You cannot change other attributes.
- The outer frame of the chart, including line style, color, and fill pattern, is always applied. The inner frame is applied except for those charts that do not have an inner frame. The template overrides the system default.
- Label formats are applied wherever applicable. The template overrides the system default. Label text, however, is not applied. GRAPH automatically provides axis labels according to the function/variable specification.
- Legends and the legend title attributes, including color, font type and size, and alignment, are applied provided the current chart requires legends. The legend title text, however, is not applied. GRAPH provides the legend title according to the function/variable specification.

Elements and Attributes Dependent on Chart Type

Elements and attributes dependent on the chart type are those that exist only in a specific chart type. They include bars (in bar charts), lines and areas (in line charts), markers (in scatterplots), boxes (in boxplots), and pie sectors (in pie charts). These elements and their attributes are usually applied only when the template chart and the requested chart are of the same type. Some elements or their attributes may override the default settings across chart type.

- Color and pattern are always applied except for pie charts. The template overrides the system default.
- Scale axis lines are applied across chart types.
- Interval axis lines are applied from interval axis to interval axis. Interval axis bins are never applied.
- If the template is a 3-D bar chart and you request a chart with one category axis, attributes of the first axis are applied from the template. If you request a 3-D bar chart and the template is not a 3-D chart, no category axis attributes are applied.

Elements and Attributes Dependent on Data

Data-dependent elements and attributes are applied only when the template and the requested chart are of the same type and the template has at least as many series assigned to the same types of chart elements as the requested chart.

- Category attributes and elements, including fill, border, color, pattern, line style, weight of pie sectors, pie sector explosion, reference lines, projection lines, and annotations, are applied only when category values in the requested chart match those in the template.
- The attributes of data-related elements with on/off states are always applied. For example, the line style, weight, and color of a quadratic fit in a simple bivariate scatterplot are applied if the requested chart is also a simple bivariate scatterplot. The specification on the GRAPH

command, for example, HISTOGRAM(NORMAL), overrides the applied on/off status; in this case, a normal curve is displayed regardless of whether the template displays a normal curve.

- In bar, line, and area charts, the assignment of series to bars, lines, and areas is not applied.

MISSING Subcommand

MISSING controls the treatment of missing values in the chart drawn by GRAPH.

- The default is LISTWISE.
- The MISSING subcommand has no effect on variables used with the VALUE function to create nonaggregated charts. User-missing and system-missing values create empty cells.
- LISTWISE and VARIABLE are alternatives and apply to variables used in summary functions for a chart or to variables being plotted in a scatterplot.
- REPORT and NOREPORT are alternatives and apply only to category variables. They control whether categories and series with missing values are created. NOREPORT is the default.
- INCLUDE and EXCLUDE are alternatives and apply to both summary and category variables. EXCLUDE is the default.
- When a case has a missing value for the name variable but contains valid values for the dependent variable in a scatterplot, the case is always included. User-missing values are displayed as point labels; system-missing values are not displayed.
- For an aggregated categorical chart, if every aggregated series is empty in a category, the empty category is excluded.
- A nonaggregated categorical chart created with the VALUE function can contain completely empty categories. There are always as many categories as rows of data. However, at least one nonempty cell must be present; otherwise the chart is not created.

LISTWISE	*Listwise deletion of cases with missing values.* A case with a missing value for any dependent variable is excluded from computations and graphs.
VARIABLE	*Variable-wise deletion.* A case is deleted from the analysis only if it has a missing value for the dependent variable being analyzed.
NOREPORT	*Suppress missing-value categories.* This is the default.
REPORT	*Report and graph missing-value categories.*
EXCLUDE	*Exclude user-missing values.* Both user- and system-missing values for dependent variables are excluded from computations and graphs. This is the default.
INCLUDE	*Include user-missing values.* Only system-missing values for dependent variables are excluded from computations and graphs.

HILOGLINEAR

HILOGLINEAR is available in the Advanced Models option.

```
HILOGLINEAR {varlist} (min,max) [varlist ...]
            {ALL    }

 [/METHOD [= BACKWARD]]

 [/MAXORDER = k]

 [/CRITERIA = [CONVERGE({0.25**})] [ITERATE({20**})] [P({0.05**})]
                        {n     }            {n   }       {prob  }
              [DELTA({0.5**})] [MAXSTEPS({10**})]
                     {d    }             {n   }
              [DEFAULT] ]

 [/CWEIGHT = {varname }]
             {(matrix)}

 [/PRINT = {[FREQ**] [RESID**] [ESTIM**][ASSOCIATION**]}]
           {DEFAULT**                                  }
           {ALL                                        }
           {NONE                                       }

 [/PLOT = [{NONE**             } ]
           {DEFAULT            }
           {[RESID] [NORMPROB]}
           {ALL                }

 [/MISSING = [{EXCLUDE**}]]
              {INCLUDE  }

 [/DESIGN = effectname effectname*effectname ...]
```

** Default if subcommand or keyword is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
HILOGLINEAR V1(1,2) V2(1,2)
  /DESIGN=V1*V2.
```

Overview

HILOGLINEAR fits hierarchical loglinear models to multidimensional contingency tables using an iterative proportional-fitting algorithm. HILOGLINEAR also estimates parameters for saturated models. These techniques are described elsewhere in (Everitt, 1977), (Bishop, Feinberg, and Holland, 1975), and (Goodman, 1978). HILOGLINEAR is much more efficient for these models than the LOGLINEAR procedure because HILOGLINEAR uses an iterative proportional-fitting algorithm rather than the Newton-Raphson method used in LOGLINEAR.

Options

Design Specification. You can request automatic model selection using backward elimination with the METHOD subcommand. You can also specify any hierarchical design and request multiple designs using the DESIGN subcommand.

Design Control. You can control the criteria used in the iterative proportional-fitting and model-selection routines with the CRITERIA subcommand. You can also limit the order of effects in the model with the MAXORDER subcommand and specify structural zeros for cells in the tables you analyze with the CWEIGHT subcommand.

Display and Plots. You can select the display for each design with the PRINT subcommand. For saturated models, you can request tests for different orders of effects as well. With the PLOT subcommand, you can request residuals plots or normal probability plots of residuals.

Basic Specification

- The basic specification is a variable list with at least two variables followed by their minimum and maximum values.
- HILOGLINEAR estimates a saturated model for all variables in the analysis.
- By default, HILOGLINEAR displays parameter estimates, measures of partial association, goodness of fit, and frequencies for the saturated model.

Subcommand Order

- The variable list must be specified first.
- Subcommands affecting a given DESIGN must appear before the DESIGN subcommand. Otherwise, subcommands can appear in any order.
- MISSING can be placed anywhere after the variable list.

Syntax Rules

- DESIGN is optional. If DESIGN is omitted or the last specification is not a DESIGN subcommand, a default saturated model is estimated.
- You can specify multiple PRINT, PLOT, CRITERIA, MAXORDER, and CWEIGHT subcommands. The last of each type specified is in effect for subsequent designs.
- PRINT, PLOT, CRITERIA, MAXORDER, and CWEIGHT specifications remain in effect until they are overridden by new specifications on these subcommands.
- You can specify multiple METHOD subcommands, but each one affects only the next design.
- MISSING can be specified only once.

Operations

- HILOGLINEAR builds a contingency table using all variables on the variable list. The table contains a cell for each possible combination of values within the range specified for each variable.

- HILOGLINEAR assumes that there is a category for every integer value in the range of each variable. Empty categories waste space and can cause computational problems. If there are empty categories, use the RECODE command to create consecutive integer values for categories.
- Cases with values outside the range specified for a variable are excluded.
- If the last subcommand is not a DESIGN subcommand, HILOGLINEAR displays a warning and generates the default model. This is the saturated model unless MAXORDER is specified. This model is in addition to any that are explicitly requested.
- If the model is not saturated (for example, when MAXORDER is less than the number of factors), only the goodness of fit and the observed and expected frequencies are given.
- The display uses the WIDTH subcommand defined on the SET command. If the defined width is less than 132, some portions of the display may be deleted.

Limitations

The HILOGLINEAR procedure cannot estimate all possible frequency models, and it produces limited output for unsaturated models.

- It can estimate only hierarchical loglinear models.
- It treats all table variables as nominal. (You can use LOGLINEAR to fit nonhierarchical models to tables involving variables that are ordinal.)
- It can produce parameter estimates for saturated models only (those with all possible main-effect and interaction terms).
- It can estimate partial associations for saturated models only.
- It can handle tables with no more than 10 factors.

Example

```
HILOGLINEAR V1(1,2) V2(1,2) V3(1,3) V4(1,3)
  /DESIGN=V1*V2*V3, V4.
```

- HILOGLINEAR builds a 2 × 2 × 3 × 3 contingency table for analysis.
- DESIGN specifies the generating class for a hierarchical model. This model consists of main effects for all four variables, two-way interactions among *V1*, *V2*, and *V3*, and the three-way interaction term *V1* by *V2* by *V3*.

Backward Elimination

```
HILOGLINEAR
  inccat(1 4) news(0 1) response(0 1)  /METHOD=BACKWARD
  /CRITERIA MAXSTEPS(10) P(.05) ITERATION(20) DELTA(.5)
  /PRINT=FREQ RESID
  /DESIGN .
```

- HILOGLINEAR builds a 4× 2 × 2 contingency table for analysis.

- METHOD specifies that backward elimination should be used to choose a final model.
- All other options are set to their default values. The empty DESIGN subcommand indicates that the procedure will start with a saturated model.

Variable List

The required variable list specifies the variables in the analysis. The variable list must precede all other subcommands.

- Variables must be numeric and have integer values. If a variable has a fractional value, the fractional portion is truncated.
- Keyword ALL can be used to refer to all user-defined variables in the active dataset.
- A range must be specified for each variable, with the minimum and maximum values separated by a comma and enclosed in parentheses.
- If the same range applies to several variables, the range can be specified once after the last variable to which it applies.
- If ALL is specified, all variables must have the same range.

METHOD Subcommand

By default, HILOGLINEAR tests the model specified on the DESIGN subcommand (or the default model) and does not perform any model selection. All variables are entered and none are removed. Use METHOD to specify automatic model selection using backward elimination for the next design specified.

- You can specify METHOD alone or with the keyword BACKWARD for an explicit specification.
- When the backward-elimination method is requested, a step-by-step output is displayed regardless of the specification on the PRINT subcommand.
- METHOD affects only the next design.

BACKWARD *Backward elimination.* Perform backward elimination of terms in the model. All terms are entered. Those that do not meet the P criterion specified on the CRITERIA subcommand (or the default P) are removed one at a time.

MAXORDER Subcommand

MAXORDER controls the maximum order of terms in the model estimated for subsequent designs. If MAXORDER is specified, HILOGLINEAR tests a model only with terms of that order or less.

- MAXORDER specifies the highest-order term that will be considered for the next design. MAXORDER can thus be used to abbreviate computations for the BACKWARD method.
- If the integer on MAXORDER is less than the number of factors, parameter estimates and measures of partial association are not available. Only the goodness of fit and the observed and expected frequencies are displayed.

- You can use MAXORDER with backward elimination to find the best model with terms of a certain order or less. This is computationally much more efficient than eliminating terms from the saturated model.

Example

```
HILOGLINEAR V1 V2 V3(1,2)
  /MAXORDER=2
  /DESIGN=V1 V2 V3
  /DESIGN=V1*V2*V3.
```

- HILOGLINEAR builds a 2 × 2 × 2 contingency table for *V1*, *V2*, and *V3*.
- MAXORDER has no effect on the first DESIGN subcommand because the design requested considers only main effects.
- MAXORDER restricts the terms in the model specified on the second DESIGN subcommand to two-way interactions and main effects.

CRITERIA Subcommand

Use the CRITERIA subcommand to change the values of constants in the iterative proportional-fitting and model-selection routines for subsequent designs.

- The default criteria are in effect if the CRITERIA subcommand is omitted (see below).
- You cannot specify the CRITERIA subcommand without any keywords.
- Specify each CRITERIA keyword followed by a criterion value in parentheses. Only those criteria specifically altered are changed.
- You can specify more than one keyword on CRITERIA, and they can be in any order.

DEFAULT *Reset parameters to their default values.* If you have specified criteria other than the defaults for a design, use this keyword to restore the defaults for subsequent designs.

CONVERGE(n) *Convergence criterion*. The default is 10^{-3} times the largest cell size, or 0.25, whichever is larger.

ITERATE(n) *Maximum number of iterations.* The default is 20.

P(n) *Probability for change in chi-square if term is removed.* Specify a value between (but not including) 0 and 1 for the significance level. The default is 0.05. P is in effect only when you request BACKWARD on the METHOD subcommand.

MAXSTEPS(n) *Maximum number of steps for model selection.* Specify an integer between 1 and 99, inclusive. The default is 10.

DELTA(d) *Cell delta value.* The value of delta is added to each cell frequency for the first iteration when estimating saturated models; it is ignored for unsaturated models. The default value is 0.5. You can specify any decimal value between 0 and 1 for *d*. HILOGLINEAR does not display parameter estimates or the covariance matrix of parameter estimates if any zero cells (either structural or sampling) exist in the expected table after delta is added.

CWEIGHT Subcommand

CWEIGHT specifies cell weights for a model. CWEIGHT is typically used to specify structural zeros in the table. You can also use CWEIGHT to adjust tables to fit new margins.

- You can specify the name of a variable whose values are cell weights, or provide a matrix of cell weights enclosed in parentheses.
- If you use a variable to specify cell weights, you are allowed only one CWEIGHT subcommand.
- If you specify a matrix, you must provide a weight for every cell in the contingency table, where the number of cells equals the product of the number of values of all variables.
- Cell weights are indexed by the values of the variables in the order in which they are specified on the variable list. The index values of the rightmost variable change the most quickly.
- You can use the notation *n*cw* to indicate that cell weight *cw* is repeated *n* times in the matrix.

Example

```
HILOGLINEAR V1(1,2) V2(1,2) V3(1,3)
  /CWEIGHT=CELLWGT
  /DESIGN=V1*V2, V2*V3, V1*V3.
```

- This example uses the variable *CELLWGT* to assign cell weights for the table. Only one CWEIGHT subcommand is allowed.

Example

```
HILOGLINEAR V4(1,3) V5(1,3)
  /CWEIGHT=(0 1 1  1 0 1  1 1 0)
  /DESIGN=V4, V5.
```

- The HILOGLINEAR command sets the diagonal cells in the model to structural zeros. This type of model is known as a **quasi-independence model**.
- Because both *V4* and *V5* have three values, weights must be specified for nine cells.
- The first cell weight is applied to the cell in which *V4* is 1 and *V5* is 1; the second weight is applied to the cell in which *V4* is 1 and *V5* is 2; and so on.

Example

```
HILOGLINEAR V4(1,3) V5(1,3)
  /CWEIGHT=(0 3*1 0 3*1 0)
  /DESIGN=V4,V5.
```

- This example is the same as the previous example except that the *n*cw* notation is used.

Example

```
* An Incomplete Rectangular Table

DATA LIST FREE / LOCULAR RADIAL FREQ.
WEIGHT BY FREQ.
BEGIN DATA
1 1 462
1 2 130
1 3 2
```

```
1 4 1
2 1 103
2 2 35
2 3 1
2 4 0
3 5 614
3 6 138
3 7 21
3 8 14
3 9 1
4 5 443
4 6 95
4 7 22
4 8 8
4 9 5
END DATA.
HILOGLINEAR LOCULAR (1,4) RADIAL (1,9)
  /CWEIGHT=(4*1 5*0   4*1 5*0   4*0 5*1   4*0 5*1)
  /DESIGN LOCULAR RADIAL.
```

- This example uses aggregated table data as input.
- The DATA LIST command defines three variables. The values of *LOCULAR* and *RADIAL* index the levels of those variables, so that each case defines a cell in the table. The values of *FREQ* are the cell frequencies.
- The WEIGHT command weights each case by the value of the variable *FREQ*. Because each case represents a cell in this example, the WEIGHT command assigns the frequencies for each cell.
- The BEGIN DATA and END DATA commands enclose the inline data.
- The HILOGLINEAR variable list specifies two variables. *LOCULAR* has values 1, 2, 3, and 4. *RADIAL* has integer values 1 through 9.
- The CWEIGHT subcommand identifies a block rectangular pattern of cells that are logically empty. There is one weight specified for each cell of the 36-cell table.
- In this example, the matrix form needs to be used in CWEIGHT because the structural zeros do not appear in the actual data. (For example, there is no case corresponding to *LOCULAR* = 1, *RADIAL* = 5.)
- The DESIGN subcommand specifies main effects only for *LOCULAR* and *RADIAL*. Lack of fit for this model indicates an interaction of the two variables.
- Because there is no PRINT or PLOT subcommand, HILOGLINEAR produces the default output for an unsaturated model.

PRINT Subcommand

PRINT controls the display produced for the subsequent designs.

- If PRINT is omitted or included with no specifications, the default display is produced.
- If any keywords are specified on PRINT, only output specifically requested is displayed.
- HILOGLINEAR displays Pearson and likelihood-ratio chi-square goodness-of-fit tests for models. For saturated models, it also provides tests that the *k*-way effects and the *k*-way and higher-order effects are 0.

- Both adjusted and unadjusted degrees of freedom are displayed for tables with sampling or structural zeros. *K*-way and higher-order tests use the unadjusted degrees of freedom.
- The unadjusted degrees of freedom are not adjusted for zero cells, and they estimate the upper bound of the true degrees of freedom. These are the same degrees of freedom you would get if all cells were filled.
- The adjusted degrees of freedom are calculated from the number of non-zero-fitted cells minus the number of parameters that would be estimated if all cells were filled (that is, unadjusted degrees of freedom minus the number of zero-fitted cells). This estimate of degrees of freedom may be too low if some parameters do not exist because of zeros.

DEFAULT	*Default displays*. This option includes FREQ and RESID output for nonsaturated models, and FREQ, RESID, ESTIM, and ASSOCIATION output for saturated models. For saturated models, the observed and expected frequencies are equal, and the residuals are zeros.
FREQ	*Observed and expected cell frequencies.*
RESID	*Raw and standardized residuals.*
ESTIM	*Parameter estimates for a saturated model.*
ASSOCIATION	*Partial associations*. You can request partial associations of effects only when you specify a saturated model. This option is computationally expensive for tables with many factors.
ALL	*All available output.*
NONE	*Design information and goodness-of-fit statistics only.* Use of this option overrides all other specifications on PRINT.

PLOT Subcommand

Use PLOT to request residuals plots.

- If PLOT is included without specifications, standardized residuals and normal probability plots are produced.
- No plots are displayed for saturated models.
- If PLOT is omitted, no plots are produced.

RESID	*Standardized residuals by observed and expected counts.*
NORMPLOT	*Normal probability plots of adjusted residuals.*
NONE	*No plots.* Specify NONE to suppress plots requested on a previous PLOT subcommand. This is the default if PLOT is omitted.
DEFAULT	*Default plots.* Includes RESID and NORMPLOT. This is the default when PLOT is specified without keywords.
ALL	*All available plots.*

MISSING Subcommand

By default, a case with either system-missing or user-missing values for any variable named on the HILOGLINEAR variable list is omitted from the analysis. Use MISSING to change the treatment of cases with user-missing values.

- MISSING can be named only once and can be placed anywhere following the variable list.
- MISSING cannot be used without specifications.
- A case with a system-missing value for any variable named on the variable list is always excluded from the analysis.

EXCLUDE	*Delete cases with missing values.* This is the default if the subcommand is omitted. You can also specify keyword DEFAULT.
INCLUDE	*Include user-missing values as valid.* Only cases with system-missing values are deleted.

DESIGN Subcommand

By default, HILOGLINEAR uses a saturated model that includes all variables on the variable list. The model contains all main effects and interactions for those variables. Use DESIGN to specify a different generating class for the model.

- If DESIGN is omitted or included without specifications, the default model is estimated. When DESIGN is omitted, a warning message is issued.
- To specify a design, list the highest-order terms, using variable names and asterisks (*) to indicate interaction effects.
- In a hierarchical model, higher-order interaction effects imply lower-order interaction and main effects. V1*V2*V3 implies the three-way interaction *V1* by *V2* by *V3*, two-way interactions *V1* by *V2*, *V1* by *V3*, and *V2* by *V3*, and main effects for *V1*, *V2*, and *V3*. The highest-order effects to be estimated are the generating class.
- Any PRINT, PLOT, CRITERIA, METHOD, and MAXORDER subcommands that apply to a DESIGN subcommand must appear before it.
- All variables named on DESIGN must be named or implied on the variable list.
- You can specify more than one DESIGN subcommand. One model is estimated for each DESIGN subcommand.
- If the last subcommand on HILOGLINEAR is not DESIGN, the default model will be estimated in addition to models explicitly requested. A warning message is issued for a missing DESIGN subcommand.

**Default if the subcommand or keyword is omitted.

This command reads the active dataset and causes execution of any pending commands. For more information, see Command Order on p. 36.

Example

```
HOMALS  VARIABLES=ACOLA(2) BCOLA(2) CCOLA(2) DCOLA(2).
```

Overview

HOMALS (*hom*ogeneity analysis by means of *a*lternating *l*east *s*quares) estimates category quantifications, object scores, and other associated statistics that separate categories (levels) of nominal variables as much as possible and divide cases into homogeneous subgroups.

Options

Data and variable selection. You can use a subset of the variables in the analysis and restrict the analysis to the first *n* observations.

Number of dimensions. You can specify the number of dimensions HOMALS should compute.

Iterations and convergence. You can specify the maximum number of iterations and the value of a convergence criterion.

Display output. The output can include all available statistics; just the default frequencies, eigenvalues, discrimination measures and category quantifications; or just the specific statistics you request. You can also control which statistics are plotted and specify the number of characters used in plot labels.

Saving scores. You can save object scores in the working data file.

Writing matrices. You can write a matrix data file containing category quantifications for use in further analyses.

Basic Specification

- The basic specification is HOMALS and the VARIABLES subcommand. By default, HOMALS analyzes all of the variables listed for all cases and computes two solutions. Frequencies, eigenvalues, discrimination measures, and category quantifications are displayed, and category quantifications and object scores are plotted.

Subcommand Order

- Subcommands can appear in any order.

Syntax Rules

- If ANALYSIS is specified more than once, HOMALS is not executed. For all other subcommands, if a subcommand is specified more than once, only the last occurrence is executed.

Operations

- HOMALS treats every value in the range of 1 to the maximum value specified on VARIABLES as a valid category. If the data are not sequential, the empty categories (categories with no valid data) are assigned zeros for all statistics. You may want to use RECODE or AUTORECODE before HOMALS to get rid of these empty categories and avoid the unnecessary output (see RECODE and AUTORECODE for more information).

Limitations

- String variables are not allowed; use AUTORECODE to recode string variables into numeric variables.
- The data (category values) must be positive integers. Zeros and negative values are treated as system-missing, which means that they are excluded from the analysis. Fractional values are truncated after the decimal and are included in the analysis. If one of the levels of a variable has been coded 0 or a negative value and you want to treat it as a valid category, use the AUTORECODE or RECODE command to recode the values of that variable.
- HOMALS ignores user-missing value specifications. Positive user-missing values less than the maximum value specified on the VARIABLES subcommand are treated as valid category values and are included in the analysis. If you do not want the category included, use COMPUTE or RECODE to change the value to something outside of the valid range. Values outside of the range (less than 1 or greater than the maximum value) are treated as system-missing and are excluded from the analysis.

Example

```
HOMALS  VARIABLES=ACOLA(2) BCOLA(2) CCOLA(2) DCOLA(2)
  /PRINT=FREQ EIGEN QUANT OBJECT.
```

- The four variables are analyzed using all available observations. Each variable has two categories, 1 and 2.
- The PRINT subcommand lists the frequencies, eigenvalues, category quantifications, and object scores.
- By default, plots of the category quantifications and the object scores are produced.

VARIABLES Subcommand

VARIABLES specifies the variables that will be used in the analysis.

- The VARIABLES subcommand is required. The actual word VARIABLES can be omitted.
- After each variable or variable list, specify in parentheses the maximum number of categories (levels) of the variables.
- The number specified in parentheses indicates the number of categories *and* the maximum category value. For example, *VAR1(3)* indicates that *VAR1* has three categories coded 1, 2, and 3. However, if a variable is not coded with consecutive integers, the number of categories used in the analysis will differ from the number of observed categories. For example, if a three-category variable is coded {2, 4, 6}, the maximum category value is 6. The analysis treats the variable as having six categories, three of which (categories 1, 3, and 5) are not observed and receive quantifications of 0.
- To avoid unnecessary output, use the AUTORECODE or RECODE command before HOMALS to recode a variable that does not have sequential values (see AUTORECODE and RECODE for more information).

Example

```
DATA LIST FREE/V1 V2 V3.
BEGIN DATA
3 1 1
6 1 1
3 1 3
3 2 2
3 2 2
6 2 2
6 1 3
6 2 2
3 2 2
6 2 1
END DATA.
AUTORECODE V1 /INTO NEWVAR1.
HOMALS VARIABLES=NEWVAR1 V2(2) V3(3).
```

- DATA LIST defines three variables, *V1*, *V2*, and *V3*.
- *V1* has two levels, coded 3 and 6, *V2* has two levels, coded 1 and 2, and *V3* has three levels, coded 1, 2, and 3.

- The AUTORECODE command creates *NEWVAR1* containing recoded values of *V1*. Values of 3 are recoded to 1; values of 6 are recoded to 2.
- The maximum category value for both *NEWVAR1* and *V2* is 2. A maximum value of 3 is specified for *V3*.

ANALYSIS Subcommand

ANALYSIS limits the analysis to a specific subset of the variables named on the VARIABLES subcommand.

- If ANALYSIS is not specified, all variables listed on the VARIABLES subcommand are used.
- ANALYSIS is followed by a variable list. The variables on the list must be specified on the VARIABLES subcommand.
- Variables listed on the VARIABLES subcommand but not on the ANALYSIS subcommand can still be used to label object scores on the PLOT subcommand.

Example

```
HOMALS VARIABLES=ACOLA(2) BCOLA(2) CCOLA(2) DCOLA(2)
  /ANALYSIS=ACOLA BCOLA
  /PRINT=OBJECT QUANT
  /PLOT=OBJECT(CCOLA).
```

- The VARIABLES subcommand specifies four variables.
- The ANALYSIS subcommand limits analysis to the first two variables. The PRINT subcommand lists the object scores and category quantifications from this analysis.
- The plot of the object scores is labeled with variable *CCOLA*, even though this variable is not included in the computations.

NOBSERVATIONS Subcommand

NOBSERVATIONS specifies how many cases are used in the analysis.

- If NOBSERVATIONS is not specified, all available observations in the working data file are used.
- NOBSERVATIONS is followed by an integer indicating that the first *n* cases are to be used.

DIMENSION Subcommand

DIMENSION specifies the number of dimensions you want HOMALS to compute.

- If you do not specify the DIMENSION subcommand, HOMALS computes two dimensions.
- The specification on DIMENSION is a positive integer indicating the number of dimensions.

- The minimum number of dimensions is 1.
- The maximum number of dimensions is equal to the smaller of the two values below:

MAXITER Subcommand

MAXITER specifies the maximum number of iterations HOMALS can go through in its computations.

- If MAXITER is not specified, HOMALS will iterate up to 100 times.
- The specification on MAXITER is a positive integer indicating the maximum number of iterations.

CONVERGENCE Subcommand

CONVERGENCE specifies a convergence criterion value. HOMALS stops iterating if the difference in total fit between the last two iterations is less than the CONVERGENCE value.

- If CONVERGENCE is not specified, the default value is 0.00001.
- The specification on CONVERGENCE is a positive value.

PRINT Subcommand

PRINT controls which statistics are included in your display output. The default display includes the frequencies, eigenvalues, discrimination measures, and category quantifications.

The following keywords are available:

FREQ	*Marginal frequencies for the variables in the analysis*.
HISTORY	*History of the iterations*.
EIGEN	*Eigenvalues*.
DISCRIM	*Discrimination measures for the variables in the analysis*.
OBJECT	*Object scores*.
QUANT	*Category quantifications for the variables in the analysis*.
DEFAULT	*FREQ, EIGEN, DISCRIM, and QUANT*. These statistics are also displayed when you omit the PRINT subcommand.
ALL	*All available statistics*.
NONE	*No statistics*.

PLOT Subcommand

PLOT can be used to produce plots of category quantifications, object scores, and discrimination measures.

- If PLOT is not specified, plots of the object scores and of the quantifications are produced.
- No plots are produced for a one-dimensional solution.

The following keywords can be specified on PLOT:

DISCRIM	*Plots of the discrimination measures.*
OBJECT	*Plots of the object scores.*
QUANT	*Plots of the category quantifications.*
DEFAULT	*QUANT and OBJECT.*
ALL	*All available plots.*
NONE	*No plots.*

- Keywords OBJECT and QUANT can each be followed by a variable list in parentheses to indicate that plots should be labeled with those variables. For QUANT, the labeling variables must be specified on both the VARIABLES and ANALYSIS subcommands. For OBJECT, the variables must be specified on the VARIABLES subcommand but need not appear on the ANALYSIS subcommand. This means that variables not used in the computations can be used to label OBJECT plots. If the variable list is omitted, the default object and quantification plots are produced.
- Object score plots labeled with variables that appear on the ANALYSIS subcommand use category labels corresponding to all categories within the defined range. Objects in a category that is outside the defined range are labeled with the label corresponding to the category immediately following the defined maximum category value.
- Object score plots labeled with variables not included on the ANALYSIS subcommand use all category labels, regardless of whether or not the category value is inside the defined range.
- All keywords except NONE can be followed by an integer value in parentheses to indicate how many characters of the variable or value label are to be used on the plot. (If you specify a variable list after OBJECT or QUANT, specify the value in parentheses after the list.) The value can range from 1 to 20; the default is to use 12 characters. Spaces between words count as characters.
- DISCRIM plots use variable labels; all other plots use value labels.
- If a variable label is not supplied, the variable name is used for that variable. If a value label is not supplied, the actual value is used.
- Variable and value labels should be unique.
- When points overlap, the points involved are described in a summary following the plot.

Example

```
HOMALS VARIABLES COLA1 (4) COLA2 (4) COLA3 (4) COLA4 (2)
/ANALYSIS COLA1 COLA2 COLA3 COLA4
/PLOT OBJECT(COLA4).
```

- Four variables are included in the analysis.
- OBJECT requests a plot of the object scores labeled with the values of *COLA4*. Any object whose *COLA4* value is not 1 or 2, is labeled 3 (or the value label for category 3, if supplied).

Example

```
HOMALS VARIABLES COLA1 (4) COLA2 (4) COLA3 (4) COLA4 (2)
```

```
/ANALYSIS COLA1 COLA2 COLA3
/PLOT OBJECT(COLA4).
```

- Three variables are included in the analysis.
- OBJECT requests a plot of the object scores labeled with the values of *COLA4,* a variable not included in the analysis. Objects are labeled using all values of *COLA4.*

In addition to the plot keywords, the following can be specified:

NDIM *Dimension pairs to be plotted.* NDIM is followed by a pair of values in parentheses. If NDIM is not specified, plots are produced for dimension 1 versus dimension 2.

- The first value indicates the dimension that is plotted against all higher dimensions. This value can be any integer from 1 to the number of dimensions minus 1.
- The second value indicates the highest dimension to be used in plotting the dimension pairs. This value can be any integer from 2 to the number of dimensions.
- Keyword ALL can be used instead of the first value to indicate that all dimensions are paired with higher dimensions.
- Keyword MAX can be used instead of the second value to indicate that plots should be produced up to and including the highest dimension fit by the procedure.

Example

```
HOMALS COLA1 COLA2 COLA3 COLA4 (4)
 /PLOT NDIM(1,3) QUANT(5).
```

- The NDIM(1,3) specification indicates that plots should be produced for two dimension pairs—dimension 1 versus dimension 2 and dimension 1 versus dimension 3.
- QUANT requests plots of the category quantifications. The (5) specification indicates that the first five characters of the value labels are to be used on the plots.

Example

```
HOMALS COLA1 COLA2 COLA3 COLA4 (4)
 /PLOT NDIM(ALL,3) QUANT(5).
```

- This plot is the same as above except for the ALL specification following NDIM. This indicates that all possible pairs up to the second value should be plotted, so QUANT plots will be produced for dimension 1 versus dimension 2, dimension 2 versus dimension 3, and dimension 1 versus dimension 3.

SAVE Subcommand

SAVE lets you add variables containing the object scores computed by HOMALS to the working data file.

- If SAVE is not specified, object scores are not added to the working data file.

- A variable rootname can be specified on the SAVE subcommand to which HOMALS adds the number of the dimension. Only one rootname can be specified and it can contain up to six characters.
- If a rootname is not specified, unique variable names are automatically generated. The variable names are *HOMn_m*, where *n* is a dimension number and *m* is a set number. If three dimensions are saved, the first set of names is *HOM1_1*, *HOM2_1*, and *HOM3_1*. If another HOMALS is then run, the variable names for the second set are *HOM1_2*, *HOM2_2*, *HOM3_2*, and so on.
- Following the rootname, the number of dimensions for which you want to save object scores can be specified in parentheses. The number cannot exceed the value on the DIMENSION subcommand.
- If the number of dimensions is not specified, the SAVE subcommand saves object scores for all dimensions.
- If you replace the working data file by specifying an asterisk (*) on a MATRIX subcommand, the SAVE subcommand is not executed.

Example

```
HOMALS CAR1 CAR2 CAR3 CAR4(5)
 /DIMENSION=3
 /SAVE=DIM(2).
```

- Four variables, each with five categories, are analyzed.
- The DIMENSION subcommand specifies that results for three dimensions will be computed.
- SAVE adds the object scores from the first two dimensions to the working data file. The names of these new variables will be *DIM00001* and *DIM00002*, respectively.

MATRIX Subcommand

The MATRIX subcommand is used to write category quantifications to a matrix data file or a previously declared dataset name (DATASET DECLARE command).

- The specification on MATRIX is keyword OUT and a quoted file specification of dataset name, enclosed in parentheses.
- You can specify an asterisk (*) replace the active dataset.
- The matrix data file has one case for each value of each original variable.

The variables of the matrix data file and their values are:

ROWTYPE_	*String variable containing value QUANT for all cases.*
LEVEL	*String variable LEVEL containing the values (or value labels if present) of each original variable.*
VARNAME_	*String variable containing the original variable names.*
DIM1...DIMn	*Numeric variable containing the category quantifications for each dimension.* Each variable is labeled *DIMn*, where *n* represents the dimension number.

HOST

Note: Square brackets used in the HOST syntax chart are required parts of the syntax and are not used to indicate optional elements. Equals signs (=) used in the syntax chart are required elements.

```
HOST COMMAND=['command' 'command'...'command']
  TIMELIMIT=n.
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Release History

Release 13.0

- Command introduced.

Example

```
HOST COMMAND=['dir c:\myfiles\*.sav'].
```

Overview

The HOST command executes external commands at the operating system level. For a Windows operating system, for example, this is equivalent to running commands from a command prompt in a command window.

- No output is displayed in a command window. Output is either displayed in the Viewer or redirected as specified in the operating system command.
- Standard output is either displayed in a text object in the Viewer window or redirected as specified in the operating system command.
- Standard errors are displayed as text objects in the Viewer.
- Commands that return a prompt for user input result in an EOF condition without waiting for any user input (unless input has been redirected to read from a file).
- A command that generates an error condition terminates the HOST command, and no subsequent commands specified on the HOST command are executed.
- The HOST command runs synchronously. Commands that launch applications result in the suspension of further SPSS processing until the application finishes execution, unless you also specify a time limit (see keyword TIMELIMIT on p. 874). For example, in Windows operating systems, if a file extension is associated with an application, simply specifying a file a name an extension on the command line will launch the associated application, and no further commands will be executed until the application is closed.

- The HOST command starts in the current working directory. By default, the initial working directory is the installation directory.
- In distributed analysis mode (available with SPSS Server), file paths in command specifications are relative to the remote server.

Syntax

The minimum specification is the command name HOST, followed by the keyword COMMAND, an equals sign (=), and one or more operating system level commands, each enclosed in quotes, with the entire set of commands enclosed in square brackets.

Example

```
HOST COMMAND=['dir c:\myfiles\*.sav'
              'dir c:\myfiles\*.sps > c:\myfiles\command_files.txt'
              'copy c:\myfiles\file1.txt > c:\myfiles\file2.txt'
              'dur c:\myfiles\*.xml > c:\myfiles\xmlfiles.txt'
              'c:\myfiles\myjobs\report.bat'].
```

- The directory listing for all *.sav* files is displayed in a text output object in the Viewer window.
- The directory listing for *.sps* files is redirected to a text file; so no output is displayed in the Viewer window.
- If *file2.txt* does not already exist, the copy command will copy the contents of *file1.txt* to a new file called *file2.txt*. If *file2.txt* exists, the copy command will not be executed since this would result in a user prompt asking for the user to confirm overwriting the file.
- The invalid dur command generates an error, which is displayed in the Viewer, and no output for that command is redirected to specified text file.
- The error condition caused by the invalid dur command terminates the HOST command, and *report.bat* is not run.

Quoted Strings

If the command at the operating system level uses quoted strings, the standard rules for quoted strings within quoted strings apply. In general, use double-quotes to enclose a string that includes a string enclosed in single quotes, and vice-versa. For more information, see String Values in Command Specifications on p. 35.

TIMELIMIT Keyword

The optional TIMELIMIT keyword sets a time limit in seconds for execution of the bracketed list of commands. Fractional time values are rounded to the nearest integer.

Example

```
HOST COMMAND=['c:\myfiles\report.bat'] TIMELIMIT=10.
```

Using TIMELIMIT to Return Control

Since the HOST command runs synchronously, commands that launch applications result in the suspension of further SPSS processing until the application finishes execution. That means that any commands that follow the HOST command will not be executed until any applications launched by the command are closed.

Example

```
OMS /DESTINATION FORMAT=HTML
  OUTFILE='c:\temp\temp.htm'.
FREQUENCIES VARIABLES=ALL.
OMSEND.
HOST COMMAND=['c:\temp\temp.htm'].
DESCRIPTIVES VARIABLES=ALL.
```

- On Windows operating systems, if the *.htm* extension is associated with an application (typically Internet Explorer), the HOST command in this example will launch the associated application.
- In the absence of a TIMELIMIT specification, the subsequent DESCRIPTIVES command will not be executed until the application launched by the HOST command is closed.

To make sure control is automatically returned to SPSS and subsequent commands are executed, include a TIMELIMIT value, as in:

```
OMS /DESTINATION FORMAT=HTML
  OUTFILE='c:\temp\temp.htm'.
FREQUENCIES VARIABLES=ALL.
OMSEND.
HOST COMMAND=['c:\temp\temp.htm'] TIMELIMIT=5.
DESCRIPTIVES VARIABLES=ALL.
```

Working Directory

The HOST command starts in the current working directory. By default, the initial working directory is the installation directory. So, for example, HOST COMMAND=['dir'] executed at the start of a session would typically return a directory listing of the installation directory. The working directory can be changed, however, by the CD command and the CD keyword of the INSERT command.

Example

```
*start of session.
HOST COMMAND=['dir']. /*lists contents of install directory.
CD 'c:\temp'.
HOST COMMAND=['dir']. /*lists contents of c:\temp directory.
```

UNC Paths on Windows Operating Systems

To start in the SPSS working directory, the HOST command actually issues an OS-level CD command that specifies the SPSS working directory. On Windows operating systems, if you use UNC path specifications of the general form:

```
\\servername\sharename\path
```

on SPSS commands such as CD or INSERT to set the working directory location, the HOST command will fail because UNC paths are not valid on the Windows CD command.

Example

```
INSERT FILE='\\hqserver\public\report.sps' CD=YES.
HOST ['dir'].
```

- The INSERT command uses a UNC path specification, and CD=YES makes that directory the working directory.
- The subsequent HOST command will generate an OS-level error message that says the current directory path is invalid because UNC paths are not supported.

IF

```
IF [()]logical expression[)] target variable=expression
```

This command does not read the active dataset. It is stored, pending execution with the next command that reads the dataset. For more information, see Command Order on p. 36.

The following relational operators can be used in logical expressions:

Symbol	Definition
EQ or =	Equal to
NE or ~= or ¬ = or <>	Not equal to
LT or <	Less than
LE or <=	Less than or equal to
GT or >	Greater than
GE or >=	Greater than or equal to

The following logical operators can be used in logical expressions:

Symbol	Definition
AND or &	Both relations must be true
OR or |	Either relation can be true
NOT	Reverses the outcome of an expression

Example

```
IF (AGE > 20 AND SEX = 1) GROUP=2.
```

Overview

IF conditionally executes a single transformation command based upon logical conditions found in the data. The transformation can create a new variable or modify the values of an existing variable for each case in the active dataset. You can create or modify the values of both numeric and string variables. If you create a new string variable, you must first declare it on the STRING command.

IF has three components: a *logical expression* that sets up the logical criteria, a *target variable* (the one to be modified or created), and an *assignment expression.* The target variable's values are modified according to the assignment expression.

IF is most efficient when used to execute a single, conditional, COMPUTE-like transformation. If you need multiple IF statements to define the condition, it is usually more efficient to use the RECODE command or a DO IF–END IF structure.

Basic Specification

The basic specification is a logical expression followed by a target variable, a required equals sign, and the assignment expression. The assignment is executed only if the logical expression is true.

Syntax Rules

- Logical expressions can be simple logical variables or relations, or complex logical tests involving variables, constants, functions, relational operators, and logical operators. Both the logical expression and the assignment expression can use any of the numeric or string functions allowed in `COMPUTE` transformations.
- Parentheses can be used to enclose the logical expression. Parentheses can also be used within the logical expression to specify the order of operations. Extra blanks or parentheses can be used to make the expression easier to read.
- A relation can compare variables, constants, or more complicated arithmetic expressions. Relations cannot be abbreviated. For example, `(A EQ 2 OR A EQ 5)` is valid, while `(A EQ 2 OR 5)` is not. Blanks (not commas) must be used to separate relational operators from the expressions being compared.
- A relation cannot compare a string variable to a numeric value or variable, or vice versa. A relation cannot compare the result of the logical functions `SYSMIS`, `MISSING`, `ANY`, or `RANGE` to a number.
- String values used in expressions must be specified in quotes and must include any leading or trailing blanks. Lowercase letters are considered distinct from uppercase letters.
- String variables that are used as target variables must already exist. To declare a new string variable, first create the variable with the `STRING` command and then specify the new variable as the target variable on `IF`.

Examples

IF with Numeric Values

```
IF (AGE > 20 AND SEX = 1) GROUP=2.
```

- The numeric variable *GROUP* is set to 2 for cases where *AGE* is greater than 20 *and SEX* is equal to 1.
- When the expression is false or missing, the value of *GROUP* remains unchanged. If *GROUP* has not been previously defined, it contains the system-missing value.

IF with String Values

```
IF (SEX EQ 'F') EEO=QUOTA+GAIN.
```

- The logical expression tests the string variable *SEX* for the value *F*.
- When the expression is true (when *SEX* equals *F*), the value of the numeric variable *EEO* is assigned the value of *QUOTA* plus *GAIN*. Both *QUOTA* and *GAIN* must be previously defined numeric variables.

- When the expression is false or missing (for example, if *SEX* equals *F*), the value of *EEO* remains unchanged. If *EEO* has not been previously defined, it contains the system-missing value.

Conditional Expressions with Arithmetic Operations

```
COMPUTE V3=0.
IF ((V1-V2) LE 7) V3=V1**2.
```

- COMPUTE assigns *V3* the value 0.
- The logical expression tests whether *V1* minus *V2* is less than or equal to 7. If it is, the value of *V3* is assigned the value of *V1* squared. Otherwise, the value of *V3* remains at 0.

Conditional Expressions with Arithmetic Operations and Functions

```
IF (ABS(A-C) LT 100) INT=100.
```

- IF tests whether the absolute value of the variable *A* minus the variable *C* is less than 100. If it is, *INT* is assigned the value 100. Otherwise, the value is unchanged. If *INT* has not been previously defined, it is system-missing.

Testing for Missing Values

```
* Test for listwise deletion of missing values.

DATA LIST  /V1 TO V6 1-6.
STRING SELECT(A1).
COMPUTE SELECT='V'.
VECTOR V=V1 TO V6.

LOOP #I=1 TO 6.
IF MISSING(V(#I)) SELECT='M'.
END LOOP.

BEGIN DATA
123456
    56
1 3456
123456
123456
END DATA.

FREQUENCIES VAR=SELECT.
```

- STRING creates the string variable *SELECT* with an A1 format and COMPUTE sets the value of *SELECT* to *V*.
- VECTOR defines the vector *V* as the original variables *V1* to *V6*. Variables on a single vector must be all numeric or all string variables. In this example, because the vector *V* is used as an argument on the MISSING function of IF, the variables must be numeric (MISSING is not available for string variables).
- The loop structure executes six times: once for each VECTOR element. If a value is missing for any element, SELECT is set equal to *M*. In effect, if any case has a missing value for any of the variables *V1* to *V6*, SELECT is set to *M*.

- FREQUENCIES generates a frequency table for SELECT. The table gives a count of how many cases have missing values for at least one variable and how many cases have valid values for all variables. This table can be used to determine how many cases would be dropped from an analysis that uses listwise deletion of missing values.

Example

```
IF YRHIRED LT 1980 RATE=0.02.
IF DEPT='SALES' DIVISION='TRANSFERRED'.
```

- The logical expression on the first IF command tests whether *YRHIRED* is less than 1980 (hired before 1980). If so, the variable *RATE* is set to 0.02.
- The logical expression on the second IF command tests whether *DEPT* equals *SALES*. When the condition is true, the value for the string variable *DIVISION* is changed to *TRANSFERRED* but is truncated if the format for *DIVISION* is not at least 11 characters wide. For any other value of *DEPT*, the value of *DIVISION* remains unchanged.
- Although there are two IF statements, each defines a separate and independent condition. The IF command is used rather than the DO IF–END IF structure in order to test both conditions on every case. If DO IF–END IF is used, control passes out of the structure as soon as the first logical condition is met.

Example

```
IF (STATE EQ 'IL' AND CITY EQ 13) COST=1.07 * COST.
```

- The logical expression tests whether *STATE* equals *IL* and *CITY* equals 13.
- If the logical expression is true, the numeric variable *COST* is increased by 7%.
- For any other value of *STATE* or *CITY*, the value of *COST* remains unchanged.

Example

```
STRING GROUP (A18).
IF (HIRED GE 1988) GROUP='Hired after merger'.
```

- STRING declares the string variable *GROUP* and assigns it a width of 18 characters.
- When *HIRED* is greater than or equal to 1988, *GROUP* is assigned the value *Hired after merger*. When *HIRED* is less than 1988, *GROUP* remains blank.

Example

```
IF (RECV GT DUE OR (REVNUES GE EXPNS AND BALNCE GT 0))STATUS='SOLVENT'.
```

- First, the program tests whether *REVNUES* is greater than or equal to *EXPNS* and whether *BALNCE* is greater than 0.
- Second, the program evaluates if *RECV* is greater than *DUE*.
- If either of these expressions is true, *STATUS* is assigned the value *SOLVENT*.
- If both expressions are false, *STATUS* remains unchanged.

- *STATUS* is an existing string variable in the active dataset. Otherwise, it would have to be declared on a preceding STRING command.

Operations

- Each IF command evaluates every case in the data. Compare IF with DO IF, which passes control for a case out of the DO IF–END IF structure as soon as a logical condition is met.
- The logical expression is evaluated as true, false, or missing. The assignment is executed only if the logical expression is true. If the logical expression is false or missing, the assignment is not made. Existing target variables remain unchanged; new numeric variables retain their initial (system-missing) values.
- In general, a logical expression is evaluated as missing if any one of the variables used in the logical expression is system- or user-missing. However, when relations are joined by the logical operators AND or OR, the expression can sometimes be evaluated as true or false even when variables have missing values. For more information, see Missing Values and Logical Operators on p. 881.

Numeric Variables

- Numeric variables created with IF are initially set to the system-missing value. By default, they are assigned an F8.2 format.
- Logical expressions are evaluated in the following order: functions, followed by exponentiation, arithmetic operations, relations, and logical operators. When more than one logical operator is used, NOT is evaluated first, followed by AND, and then OR. You can change the order of operations using parentheses.
- Assignment expressions are evaluated in the following order: functions, then exponentiation, and then arithmetic operators.

String Variables

- New string variables declared on IF are initially set to a blank value and are assigned the format specified on the STRING command that creates them.
- Logical expressions are evaluated in the following order: string functions, then relations, and then logical operators. When more than one logical operator is used, NOT is evaluated first, followed by AND, and then OR. You can change the order of operations using parentheses.
- If the transformed value of a string variable exceeds the variable's defined width, the transformed value is truncated. If the transformed value is shorter than the defined width, the string is right-padded with blanks.

Missing Values and Logical Operators

When two or more relations are joined by logical operators AND or OR, the program always returns a missing value if all of the relations in the expression are missing. However, if any one of the relations can be determined, the program interprets the expression as true or false according to the logical outcomes below. The asterisk flags expressions where the program can evaluate the outcome with incomplete information.

Table 103-1
Logical outcomes

Expression	**Outcome**	**Expression**	**Outcome**
true AND true	= true	true OR true	= true
true AND false	= false	true OR false	= true
false AND false	= false	false OR false	= false
true AND missing	= missing	true OR missing	= true*
missing AND missing	= missing	missing OR missing	= missing
false AND missing	= false*	false OR missing	= missing

Release History

Release 16.0

- X2LENGTH subcommand is ignored.
- ChartLook *.clo* files are no longer supported by the CHARTLOOK subcommand. Use chart templates (*.sgt* files) instead.
- COINCIDENT keyword for the SCATTER subcommand can no longer specify a jittering amount.
- SHAPE keyword for the BAR subcommand is ignored. The shape of the bars is always a rectangle.
- BARBASE keyword for the BAR subcommand is ignored.
- CLUSTER keyword for the PIE subcommand is now an alias for STACK.
- TEXTIN and NUMIN are ignored by the SLICE keyword for the PIE subcommand.
- Label position values (URIGHT, LRIGHT, ULEFT, and LLEFT) are ignored by STACK keyword for the PIE subcommand. The position is always an optimal one.
- BOXBASE keyword for the BOX subcommand is ignored.

- FANCY value is ignored by the WHISKER keyword for the BOX subcommand.
- LAGRANGE3 and LAGRANGE5 values are now aliases for SPLINE for the INTERPOLATE keyword for the LINE subcommand.
- DIRECTION keyword is ignored by the ERRORBAR subcommand. Error bars always extend both above and below the mean values.
- FANCY value is ignored by the CAPSTYLE keyword for the ERRORBAR subcommand.
- TOTAL and MEFFECT values are ignored by the CENTROID keyword for the SPIKE subcommand. Spikes are always drawn to subgroup means.

Example

```
IGRAPH
    /VIEWNAME='Scatterplot'
    /X1=VAR(trial1) TYPE=SCALE
    /Y=VAR(trial3) TYPE=SCALE
    /X2=VAR(trial2) TYPE=SCALE
    /COORDINATE=THREE
    /X1LENGTH=3.0
    /YLENGTH=3.0
    /SCATTER COINCIDENT=NONE
    /FITLINE METHOD=REGRESSION LINEAR INTERVAL(90.0)=MEAN  LINE=TOTAL.
```

Overview

The interactive Chart Editor is designed to emulate the experience of drawing a statistical chart with a pencil and paper. The Chart Editor is a highly interactive, direct manipulation environment that automates the data manipulation and drawing tasks required to draw a chart by hand, such as determining data ranges for axes; drawing ticks and labels; aggregating and summarizing data; drawing data representations such as bars, boxes, or clouds; and incorporating data dimensions as legends when the supply of dependent axes is exhausted.

The IGRAPH command creates a chart in an interactive environment. The interactive Chart Editor allows you to make extensive and fundamental changes to this chart instead of creating a new chart. The Chart Editor allows you to replace data, add new data, change dimensionality, create separate chart panels for different groups, or change the way data are represented in a chart (that is, change a bar chart into a boxplot). The Chart Editor is not a "typed" chart system. You can use chart elements in any combination, and you are not limited by "types" that the application recognizes.

To create a chart, you assign data dimensions to the domain (independent) and range (dependent) axes to create a "data region." You also add data representations such as bars or clouds to the data region. Data representations automatically position themselves according to the data dimensions assigned to the data region.

There is no required order for assigning data dimensions or adding data representations; you can add the data dimensions first or add the data representations first. When defining the data region, you can define the range axis first or the domain axis first.

Options

Titles and Captions. You can specify a title, subtitle, and caption for the chart.

Chart Type. You can request a specific type of chart using the BAR, PIE, BOX, LINE, ERRORBAR, HISTOGRAM, and SCATTERPLOT subcommands.

Chart Content. You can combine elements in a single chart. For example, you can add error bars to a bar chart.

Chart Legends. You can specify either scale legends or categorical legends. Moreover, you can specify whether a color or style is used to distinguish the legend variables.

Chart Appearance. You can specify a template, using the CHARTLOOK subcommand, to override the default chart attribute settings.

Basic Specification

The minimum syntax to create a graph is simply the IGRAPH command, without any variable assignment. This will create an empty graph. To create an element in a chart, a dependent variable must be assigned and a chart element specified.

Subcommand Order

- Subcommands can be used in any order.

Syntax Rules

- EFFECT=THREE and COORDINATE=THREE cannot be specified together. If they are, the EFFECT keyword will be ignored.

Operations

- The chart title, subtitle, and caption are assigned as they are specified on the TITLE, SUBTITLE, and CAPTION subcommands. In the absence of any of these subcommands, the missing title, subtitle, or caption are null.

General Syntax

Following are the most general-purpose subcommands. Even so, not all plots will use all subcommands. For example, if the only element in a chart is a bar, the SIZE subcommand will not be shown in the graph.

Each general subcommand may be specified only once. If one of these subcommands appears more than once, the last one is used.

X1, Y, and X2 Subcommands

X1 and Y, and X2 assign variables to the *X1*, *Y*, and *X2* dimensions of the chart.

- The variable must be enclosed in parentheses after the VAR keyword.

- Each of these subcommands can include the TITLE keyword, specifying a string with which to title the corresponding axis.
- Each variable must be either a scale variable, a categorical variable, or a built-in data dimension. If a type is not specified, a default type is used from the variable's definition.

SCALE	A scale dimension is interpreted as a measurement on some continuous scale for each case. Optionally, the minimum (MIN) and maximum (MAX) scale values can be specified. In the absence of MIN and MAX, the entire data range is used.
CATEGORICAL	A categorical dimension partitions cases into exclusive groups (each case is a member of exactly one group). The categories are represented by evenly spaced ticks.

A built-in dimension is a user interface object used to create a chart of counts or percentages and to make a casewise chart of elements that usually aggregate data like bars or lines. The built-in dimensions are count ($COUNT), percentage ($PCT), and case ($CASE).

- To create a chart that displays counts or percentages, one of the built-in data dimensions is assigned to the range (*Y*) axis. The VAR keyword is not used for built-in dimensions.
- Built-in count and percentage data dimensions cannot be assigned to a domain axis (*X1* or *X2*) or to a legend subcommand.
- The count and percentage data dimensions are all scales and cannot be changed into categorizations.

CATORDER Subcommand

The CATORDER subcommand defines the order in which categories are displayed in a chart and controls the display of empty categories, based on the characteristics of a variable specified in parenthesis after the subcommand name.

- You can display categories in ascending or descending order based on category values, category value labels, counts, or values of a summary variable.
- You can either show or hide empty categories (categories with no cases).

Keywords for the CATORDER subcommand include:

ASCENDING	*Display categories in ascending order of the specified order keyword.*
DESCENDING	*Display categories in descending order of the specified order keyword.*
SHOWEMPTY	*Include empty categories in the chart.*
OMITEMPTY	*Do not include empty categories in the chart.*

ASCENDING and DESCENDING are mutually exclusive. SHOWEMPTY and OMITEMPTY are mutually exclusive.

Order keywords include:

COUNT	*Sort categories based on the number of observations in each category.*
OCCURRENCE	*Sort categories based on the first occurrence of each unique value in the data file.*

LABEL	*Sort categories based on defined value labels for each category.* For categories without defined value labels, the category value is used.
VALUE	*Sort categories based on the values of the categories or the values of a specified summary function for the specified variable.* For more information, see Summary Functions on p. 904.

Order keywords are mutually exclusive. You can specify only one order keyword on each CATORDER subcommand.

X1LENGTH, YLENGTH, and X2LENGTH Subcommands

X1LENGTH and YLENGTH define the length in inches of the chart size in the direction of the corresponding axis. X2LENGTH is no longer supported and is ignored.

Example

```
IGRAPH
    /VIEWNAME='Scatterplot'
    /Y=VAR(sales96) TYPE=SCALE
    /X1=VAR(sales95) TYPE=SCALE
    /X2=VAR(region) TYPE=CATEGORICAL
    /X1LENGTH=2.39
    /YLENGTH=2.42
    /SCATTER.
```

- Y assigns *sales96* to the dependent axis, defining it to be continuous.
- X1 assigns *sales95* to the *X1* axis, defining it to be a scale variable (continuous).
- X1LENGTH and YLENGTH define the width and height of the chart in inches.

NORMALIZE Subcommand

The NORMALIZE subcommand creates 100% stacking for counts and converts statistics to percents. It has no additional specifications. This subcommand is valid only with the SUM, SUMAV, and SUMSQ summary functions or the $count and $pct built-in dimensions.

COLOR, STYLE, and SIZE Subcommands

COLOR, STYLE, and SIZE specify variables used to create a legend. Each value of these variables corresponds to a unique property of the chart. The effect of these variables depends on the type of chart.

- Most charts use color in a similar fashion; casewise elements draw each case representation using the color value for the case, and summary elements draw each group representation in the color that represents a summarized value in the color data dimension.
- For dot-line charts, dot charts, and scatterplots, symbol shape is used for style variables and symbol size is used for size variables.

- For line charts and lines in a scatterplot, dash patterns encode style variables and line thickness encodes size variables.
- For bar charts, pie charts, boxplots, histograms, and error bars, fill pattern encodes style variables. Typically, these charts are not sensitive to size variables.

CATEGORICAL legend variables split the elements in the chart into categories. A categorical legend shows the reader which color, style, or size is associated with which category of the variable. The colors, styles, or sizes are assigned according to the discrete categories of the variable.

SCALE legend variables apply color or size to the elements by the value or a summary value of the legend variable, creating a continuum across the values. COLOR and SIZE can create either scale legends or categorical legends. STYLE can create categorical legends only.

Scale variables have the following keywords:

MIN	*Defines the minimum value of the scale.*
MAX	*Defines the maximum value of the scale.*

- The keywords MIN and MAX and their assigned values must be enclosed in parentheses.

In addition, the following keywords are available for COLOR, STYLE, and SIZE:

LEGEND	*Determines if the legend is displayed or not.* The legend explains how to decode color, size, or style in a chart.
TITLE	*Specifies a string used to title the legend.*

The following keywords are available for COLOR and STYLE:

CLUSTER	*Creates clustered charts based on color or size variables.*
STACK	*Creates stacked charts based on color or size variables.*

CLUSTER and STACK are mutually exclusive. Only one can be specified. Also, CLUSTER should not be used for *both* COLOR and STYLE.

Example

```
IGRAPH
    /VIEWNAME='Scatterplot'
    /Y=VAR(sales96) TYPE=SCALE
    /X1=VAR(sales95) TYPE=SCALE
    /X2=VAR(region) TYPE=CATEGORICAL
    /COLOR=VAR(tenure) TYPE=SCALE
    /STYLE=VAR(vol94)
    /SCATTER.
```

- The chart contains a three-dimensional scatterplot.
- COLOR defines a scale legend corresponding to the variable *TENURE*. Points appear in a continuum of colors, with the point color reflecting the value of *TENURE*.
- STYLE defines a categorical legend. Points appear with different shapes, with the point shape reflecting the value of *VOL94*.

CLUSTER Subcommand

CLUSTER defines the variable used to create clustered pie charts. The variable specified must be categorical. The cluster will contain as many pies as there are categories in the cluster variable.

SUMMARYVAR Subcommand

SUMMARYVAR specifies the variable or function for summarizing a pie element. It can only have the built-in variables $COUNT or $PCT or a user-defined variable name.

Specifying a user-defined variable on SUMMARYVAR requires specifying a summary function on the PIE subcommand. Valid summary functions include SUM, SUMAV, SUMSQ, NLT(x), NLE(x), NEQ(x), NGT(x), and NGE(x). The slices of the pie represent categories defined by the values of the summary function applied to SUMMARYVAR.

PANEL Subcommand

PANEL specifies a categorical variable or variables for which separate charts will be created.

- Specifying a single panel variable results in a separate chart for each level of the panel variable.
- Specifying multiple panel variables results in a separate chart for each combination of levels of the panel variables.

POINTLABEL Subcommand

POINTLABEL specifies a variable used to label points in a boxplot or scatterplot.

- If a label variable is specified without ALL or NONE, no labels are turned on (NONE).
- The keyword NONE turns all labels off.

CASELABEL Subcommand

CASELABEL specifies a variable used to label cases in a chart of individual cases. For example, if you were creating a bar chart whose *x* axis specification was $case, CASELABEL would specify the content of the tick labels that appear on the *x* axis.

COORDINATE Subcommand

COORDINATE specifies the orientation of the chart.

HORIZONTAL	*The* Y *variable appears along the horizontal axis and the* X1 *variable appears along the vertical axis.*
VERTICAL	*The* Y *variable appears along the vertical axis and the* X1 *variable appears along the horizontal axis.*
THREE	*Create a three-dimensional chart.* Three-dimensional charts have a default orientation that cannot be altered.

Example

```
IGRAPH
    /VIEWNAME='Scatterplot'
    /Y=VAR(sales96) TYPE=SCALE
    /X1=VAR(region) TYPE=CATEGORICAL
    /COORDINATE=HORIZONTAL
    /BAR (mean).
```

- The COORDINATE subcommand defines the bar chart as horizontal with *region* on the vertical dimension and means of *sales96* on the horizontal dimension.

EFFECT Subcommand

EFFECT displays a two-dimensional chart with additional depth along a third dimension. Two-dimensional objects other than points are displayed as three-dimensional solids.

- EFFECT is unavailable for three-dimensional charts.

TITLE, SUBTITLE, and CAPTION Subcommands

TITLE, SUBTITLE, and CAPTION specify lines of text placed at the top or bottom of a chart.

- Multiple lines of text can be entered using the carriage control character (\n).
- Each title, subtitle, or caption must be enclosed in apostrophes or quotation marks.
- The maximum length of a title, subtitle, or caption is 255 characters.
- The font, point size, color, alignment, and orientation of the title, subtitle, and caption text is determined by the ChartLook.

VIEWNAME Subcommand

VIEWNAME assigns a name to the chart, which will appear in the outline pane of the Viewer. The name can have a maximum of 255 characters.

CHARTLOOK Subcommand

CHARTLOOK identifies a template file containing specifications concerning the initial visual properties of a chart, such as fill, color, font, style, and symbol. By specifying a template, you can control cosmetic properties that are not explicitly available as syntax keywords.

Valid template files have an *.sgt* extension (old ChartLook *.clo* files are no longer supported). Files designated on CHARTLOOK must either be included with the software or created in the Chart Editor by saving a chart as a template.

You can specify multiple templates by listing them in square brackets and separating each file name with a space (for example, CHARTLOOK=['template1.sgt' 'template2.sgt']). Templates are applied in the order in which they appear. If any of the settings in multiple templates conflict, the settings in the last template override the conflicting settings in previous templates.

A template contains values for the following properties:

- Color sequence for categorical color legends

- Color range for scale color legends
- Line style sequence for categorical style legends
- Symbol style sequence for categorical style legends
- Categorical legend fill styles
- Categorical symbol size sequence for categorical size legends
- Symbol size sequence for scale size sequences
- Categorical line weight sequence for categorical size legends
- Font, size, alignment, bold, and italic properties for text objects
- Fill and border for filled objects
- Style, weight, and color for line objects
- Font, shape, size, and color for symbol objects
- Style, weight, and color for visual connectors
- Axis properties: axis line style, color, and weight; major tick shape, location, color, and size

Example

```
IGRAPH
    /VIEWNAME='Slide 1'
    /X1=VAR(sales95) TYPE=SCALE
    /Y=VAR(sales96) TYPE=SCALE
    /X2=VAR(region) TYPE=CATEGORICAL
    /COORDINATE=THREE
    /POINTLABEL=VAR(division) NONE
    /TITLE='Scatterplot Comparing Regions'
    /SUBTITLE='Predicting 1996 Sales\nfrom 1995 Sales'
    /CHARTLOOK='Classic.sgt'
    /SCATTER.
```

- `VIEWNAME` assigns the name *Slide 1* to the chart. The outline pane of the Viewer uses this name for the chart.
- Points in the chart are labeled with the values of *division*. Initially, all labels are off. Labels for individual points can be turned on interactively after creating the chart.
- `TITLE` and `SUBTITLE` define text to appear of the plot. The subtitle contains a carriage return between *Sales* and *from*.
- The appearance of the chart is defined in the Classic template.

REFLINE Subcommand

The `REFLINE` subcommand inserts a reference line for the specified variable at the specified value. Optional keywords are:

LABEL={ON|OFF} *Display a label for the reference line.* For variables with defined value labels, the value label for the specified value is displayed. If there is no defined value label for the specified value, the specified value is displayed.

SPIKE={ON|OFF} *Display spikes from the reference line to individual data points.*

Example

```
IGRAPH
  /X1 = VAR(gender) TYPE = CATEGORICAL
  /Y = VAR(salary) TYPE = SCALE
  /BAR(MEAN)
  /REFLINE salary 30000 LABEL=ON.
```

SPIKE Subcommand

The SPIKE subcommand inserts spikes from individual data points to the specified location. Keywords for location include:

X1	*Display spikes to the* X1 *axis.*
X2	*Display spikes to the* X2 *axis.*
Y	*Display spikes to the* Y *axis.*
CORNER	*Display spikes to the corner defined by the lowest displayed values of the* X1, X2, *and* Y *axes.*
ORIGIN	*Display spikes to the origin. The origin is the point defined by the 0 values for the* X1, X2, *and* Y *axes.*
FLOOR	*Display spikes to the "floor" defined by the* X1 *and* X2 *axes.*
CENTROID	*Display spikes to the point defined by the subgroup mean values of the* X1, X2, *and* Y *variables.* CENTROID=TOTAL is no longer supported. Spikes are always drawn to subgroup means defined by color and/or style variables.

Example:

```
IGRAPH
  /X1 = VAR(salbegin) TYPE = SCALE
  /Y = VAR(salary) TYPE = SCALE
  /COLOR = VAR(gender) TYPE = CATEGORICAL
  /SPIKE CENTROID.
```

FORMAT Subcommand

For charts with color or style variables, the FORMAT subcommand controls the color and style attributes of spikes. The keywords are:

SPIKE	*Applies color and style specifications to spikes.* This keyword is required.
COLOR{ON|OFF}	*Controls use of color in spikes as defined by color variable.* The default is ON.
STYLE {ON|OFF}	*Controls use of line style in spikes as defined by style variable.* The default is ON.

Example

```
IGRAPH
  /X1 = VAR(salbegin) TYPE = SCALE
  /Y = VAR(salary) TYPE = SCALE
  /COLOR = VAR(gender) TYPE = CATEGORICAL
  /SPIKE CENTROID
  /FORMAT COLOR=OFF.
```

KEY Keyword

All interactive chart types except histograms include a key element that identifies the summary measures displayed in the chart (for example, counts, means, and medians). The KEY keyword controls the display of the key in the chart. The default is ON, which displays the key. The OFF specification hides the key. The KEY specification is part of the subcommand that defines the chart type.

Example

```
IGRAPH
  /X1 = VAR(jobcat) TYPE = CATEGORICAL
  /Y = $count
  /BAR KEY=OFF.
```

Element Syntax

The following subcommands add elements to a chart. The same subcommand can be specified more than once. Each subcommand adds another element to the chart.

SCATTER Subcommand

SCATTER produces two- or three-dimensional scatterplots. Scatterplots can use either categorical or scale dimensions to create color or size legends. Categorical dimensions are required to create style legends.

The keyword COINCIDENT controls the placement of markers that have identical values on all axes. COINCIDENT can have one of the following two values:

NONE	*Places coincident markers on top of one another.* This is the default value.
JITTER	*Adds a small amount of random noise to all scale axis dimensions.* Specifying an amount is no longer supported and is ignored.

Example

```
IGRAPH
    /Y=VAR(sales96) TYPE=SCALE
    /X1=VAR(sales95) TYPE=SCALE
    /COORDINATE=VERTICAL
    /SCATTER COINCIDENT=JITTER.
```

- COORDINATE defines the chart as two-dimensional with *sales96* on the vertical dimension.
- SCATTER creates a scatterplot of *sales96* and *sales95*.
- The scale axes have random noise added by the JITTER keyword allowing separation of coincident points.

AREA Subcommand

AREA creates area charts. These charts summarize categories of one or more variables. The following keywords are available:

summary function *Defines a function used to summarize the variable defined on the Y subcommand.* If the *Y* axis assignment is $COUNT or $PCT, the AREA subcommand cannot have a summary function. If the Y subcommand specifies TYPE=CATEGORICAL, then AREA can only specify MODE as the summary function.

POINTLABEL *Labels points with the actual values corresponding to the dependent axis (VAL), the percentage of cases (PCT), and the number of cases included in each data point (N).* The default is no labels.

AREALABEL *Labels area with category labels (CAT), the percentage of cases (PCT), and the number of cases included in each line (N).* The default is no labels.

BREAK *Indicates whether the lines break at missing values (MISSING) or not (NONE).*

BASELINE *The baseline value determines the location from which the areas will hang (vertical) or extend (horizontal).* The default value is 0.

The INTERPOLATE keyword determines how the lines connecting the points are drawn. Options include:

STRAIGHT *Straight lines.*

LSTEP *A horizontal line extends from each data point.* A vertical riser connects the line to the next data point.

CSTEP *Each data point is centered on a horizontal line that extends half of the distance between consecutive points.* Vertical risers connect the line to the next horizontal line.

RSTEP *A horizontal line terminates at each data point.* A vertical riser extends from each data point, connecting to the next horizontal line.

BAR Subcommand

BAR creates a bar element in a chart, corresponding to the *X1*, *X2*, and *Y* axis assignments. Bars can be clustered by assigning variables to COLOR or STYLE. Horizontal or vertical orientation is specified by the COORDINATE subcommand.

summary function *Defines a function used to summarize the variable defined on the Y subcommand.* If the *Y* axis assignment is $COUNT or $PCT, the BAR subcommand cannot have a summary function. If the Y subcommand specifies TYPE=CATEGORICAL, then BAR can specify only MODE as the summary function.

LABEL *Bars can be labeled with the actual values corresponding to the dependent axis* (VAL) *or with the number of cases included in each bar* (N). The default is no labels. The placement of the labels is inside the bars (INSIDE) or outside the bars (OUTSIDE).

SHAPE This keyword is no longer supported and is ignored. Bars are always drawn as rectangles.

BARBASE This keyword is no longer supported and is ignored.

BASELINE *The baseline value determines the location from which the bars will hang (vertical) or extend (horizontal).* The default value is 0.

Example

```
IGRAPH
    /X1=VAR(volume96) TYPE=CATEGORICAL
    /Y=$count
    /COORDINATE=VERTICAL
    /EFFECT=THREE
    /BAR LABEL INSIDE N.
```

- X1 assigns the categorical variable *volume96* to the *X1* axis.
- Y assigns the built-in dimension $count to the range axis.
- VERTICAL defines the counts to appear along the vertical dimension.
- BAR adds a bar element to the chart.
- LABEL labels the bars in the chart with the number of cases included in the bars. These labels appear inside the bars.

Example

```
IGRAPH
    /X1=VAR(volume94) TYPE=CATEGORICAL
    /Y=VAR(sales96) TYPE=SCALE
    /COORDINATE=HORIZONTAL
    /EFFECT=NONE
    /BAR (MEAN) LABEL OUTSIDE VAL BASELINE=370.00.
```

- X1 assigns the categorical variable *volume94* to the *X1* axis.
- Y assigns the scale variable *sales96* to the range axis.
- HORIZONTAL defines *sales96* to appear along the horizontal dimension.
- EFFECT defines the chart as two-dimensional.
- BAR adds a bar element to the chart.
- MEAN defines the summary function to apply to *sales96*. Each bar represents the mean *sales96* value for the corresponding category of *volume94*.
- LABEL labels the bars in the chart with the mean *sales96* value. These labels appear outside the bars.
- BASELINE indicates that bars should extend from 370. Any bar with a mean value above 370 extends to the right. Any bar with a mean value below 370 extends to the left.

PIE Subcommand

A simple pie chart summarizes categories defined by a single variable or by a group of related variables. A clustered pie chart contains a cluster of simple pies, all of which are stacked into categories by the same variable. The pies are of different sizes and appear to be stacked on top of one another. The cluster contains as many pies as there are categories in the cluster variable. For both simple and clustered pie charts, the size of each slice represents the count, the percentage, or a summary function of a variable.

The following keywords are available:

summary function *Defines a function used to summarize the variable defined on the SUMMARYVAR subcommand.* If the SUMMARYVAR assignment is $COUNT or $PCT, the PIE subcommand cannot have a summary function. Otherwise, SUM, SUMAV, SUMSQ, NGT(x), NLE(x), NEQ(x), NGE(x), NGT(x), and NIN(x1,x2) are available. For more information, see Summary Functions on p. 904.

START num *Indicates the starting position of the smallest slice of the pie chart.* Any integer can be specified for num. The value is converted to a number between 0 and 360, which represents the degree of rotation of the smallest slice.

CW | CCW *Sets the positive rotation of the pie to either clockwise (CW) or counterclockwise (CCW).* The default rotation is clockwise.

SLICE *Sets the labeling characteristics for the slices of the pie.* The pie slices can be labeled with the category labels (LABEL), the category percentages (PCT), the number of cases (N), and the category values (VAL). Label position is either all labels inside the pie (INSIDE) or all labels outside the pie (OUTSIDE). TEXTIN and NUMIN are no longer supported and are ignored.

STACK *Sets the labeling characteristics for the pies from stacks.* The pies are labeled with the category labels (PCT, N, and VAL are no longer supported and are ignored.) Options for specifying the label position are no longer supported and are ignored. An optimal label position is always used.

Example

```
IGRAPH
    /SUMMARYVAR=$count
    /COLOR=VAR(volume96) TYPE=CATEGORICAL
    /EFFECT=THREE
    /PIE START 180 CW SLICE=INSIDE LABEL PCT N.
```

- The pie slices represent the number of cases (SUMMARYVAR=$count) in each category of *volume96* (specified on the COLOR subcommand).
- EFFECT yields a pie chart with an additional third dimension.
- PIE creates a pie chart.
- The first slice begins at 180 degrees and the rotation of the pie is clockwise.
- SLICE labels the slices with category labels, the percentage in each category, and the number of cases in each category. INSIDE places the category and numeric labels inside the pie slices .

Example

```
IGRAPH
    /SUMMARYVAR=VAR(sales96)
    /COLOR=VAR(volume95) TYPE=CATEGORICAL
    /X1=VAR(region) TYPE=CATEGORICAL
    /Y=VAR(division) TYPE=CATEGORICAL
    /COORDINATE=VERTICAL
    /PIE (SUM) START 0 CW SLICE=INSIDE VAL.
```

- The pie slices represent the sums of *sales96* values for each category of *volume95* (specified on the COLOR subcommand).
- X1 and Y define two axes representing *region* and *division*. A pie chart is created for each combination of these variables.
- The first slice in each pie begins at 0 degrees and the rotation of the pie is clockwise.

- SUM indicates the summary function applied to the summary variable, *sales96*. The pie slices represent the sum of the *sales96* values.
- SLICE labels the slices with the value of the summary function. INSIDE places the labels inside the pie slices.

BOX Subcommand

BOX creates a boxplot, sometimes called a box-and-whiskers plot, showing the median, quartiles, and outlier and extreme values for a scale variable. The interquartile range (IQR) is the difference between the 75th and 25th percentiles and corresponds to the length of the box.

The following keywords are available:

OUTLIERS	*Indicates whether outliers should be displayed.* Outliers are values between 1.5 IQR's and 3 IQR's from the end of a box. By default, the boxplot displays outliers (ON).
EXTREME	*Indicates whether extreme values should be displayed.* Values more than 3 IQR's from the end of a box are defined as extreme. By default, the boxplot displays extreme values (ON).
MEDIAN	*Indicates whether a line representing the median should be included in the box.* By default, the boxplot displays the median line (ON).
LABEL	*Displays the number of cases (N) represented by each box.*
BOXBASE	This keyword is no longer supported and is ignored.
WHISKER	*Controls the appearance of the whiskers.* Whiskers can be straight lines (LINE) or end in a *T*-shape (T). FANCY is no longer supported and is ignored.
CAPWIDTH(pct)	*Controls the width of the whisker cap relative to the corresponding box.* Pct equals the percentage of the box width. The default value for pct is 45.

Example

```
IGRAPH
    /X1=VAR(region) TYPE=CATEGORICAL
    /Y=VAR(sales96) TYPE=SCALE
    /COORDINATE=HORIZONTAL
    /BOX OUTLIERS=ON EXTREME=ON MEDIAN=ON WHISKER=LINE.
```

- X1 assigns the variable *region* to the *X1* axis.
- Y assigns the variable *sales96* to the range axis.
- COORDINATE positions the range axis along the horizontal dimension.
- BOX creates a boxplot. The outliers and extreme vales are shown. In addition, a line representing the median is added to the box.
- WHISKER yields whiskers ending in a straight lines.

Example

```
IGRAPH
    /X1=VAR(region) TYPE=CATEGORICAL
    /Y=VAR(sales96) TYPE=SCALE
    /X2=VAR(division) TYPE=CATEGORICAL
    /COORDINATE=THREE
    /BOX OUTLIERS=OFF EXTREME=ON MEDIAN=OFF LABEL=N WHISKER=T.
```

- X2 adds a third dimension, corresponding to *division*, to the boxplot in the previous example.
- COORDINATE indicates that the chart displays the third dimension.
- BOX creates a boxplot without outliers or a median line. Extreme values are shown.
- LABEL labels each box with the number of cases represented by each box.

LINE Subcommand

LINE creates line charts, dot charts, and ribbon charts. These charts summarize categories of one or more variables. Line charts tend to emphasize flow or movement instead of individual values. They are commonly used to display data over time and therefore can be used to give a good sense of trends. A ribbon chart is similar to a line chart, with the lines displayed as ribbons in a third dimension. Ribbon charts can either have two dimensions displayed with a 3-D effect, or they can have three dimensions.

The following keywords are available:

summary function *Defines a function used to summarize the variable defined on the Y subcommand.* If the *Y* axis assignment is $COUNT or $PCT, the LINE subcommand cannot have a summary function. If the Y subcommand specifies TYPE=CATEGORICAL, then LINE can specify only MODE as the summary function.

STYLE *Chart can include dots and lines (DOTLINE), lines only (LINE), or dots only (DOT).* The keyword NONE creates an empty chart.

DROPLINE *Indicates whether drop lines through points having the same value of a variable are included in the chart (ON) or not (OFF).* To include drop lines, specify a categorical variable on the STYLE, COLOR, or SIZE subcommands.

LABEL *Labels points with the actual values corresponding to the dependent axis (VAL), the percentage of cases (PCT), and the number of cases included in each data point (N).* The default is no labels.

LINELABEL *Labels lines with category labels (CAT), the percentage of cases (PCT), and the number of cases included in each line (N).* The default is no labels.

BREAK *Indicates whether the lines break at missing values (MISSING) or not (NONE).*

The INTERPOLATE keyword determines how the lines connecting the points are drawn. Options include:

STRAIGHT *Straight lines.*

LSTEP *A horizontal line extends from each data point.* A vertical riser connects the line to the next data point.

CSTEP *Each data point is centered on a horizontal line that extends half of the distance between consecutive points.* Vertical risers connect the line to the next horizontal line.

RSTEP *A horizontal line terminates at each data point.* A vertical riser extends from each data point, connecting to the next horizontal line.

LJUMP *A horizontal line extends from each data point.* No vertical risers connect the lines to the points.

RJUMP *A horizontal line terminates at each data point.* No vertical risers connect the points to the next horizontal line.

CJUMP *A horizontal line is centered at each data point, extending half of the distance between consecutive points.* No vertical risers connect the lines.

SPLINE	*Connects data points with a cubic spline.*
LAGRANGE3	This is no longer supported and is now an alias for SPLINE.
LAGRANGE5	This is no longer supported and is now an alias for SPLINE.

Example

```
IGRAPH
    /X1=VAR(volume95) TYPE=CATEGORICAL
    /Y=VAR(sales96) TYPE=SCALE
    /COLOR=VAR(volume94) TYPE=CATEGORICAL
    /COORDINATE=VERTICAL
    /LINE (MEAN) STYLE=LINE DROPLINE=ON LABEL VAL
        INTERPOLATE=STRAIGHT BREAK=MISSING.
```

- LINE creates a line chart. The lines represent the mean value of *sales96* for each category of *volume95*.
- The chart contains a line for each category of *volume94*, with droplines connecting the lines at each category of *volume95*.
- LABEL labels the lines with the mean *sales96* value for each category of *volume95*.
- INTERPOLATE specifies that straight lines connect the mean *sales96* values across the *volume95* categories.
- BREAK indicates that the lines will break at any missing values.

ERRORBAR Subcommand

Error bars help you to visualize distributions and dispersion by indicating the variability of the measure being displayed. The mean of a scale variable is plotted for a set of categories, and the length of an error bar on either side of the mean value indicates a confidence interval or a specified number of standard errors or standard deviations. Error bars can extend in one direction or in both directions from the mean. Error bars are sometimes displayed in the same chart with other chart elements, such as bars.

One of the following three keywords indicating the statistic and percentage/multiplier applied to the error bars must be specified:

CI(Pct)	*Error bars represent confidence intervals.* Pct indicates the level of confidence and varies from 0 to 100.
SD(sdval)	*Error bars represent standard deviations.* Sdval indicates how many standard deviations above and below the mean the error bars extend. Sdval must between 0 and 6.
SE(seval)	*Error bars represent standard errors.* Seval indicates how many standard errors above and below the mean the error bars extend. Seval must between 0 and 6.

In addition, the following keywords can be specified:

LABEL	*Labels error bars with means (*VAL*) and the number of cases (*N*).*
DIRECTION	This keyword is no longer supported and is ignored. Error bars always extend both above and below the mean values.
CAPSTYLE	*For error bars, the style can be* T*-shaped (*T*) or no cap (*NONE*).* The default style is *T*-shaped. FANCY is no longer supported and is ignored.

SYMBOL	*Displays the mean marker (*ON*).* For no symbol, specify OFF.
BASELINE val	*Defines the value (*val*) above which the error bars extend above the bars and below which the error bars extend below the bars.*
CAPWIDTH(pct)	*Controls the width of the cap relative to the distance between categories.* Pct equals the percent of the distance. The default value for pct is 45.

Example

```
IGRAPH
    /X1=VAR(volume94) TYPE=CATEGORICAL
    /Y=VAR(sales96) TYPE=SCALE
    /BAR (MEAN) LABEL INSIDE VAL SHAPE=RECTANGLE BASELINE=0.00
    /ERRORBAR SE(2.0) CAPWIDTH (45) CAPSTYLE=NONE.
```

- BAR creates a bar chart with rectangular bars. The bars represent the mean *sales96* values for the *volume94* categories.
- ERRORBAR adds error bars to the bar chart. The error bars extend two standard errors above and below the mean.

HISTOGRAM Subcommand

HISTOGRAM creates a histogram element in a chart, corresponding to the *X1*, *X2*, and *Y* axis assignments. Horizontal or vertical orientation is specified by the COORDINATE subcommand. A histogram groups the values of a variable into evenly spaced groups (intervals or bins) and plots a count of the number of cases in each group. The count can be expressed as a percentage. Percentages are useful for comparing datasets of different sizes. The count or percentage can also be accumulated across the groups.

- $COUNT or $PCT must be specified on the Y subcommand.

The following keywords are available:

SHAPE	*Defines the shape of the histogram.* Currently, the only value for SHAPE is HISTOGRAM.
CUM	*Specifies a cumulative histogram.* Counts or percentages are aggregated across the values of the domain variables.
X1INTERVAL	*Intervals on the* X1 *axis can be set automatically, or you can specify the number of intervals (1 to 250) along the axis* (NUM) *or the width of an interval* (WIDTH).
X2INTERVAL	*Intervals on the* X2 *axis can be set automatically, or you can specify the number of intervals (1 to 250) along the axis* (NUM) *or the width of an interval* (WIDTH).
CURVE	*Superimposes a normal curve on a 2-D histogram.* The normal curve has the same mean and variance as the data.
X1START	*The starting point along the* X1 *axis.* Indicates the percentage of an interval width above the minimum value along the *X1* axis at which to begin the histogram. The value can range from 0 to 99.
X2START	*The starting point along the* X2 *axis.* Indicates the percentage of an interval width above the minimum value along the *X2* axis at which to begin the histogram. The value can range from 0 to 99.

Example

```
IGRAPH
```

```
    /X1=VAR(sales96) TYPE=SCALE
    /Y=$count
    /Histogram SHAPE=HISTOGRAM CURVE=ON X1INTERVAL WIDTH=100.
```

- `Histogram` creates a histogram of *sales96*. The *sales96* intervals are 100 units wide.
- `CURVE` superimposes a normal curve on the histogram.

FITLINE Subcommand

`FITLINE` adds a line or surface to a scatterplot to help you discern the relationship shown in the plot. The following general methods are available:

NONE	*No line is fit.*
REGRESSION	*Fits a straight line (or surface) using ordinary least squares.* Must be followed by the keyword `LINEAR`.
ORIGIN	*Fits a straight line (or surface) through the origin.* Must be followed by the keyword `LINEAR`.
MEAN	*For a 2-D chart, fits a line at the mean of the dependent (Y) variable.* For a 3-D chart, the *Y* mean is shown as a plane.
LLR	*Fits a local linear regression curve or surface.* A normal (`NORMAL`) kernel is the default. With `EPANECHNIKOV`, the curve is not as smooth as with a normal kernel and is smoother than with a uniform (`UNIFORM`) kernel.

The keyword `LINE` indicates the number of fit lines. `TOTAL` fits the line to all of the cases. `MEFFECT` fits a separate line to the data for each value of a legend variable.

The `REGRESSION`, `ORIGIN`, and `MEAN` methods offer the option of including prediction intervals with the following keyword:

INTERVAL[(cval)]	*The intervals are based on the mean* (`MEAN`) *or on the individual cases* (`INDIVIDUAL`). `Cval` indicates the size of the interval and ranges from 50 to 100.

The local linear regression (`LLR`) smoother offers the following controls for the smoothing process:

BANDWIDTH	*Constrains the bandwidth to be constant across subgroups or panels* (`CONSTRAINED`). The default is unconstrained (`FAST`).
X1MULTIPLIER	*Specifies the bandwidth multiplier for the* X1 *axis.* The bandwidth multiplier changes the amount of data that is included in each calculation of a small part of the smoother. The multiplier can be adjusted to emphasize specific features of the plot that are of interest. Any positive multiplier (including fractions) is allowed. The larger the multiplier, the smoother the curve. The range between 0 and 10 should suffice in most applications.
X2MULTIPLIER	*Specifies the bandwidth multiplier for the* X2 *axis.* The bandwidth multiplier changes the amount of data that is included in each calculation of a small part of the smoother. The multiplier can be adjusted to emphasize specific features of the plot that are of interest. Any positive multiplier (including fractions) is allowed. The larger the multiplier, the smoother the curve. The range between 0 and 10 should suffice in most applications.

Example

```
IGRAPH
    /X1=VAR(sales95) TYPE=SCALE
    /Y=VAR(sales96) TYPE=SCALE
```

```
/COLOR=VAR(region) TYPE=CATEGORICAL
/SCATTER
/FITLINE METHOD=LLR EPANECHNIKOV BANDWIDTH=CONSTRAINED
    X1MULTIPLIER=2.00 LINE=MEFFECT.
```

- SCATTER creates a scatterplot of *sales95* and *sales96*.
- FITLINE adds a local linear regression smoother to the scatterplot. The Epanechnikov smoother is used with an *X1* multiplier of 2. A separate line is fit for each category of region, and the bandwidth is constrained to be equal across region categories.

Summary Functions

Summary functions apply to scale variables selected for a dependent axis or a slice summary. Percentages are based on the specified percent base. For a slice summary, only summary functions appropriate for the type of chart are available.

The following summary functions are available:

First Values (FIRST). The value found in the first case for each category in the data file at the time the summary was defined.

Kurtosis (KURTOSIS). A measure of the extent to which observations cluster around a central point. For a normal distribution, the value of the kurtosis statistic is 0. Positive kurtosis indicates that the observations cluster more and have longer tails than those in the normal distribution, and negative kurtosis indicates the observations cluster less and have shorter tails.

Last Values (LAST). The value found in the last case for each category in the data file at the time the summary was defined.

Maximum Values (MAXIMUM). The largest value for each category.

Minimum Values (MINIMUM). The smallest value within the category.

Means (MEAN). The arithmetic average for each category.

Medians (MEDIAN). The values below which half of the cases fall in each category.

Modes (MODE). The most frequently occurring value within each category.

Number of Cases Above (NGT(x)). The number of cases having values above the specified value.

Number of Cases Between (NIN(x1,x2)). The number of cases between two specified values.

Number of Cases Equal to (NEQ(x)). The number of cases equal to the specified value.

Number of Cases Greater Than or Equal to (NGE(x)). The number of cases having values above or equal to the specified value.

Number of Cases Less Than (NLT(x)). The number of cases below the specified value.

Number of Cases Less Than or Equal to (NLE(x)). The number of cases below or equal to the specified value.

Percentage of Cases Above (PGT(x)). The percentage of cases having values above the specified value.

Percentage of Cases Between (PIN(x1,x2)). The percentage of cases between two specified values.

Percentage of Cases Equal to (PEQ(x)). The percentage of cases equal to the specified value.

Percentage of Cases Greater Than or Equal to (PGE(x)). The percentage of cases having values above or equal to the specified value.

Percentage of Cases Less Than (PLT(x)). The percentage of cases having values below the specified value.

Percentage of Cases Less Than or Equal to (PLE(x)). The percentage of cases having values below or equal to the specified value.

Percentiles (PTILE(x)). The data value below which the specified percentage of values fall within each category.

Skewness (SKEW). A measure of the asymmetry of a distribution. The normal distribution is symmetric and has a skewness value of 0. A distribution with a significant positive skewness has a long right tail. A distribution with a significant negative skewness has a long left tail.

Standard Deviations (STDDEV). A measure of dispersion around the mean, expressed in the same units of measurement as the observations, equal to the square root of the variance. In a normal distribution, 68% of cases fall within one SD of the mean and 95% of cases fall within two SD's.

Standard Errors of Kurtosis (SEKURT). The ratio of kurtosis to its standard error can be used as a test of normality (that is, you can reject normality if the ratio is less than –2 or greater than +2). A large positive value for kurtosis indicates that the tails of the distribution are longer than those of a normal distribution; a negative value for kurtosis indicates shorter tails (becoming like those of a box-shaped uniform distribution).

Standard Errors of the Mean (SEMEAN). A measure of how much the value of the mean may vary from sample to sample taken from the same distribution. It can be used to roughly compare the observed mean to a hypothesized value (that is, you can conclude the two values are different if the ratio of the difference to the standard error is less than –2 or greater than +2).

Standard Errors of Skewness (SESKEW). The ratio of skewness to its standard error can be used as a test of normality (that is, you can reject normality if the ratio is less than –2 or greater than +2). A large positive value for skewness indicates a long right tail; an extreme negative value, a long left tail.

Sums (SUM). The sums of the values within each category.

Sums of Absolute Values (SUMAV). The sums of the absolute values within each category.

Sums of Squares (SUMSQ). The sums of the squares of the values within each category.

Variances (VARIANCE). A measure of how much observations vary from the mean, expressed in squared units.

IMPORT

```
IMPORT FILE='file'

 [/TYPE={COMM}]
        {TAPE}

 [/KEEP={ALL**  }] [/DROP=varlist]
        {varlist}

 [/RENAME=(old varnames=new varnames)...]

 [/MAP]
```

**Default if the subcommand is omitted.

Example

```
IMPORT FILE='/data/newdata.por'.
```

Overview

IMPORT reads portable data files created with the EXPORT command. A portable data file is a data file created by the program and used to transport data between different types of computers and operating systems (such as between IBM CMS and Digital VAX/VMS) or between SPSS and other software using the same portable file format. Like an SPSS-format data file, a portable file contains all of the data and dictionary information stored in the active dataset from which it was created.

The program can also read data files created by other software programs. See GET TRANSLATE for information on reading files created by spreadsheet and database programs such as dBASE, Lotus, and Excel.

Options

Format. You can specify the format of the portable file (magnetic tape or communications program) on the TYPE subcommand.

Variables. You can read a subset of variables from the active dataset with the DROP and KEEP subcommands. You can rename variables using RENAME. You can also produce a record of all variables and their names in the active dataset with the MAP subcommand.

Basic Specification

The basic specification is the FILE subcommand with a file specification. All variables from the portable file are copied into the active dataset with their original names, variable and value labels, missing-value flags, and print and write formats.

Subcommand Order

- FILE and TYPE must precede all other subcommands.
- No specific order is required between FILE and TYPE or among other subcommands.

Operations

- The portable data file and dictionary become the active dataset and dictionary.
- A file saved with weighting in effect (using the WEIGHT command) automatically uses the case weights when the file is read.

Examples

```
IMPORT FILE="/data/newdata.por"
  /RENAME=(V1 TO V3=ID,SEX,AGE) /MAP.
```

- The active dataset is generated from the portable file *newdata.por*.
- Variables *V1, V2,* and *V3* are renamed *ID, SEX,* and *AGE* in the active dataset. Their names remain *V1, V2,* and *V3* in the portable file. None of the other variables copied into the active dataset are renamed.
- MAP requests a display of the variables in the active dataset.

FILE Subcommand

FILE specifies the portable file. FILE is the only required subcommand on IMPORT.

TYPE Subcommand

TYPE indicates whether the portable file is formatted for magnetic tape or for a communications program. TYPE can specify either COMM or TAPE. For more information on magnetic tapes and communications programs, see EXPORT.

COMM	*Communications-formatted file.* This is the default.
TAPE	*Tape-formatted file.*

Example

```
IMPORT TYPE=TAPE /FILE='hubout.por'.
```

- The file *hubout.por* is read as a tape-formatted portable file.

DROP and KEEP Subcommands

DROP and KEEP are used to read a subset of variables from the portable file.

- DROP excludes a variable or list of variables from the active dataset. All variables not named are included in the file.
- KEEP includes a variable or list of variables in the active dataset. All variables not specified on KEEP are excluded.
- DROP and KEEP cannot precede the FILE or TYPE subcommands.

- Variables can be specified in any order. The order of variables on KEEP determines the order of variables in the active dataset. The order on DROP does not affect the order of variables in the active dataset.
- If a variable is referred to twice on the same subcommand, only the first mention is recognized.
- Multiple DROP and KEEP subcommands are allowed; the effect is cumulative. Specifying a variable named on a previous DROP or not named on a previous KEEP results in an error and the command is not executed.
- The keyword TO can be used to specify a group of consecutive variables in the portable file.
- The portable file is not affected by DROP or KEEP.

Example

```
IMPORT FILE='/data/newsum.por'
  /DROP=DEPT TO DIVISION.
```

- The active dataset is generated from the portable file *newsum.por*. Variables between and including *DEPT* and *DIVISION* in the portable file are excluded from the active dataset.
- All other variables are copied into the active dataset.

RENAME Subcommand

RENAME renames variables being read from the portable file. The renamed variables retain the variable and value labels, missing-value flags, and print formats contained in the portable file.

- To rename a variable, specify the name of the variable in the portable file, a required equals sign, and the new name.
- A variable list can be specified on both sides of the equals sign. The number of variables on both sides must be the same, and the entire specification must be enclosed in parentheses.
- The keyword TO can be used for both variable lists.
- Any DROP or KEEP subcommand after RENAME must use the new variable names.

Example

```
IMPORT FILE='/data/newsum.por'
  /DROP=DEPT TO DIVISION
  /RENAME=(NAME,WAGE=LNAME,SALARY).
```

- RENAME renames *NAME* and *WAGE* to *LNAME* and *SALARY*.
- *LNAME* and *SALARY* retain the variable and value labels, missing-value flags, and print formats assigned to *NAME* and *WAGE*.

MAP Subcommand

MAP displays a list of variables in the active dataset, showing all changes that have been specified on the RENAME, DROP, or KEEP subcommands.

- MAP can be specified as often as desired.

- MAP confirms only the changes specified on the subcommands that precede the MAP request.
- Results of subcommands that follow MAP are not mapped. When MAP is specified last, it also produces a description of the file.

Example

```
IMPORT FILE='/data/newsum.por'
  /DROP=DEPT TO DIVISION /MAP
  /RENAME NAME=LNAME WAGE=SALARY /MAP.
```

- The first MAP subcommand produces a listing of the variables in the file after DROP has dropped the specified variables.
- RENAME renames *NAME* and *WAGE*.
- The second MAP subcommand shows the variables in the file after renaming.

INCLUDE

```
INCLUDE FILE='file'
       [ENCODING = 'encoding specification']
```

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Release History

Release 16.0

- ENCODING keyword added for Unicode support.

Example

```
INCLUDE FILE='/data/gsslabs.sps'.
```

Overview

INCLUDE includes a file of commands in a session. INCLUDE is especially useful for including a long series of data definition statements or transformations. Another use for INCLUDE is to set up a library of commonly used commands and include them in the command sequence as they are needed.

Note: The newer INSERT provides equivalent functionality, plus additional features not available with INCLUDE. For more information, see INSERT on p. 917.

INCLUDE allows you to run multiple commands together during a session and can save time. Complex or repetitive commands can be stored in a command file and included in the session, while simpler commands or commands unique to the current analysis can be entered during the session, before and after the included file.

Basic Specification

The only specification is the FILE subcommand, which specifies the file to include. When INCLUDE is executed, the commands in the specified file are processed.

Syntax Rules

- Commands in an included file must begin in column 1, and continuation lines for each command must be indented at least one column.
- The maximum line length for a command syntax file run via the INCLUDE command is 256 characters. Any characters beyond this limit are truncated.
- As many INCLUDE commands as needed can be used in a session.

- INCLUDE commands can be nested so that one set of included commands includes another set of commands. This nesting can go to five levels. However, a file cannot be included that is still open from a previous step.

Operations

- If an included file contains a FINISH command, the session ends and no further commands are processed.
- If a journal file is created for the session, INCLUDE is copied to the journal file. Commands from the included file are also copied to the journal file but are treated like printed messages. Thus, INCLUDE can be executed from the journal file if the journal file is later used as a command file. Commands from the included file are executed only once.

ENCODING Keyword

ENCODING specifies the encoding format of the file. The keyword is followed by an equals sign and a quoted encoding specification.

- In Unicode mode, the default is UTF8. For more information, see SET command, UNICODE subcommand.
- In code page mode, the default is the current locale setting. For more information, see SET command, LOCALE subcommand.
- The quoted encoding value can be: Locale (the current locale setting), UTF8, UTF16, UTF16BE (big endian), UTF16LE (little endian), a numeric Windows code page value (for example, '1252'), or an IANA code page value (for example, 'iso8859-1' or cp1252).

Examples

```
INCLUDE FILE='/data/gsslabs.sps'.
```

- INCLUDE includes the file *gsslabs.sps* in the prompted session. When INCLUDE is executed, the commands in *gsslabs.sps* are processed.
- Assume that the include file *gsslabs.sps* contains the following:

```
DATA LIST FILE='/data/data52.txt'
  /RELIGION 5 OCCUPAT 7 SES 12 ETHNIC 15
   PARTY 19 VOTE48 33 VOTE52 41.
```

The active dataset will be defined and ready for analysis after INCLUDE is executed.

FILE Subcommand

FILE identifies the file containing commands. FILE is the only specification on INCLUDE and is required.

INFO

This command is obsolete and no longer supported.

INPUT PROGRAM-END INPUT PROGRAM

```
INPUT PROGRAM

commands to create or define cases

END INPUT PROGRAM
```

Example

```
INPUT PROGRAM.
DATA LIST FILE=PRICES /YEAR 1-4 QUARTER 6 PRICE 8-12(2).

DO IF (YEAR GE 1881).  /*Stop reading before 1881
END FILE.
END IF.
END INPUT PROGRAM.
```

Overview

The INPUT PROGRAM and END INPUT PROGRAM commands enclose data definition and transformation commands that build cases from input records. The input program often encloses one or more DO IF-END IF or LOOP-END LOOP structures, and it must include at least one file definition command, such as DATA LIST. One of the following utility commands is also usually used:

END CASE	*Build cases from the commands within the input program and pass the cases to the commands immediately following the input program.*
END FILE	*Terminate processing of a data file before the actual end of the file or define the end of the file when the input program is used to read raw data.*
REREAD	*Reread the current record using a different* DATA LIST.
REPEATING DATA	*Read repeating groups of data from the same input record.*

For more information on the commands used in an input program, see the discussion of each command.

Input programs create a dictionary and data for an active dataset from raw data files; they cannot be used to read SPSS-format data files. They can be used to process direct-access and keyed data files. For details, see KEYED DATA LIST.

Basic Specification

The basic specification is INPUT PROGRAM, the commands used to create cases and define the active dataset, and END INPUT PROGRAM.

- INPUT PROGRAM and END INPUT PROGRAM each must be specified on a separate line and have no additional specifications.

- To define an active dataset, the input program must include at least one DATA LIST or END FILE command.

Operations

- The INPUT PROGRAM–END INPUT PROGRAM structure defines an active dataset and is not executed until the program encounters a procedure or the EXECUTE command.
- INPUT PROGRAM clears the current active dataset.

Examples

Select Cases with an Input Program

```
INPUT PROGRAM.
DATA LIST FILE=PRICES /YEAR 1-4 QUARTER 6 PRICE 8-12(2).

DO IF (YEAR GE 1881).  /*Stop reading when reaching 1881
END FILE.
END IF.
END INPUT PROGRAM.

LIST.
```

- The input program is defined between the INPUT PROGRAM and END INPUT PROGRAM commands.
- This example assumes that data records are entered chronologically by year. The DO IF-END IF structure specifies an end of file when the first case with a value of 1881 or later for *YEAR* is reached.
- LIST executes the input program and lists cases in the active dataset. The case that causes the end of the file is not included in the active dataset generated by the input program.
- As an alternative to this input program, you can use N OF CASES to select cases if you know the exact number of cases. Another alternative is to use SELECT IF to select cases before 1881, but then the program would unnecessarily read the entire input file.

Skip the First n Records in a File

```
INPUT PROGRAM.
NUMERIC        #INIT.
DO IF          NOT (#INIT).
+  LOOP           #I = 1 TO 5.
+     DATA LIST      NOTABLE/.   /* No data - just skip record
+  END LOOP.
+  COMPUTE        #INIT = 1.
END IF.
DATA LIST      NOTABLE/ X 1.
END INPUT PROGRAM.

BEGIN DATA
A                          /* The first 5 records are skipped
B
C
D
E
1
2
```

```
3
4
5
END DATA.
LIST.
```

- NUMERIC declares the scratch variable *#INIT*, which is initialized to system-missing.
- The DO IF structure is executed as long as *#INIT* does not equal 1.
- LOOP is executed five times. Within the loop, DATA LIST is specified without variable names, causing the program to read records in the data file without copying them into the active dataset. LOOP is executed five times, so the program reads five records in this manner. END LOOP terminates this loop.
- COMPUTE creates the scratch variable *#INIT* and sets it equal to 1. The DO IF structure is therefore not executed again.
- END IF terminates the DO IF structure.
- The second DATA LIST specifies numeric variable *X*, which is located in column 1 of each record. Because the program has already read five records, the first value for *X* that is copied into the active dataset is read from record 6.

Input Programs

The program builds the active dataset dictionary when it encounters commands that create and define variables. At the same time, the program builds an *input program* that constructs cases and an optional *transformation program* that modifies cases prior to analysis or display. By the time the program encounters a procedure command that tells it to read the data, the active dataset dictionary is ready, and the programs that construct and modify the cases in the active dataset are built.

The internal input program is usually built from either a single DATA LIST command or from any of the commands that read or combine SPSS-format data files (for example, GET, ADD FILES, MATCH FILES, UPDATE, and so on). The input program can also be built from the FILE TYPE-END FILE TYPE structure used to define nested, mixed, or grouped files. The third type of input program is specified with the INPUT PROGRAM-END INPUT PROGRAM commands.

With INPUT PROGRAM-END INPUT PROGRAM, you can create your own input program to perform many different operations on raw data. You can use transformation commands to build cases. You can read nonrectangular files, concatenate raw data files, and build cases selectively. You can also create an active dataset without reading any data at all.

Input State

There are four program states in the program: the *initial state,* in which there is no active dataset dictionary; the *input state,* in which cases are created from the input file; the *transformation state,* in which cases are transformed; and the *procedure state,* in which procedures are executed. When you specify INPUT PROGRAM-END INPUT PROGRAM, you must pay attention to which commands are allowed within the input state, which commands can appear only within the input state, and which are not allowed within the input state.

More Examples

For additional examples of input programs, refer to DATA LIST, DO IF, DO REPEAT, END CASE, END FILE, LOOP, NUMERIC, POINT, REPEATING DATA, REREAD, and VECTOR.

INSERT

Note: Equals signs (=) used in the syntax chart are required elements.

```
INSERT  FILE='file specification'
       [SYNTAX = {INTERACTIVE*}]
                 {BATCH       }
       [ERROR = {CONTINUE*}]
                {STOP     }
       [CD = {NO*}]
             {YES}
       [ENCODING = 'encoding specification']
```

*Default if keyword omitted.

This command takes effect immediately. It does not read the active dataset or execute pending transformations. For more information, see Command Order on p. 36.

Release History

Release 13.0

- Command introduced.

Release 16.0

- ENCODING keyword added for Unicode support.

Example

```
INSERT FILE='/examples/commands/file1.sps'
  SYNTAX=BATCH ERROR=STOP CD=YES ENCODING='UTF8'.
```

OVERVIEW

INSERT includes a file of commands in a session. INSERT is especially useful for including a long series of data definition statements or transformations. Another use for INSERT is to set up a library of commonly used commands and include them in the command sequence as they are needed.

INSERT allows you to run multiple commands together during a session and can save time. Complex or repetitive commands can be stored in a command file and included in the session, while simpler commands or commands unique to the current analysis can be entered during the session, before and after the included file.

INSERT provides the same basic functionality as INCLUDE, plus the ability to:

- Insert files that use either batch or interactive syntax rules.
- Control treatment of error conditions in inserted files.
- Change the working directory to the directory containing an inserted file.

Limitations

The maximum line length for a command syntax file run via the INSERT command is 256 characters. Any characters beyond this limit are truncated.

FILE Keyword

The minimum specification is the FILE keyword, followed by an equals sign and a quoted file specification (or quoted file handle) that specifies the file to insert. When the INSERT command is run, the commands in the specified file are processed.

Example

```
INSERT FILE='/examples/commands/file1.sps'.
```

SYNTAX Keyword

The optional SYNTAX keyword specifies the syntax rules that apply to the inserted file. The keyword is followed by an equals sign (=) and one of the following alternatives:

INTERACTIVE *Each command must end with a period.* Periods can appear anywhere within the command, and commands can continue on multiple lines, but a period as the last non-blank character on a line is interpreted as the end of the command. Continuation lines and new commands can start anywhere on a new line. These are the "interactive" rules in effect when you select and run commands in a syntax window. This is the default if the SYNTAX keyword is omitted.

BATCH *Each command must start at the beginning of a new line (no blank spaces before the start of the command), and continuation lines must be indented at least one space.* If you want to indent new commands, you can use a plus sign, dash, or period as the first character at the start of the line and then indent the actual command. The period at the end of the command is optional. This setting is compatible with the syntax rules for command files included with the INCLUDE command.

Command syntax created with the Paste button in dialogs will work in either interactive or batch modes. For more information on interactive and batch syntax rules, see Running Commands on p. 33.

ERROR Keyword

The optional ERROR keyword controls the handling of error conditions in inserted files. The keyword is followed by an equals sign (=) and one of the following alternatives:

CONTINUE *Errors in inserted files do not automatically stop command processing.* The inserted commands are treated as part of the normal command stream, and command processing continues in the normal fashion. This is the default if the ERROR keyword is omitted.

STOP *Command processing stops when the first error in an inserted file is encountered.* This is compatible with the behavior of command files included with the INCLUDE command.

CD Keyword

The optional CD keyword can specify the directory containing the inserted file as the working directory, making it possible to use relative paths for file specifications within the inserted file. The keyword is followed by an equals sign (=) and one of the following alternatives:

NO	*The working directory is not changed.* This is the default if the CD keyword is omitted.
YES	*The working directory is changed to the directory containing the inserted file.* Subsequent relative paths in command file specifications are interpreted as being relative to the location of the inserted file.

The change in the working directory remains in effect until some other condition occurs that changes the working directory during the session, such as explicitly changing the working directory on another INSERT command with a CD keyword or a CD command that specifies a different directory (see CD on p. 269).

The CD keyword has no effect on the relative directory location for SET command file specifications, including JOURNAL , CTEMPLATE, and TLOOK. File specifications on the SET command should include complete path information.

The original working directory can be preserved with the PRESERVE command and later restored with the RESTORE command, as in:

```
PRESERVE.
INSERT FILE='/commands/examples/file1.sps'
  CD=YES.
INSERT FILE='file2.sps'.
RESTORE.
```

- PRESERVE retains the original working directory location.
- The first INSERT command changes the working directory.
- The second INSERT command will look for file2.sps in /commands/examples.
- RESTORE resets the working directory to whatever it was prior to the first INSERT command.

For more information, see the PRESERVE and RESTORE commands.

ENCODING Keyword

ENCODING specifies the encoding format of the file. The keyword is followed by an equals sign and a quoted encoding specification.

- In Unicode mode, the default is UTF8. For more information, see SET command, UNICODE subcommand.
- In code page mode, the default is the current locale setting. For more information, see SET command, LOCALE subcommand.
- The quoted encoding value can be: Locale (the current locale setting), UTF8, UTF16, UTF16BE (big endian), UTF16LE (little endian), a numeric Windows code page value (for example, '1252'), or an IANA code page value (for example, 'iso8859-1' or cp1252).

INSERT vs. INCLUDE

INSERT is a newer, more powerful and flexible alternative to INCLUDE. Files included with INCLUDE must always adhere to batch syntax rules, and command processing stops when the first error in an included file is encountered. You can effectively duplicate the INCLUDE behavior with SYNTAX=BATCH and ERROR=STOP on the INSERT command.

KEYED DATA LIST

```
KEYED DATA LIST KEY=varname IN=varname

 FILE='file' [{TABLE   }] [ENCODING='encoding specification']
              {NOTABLE}

 /varname {col location [(format)]} [varname ..]
          {(FORTRAN-like format)  }
```

Release History

Release 16.0

- ENCODING subcommand added for Unicode support.

Example

```
FILE HANDLE EMPL/ file specifications.
KEYED DATA LIST FILE=EMPL KEY=#NXTCASE IN=#FOUND
           /YRHIRED 1-2 SEX 3 JOBCLASS 4.
```

Overview

KEYED DATA LIST reads raw data from two types of nonsequential files: direct-access files, which provide direct access by a record number, and keyed files, which provide access by a record key. An example of a direct-access file is a file of 50 records, each corresponding to one of the United States. If you know the relationship between the states and the record numbers, you can retrieve the data for any specific state. An example of a keyed file is a file containing social security numbers and other information about a firm's employees. The social security number can be used to identify the records in the file.

Direct-Access Files

There are various types of direct-access files. This program's concept of a direct-access file, however, is very specific. The file must be one from which individual records can be selected according to their number. The records in a 100-record direct-access file, for example, are numbered from 1 to 100.

Although the concept of record number applies to almost any file, not all files can be treated by this program as direct-access files. In fact, some operating systems provide no direct-access capabilities at all, and others permit only a narrowly defined subset of all files to be treated as direct access.

Very few files turn out to be good candidates for direct-access organization. In the case of an inventory file, for example, the usual large gaps in the part numbering sequence would result in large amounts of wasted file space. Gaps are not a problem, however, if they are predictable. For example, if you recognize that telephone area codes have first digits of 2 through 9, second digits

of 0 or 1, and third digits of 0 through 9, you can transform an area code into a record number by using the following COMPUTE statement:

```
COMPUTE RECNUM = 20*(DIGIT1-2) + 10*DIGIT2 + DIGIT3 + 1.
```

where *DIGIT1*, *DIGIT2*, and *DIGIT3* are variables corresponding to the respective digits in the area code, and *RECNUM* is the resulting record number. The record numbers would range from 1, for the nonexistent area code 200, through 160, for area code 919. The file would then have a manageable number of unused records.

Keyed Files

Of the many kinds of keyed files, the ones to which the program can provide access are generally known as *indexed sequential files.* A file of this kind is basically a sequential file in which an index is maintained so that the file can be processed either sequentially or selectively. In effect, there is an underlying data file that is accessed through a file of index entries. The file of index entries may, for example, contain the fact that data record 797 is associated with social security number 476-77-1359. Depending on the implementation, the underlying data may or may not be maintained in sequential order.

The key for each record in the file generally comprises one or more pieces of information found within the record. An example of a complex key is a customer's last name and house number, plus the consonants in the street name, plus the zip code, plus a unique digit in case there are duplicates. Regardless of the information contained in the key, the program treats it as a character string.

On some systems, more than one key is associated with each record. That is, the records in a file can be identified according to different types of information. Although the primary key for a file normally must be unique, sometimes the secondary keys need not be. For example, the records in an employee file might be identified by social security number and job classification.

Options

Data Source. You can specify the name of the keyed file on the FILE subcommand. By default, the last file that was specified on an input command, such as DATA LIST or REPEATING DATA, is read.

Summary Table. You can display a table that summarizes the variable definitions.

Basic Specification

- The basic specification requires FILE, KEY, and IN, each of which specifies one variable, followed by a slash and variable definitions.
- FILE specifies the direct-access or keyed file. The file must have a file handle already defined.
- KEY specifies the variable whose value will be used to read a record. For direct-access files, the variable must be numeric; for keyed files, it must be string.
- IN creates a logical variable that flags whether a record was successfully read.
- Variable definitions follow all subcommands; the slash preceding them is required. Variable definitions are similar to those specified on DATA LIST.

Subcommand Order

- Subcommands can be named in any order.
- Variable definitions must follow all specified subcommands.

Syntax Rules

- Specifications for the variable definitions are the same as those described for DATA LIST. The only difference is that only one record can be defined per case.
